Tell us about your PDF experience.

System Namespace

Reference

Contains fundamental classes and base classes that define commonly-used value and reference data types, events and event handlers, interfaces, attributes, and processing exceptions.

Classes

Expand table

AccessViolationException	The exception that is thrown when there is an attempt to read or write protected memory.
Activator	Contains methods to create types of objects locally or remotely, or obtain references to existing remote objects. This class cannot be inherited.
AggregateException	Represents one or more errors that occur during application execution.
AppContext	Provides members for setting and retrieving data about an application's context.
AppDomain	Represents an application domain, which is an isolated environment where applications execute. This class cannot be inherited.
AppDomainSetup	Represents assembly binding information that can be added to an instance of AppDomain.
AppDomainUnloadedException	The exception that is thrown when an attempt is made to access an unloaded application domain.
ApplicationException	Serves as the base class for application-defined exceptions.
ApplicationId	Contains information used to uniquely identify a manifest-based application. This class cannot be inherited.
ArgumentException	The exception that is thrown when one of the arguments provided to a method is not valid.
ArgumentNullException	The exception that is thrown when a null reference (`Nothing` in Visual Basic) is passed to a method that does not accept it as a valid argument.

ArgumentOutOfRangeException	The exception that is thrown when the value of an argument is outside the allowable range of values as defined by the invoked method.
ArithmeticException	The exception that is thrown for errors in an arithmetic, casting, or conversion operation.
Array	Provides methods for creating, manipulating, searching, and sorting arrays, thereby serving as the base class for all arrays in the common language runtime.
ArrayTypeMismatchException	The exception that is thrown when an attempt is made to store an element of the wrong type within an array.
AssemblyLoadEventArgs	Provides data for the AssemblyLoad event.
Attribute	Represents the base class for custom attributes.
AttributeUsageAttribute	Specifies the usage of another attribute class. This class cannot be inherited.
BadImageFormatException	The exception that is thrown when the file image of a dynamic link library (DLL) or an executable program is invalid.
BitConverter	Converts base data types to an array of bytes, and an array of bytes to base data types.
Buffer	Manipulates arrays of primitive types.
CannotUnloadAppDomain Exception	The exception that is thrown when an attempt to unload an application domain fails.
CharEnumerator	Supports iterating over a String object and reading its individual characters. This class cannot be inherited.
CLSCompliantAttribute	Indicates whether a program element is compliant with the Common Language Specification (CLS). This class cannot be inherited.
Console	Represents the standard input, output, and error streams for console applications. This class cannot be inherited.
ConsoleCancelEventArgs	Provides data for the CancelKeyPress event. This class cannot be inherited.
ContextBoundObject	Defines the base class for all context-bound classes.
ContextMarshalException	The exception that is thrown when an attempt to marshal an object across a context boundary fails.

ContextStaticAttribute	Indicates that the value of a static field is unique for a particular context.
Convert	Converts a base data type to another base data type.
DataMisalignedException	The exception that is thrown when a unit of data is read from or written to an address that is not a multiple of the data size. This class cannot be inherited.
DBNull	Represents a nonexistent value. This class cannot be inherited.
Delegate	Represents a delegate, which is a data structure that refers to a static method or to a class instance and an instance method of that class.
DivideByZeroException	The exception that is thrown when there is an attempt to divide an integral or Decimal value by zero.
DllNotFoundException	The exception that is thrown when a DLL specified in a DLL import cannot be found.
DuplicateWaitObjectException	The exception that is thrown when an object appears more than once in an array of synchronization objects.
EntryPointNotFoundException	The exception that is thrown when an attempt to load a class fails due to the absence of an entry method.
Enum	Provides the base class for enumerations.
Environment	Provides information about, and means to manipulate, the current environment and platform. This class cannot be inherited.
EventArgs	Represents the base class for classes that contain event data, and provides a value to use for events that do not include event data.
Exception	Represents errors that occur during application execution.
ExecutionEngineException	The exception that is thrown when there is an internal error in the execution engine of the common language runtime. This class cannot be inherited.
FieldAccessException	The exception that is thrown when there is an invalid attempt to access a private or protected field inside a class.
FileStyleUriParser	A customizable parser based on the File scheme.
FlagsAttribute	Indicates that an enumeration can be treated as a bit field; that is, a set of flags.

FormatException	The exception that is thrown when the format of an argument is invalid, or when a composite format string is not well formed.
FormattableString	Represents a composite format string, along with the arguments to be formatted.
FtpStyleUriParser	A customizable parser based on the File Transfer Protocol (FTP) scheme.
GC	Controls the system garbage collector, a service that automatically reclaims unused memory.
GenericUriParser	A customizable parser for a hierarchical URI.
GopherStyleUriParser	A customizable parser based on the Gopher scheme.
HttpStyleUriParser	A customizable parser based on the HTTP scheme.
IndexOutOfRangeException	The exception that is thrown when an attempt is made to access an element of an array or collection with an index that is outside its bounds.
InsufficientExecutionStack Exception	The exception that is thrown when there is insufficient execution stack available to allow most methods to execute.
InsufficientMemoryException	The exception that is thrown when a check for sufficient available memory fails. This class cannot be inherited.
InvalidCastException	The exception that is thrown for invalid casting or explicit conversion.
InvalidOperationException	The exception that is thrown when a method call is invalid for the object's current state.
InvalidProgramException	The exception that is thrown when a program contains invalid Microsoft intermediate language (MSIL) or metadata. Generally this indicates a bug in the compiler that generated the program. This exception is also thrown when internal runtime implementation limits have been exceeded by the program.
InvalidTimeZoneException	The exception that is thrown when time zone information is invalid.
Lazy<T>	Provides support for lazy initialization.
Lazy<T,TMetadata>	Provides a lazy indirect reference to an object and its associated metadata for use by the Managed Extensibility Framework.

LdapStyleUriParser	A customizable parser based on the Lightweight Directory Access Protocol (LDAP) scheme.
LoaderOptimizationAttribute	Used to set the default loader optimization policy for the main method of an executable application.
LocalDataStoreSlot	Encapsulates a memory slot to store local data. This class cannot be inherited.
MarshalByRefObject	Enables access to objects across application domain boundaries in applications that support remoting.
Math	Provides constants and static methods for trigonometric, logarithmic, and other common mathematical functions.
MathF	Provides constants and static methods for trigonometric, logarithmic, and other common mathematical functions.
MemberAccessException	The exception that is thrown when an attempt to access a class member fails.
MemoryExtensions	Provides extension methods for the memory-related and span-related types, such as Memory<T>, ReadOnlyMemory<T>, Span<T>, and ReadOnlySpan<T>.
MethodAccessException	The exception that is thrown when there is an invalid attempt to access a method, such as accessing a private method from partially trusted code.
MissingFieldException	The exception that is thrown when there is an attempt to dynamically access a field that does not exist. If a field in a class library has been removed or renamed, recompile any assemblies that reference that library.
MissingMemberException	The exception that is thrown when there is an attempt to dynamically access a class member that does not exist or that is not declared as public. If a member in a class library has been removed or renamed, recompile any assemblies that reference that library.
MissingMethodException	The exception that is thrown when there is an attempt to dynamically access a method that does not exist.
MTAThreadAttribute	Indicates that the COM threading model for an application is multithreaded apartment (MTA).
MulticastDelegate	Represents a multicast delegate; that is, a delegate that can have more than one element in its invocation list.
MulticastNotSupportedException	The exception that is thrown when there is an attempt to combine two delegates based on the Delegate type instead

	of the MulticastDelegate type. This class cannot be inherited.
NetPipeStyleUriParser	A parser based on the NetPipe scheme for the "Indigo" system.
NetTcpStyleUriParser	A parser based on the NetTcp scheme for the "Indigo" system.
NewsStyleUriParser	A customizable parser based on the news scheme using the Network News Transfer Protocol (NNTP).
NonSerializedAttribute	Indicates that a field of a serializable class should not be serialized. This class cannot be inherited.
NotFiniteNumberException	The exception that is thrown when a floating-point value is positive infinity, negative infinity, or Not-a-Number (NaN).
NotImplementedException	The exception that is thrown when a requested method or operation is not implemented.
NotSupportedException	The exception that is thrown when an invoked method is not supported, or when there is an attempt to read, seek, or write to a stream that does not support the invoked functionality.
Nullable	Supports a value type that can be assigned `null`. This class cannot be inherited.
NullReferenceException	The exception that is thrown when there is an attempt to dereference a null object reference.
Object	Supports all classes in the .NET class hierarchy and provides low-level services to derived classes. This is the ultimate base class of all .NET classes; it is the root of the type hierarchy.
ObjectDisposedException	The exception that is thrown when an operation is performed on a disposed object.
ObsoleteAttribute	Marks the program elements that are no longer in use. This class cannot be inherited.
OperatingSystem	Represents information about an operating system, such as the version and platform identifier. This class cannot be inherited.
OperationCanceledException	The exception that is thrown in a thread upon cancellation of an operation that the thread was executing.
OutOfMemoryException	The exception that is thrown when there is not enough memory to continue the execution of a program.

OverflowException	The exception that is thrown when an arithmetic, casting, or conversion operation in a checked context results in an overflow.
ParamArrayAttribute	Indicates that a method will allow a variable number of arguments in its invocation. This class cannot be inherited.
PlatformNotSupportedException	The exception that is thrown when a feature does not run on a particular platform.
Progress<T>	Provides an IProgress<T> that invokes callbacks for each reported progress value.
Random	Represents a pseudo-random number generator, which is an algorithm that produces a sequence of numbers that meet certain statistical requirements for randomness.
RankException	The exception that is thrown when an array with the wrong number of dimensions is passed to a method.
ResolveEventArgs	Provides data for loader resolution events, such as the TypeResolve, ResourceResolve, ReflectionOnlyAssemblyResolve, and AssemblyResolve events.
SerializableAttribute	Indicates that a class can be serialized using binary or XML serialization. This class cannot be inherited.
StackOverflowException	The exception that is thrown when the execution stack exceeds the stack size. This class cannot be inherited.
STAThreadAttribute	Indicates that the COM threading model for an application is single-threaded apartment (STA).
String	Represents text as a sequence of UTF-16 code units.
StringComparer	Represents a string comparison operation that uses specific case and culture-based or ordinal comparison rules.
StringNormalizationExtensions	Provides extension methods to work with string normalization.
SystemException	Serves as the base class for system exceptions namespace.
ThreadStaticAttribute	Indicates that the value of a static field is unique for each thread.
TimeoutException	The exception that is thrown when the time allotted for a process or operation has expired.
TimeProvider	Provides an abstraction for time.

TimeZone	Represents a time zone.
TimeZoneInfo	Represents any time zone in the world.
TimeZoneInfo.AdjustmentRule	Provides information about a time zone adjustment, such as the transition to and from daylight saving time.
TimeZoneNotFoundException	The exception that is thrown when a time zone cannot be found.
Tuple	Provides static methods for creating tuple objects.
Tuple<T1>	Represents a 1-tuple, or singleton.
Tuple<T1,T2>	Represents a 2-tuple, or pair.
Tuple<T1,T2,T3>	Represents a 3-tuple, or triple.
Tuple<T1,T2,T3,T4>	Represents a 4-tuple, or quadruple.
Tuple<T1,T2,T3,T4,T5>	Represents a 5-tuple, or quintuple.
Tuple<T1,T2,T3,T4,T5,T6>	Represents a 6-tuple, or sextuple.
Tuple<T1,T2,T3,T4,T5,T6,T7>	Represents a 7-tuple, or septuple.
Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>	Represents an *n*-tuple, where *n* is 8 or greater.
TupleExtensions	Provides extension methods for tuples to interoperate with language support for tuples in C#.
Type	Represents type declarations: class types, interface types, array types, value types, enumeration types, type parameters, generic type definitions, and open or closed constructed generic types.
TypeAccessException	The exception that is thrown when a method attempts to use a type that it does not have access to.
TypeInitializationException	The exception that is thrown as a wrapper around the exception thrown by the class initializer. This class cannot be inherited.
TypeLoadException	The exception that is thrown when type-loading failures occur.
TypeUnloadedException	The exception that is thrown when there is an attempt to access an unloaded class.
UnauthorizedAccessException	The exception that is thrown when the operating system denies access because of an I/O error or a specific type of security error.

UnhandledExceptionEventArgs	Provides data for the event that is raised when there is an exception that is not handled in any application domain.
Uri	Provides an object representation of a uniform resource identifier (URI) and easy access to the parts of the URI.
UriBuilder	Provides a custom constructor for uniform resource identifiers (URIs) and modifies URIs for the Uri class.
UriFormatException	The exception that is thrown when an invalid Uniform Resource Identifier (URI) is detected.
UriParser	Parses a new URI scheme. This is an abstract class.
UriTypeConverter	Converts a String type to a Uri type, and vice versa.
ValueType	Provides the base class for value types.
Version	Represents the version number of an assembly, operating system, or the common language runtime. This class cannot be inherited.
WeakReference	Represents a weak reference, which references an object while still allowing that object to be reclaimed by garbage collection.
WeakReference<T>	Represents a typed weak reference, which references an object while still allowing that object to be reclaimed by garbage collection.

Structs

Expand table

ArgIterator	Represents a variable-length argument list; that is, the parameters of a function that takes a variable number of arguments.
ArraySegment<T>.Enumerator	Provides an enumerator for the elements of an ArraySegment<T>.
ArraySegment<T>	Delimits a section of a one-dimensional array.
Boolean	Represents a Boolean (`true` or `false`) value.
Byte	Represents an 8-bit unsigned integer.
Char	Represents a character as a UTF-16 code unit.

ConsoleKeyInfo	Describes the console key that was pressed, including the character represented by the console key and the state of the SHIFT, ALT, and CTRL modifier keys.
DateOnly	Represents dates with values ranging from January 1, 0001 Anno Domini (Common Era) through December 31, 9999 A.D. (C.E.) in the Gregorian calendar.
DateTime	Represents an instant in time, typically expressed as a date and time of day.
DateTimeOffset	Represents a point in time, typically expressed as a date and time of day, relative to Coordinated Universal Time (UTC).
Decimal	Represents a decimal floating-point number.
Double	Represents a double-precision floating-point number.
GCGenerationInfo	Represents the size and the fragmenation of a generation on entry and on exit of the GC reported in GCMemoryInfo.
GCMemoryInfo	Provides a set of APIs that can be used to retrieve garbage collection information.
Guid	Represents a globally unique identifier (GUID).
Half	Represents a half-precision floating-point number.
HashCode	Combines the hash code for multiple values into a single hash code.
Index	Represents a type that can be used to index a collection either from the beginning or the end.
Int128	Represents a 128-bit signed integer.
Int16	Represents a 16-bit signed integer.
Int32	Represents a 32-bit signed integer.
Int64	Represents a 64-bit signed integer.
IntPtr	Represents a signed integer where the bit-width is the same as a pointer.
Memory<T>	Represents a contiguous region of memory.
MemoryExtensions.TryWriteInterpolatedStringHandler	Provides a handler used by the language compiler to format interpolated strings into character spans.

ModuleHandle	Represents a runtime handle for a module.
Nullable<T>	Represents a value type that can be assigned `null`.
Range	Represents a range that has start and end indexes.
ReadOnlyMemory<T>	Represents a contiguous region of memory, similar to ReadOnlySpan<T>. Unlike ReadOnlySpan<T>, it is not a byref-like type.
ReadOnlySpan<T>.Enumerator	Provides an enumerator for the elements of a ReadOnlySpan<T>.
ReadOnlySpan<T>	Provides a type-safe and memory-safe read-only representation of a contiguous region of arbitrary memory.
RuntimeArgumentHandle	References a variable-length argument list.
RuntimeFieldHandle	Represents a field using an internal metadata token.
RuntimeMethodHandle	RuntimeMethodHandle is a handle to the internal metadata representation of a method.
RuntimeTypeHandle	Represents a type using an internal metadata token.
SByte	Represents an 8-bit signed integer.
SequencePosition	Represents a position in a non-contiguous set of memory. Properties of this type should not be interpreted by anything but the type that created it.
Single	Represents a single-precision floating-point number.
Span<T>.Enumerator	Provides an enumerator for the elements of a Span<T>.
Span<T>	Provides a type-safe and memory-safe representation of a contiguous region of arbitrary memory.
TimeOnly	Represents a time of day, as would be read from a clock, within the range 00:00:00 to 23:59:59.9999999.
TimeSpan	Represents a time interval.
TimeZoneInfo.TransitionTime	Provides information about a specific time change, such as the change from daylight saving time to standard time or vice versa, in a particular time zone.
TypedReference	Describes objects that contain both a managed pointer to a location and a runtime representation of the type that may be stored at that location.

UInt128	Represents a 128-bit unsigned integer.
UInt16	Represents a 16-bit unsigned integer.
UInt32	Represents a 32-bit unsigned integer.
UInt64	Represents a 64-bit unsigned integer.
UIntPtr	Represents an unsigned integer where the bit-width is the same as a pointer.
UriCreationOptions	Provides options that control how a Uri is created and behaves.
ValueTuple	Provides static methods for creating value tuples.
ValueTuple<T1>	Represents a value tuple with a single component.
ValueTuple<T1,T2>	Represents a value tuple with 2 components.
ValueTuple<T1,T2,T3>	Represents a value tuple with 3 components.
ValueTuple<T1,T2,T3,T4>	Represents a value tuple with 4 components.
ValueTuple<T1,T2,T3,T4,T5>	Represents a value tuple with 5 components.
ValueTuple<T1,T2,T3,T4,T5,T6>	Represents a value tuple with 6 components.
ValueTuple<T1,T2,T3,T4,T5,T6,T7>	Represents a value tuple with 7 components.
ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>	Represents an *n*-value tuple, where *n* is 8 or greater.
Void	Specifies a return value type for a method that does not return a value.

Interfaces

Expand table

IAsyncDisposable	Provides a mechanism for releasing unmanaged resources asynchronously.
IAsyncResult	Represents the status of an asynchronous operation.
ICloneable	Supports cloning, which creates a new instance of a class with the same value as an existing instance.
IComparable	Defines a generalized type-specific comparison method that a value type or class implements to order or sort its instances.

IComparable<T>	Defines a generalized comparison method that a value type or class implements to create a type-specific comparison method for ordering or sorting its instances.
IConvertible	Defines methods that convert the value of the implementing reference or value type to a common language runtime type that has an equivalent value.
ICustomFormatter	Defines a method that supports custom formatting of the value of an object.
IDisposable	Provides a mechanism for releasing unmanaged resources.
IEquatable<T>	Defines a generalized method that a value type or class implements to create a type-specific method for determining equality of instances.
IFormatProvider	Provides a mechanism for retrieving an object to control formatting.
IFormattable	Provides functionality to format the value of an object into a string representation.
IObservable<T>	Defines a provider for push-based notification.
IObserver<T>	Provides a mechanism for receiving push-based notifications.
IParsable<TSelf>	Defines a mechanism for parsing a string to a value.
IProgress<T>	Defines a provider for progress updates.
IServiceProvider	Defines a mechanism for retrieving a service object; that is, an object that provides custom support to other objects.
ISpanFormattable	Provides functionality to format the string representation of an object into a span.
ISpanParsable<TSelf>	Defines a mechanism for parsing a span of characters to a value.
IUtf8SpanFormattable	Provides functionality to format the string representation of an object into a span as UTF-8.
IUtf8SpanParsable<TSelf>	Defines a mechanism for parsing a span of UTF-8 characters to a value.

Enums

Expand table

AttributeTargets	Specifies the application elements on which it is valid to apply an

	attribute.
Base64FormattingOptions	Specifies whether relevant ToBase64CharArray and ToBase64String methods insert line breaks in their output.
ConsoleColor	Specifies constants that define foreground and background colors for the console.
ConsoleKey	Specifies the standard keys on a console.
ConsoleModifiers	Represents the SHIFT, ALT, and CTRL modifier keys on a keyboard.
ConsoleSpecialKey	Specifies combinations of modifier and console keys that can interrupt the current process.
DateTimeKind	Specifies whether a DateTime object represents a local time, a Coordinated Universal Time (UTC), or is not specified as either local time or UTC.
DayOfWeek	Specifies the day of the week.
Environment.SpecialFolder	Specifies enumerated constants used to retrieve directory paths to system special folders.
Environment.SpecialFolderOption	Specifies options to use for getting the path to a special folder.
EnvironmentVariableTarget	Specifies the location where an environment variable is stored or retrieved in a set or get operation.
GCCollectionMode	Specifies the behavior for a forced garbage collection.
GCKind	Specifies the kind of a garbage collection.
GCNotificationStatus	Provides information about the current registration for notification of the next full garbage collection.
GenericUriParserOptions	Specifies options for a UriParser.
LoaderOptimization	An enumeration used with the LoaderOptimizationAttribute class to specify loader optimizations for an executable.
MidpointRounding	Specifies the strategy that mathematical rounding methods should use to round a number.
PlatformID	Identifies the operating system, or platform, supported by an assembly.
StringComparison	Specifies the culture, case, and sort rules to be used by certain overloads of the Compare(String, String) and Equals(Object) methods.
StringSplitOptions	Specifies options for applicable Split method overloads, such as whether to omit empty substrings from the returned array or trim

	whitespace from substrings.
TypeCode	Specifies the type of an object.
UriComponents	Specifies the parts of a Uri.
UriFormat	Controls how URI information is escaped.
UriHostNameType	Defines host name types for the CheckHostName(String) method.
UriKind	Defines the different kinds of URIs.
UriPartial	Defines the parts of a URI for the GetLeftPart(UriPartial) method.

Delegates

Expand table

Action	Encapsulates a method that has no parameters and does not return a value.
Action<T>	Encapsulates a method that has a single parameter and does not return a value.
Action<T1,T2>	Encapsulates a method that has two parameters and does not return a value.
Action<T1,T2,T3>	Encapsulates a method that has three parameters and does not return a value.
Action<T1,T2,T3,T4>	Encapsulates a method that has four parameters and does not return a value.
Action<T1,T2,T3,T4,T5>	Encapsulates a method that has five parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6>	Encapsulates a method that has six parameters

	and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7>	Encapsulates a method that has seven parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8>	Encapsulates a method that has eight parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9>	Encapsulates a method that has nine parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>	Encapsulates a method that has 10 parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>	Encapsulates a method that has 11 parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>	Encapsulates a method that has 12 parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>	Encapsulates a method that has 13 parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14>	Encapsulates a method that has 14 parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>	Encapsulates a method that has 15 parameters and does not return a value.
Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>	Encapsulates a method that has 16 parameters

	and does not return a value.
AssemblyLoadEventHandler	Represents the method that handles the AssemblyLoad event of an AppDomain.
AsyncCallback	References a method to be called when a corresponding asynchronous operation completes.
Comparison<T>	Represents the method that compares two objects of the same type.
ConsoleCancelEventHandler	Represents the method that will handle the CancelKeyPress event of a Console.
Converter<TInput,TOutput>	Represents a method that converts an object from one type to another type.
EventHandler	Represents the method that will handle an event that has no event data.
EventHandler<TEventArgs>	Represents the method that will handle an event when the event provides data.
Func<TResult>	Encapsulates a method that has no parameters and returns a value of the type specified by the `TResult` parameter.
Func<T,TResult>	Encapsulates a method that has one parameter and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,TResult>	Encapsulates a method that has two parameters

	and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,TResult>	Encapsulates a method that has three parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,TResult>	Encapsulates a method that has four parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,TResult>	Encapsulates a method that has five parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,TResult>	Encapsulates a method that has six parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,TResult>	Encapsulates a method that has seven parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,TResult>	Encapsulates a method that has eight parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,TResult>	Encapsulates a method that has nine parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,TResult>	Encapsulates a method that has 10 parameters

	and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,TResult>	Encapsulates a method that has 11 parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,TResult>	Encapsulates a method that has 12 parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,TResult>	Encapsulates a method that has 13 parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,TResult>	Encapsulates a method that has 14 parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,TResult>	Encapsulates a method that has 15 parameters and returns a value of the type specified by the `TResult` parameter.
Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,TResult>	Encapsulates a method that has 16 parameters and returns a value of the type specified by the `TResult` parameter.
Predicate<T>	Represents the method that defines a set of criteria and determines whether the specified object meets those criteria.
ResolveEventHandler	Represents a method that handles the TypeResolve, ResourceResolve, or

	AssemblyResolve event of an AppDomain.
UnhandledExceptionEventHandler	Represents the method that will handle the event raised by an exception that is not handled by the application domain.

Remarks

Other classes provide services supporting data type conversion, method parameter manipulation, mathematics, remote and local program invocation, application environment management, and supervision of managed and unmanaged applications.

To access types in the System namespace from C# code without having to provide fully qualified type names, include the `using System;` statement at the beginning of your source code file.

To access types in the System namespace from C++/CLI code without having to provide fully qualified type names, include the `using namespace System;` statement at the beginning of your source code file. In addition, you must compile with the /clr switch.

AccessViolationException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to read or write protected memory.

C#

```
public class AccessViolationException : SystemException
```

Inheritance Object → Exception → SystemException → AccessViolationException

Remarks

For more information about this API, see Supplemental API remarks for AccessViolationException.

Constructors

Expand table

AccessViolationException()	Initializes a new instance of the AccessViolationException class with a system-supplied message that describes the error.
AccessViolationException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AccessViolationException class with serialized data.
AccessViolationException(String)	Initializes a new instance of the AccessViolationException class with a specified message that describes the error.
AccessViolationException(String, Exception)	Initializes a new instance of the AccessViolationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.**

	When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

AccessViolationException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the AccessViolationException class.

Overloads

Expand table

AccessViolationException()	Initializes a new instance of the AccessViolationException class with a system-supplied message that describes the error.
AccessViolationException(String)	Initializes a new instance of the AccessViolationException class with a specified message that describes the error.
AccessViolationException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AccessViolationException class with serialized data.
AccessViolationException(String, Exception)	Initializes a new instance of the AccessViolationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

AccessViolationException()

Initializes a new instance of the AccessViolationException class with a system-supplied message that describes the error.

C#

```
public AccessViolationException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to read or write protected memory. This is often an indication that other memory has been corrupted." This message takes into account the current system culture.

The following table shows the initial property values for an instance of AccessViolationException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AccessViolationException(String)

Initializes a new instance of the AccessViolationException class with a specified message that describes the error.

C#

```
public AccessViolationException (string? message);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of AccessViolationException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string specified in `message`.

.NET Standard	2.0, 2.1

AccessViolationException(SerializationInfo, StreamingContext)

⊗ Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the AccessViolationException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected AccessViolationException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

.NET Framework	2.0, 3.0, 3.5, 3.5 Client Profile, 4, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AccessViolationException(String, Exception)

Initializes a new instance of the AccessViolationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public AccessViolationException (string? message, Exception?
innerException);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of AccessViolationException.

Expand table

Property	Value
InnerException	`null`.

Property	Value
Message	The error message string specified in `message`.

Action Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has no parameters and does not return a value.

C#

```
public delegate void Action();
```

Remarks

You can use this delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have no parameters and no return value. (In C#, the method must return `void`. In F# the function or method must return `unit`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has no parameters and returns a value, use the generic **Func<TResult>** delegate instead.

When you use the Action delegate, you do not have to explicitly define a delegate that encapsulates a parameterless procedure. For example, the following code explicitly declares a delegate named `ShowValue` and assigns a reference to the `Name.DisplayToWindow` instance method to its delegate instance.

C#

```
using System;
using System.Windows.Forms;

public delegate void ShowValue();
```

```
public class Name
{
   private string instanceName;

   public Name(string name)
   {
      this.instanceName = name;
   }

   public void DisplayToConsole()
   {
      Console.WriteLine(this.instanceName);
   }

   public void DisplayToWindow()
   {
      MessageBox.Show(this.instanceName);
   }
}

public class testTestDelegate
{
   public static void Main()
   {
      Name testName = new Name("Koani");
      ShowValue showMethod = testName.DisplayToWindow;
      showMethod();
   }
}
```

The following example simplifies this code by instantiating the Action delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;
using System.Windows.Forms;

public class Name
{
   private string instanceName;

   public Name(string name)
   {
      this.instanceName = name;
   }

   public void DisplayToConsole()
   {
      Console.WriteLine(this.instanceName);
   }
```

```
    public void DisplayToWindow()
    {
        MessageBox.Show(this.instanceName);
    }
}

public class testTestDelegate
{
    public static void Main()
    {
        Name testName = new Name("Koani");
        Action showMethod = testName.DisplayToWindow;
        showMethod();
    }
}
```

You can also use the Action delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;
using System.Windows.Forms;

public class Name
{
    private string instanceName;

    public Name(string name)
    {
        this.instanceName = name;
    }

    public void DisplayToConsole()
    {
        Console.WriteLine(this.instanceName);
    }

    public void DisplayToWindow()
    {
        MessageBox.Show(this.instanceName);
    }
}

public class Anonymous
{
    public static void Main()
    {
        Name testName = new Name("Koani");
        Action showMethod = delegate() { testName.DisplayToWindow();} ;
        showMethod();
```

```
    }
}
```

You can also assign a lambda expression to an Action delegate instance, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (C#) or Lambda Expressions (F#).)

C#

```
using System;
using System.Windows.Forms;

public class Name
{
    private string instanceName;

    public Name(string name)
    {
        this.instanceName = name;
    }

    public void DisplayToConsole()
    {
        Console.WriteLine(this.instanceName);
    }

    public void DisplayToWindow()
    {
        MessageBox.Show(this.instanceName);
    }
}

public class LambdaExpression
{
    public static void Main()
    {
        Name testName = new Name("Koani");
        Action showMethod = () => testName.DisplayToWindow();
        showMethod();
    }
}
```

Action<T> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has a single parameter and does not return a value.

```
C#
public delegate void Action<in T>(T obj);
```

Type Parameters

T

The type of the parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

obj T

The parameter of the method that this delegate encapsulates.

Examples

The following example demonstrates the use of the Action<T> delegate to print the contents of a List<T> object. In this example, the `Print` method is used to display the contents of the list to the console. In addition, the C# example also demonstrates the use of anonymous methods to display the contents to the console. Note that the example does not explicitly declare an Action<T> variable. Instead, it passes a reference to a method that takes a single parameter and that does not return a value to the List<T>.ForEach method, whose single parameter is an Action<T> delegate. Similarly, in the C# example, an Action<T> delegate is not explicitly instantiated because the signature of the anonymous method matches the signature of the Action<T> delegate that is expected by the List<T>.ForEach method.

C#

```
List<string> names = new List<string>();
names.Add("Bruce");
names.Add("Alfred");
names.Add("Tim");
names.Add("Richard");

// Display the contents of the list using the Print method.
names.ForEach(Print);

// The following demonstrates the anonymous method feature of C#
// to display the contents of the list to the console.
names.ForEach(delegate(string name)
{
    Console.WriteLine(name);
});

void Print(string s)
{
    Console.WriteLine(s);
}

/* This code will produce output similar to the following:
* Bruce
* Alfred
* Tim
* Richard
* Bruce
* Alfred
* Tim
* Richard
*/
```

Remarks

You can use the Action<T> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have one parameter that is passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

ⓘ **Note**

To reference a method that has one parameter and returns a value, use the generic **Func<T,TResult>** delegate instead.

When you use the Action<T> delegate, you do not have to explicitly define a delegate that encapsulates a method with a single parameter. For example, the following code explicitly declares a delegate named `DisplayMessage` and assigns a reference to either the WriteLine method or the `ShowWindowsMessage` method to its delegate instance.

C#

```
using System;
using System.Windows.Forms;

delegate void DisplayMessage(string message);

public class TestCustomDelegate
{
   public static void Main()
   {
      DisplayMessage messageTarget;

      if (Environment.GetCommandLineArgs().Length > 1)
         messageTarget = ShowWindowsMessage;
      else
         messageTarget = Console.WriteLine;

      messageTarget("Hello, World!");
   }

   private static void ShowWindowsMessage(string message)
   {
      MessageBox.Show(message);
   }
}
```

The following example simplifies this code by instantiating the Action<T> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;
using System.Windows.Forms;

public class TestAction1
{
   public static void Main()
   {
      Action<string> messageTarget;
```

```
        if (Environment.GetCommandLineArgs().Length > 1)
            messageTarget = ShowWindowsMessage;
        else
            messageTarget = Console.WriteLine;

        messageTarget("Hello, World!");
    }

    private static void ShowWindowsMessage(string message)
    {
        MessageBox.Show(message);
    }
}
```

You can also use the Action<T> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;
using System.Windows.Forms;

public class TestAnonMethod
{
    public static void Main()
    {
        Action<string> messageTarget;

        if (Environment.GetCommandLineArgs().Length > 1)
            messageTarget = delegate(string s) { ShowWindowsMessage(s); };
        else
            messageTarget = delegate(string s) { Console.WriteLine(s); };

        messageTarget("Hello, World!");
    }

    private static void ShowWindowsMessage(string message)
    {
        MessageBox.Show(message);
    }
}
```

You can also assign a lambda expression to an Action<T> delegate instance, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions.)

C#

```
using System;
using System.Windows.Forms;

public class TestLambdaExpression
{
   public static void Main()
   {
      Action<string> messageTarget;

      if (Environment.GetCommandLineArgs().Length > 1)
         messageTarget = s => ShowWindowsMessage(s);
      else
         messageTarget = s => Console.WriteLine(s);

      messageTarget("Hello, World!");
   }

   private static void ShowWindowsMessage(string message)
   {
      MessageBox.Show(message);
   }
}
```

The ForEach and ForEach methods each take an Action<T> delegate as a parameter. The method encapsulated by the delegate allows you to perform an action on each element in the array or list. The example uses the ForEach method to provide an illustration.

Extension Methods

Action<T1,T2> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has two parameters and does not return a value.

```
C#
public delegate void Action<in T1,in T2>(T1 arg1, T2 arg2);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have two parameters that are both passed to it by value, and it must not return a value. (In C#, the method must return `void`. In F#, the method or function must return unit. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has two parameters and returns a value, use the generic **Func<T1,T2,TResult>** delegate instead.

When you use the Action<T1,T2> delegate, you do not have to explicitly define a delegate that encapsulates a method with two parameters. For example, the following code explicitly declares a delegate named `ConcatStrings`. It then assigns a reference to either of two methods to its delegate instance. One method writes two strings to the console; the second writes two strings to a file.

C#

```
using System;
using System.IO;

delegate void ConcatStrings(string string1, string string2);

public class TestDelegate
{
   public static void Main()
   {
      string message1 = "The first line of a message.";
      string message2 = "The second line of a message.";
      ConcatStrings concat;

      if (Environment.GetCommandLineArgs().Length > 1)
         concat = WriteToFile;
      else
         concat = WriteToConsole;

      concat(message1, message2);
   }

   private static void WriteToConsole(string string1, string string2)
   {
      Console.WriteLine("{0}\n{1}", string1, string2);
   }
```

```
   private static void WriteToFile(string string1, string string2)
   {
      StreamWriter writer = null;
      try
      {
         writer = new StreamWriter(Environment.GetCommandLineArgs()[1],
false);
         writer.WriteLine("{0}\n{1}", string1, string2);
      }
      catch
      {
         Console.WriteLine("File write operation failed...");
      }
      finally
      {
         if (writer != null) writer.Close();
      }
   }
}
```

The following example simplifies this code by instantiating the Action<T1,T2> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;
using System.IO;

public class TestAction2
{
   public static void Main()
   {
      string message1 = "The first line of a message.";
      string message2 = "The second line of a message.";
      Action<string, string> concat;

      if (Environment.GetCommandLineArgs().Length > 1)
         concat = WriteToFile;
      else
         concat = WriteToConsole;

      concat(message1, message2);
   }

   private static void WriteToConsole(string string1, string string2)
   {
      Console.WriteLine("{0}\n{1}", string1, string2);
   }

   private static void WriteToFile(string string1, string string2)
   {
      StreamWriter writer = null;
```

```
      try
      {
         writer = new StreamWriter(Environment.GetCommandLineArgs()[1],
false);
         writer.WriteLine("{0}\n{1}", string1, string2);
      }
      catch
      {
         Console.WriteLine("File write operation failed...");
      }
      finally
      {
         if (writer != null) writer.Close();
      }
   }
}
```

You can also use the Action<T1,T2> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;
using System.IO;

public class TestAnonymousMethod
{
   public static void Main()
   {
      string message1 = "The first line of a message.";
      string message2 = "The second line of a message.";
      Action<string, string> concat;

      if (Environment.GetCommandLineArgs().Length > 1)
         concat = delegate(string s1, string s2) { WriteToFile(s1, s2); };
      else
         concat = delegate(string s1, string s2) { WriteToConsole(s1, s2);}
;

      concat(message1, message2);
   }

   private static void WriteToConsole(string string1, string string2)
   {
      Console.WriteLine("{0}\n{1}", string1, string2);
   }

   private static void WriteToFile(string string1, string string2)
   {
      StreamWriter writer = null;
      try
```

```
      {
         writer = new StreamWriter(Environment.GetCommandLineArgs()[1],
false);
         writer.WriteLine("{0}\n{1}", string1, string2);
      }
      catch
      {
         Console.WriteLine("File write operation failed...");
      }
      finally
      {
         if (writer != null) writer.Close();
      }
   }
}
```

You can also assign a lambda expression to an Action<T1,T2> delegate instance, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (C#), or Lambda Expressions (F#).)

C#

```
using System;
using System.IO;

public class TestLambdaExpression
{
   public static void Main()
   {
      string message1 = "The first line of a message.";
      string message2 = "The second line of a message.";
      Action<string, string> concat;

      if (Environment.GetCommandLineArgs().Length > 1)
         concat = (s1, s2) => WriteToFile(s1, s2);
      else
         concat = (s1, s2) => WriteToConsole(s1, s2);

      concat(message1, message2);
   }

   private static void WriteToConsole(string string1, string string2)
   {
      Console.WriteLine("{0}\n{1}", string1, string2);
   }

   private static void WriteToFile(string string1, string string2)
   {
      StreamWriter writer = null;
      try
      {
         writer = new StreamWriter(Environment.GetCommandLineArgs()[1],
```

```
false);
            writer.WriteLine("{0}\n{1}", string1, string2);
        }
        catch
        {
            Console.WriteLine("File write operation failed...");
        }
        finally
        {
            if (writer != null) writer.Close();
        }
    }
}
```

Action<T1,T2,T3> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has three parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3>(T1 arg1, T2 arg2, T3 arg3);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

arg3 T3

The third parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have three parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In F#, the method or function must return unit. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> ⓘ **Note**
>
> To reference a method that has three parameters and returns a value, use the generic **Func<T1,T2,T3,TResult>** delegate instead.

When you use the Action<T1,T2,T3> delegate, you do not have to explicitly define a delegate that encapsulates a method with three parameters. For example, the following code explicitly declares a delegate named `StringCopy` and assigns a reference to the `CopyStrings` method to its delegate instance.

C#

```
using System;

delegate void StringCopy(string[] stringArray1,
                         string[] stringArray2,
                         int indexToStart);

public class TestDelegate
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      StringCopy copyOperation = CopyStrings;
      copyOperation(ordinals, copiedOrdinals, 3);
      foreach (string ordinal in copiedOrdinals)
```

```
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target, int
startPos)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= source.Length - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

The following example simplifies this code by instantiating the Action<T1,T2,T3> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;

public class TestAction3
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      Action<string[], string[], int> copyOperation = CopyStrings;
      copyOperation(ordinals, copiedOrdinals, 3);
      foreach (string ordinal in copiedOrdinals)
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target, int
startPos)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= source.Length - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

You can also use the Action<T1,T2,T3> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see

Anonymous Methods.)

C#

```
using System;

public class TestAnon
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      Action<string[], string[], int> copyOperation = delegate(string[] s1,
                                                               string[] s2,
                                                               int pos)
                                     { CopyStrings(s1, s2, pos); };
      copyOperation(ordinals, copiedOrdinals, 3);
      foreach (string ordinal in copiedOrdinals)
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target, int
startPos)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= source.Length - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

You can also assign a lambda expression to an Action<T1,T2,T3> delegate instance, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (C#) or Lambda Expressions (F#).)

C#

```
using System;

public class TestLambda
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      Action<string[], string[], int> copyOperation = (s1, s2, pos) =>
                                     CopyStrings(s1, s2, pos);
      copyOperation(ordinals, copiedOrdinals, 3);
      foreach (string ordinal in copiedOrdinals)
```

```
            Console.WriteLine(ordinal == string.Empty ? "<None>" : ordinal);
    }

    private static void CopyStrings(string[] source, string[] target, int
startPos)
    {
        if (source.Length != target.Length)
            throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

        for (int ctr = startPos; ctr <= source.Length - 1; ctr++)
            target[ctr] = string.Copy(source[ctr]);
    }
}
```

Action<T1,T2,T3,T4> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has four parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4>(T1 arg1, T2 arg2, T3
arg3, T4 arg4);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have four parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In F#, the method or function must return unit. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has four parameters and returns a value, use the generic **Func<T1,T2,T3,T4,TResult>** delegate instead.

When you use the Action<T1,T2,T3,T4> delegate, you do not have to explicitly define a delegate that encapsulates a method with four parameters. For example, the following code explicitly declares a delegate named `StringCopy` and assigns a reference to the `CopyStrings` method to its delegate instance.

```
C#
```

```
using System;

delegate void StringCopy(string[] stringArray1,
                         string[] stringArray2,
                         int indexToStart,
                         int numberToCopy);

public class TestDelegate
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth",
                           "Sixth", "Seventh", "Eighth", "Ninth", "Tenth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      StringCopy copyOperation = CopyStrings;
      copyOperation(ordinals, copiedOrdinals, 3, 5);
      foreach (string ordinal in copiedOrdinals)
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target,
                                   int startPos, int number)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= startPos + number - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

The following example simplifies this code by instantiating the Action<T1,T2,T3,T4> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;

public class TestAction4
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth",
                           "Sixth", "Seventh", "Eighth", "Ninth", "Tenth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      Action<string[], string[], int, int> copyOperation = CopyStrings;
      copyOperation(ordinals, copiedOrdinals, 3, 5);
      foreach (string ordinal in copiedOrdinals)
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
```

```
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target,
                                   int startPos, int number)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= startPos + number - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

You can also use the Action<T1,T2,T3,T4> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;

public class TestAnonymousMethod
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth",
                           "Sixth", "Seventh", "Eighth", "Ninth", "Tenth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      Action<string[], string[], int, int> copyOperation =
                                           delegate(string[] s1, string[]
s2,
                                           int pos, int num)
                                 { CopyStrings(s1, s2, pos, num); };
      copyOperation(ordinals, copiedOrdinals, 3, 5);
      foreach (string ordinal in copiedOrdinals)
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target,
                                   int startPos, int number)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= startPos + number - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

You can also assign a lambda expression to an Action<T1,T2,T3,T4> delegate instance, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (C#) or Lambda Expressions (F#).)

C#

```
using System;

public class TestLambdaExpression
{
   public static void Main()
   {
      string[] ordinals = {"First", "Second", "Third", "Fourth", "Fifth",
                           "Sixth", "Seventh", "Eighth", "Ninth", "Tenth"};
      string[] copiedOrdinals = new string[ordinals.Length];
      Action<string[], string[], int, int> copyOperation = (s1, s2, pos,
num)
                                              => CopyStrings(s1, s2, pos, num);
      copyOperation(ordinals, copiedOrdinals, 3, 5);
      foreach (string ordinal in copiedOrdinals)
         Console.WriteLine(string.IsNullOrEmpty(ordinal) ? "<None>" :
ordinal);
   }

   private static void CopyStrings(string[] source, string[] target,
                                   int startPos, int number)
   {
      if (source.Length != target.Length)
         throw new IndexOutOfRangeException("The source and target arrays
must have the same number of elements.");

      for (int ctr = startPos; ctr <= startPos + number - 1; ctr++)
         target[ctr] = string.Copy(source[ctr]);
   }
}
```

Action<T1,T2,T3,T4,T5> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has five parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5>(T1 arg1, T2 arg2,
T3 arg3, T4 arg4, T5 arg5);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

T5

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

arg3 T3

The third parameter of the method that this delegate encapsulates.

arg4 T4

The fourth parameter of the method that this delegate encapsulates.

arg5 T5

The fifth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have five parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has five parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has six parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have six parameters that are all passed to it by value,

and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has six parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6> delegate with anonymous methods and lambda expressions.

Extension Methods

Action<T1,T2,T3,T4,T5,T6,T7> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has seven parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7>(T1
arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

T5

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T6

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T7

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

arg3 T3

The third parameter of the method that this delegate encapsulates.

arg4 T4

The fourth parameter of the method that this delegate encapsulates.

arg5 T5

The fifth parameter of the method that this delegate encapsulates.

arg6 T6

The sixth parameter of the method that this delegate encapsulates.

arg7 T7

The seventh parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have seven parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has seven parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has eight parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8>
(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T5

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T6

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T7

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T8

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

arg3 T3

The third parameter of the method that this delegate encapsulates.

arg4 T4

The fourth parameter of the method that this delegate encapsulates.

arg5 T5

The fifth parameter of the method that this delegate encapsulates.

arg6 T6

The sixth parameter of the method that this delegate encapsulates.

arg7 T7

The seventh parameter of the method that this delegate encapsulates.

arg8 T8

The eighth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have eight parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has eight parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has nine parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in
T8,in T9>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8
arg8, T9 arg9);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T5

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T6

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T7

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T8

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T9

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

arg3 T3

The third parameter of the method that this delegate encapsulates.

arg4 T4

The fourth parameter of the method that this delegate encapsulates.

arg5 T5

The fifth parameter of the method that this delegate encapsulates.

arg6 T6

The sixth parameter of the method that this delegate encapsulates.

arg7 T7

The seventh parameter of the method that this delegate encapsulates.

arg8 T8

The eighth parameter of the method that this delegate encapsulates.

arg9 T9

The ninth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have nine parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has nine parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 10 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in
T8,in T9,in T10>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7
arg7, T8 arg8, T9 arg9, T10 arg10);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 10 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that

returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has 10 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 11 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 11 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has 11 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 12 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 12 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has 12 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 13 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 13 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> ⓘ **Note**
>
> To reference a method that has 13 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 14 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13,in T14>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13, T14 arg14);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T14`

The type of the fourteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

arg6 T6

The sixth parameter of the method that this delegate encapsulates.

arg7 T7

The seventh parameter of the method that this delegate encapsulates.

arg8 T8

The eighth parameter of the method that this delegate encapsulates.

arg9 T9

The ninth parameter of the method that this delegate encapsulates.

arg10 T10

The tenth parameter of the method that this delegate encapsulates.

arg11 T11

The eleventh parameter of the method that this delegate encapsulates.

arg12 T12

The twelfth parameter of the method that this delegate encapsulates.

arg13 T13

The thirteenth parameter of the method that this delegate encapsulates.

arg14 T14

The fourteenth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 14 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

Note

To reference a method that has 14 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> delegate with anonymous methods and lambda expressions.

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 15 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13,in T14,in T15>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13, T14 arg14, T15 arg15);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T14`

The type of the fourteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T15`

The type of the fifteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

`arg14` T14

The fourteenth parameter of the method that this delegate encapsulates.

`arg15` T15

The fifteenth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 15 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has 15 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15> delegate with anonymous methods and lambda expressions.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 16 parameters and does not return a value.

C#

```
public delegate void Action<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in
T8,in T9,in T10,in T11,in T12,in T13,in T14,in T15,in T16>(T1 arg1, T2 arg2,
T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10,
T11 arg11, T12 arg12, T13 arg13, T14 arg14, T15 arg15, T16 arg16);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T11

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T12

The type of the twelfth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T13

The type of the thirteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T14

The type of the fourteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T15

The type of the fifteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T16

The type of the sixteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

arg1 T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

`arg14` T14

The fourteenth parameter of the method that this delegate encapsulates.

`arg15` T15

The fifteenth parameter of the method that this delegate encapsulates.

`arg16` T16

The sixteenth parameter of the method that this delegate encapsulates.

Remarks

You can use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16> delegate to pass a method as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 16 parameters that are all passed to it by value, and it must not return a value. (In C#, the method must return `void`. In Visual Basic, it must be defined by the `Sub`...`End Sub` construct. It can also be a method that returns a value that is ignored.) Typically, such a method is used to perform an operation.

> **Note**
>
> To reference a method that has 16 parameters and returns a value, use the generic **Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,TResult>** delegate instead.

You can also use the Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16> delegate with anonymous methods and lambda expressions.

Activator Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Contains methods to create types of objects locally or remotely, or obtain references to existing remote objects. This class cannot be inherited.

C#

```
public static class Activator
```

Inheritance Object → Activator

Examples

The following example shows how to use the Activator class to dynamically construct objects at run time.

C#

```
using System;
using System.Reflection;
using System.Text;

public class SomeType
{
    public void DoSomething(int x)
    {
        Console.WriteLine("100 / {0} = {1}", x, 100 / x);
    }
}

public class Example
{
    static void Main()
    {
        // Create an instance of the StringBuilder type using
        // Activator.CreateInstance.
        Object o = Activator.CreateInstance(typeof(StringBuilder));

        // Append a string into the StringBuilder object and display the
```

```
        // StringBuilder.
        StringBuilder sb = (StringBuilder) o;
        sb.Append("Hello, there.");
        Console.WriteLine(sb);

        // Create an instance of the SomeType class that is defined in this
        // assembly.
        System.Runtime.Remoting.ObjectHandle oh =

Activator.CreateInstanceFrom(Assembly.GetEntryAssembly().CodeBase,
                                        typeof(SomeType).FullName);

        // Call an instance method defined by the SomeType type using this
object.
        SomeType st = (SomeType) oh.Unwrap();

        st.DoSomething(5);
    }
}

/* This code produces the following output:

Hello, there.
100 / 5 = 20
 */
```

Remarks

The CreateInstance method creates an instance of a type defined in an assembly by invoking the constructor that best matches the specified arguments. If no arguments are specified, the constructor that takes no parameters, that is, the parameterless constructor, is invoked.

You must have sufficient permission to search for and call a constructor; otherwise, an exception is thrown. By default, only public constructors are considered during the search for a constructor. If no constructor or parameterless constructor can be found, an exception is thrown.

A binder parameter specifies an object that searches an assembly for a suitable constructor. You can specify your own binder and search criteria. If no binder is specified, a default binder is used. For more information, see the System.Reflection.Binder and System.Reflection.BindingFlags classes.

An evidence parameter affects the security policy and permissions for the constructor. For more information, see the System.Security.Policy.Evidence class.

An instance of a type can be created at a local or remote site. If the type is created remotely, an activation attribute parameter specifies the URI of the remote site. The call to create the instance might pass through intermediary sites before it reaches the remote site. Other activation attributes can modify the environment, or context, in which the call operates at the remote and intermediary sites.

If the instance is created locally, a reference to that object is returned. If the instance is created remotely, a reference to a proxy is returned. The remote object is manipulated through the proxy as if it were a local object.

The GetObject method creates a proxy to a currently running remote object, server-activated well-known object, or XML Web service. You can specify the connection medium, that is, the channel. For more information, see the System.Runtime.Remoting.Channels.ChannelServices class.

Assemblies contain type definitions. The CreateInstance method creates an instance of a type from a currently running assembly. The CreateInstanceFrom method creates an instance from a file that contains an assembly. The CreateComInstanceFrom method creates an instance of a COM object from a file that contains an assembly.

Methods

Expand table

CreateInstance(String, String)	Creates an instance of the type whose name is specified, using the named assembly and parameterless constructor.
CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates an instance of the type whose name is specified, using the named assembly and the constructor that best matches the specified parameters.
CreateInstance(String, String, Object[])	Creates an instance of the type whose name is specified, using the named assembly and parameterless constructor.
CreateInstance(Type)	Creates an instance of the specified type using that type's parameterless constructor.
CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo)	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates an instance of the specified type using the constructor that best matches the specified

	parameters.
CreateInstance(Type, Boolean)	Creates an instance of the specified type using that type's parameterless constructor.
CreateInstance(Type, Object[])	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance(Type, Object[], Object[])	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance<T>()	Creates an instance of the type designated by the specified generic type parameter, using the parameterless constructor.
CreateInstanceFrom(String, String)	Creates an instance of the type whose name is specified, using the named assembly file and parameterless constructor.
CreateInstanceFrom(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates an instance of the type whose name is specified, using the named assembly file and the constructor that best matches the specified parameters.
CreateInstanceFrom(String, String, Object[])	Creates an instance of the type whose name is specified, using the named assembly file and parameterless constructor.

Activator.CreateInstance Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the specified type using the constructor that best matches the specified parameters.

Overloads

Expand table

CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates an instance of the type whose name is specified, using the named assembly and the constructor that best matches the specified parameters.
CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo)	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance(Type, Object[], Object[])	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance(String, String, Object[])	Creates an instance of the type whose name is specified, using the named assembly and parameterless constructor.
CreateInstance(Type, Object[])	Creates an instance of the specified type using the constructor that best matches the specified parameters.
CreateInstance(Type, Boolean)	Creates an instance of the specified type using that type's parameterless constructor.
CreateInstance(String, String)	Creates an instance of the type whose name is specified, using the named assembly and

	parameterless constructor.
CreateInstance(Type)	Creates an instance of the specified type using that type's parameterless constructor.
CreateInstance<T>()	Creates an instance of the type designated by the specified generic type parameter, using the parameterless constructor.

CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates an instance of the type whose name is specified, using the named assembly and the constructor that best matches the specified parameters.

C#

```
public static System.Runtime.Remoting.ObjectHandle? CreateInstance
(string assemblyName, string typeName, bool ignoreCase,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, object?[]? args, System.Globalization.CultureInfo? culture,
object?[]? activationAttributes);
```

Parameters

`assemblyName` String

The name of the assembly where the type named `typeName` is sought. If `assemblyName` is `null`, the executing assembly is searched.

`typeName` String

The fully qualified name of the type to create an instance of.

`ignoreCase` Boolean

`true` to specify that the search for `typeName` is not case-sensitive; `false` to specify that the search is case-sensitive.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `typeName` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that uses `bindingAttr` and `args` to seek and identify the `typeName` constructor. If `binder` is `null`, the default binder is used.

`args` Object[]

An array of arguments that match in number, order, and type the parameters of the constructor to invoke. If `args` is an empty array or `null`, the constructor that takes no parameters (the parameterless constructor) is invoked.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `typeName` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. This is typically an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

A handle that must be unwrapped to access the newly created instance, or `null` for Nullable<T> instances with no value.

Exceptions

ArgumentNullException

`typeName` is `null`.

MissingMethodException

No matching constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

TargetInvocationException

The constructor, which was invoked through reflection, threw an exception.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

NotSupportedException

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

`activationAttributes` is not an empty array, and the type being created does not derive from MarshalByRefObject.

-or-

The constructor that best matches `args` has `varargs` arguments.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

The common language runtime (CLR) version 2.0 or later is currently loaded, and `assemblyName` was compiled for a version of the CLR that is later than the currently loaded version. Note that the .NET Framework versions 2.0, 3.0, and 3.5 all use CLR version 2.0.

FileLoadException

An assembly or module was loaded twice with two different evidences.

-or-

The assembly name or code base is invalid.

Remarks

Use ObjectHandle.Unwrap to unwrap the return value.

> ⓘ **Note**
>
> Starting with .NET Framework 2.0, this method can be used to create nonpublic types and members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types and members is restricted to the caller's grant set or to a subset thereof. (See **Security Considerations for Reflection**.) To use this functionality, your application should target .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates an instance of the specified type using the constructor that best matches the specified parameters.

C#

```
public static object? CreateInstance (Type type,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, object?[]? args, System.Globalization.CultureInfo? culture,
object?[]? activationAttributes);
```

Parameters

`type` Type

The type of object to create.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `type` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that uses `bindingAttr` and `args` to seek and identify the `type` constructor. If `binder` is `null`, the default binder is used.

`args` Object[]

An array of arguments that match in number, order, and type the parameters of the constructor to invoke. If `args` is an empty array or `null`, the constructor that takes no parameters (the parameterless constructor) is invoked.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `type` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. This is typically an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

Object

A reference to the newly created object, or `null` for Nullable<T> instances with no value.

Exceptions

ArgumentNullException

`type` is `null`.

ArgumentException

`type` is not a `RuntimeType`.

-or-

`type` is an open generic type (that is, the ContainsGenericParameters property returns `true`).

NotSupportedException

`type` cannot be a TypeBuilder.

-or-

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

`activationAttributes` is not an empty array, and the type being created does not derive from MarshalByRefObject.

-or-

The assembly that contains `type` is a dynamic assembly that was created with Save.

-or-

The constructor that best matches `args` has `varargs` arguments.

TargetInvocationException

The constructor being called throws an exception.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

MissingMethodException
No matching constructor was found.

COMException
`type` is a COM object but the class identifier used to obtain the type is invalid, or the identified class is not registered.

TypeLoadException
`type` is not a valid type.

Remarks

The constructor to be invoked must provide the most specific match with the specified argument list under the constraints of the specified binder and binding attributes.

> **Note**
>
> Starting with .NET Framework 2.0, this method can be used to access nonpublic types and members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the nonpublic types and members is restricted to the caller's grant set or to a subset thereof. (See **Security Considerations for Reflection**.) To use this functionality, your application should target .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	2.0, 2.1

CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo)

Creates an instance of the specified type using the constructor that best matches the specified parameters.

C#

```
public static object? CreateInstance (Type type,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, object?[]? args, System.Globalization.CultureInfo? culture);
```

Parameters

`type` Type

The type of object to create.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `type` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that uses `bindingAttr` and `args` to seek and identify the `type` constructor. If `binder` is `null`, the default binder is used.

`args` Object[]

An array of arguments that match in number, order, and type the parameters of the constructor to invoke. If `args` is an empty array or `null`, the constructor that takes no parameters (the parameterless constructor) is invoked.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `type` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

Returns

Object

A reference to the newly created object, or `null` for Nullable<T> instances with no value.

Exceptions

ArgumentNullException

`type` is `null`.

ArgumentException

`type` is not a `RuntimeType`.

-or-

`type` is an open generic type (that is, the ContainsGenericParameters property returns `true`).

NotSupportedException

`type` cannot be a TypeBuilder.

-or-

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

The assembly that contains `type` is a dynamic assembly that was created with Save.

-or-

The constructor that best matches `args` has `varargs` arguments.

TargetInvocationException

The constructor being called throws an exception.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

MissingMethodException
No matching constructor was found.

COMException
`type` is a COM object but the class identifier used to obtain the type is invalid, or the identified class is not registered.

TypeLoadException
`type` is not a valid type.

Remarks

The constructor to be invoked must provide the most specific match with the specified argument list under the constraints of the specified binder and binding attributes.

> **Note**
>
> Starting with .NET Framework 2.0, this method can be used to access nonpublic types and members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types and members is restricted to the caller's grant set or to a subset thereof. (See **Security Considerations for Reflection**.) To use this functionality, your application should target .NET Framework 3.5 or later.

CreateInstance(Type, Object[], Object[])

Creates an instance of the specified type using the constructor that best matches the specified parameters.

```
C#

public static object? CreateInstance (Type type, object?[]? args, object?
[]? activationAttributes);
```

Parameters

`type` Type

The type of object to create.

`args` Object[]

An array of arguments that match in number, order, and type the parameters of the constructor to invoke. If `args` is an empty array or `null`, the constructor that takes no parameters (the parameterless constructor) is invoked.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. This is typically an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

Object

A reference to the newly created object, or `null` for Nullable<T> instances with no value.

Exceptions

ArgumentNullException

`type` is `null`.

ArgumentException

`type` is not a `RuntimeType`.

-or-

`type` is an open generic type (that is, the ContainsGenericParameters property returns `true`).

NotSupportedException

`type` cannot be a TypeBuilder.

-or-

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

`activationAttributes` is not an empty array, and the type being created does not derive from MarshalByRefObject.

-or-

The assembly that contains `type` is a dynamic assembly that was created with Save.

-or-

The constructor that best matches `args` has `varargs` arguments.

TargetInvocationException

The constructor being called throws an exception.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

MissingMethodException

No matching public constructor was found.

COMException

`type` is a COM object but the class identifier used to obtain the type is invalid, or the identified class is not registered.

TypeLoadException

`type` is not a valid type.

Remarks

The constructor to be invoked must be accessible and must provide the most specific match with the specified argument list.

> ⓘ **Note**
>
> Starting with .NET Framework 2.0, this method can be used to access nonpublic types if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types is restricted to the caller's grant set or to a subset thereof. .NET Standard	2.0, 2.1

CreateInstance(String, String, Object[])

Creates an instance of the type whose name is specified, using the named assembly and parameterless constructor.

```
C#
```

```
public static System.Runtime.Remoting.ObjectHandle? CreateInstance
(string assemblyName, string typeName, object?[]? activationAttributes);
```

Parameters

`assemblyName` String

The name of the assembly where the type named `typeName` is sought. If `assemblyName` is `null`, the executing assembly is searched.

`typeName` String

The fully qualified name of the type to create an instance of.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. This is typically an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

A handle that must be unwrapped to access the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`typeName` is `null`.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

NotSupportedException

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

`activationAttributes` is not an empty array, and the type being created does not derive from MarshalByRefObject.

-or-

`activationAttributes` is not a UrlAttribute

array.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

The common language runtime (CLR) version 2.0 or later is currently loaded, and `assemblyName` was compiled for a version of the CLR that is later than the currently loaded version. Note that the .NET Framework versions 2.0, 3.0, and 3.5 all use CLR version 2.0.

FileLoadException

An assembly or module was loaded twice with two different evidences.

-or-

The assembly name or code base is invalid.

TargetInvocationException

The invoked constructor throws an exception.

-or-

An error occurred when attempting remote activation in a target specified in `activationAttributes`.

Remarks

Use ObjectHandle.Unwrap to unwrap the return value.

> ⓘ **Note**
>
> Starting with .NET Framework 2.0, this method can be used to create nonpublic types if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the nonpublic types is restricted to the caller's grant set or to a subset thereof. CreateInstance(Type, Object[])

Creates an instance of the specified type using the constructor that best matches the specified parameters.

C#

```
public static object? CreateInstance (Type type, params object?[]? args);
```

Parameters

`type` Type

The type of object to create.

`args` Object[]

An array of arguments that match in number, order, and type the parameters of the constructor to invoke. If `args` is an empty array or `null`, the constructor that takes no parameters (the parameterless constructor) is invoked.

Returns

Object

A reference to the newly created object, or `null` for Nullable<T> instances with no value.

Exceptions

ArgumentNullException

`type` is `null`.

ArgumentException

`type` is not a `RuntimeType`.

-or-

`type` is an open generic type (that is, the ContainsGenericParameters property returns `true`).

NotSupportedException

`type` cannot be a TypeBuilder.

-or-

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

The assembly that contains `type` is a dynamic assembly that was created with Save.

-or-

The constructor that best matches `args` has `varargs` arguments.

TargetInvocationException
The constructor being called throws an exception.

MethodAccessException
The caller does not have permission to call this constructor.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, MemberAccessException, instead.

MemberAccessException
Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException
The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

MissingMethodException
No matching public constructor was found.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, MissingMemberException, instead.

COMException
`type` is a COM object but the class identifier used to obtain the type is invalid, or the identified class is not registered.

TypeLoadException
`type` is not a valid type.

Examples

The following example calls the CreateInstance(Type, Object[]) method to create a String object. It calls the String.String(Char[], Int32, Int32) constructor to instantiate a string that contains ten elements from a character array starting at the fourteenth position.

```
C#

using System;
```

```
public class Example
{
   public static void Main()
   {
      // Initialize array of characters from a to z.
      char[] chars = new char[26];
      for (int ctr = 0; ctr < 26; ctr++)
         chars[ctr] = (char) (ctr + 0x0061);

      object obj = Activator.CreateInstance(typeof(string),
                                            new object[] { chars, 13, 10
} );
      Console.WriteLine(obj);
   }
}
// The example displays the following output:
//       nopqrstuvw
```

The following example creates a jagged array whose elements are arguments to be passed to a String constructor. The example then passes each array to the CreateInstance(Type, Object[]) method to invoke the appropriate string constructor.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      char[] characters = { 'a', 'b', 'c', 'd', 'e', 'f' };
      object[][] arguments = new object[3][] { new object[] { characters
},
                                               new object[] { characters,
1, 4 },
                                               new object[] {
characters[1], 20 } };

      for (int ctr = 0; ctr <= arguments.GetUpperBound(0); ctr++) {
         object[] args = arguments[ctr];
         object result = Activator.CreateInstance(typeof(string), args);
         Console.WriteLine("{0}: {1}", result.GetType().Name, result);
      }
   }
}
// The example displays the following output:
//    String: abcdef
//    String: bcde
//    String: bbbbbbbbbbbbbbbbbbb
```

Remarks

The constructor to be invoked must be accessible and must provide the most specific match with the specified argument list.

> ⓘ **Note**
>
> Starting with .NET Framework 2.0, this method can be used to access nonpublic types if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types is restricted to the caller's grant set or to a subset thereof. CreateInstance(Type, Boolean)

Creates an instance of the specified type using that type's parameterless constructor.

C#

```
public static object? CreateInstance (Type type, bool nonPublic);
```

Parameters

type Type

The type of object to create.

`nonPublic` Boolean

`true` if a public or nonpublic parameterless constructor can match; `false` if only a public parameterless constructor can match.

Returns

Object

A reference to the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`type` is `null`.

ArgumentException

`type` is not a `RuntimeType`.

-or-

`type` is an open generic type (that is, the ContainsGenericParameters property returns `true`).

NotSupportedException

`type` cannot be a TypeBuilder.

-or-

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

The assembly that contains `type` is a dynamic assembly that was created with Save.

TargetInvocationException

The constructor being called throws an exception.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

MissingMethodException

No matching public constructor was found.

COMException

`type` is a COM object but the class identifier used to obtain the type is invalid, or the identified class is not registered.

TypeLoadException

`type` is not a valid type.

Remarks

> **Note**
>
> Starting with .NET Framework 2.0, this method can be used to access nonpublic types and members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types and members is restricted to the caller's grant set or to a subset thereof. (See **Security Considerations for Reflection**.) To use this functionality, your application should target .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.5, 1.6, 2.0, 2.1

CreateInstance(String, String)

Creates an instance of the type whose name is specified, using the named assembly and parameterless constructor.

```
C#

public static System.Runtime.Remoting.ObjectHandle? CreateInstance
(string assemblyName, string typeName);
```

Parameters

`assemblyName` String

The name of the assembly where the type named `typeName` is sought. If `assemblyName` is `null`, the executing assembly is searched.

`typeName` String

The fully qualified name of the type to create an instance of.

Returns

ObjectHandle

A handle that must be unwrapped to access the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`typeName` is `null`.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

You cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

TargetInvocationException

The constructor, which was invoked through reflection, threw an exception.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

NotSupportedException

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

The common language runtime (CLR) version 2.0 or later is currently loaded, and `assemblyName` was compiled for a version of the CLR that is later than the currently loaded version. Note that the .NET Framework versions 2.0, 3.0, and 3.5 all use CLR version 2.0.

FileLoadException

An assembly or module was loaded twice with two different evidences.

-or-

The assembly name or code base is invalid.

Examples

The following example defines a class named `Person` in an assembly named `PersonInfo`. Note that the `Person` class has two constructors, one of which is parameterless.

```
C#
```

```
using System;

public class Person
{
   private string _name;

   public Person()
   { }

   public Person(string name)
   {
      this._name = name;
   }

   public string Name
   { get { return this._name; }
     set { this._name = value; } }

   public override string ToString()
   {
      return this._name;
   }
}
```

The following example calls the CreateInstance(String, String) method to instantiate the `Person` class. It requires a reference to PersonInfo.dll to be added to the project. Because the CreateInstance(String, String) method calls the `Person` class parameterless constructor, the example assigns a value to its `Name` property.

C#

```
using System;
using System.Runtime.Remoting;

public class Example
{
   public static void Main()
   {
      ObjectHandle handle = Activator.CreateInstance("PersonInfo",
"Person");
      Person p = (Person) handle.Unwrap();
      p.Name = "Samuel";
      Console.WriteLine(p);
   }
}
// The example displays the following output:
//        Samuel
```

However, CreateInstance is frequently called to instantiate a type that crosses machine boundaries or that is not known at design time. In this case, you cannot include a reference to the assembly in the project and cannot make early-bound calls to the type's members. To work around this limitation, the following example uses the CreateInstance method along with reflection to assign a value to the `Person` object's `Name` property and to display its value.

C#

```
using System;
using System.Reflection;
using System.Runtime.Remoting;

public class Example
{
   public static void Main()
   {
      ObjectHandle handle = Activator.CreateInstance("PersonInfo",
"Person");
      object p = handle.Unwrap();
      Type t = p.GetType();
      PropertyInfo prop = t.GetProperty("Name");
      if (prop != null)
         prop.SetValue(p, "Samuel");

      MethodInfo method = t.GetMethod("ToString");
      object retVal = method.Invoke(p, null);
      if (retVal != null)
         Console.WriteLine(retVal);
   }
}
// The example displays the following output:
//        Samuel
```

Remarks

Use ObjectHandle.Unwrap to unwrap the return value.

`assemblyName` can be either of the following:

- The simple name of an assembly, without its path or file extension. For example, you would specify `TypeExtensions` for an assembly whose path and name are .\bin\TypeExtensions.dll.

- The full name of a signed assembly, which consists of its simple name, version, culture, and public key token; for example, "TypeExtensions, Version=1.0.0.0, Culture=neutral, PublicKeyToken=181869f2f7435b51".

For more information on how the common language runtime identifies and loads assemblies, see How the Runtime Locates Assemblies. For information on using the application configuration file to define assembly locations, see Specifying an Assembly's Location. If `assemblyName` is found, it is loaded in the default context.

> **Note**
>
> Starting with .NET Framework 2.0, this method can be used to create nonpublic types if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types is restricted to the caller's grant set or to a subset thereof. (See **Security Considerations for Reflection**.) To use this functionality, your application should target .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstance(Type)

Creates an instance of the specified type using that type's parameterless constructor.

C#

```
public static object? CreateInstance (Type type);
```

Parameters

`type` Type

The type of object to create.

Returns

Object

A reference to the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`type` is `null`.

ArgumentException

`type` is not a `RuntimeType`.

-or-

`type` is an open generic type (that is, the ContainsGenericParameters property returns `true`).

NotSupportedException

`type` cannot be a TypeBuilder.

-or-

Creation of TypedReference, ArgIterator, Void, and RuntimeArgumentHandle types, or arrays of those types, is not supported.

-or-

The assembly that contains `type` is a dynamic assembly that was created with Save.

TargetInvocationException

The constructor being called throws an exception.

MethodAccessException

The caller does not have permission to call this constructor.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, MemberAccessException, instead.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

InvalidComObjectException

The COM type was not obtained through GetTypeFromProgID or GetTypeFromCLSID.

MissingMethodException

No matching public constructor was found.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, MissingMemberException, instead.

COMException

`type` is a COM object but the class identifier used to obtain the type is invalid, or the identified class is not registered.

TypeLoadException

`type` is not a valid type.

Examples

The following code example demonstrates how to call the CreateInstance(Type) method. Instances of several different types are created and their default values are displayed.

C#

```
using System;

class DynamicInstanceList
{
    private static string instanceSpec =
"System.EventArgs;System.Random;" +
        "System.Exception;System.Object;System.Version";

    public static void Main()
    {
        string[] instances = instanceSpec.Split(';');
        Array instlist = Array.CreateInstance(typeof(object),
instances.Length);
        object item;
        for (int i = 0; i < instances.Length; i++)
        {
            // create the object from the specification string
            Console.WriteLine("Creating instance of: {0}", instances[i]);
            item = Activator.CreateInstance(Type.GetType(instances[i]));
            instlist.SetValue(item, i);
        }
        Console.WriteLine("\nObjects and their default values:\n");
        foreach (object o in instlist)
        {
            Console.WriteLine("Type:     {0}\nValue:    {1}\nHashCode:
{2}\n",
                o.GetType().FullName, o.ToString(), o.GetHashCode());
```

```
        }
    }
}

// This program will display output similar to the following:
//
// Creating instance of: System.EventArgs
// Creating instance of: System.Random
// Creating instance of: System.Exception
// Creating instance of: System.Object
// Creating instance of: System.Version
//
// Objects and their default values:
//
// Type:     System.EventArgs
// Value:    System.EventArgs
// HashCode: 46104728
//
// Type:     System.Random
// Value:    System.Random
// HashCode: 12289376
//
// Type:     System.Exception
// Value:    System.Exception: Exception of type 'System.Exception' was
thrown.
// HashCode: 55530882
//
// Type:     System.Object
// Value:    System.Object
// HashCode: 30015890
//
// Type:     System.Version
// Value:    0.0
// HashCode: 1048575
```

Remarks

The constructor to be invoked must be accessible.

> ⓘ **Note**
>
> Starting with .NET Framework 2.0, this method can be used to access nonpublic types if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the assembly that contains the nonpublic types is restricted to the caller's grant set or to a subset thereof. (See **Security Considerations for Reflection**.) To use this functionality, your application should target .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UWP	10.0

CreateInstance<T>()

Creates an instance of the type designated by the specified generic type parameter, using the parameterless constructor.

C#

```
public static T CreateInstance<T> ();
```

Type Parameters

T

The type to create.

Returns

T

A reference to the newly created object, or `null` for Nullable<T> instances.

Exceptions

MissingMethodException

Cannot create an instance of an abstract class, or the type that is specified for `T` does not have a parameterless constructor.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, MissingMemberException, instead.

Remarks

The CreateInstance<T>() generic method is used by compilers to implement the instantiation of types specified by type parameters. For example, in the following generic method, the implementation of `new T()` (`gcnew T()` in C++) uses the CreateInstance<T>() generic method.

```
C#

public static T Factory<T>() where T : new()
{
    return new T();
}
```

In general, there is no use for the CreateInstance<T>() generic method in application code, because the type must be known at compile time. If the type is known at compile time, normal instantiation syntax can be used (`new` operator in C#, `New` in Visual Basic, `gcnew` in C++). If the type is not known at compile time, you can call a non-generic overload of CreateInstance.

There are no overloads of the CreateInstance<T>() generic method that take argument lists, because the non-generic overloads of CreateInstance already provide late-bound constructor resolution.

Activator.CreateInstanceFrom Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the type whose name is specified, using the named assembly file and the constructor that best matches the specified parameters.

Overloads

Expand table

CreateInstanceFrom(String, String, Object[])	Creates an instance of the type whose name is specified, using the named assembly file and parameterless constructor.
CreateInstanceFrom(String, String)	Creates an instance of the type whose name is specified, using the named assembly file and parameterless constructor.
CreateInstanceFrom(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates an instance of the type whose name is specified, using the named assembly file and the constructor that best matches the specified parameters.

CreateInstanceFrom(String, String, Object[])

Creates an instance of the type whose name is specified, using the named assembly file and parameterless constructor.

C#

```
public static System.Runtime.Remoting.ObjectHandle? CreateInstanceFrom
(string assemblyFile, string typeName, object?[]? activationAttributes);
```

Parameters

`assemblyFile` String

The name of a file that contains an assembly where the type named `typeName` is sought.

`typeName` String

The name of the type to create an instance of.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. This is typically an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

A handle that must be unwrapped to access the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`typeName` is `null`.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyFile`.

FileNotFoundException

`assemblyFile` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

TargetInvocationException

The constructor, which was invoked through reflection, threw an exception.

NotSupportedException

`activationAttributes` is not an empty array, and the type being created does not derive from MarshalByRefObject.

SecurityException

The caller does have the required FileIOPermission.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

The common language runtime (CLR) version 2.0 or later is currently loaded, and `assemblyName` was compiled for a version of the CLR that is later than the currently loaded version. Note that the .NET Framework versions 2.0, 3.0, and 3.5 all use CLR version 2.0.

Remarks

Use the ObjectHandle.Unwrap method to unwrap the return value.

For information about other exceptions that can be thrown by invoked methods, see the Exceptions section of the Assembly.LoadFrom and CreateInstance methods.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstanceFrom(String, String)

Creates an instance of the type whose name is specified, using the named assembly file and parameterless constructor.

```
C#

public static System.Runtime.Remoting.ObjectHandle? CreateInstanceFrom
(string assemblyFile, string typeName);
```

Parameters

`assemblyFile` String

The name of a file that contains an assembly where the type named `typeName` is sought.

`typeName` String

The name of the type to create an instance of.

Returns

ObjectHandle

A handle that must be unwrapped to access the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`typeName` is `null`.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyFile`.

FileNotFoundException

`assemblyFile` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

TargetInvocationException

The constructor, which was invoked through reflection, threw an exception.

SecurityException

The caller does have the required FileIOPermission.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

The common language runtime (CLR) version 2.0 or later is currently loaded, and `assemblyName` was compiled for a version of the CLR that is later than the currently loaded version. Note that the .NET Framework versions 2.0, 3.0, and 3.5 all use CLR version 2.0.

Examples

The following code example demonstrates how to call the CreateInstanceFrom method. This code example is part of a larger example provided for the Activator class.

C#

```
// Create an instance of the SomeType class that is defined in this
// assembly.
System.Runtime.Remoting.ObjectHandle oh =
    Activator.CreateInstanceFrom(Assembly.GetEntryAssembly().CodeBase,
                                 typeof(SomeType).FullName);

// Call an instance method defined by the SomeType type using this
object.
SomeType st = (SomeType) oh.Unwrap();

st.DoSomething(5);
```

Remarks

Use the ObjectHandle.Unwrap method to unwrap the return value.

For information about other exceptions that can be thrown by invoked methods, see the Exceptions section of the Assembly.LoadFrom and CreateInstance methods.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstanceFrom(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates an instance of the type whose name is specified, using the named assembly file and the constructor that best matches the specified parameters.

C#

```
public static System.Runtime.Remoting.ObjectHandle? CreateInstanceFrom
(string assemblyFile, string typeName, bool ignoreCase,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, object?[]? args, System.Globalization.CultureInfo? culture,
object?[]? activationAttributes);
```

Parameters

`assemblyFile` String

The name of a file that contains an assembly where the type named `typeName` is sought.

`typeName` String

The name of the type to create an instance of.

`ignoreCase` Boolean

`true` to specify that the search for `typeName` is not case-sensitive; `false` to specify that the search is case-sensitive.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `typeName` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that uses `bindingAttr` and `args` to seek and identify the `typeName` constructor. If `binder` is `null`, the default binder is used.

`args` Object[]

An array of arguments that match in number, order, and type the parameters of the constructor to invoke. If `args` is an empty array or `null`, the constructor that takes no parameters (the parameterless constructor) is invoked.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `typeName` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. This is typically an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

A handle that must be unwrapped to access the newly created object, or `null` for Nullable<T> instances.

Exceptions

ArgumentNullException

`typeName` is `null`.

MissingMethodException

No matching constructor was found.

TypeLoadException

`typename` was not found in `assemblyFile`.

FileNotFoundException

`assemblyFile` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

TargetInvocationException

The constructor, which was invoked through reflection, threw an exception.

SecurityException

The caller does not have the required FileIOPermission.

NotSupportedException

`activationAttributes` is not an empty array, and the type being created does not derive from MarshalByRefObject.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

The common language runtime (CLR) version 2.0 or later is currently loaded, and `assemblyName` was compiled for a version of the CLR that is later than the currently loaded version. Note that the .NET Framework versions 2.0, 3.0, and 3.5 all use CLR version 2.0.

Remarks

Use the ObjectHandle.Unwrap method to unwrap the return value.

For information about other exceptions that can be thrown by invoked methods, see the Exceptions section of the Assembly.LoadFrom and CreateInstance methods.

AggregateException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents one or more errors that occur during application execution.

C#

```
public class AggregateException : Exception
```

Inheritance Object → Exception → AggregateException

Examples

The following example catches the AggregateException exception and calls the Handle method to handle each exception it contains. Compiling and running the example with the first `task1` variable should result in an AggregateException object that contains an UnauthorizedAccessException exception. Commenting out that line, uncommenting the second `task1` variable, and compiling and running the example produces an AggregateException object that contains an IndexOutOfRangeException exception.

C#

```
using System;
using System.IO;
using System.Threading.Tasks;

class Example
{
   static async Task Main(string[] args)
   {
      // Get a folder path whose directories should throw an
UnauthorizedAccessException.
      string path = Directory.GetParent(
                                Environment.GetFolderPath(

Environment.SpecialFolder.UserProfile)).FullName;

      // Use this line to throw UnauthorizedAccessException, which we
```

```
handle.
      Task<string[]> task1 = Task<string[]>.Factory.StartNew(() =>
GetAllFiles(path));

      // Use this line to throw an exception that is not handled.
      // Task task1 = Task.Factory.StartNew(() => { throw new
IndexOutOfRangeException(); } );
      try
      {
          await task1;
      }
      catch (UnauthorizedAccessException ae)
      {
          Console.WriteLine("Caught unauthorized access exception-await
behavior");
      }
      catch (AggregateException ae)
      {
          Console.WriteLine("Caught aggregate exception-Task.Wait
behavior");
          ae.Handle((x) =>
          {
              if (x is UnauthorizedAccessException) // This we know how to
handle.
              {
                  Console.WriteLine("You do not have permission to access
all folders in this path.");
                  Console.WriteLine("See your network administrator or try
another path.");
                  return true;
              }
              return false; // Let anything else stop the application.
          });
      }

      Console.WriteLine("task1 Status: {0}{1}", task1.IsCompleted ?
"Completed," : "",
                                                  task1.Status);
   }

   static string[] GetAllFiles(string str)
   {
      // Should throw an UnauthorizedAccessException exception.
      return System.IO.Directory.GetFiles(str, "*.txt",
System.IO.SearchOption.AllDirectories);
   }
}
// The example displays the following output if the file access task is run:
//       You do not have permission to access all folders in this path.
//       See your network administrator or try another path.
//       task1 Status: Completed,Faulted
// It displays the following output if the second task is run:
//       Unhandled Exception: System.AggregateException: One or more errors
occurred. ---
//       > System.IndexOutOfRangeException: Index was outside the bounds of
```

```
the array.
//          at Example.<Main>b__0()
//          at System.Threading.Tasks.Task.Execute()
//          --- End of inner exception stack trace ---
//          at System.AggregateException.Handle(Func`2 predicate)
//          at Example.Main(String[] args)
```

Remarks

AggregateException is used to consolidate multiple failures into a single, throwable exception object. It is used extensively in the Task Parallel Library (TPL) and Parallel LINQ (PLINQ). For more information, see Exception Handling and How to: Handle Exceptions in a PLINQ Query. For additional information, see the Aggregating Exceptions entry in the .NET Matters blog.

Constructors

Expand table

AggregateException()	Initializes a new instance of the AggregateException class with a system-supplied message that describes the error.
AggregateException(Exception[])	Initializes a new instance of the AggregateException class with references to the inner exceptions that are the cause of this exception.
Aggregate Exception(IEnumerable<Exception>)	Initializes a new instance of the AggregateException class with references to the inner exceptions that are the cause of this exception.
AggregateException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AggregateException class with serialized data.
AggregateException(String)	Initializes a new instance of the AggregateException class with a specified message that describes the error.
AggregateException(String, Exception)	Initializes a new instance of the AggregateException class with a specified error message and a reference to the inner exception that is the cause of this exception.
AggregateException(String, Exception[])	Initializes a new instance of the AggregateException class with a specified error message and references

	to the inner exceptions that are the cause of this exception.
AggregateException(String, IEnumerable<Exception>)	Initializes a new instance of the AggregateException class with a specified error message and references to the inner exceptions that are the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Inner Exceptions	Gets a read-only collection of the Exception instances that caused the current exception.
Message	Gets a message that describes the exception.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object.

	(Inherited from Object)
Flatten()	Flattens an AggregateException instances into a single, new instance.
GetBaseException()	Returns the AggregateException that is the root cause of this exception.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AggregateException class with serialized data.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
Handle(Func<Exception,Boolean>)	Invokes a handler on each Exception contained by this AggregateException.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current AggregateException.

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

AggregateException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the AggregateException class.

Overloads

Expand table

AggregateException()	Initializes a new instance of the AggregateException class with a system-supplied message that describes the error.
AggregateException(IEnumerable<Exception>)	Initializes a new instance of the AggregateException class with references to the inner exceptions that are the cause of this exception.
AggregateException(Exception[])	Initializes a new instance of the AggregateException class with references to the inner exceptions that are the cause of this exception.
AggregateException(String)	Initializes a new instance of the AggregateException class with a specified message that describes the error.
AggregateException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AggregateException class with serialized data.
AggregateException(String, IEnumerable<Exception>)	Initializes a new instance of the AggregateException class with a specified error message and references to the inner exceptions that are the cause of this exception.
AggregateException(String, Exception)	Initializes a new instance of the AggregateException class with a specified

	error message and a reference to the inner exception that is the cause of this exception.
AggregateException(String, Exception[])	Initializes a new instance of the AggregateException class with a specified error message and references to the inner exceptions that are the cause of this exception.

AggregateException()

Initializes a new instance of the AggregateException class with a system-supplied message that describes the error.

```
C#

public AggregateException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "System.AggregateException: One or more errors occurred." This message takes into account the current system culture.

The following table shows the initial property values for an instance of AggregateException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

AggregateException(IEnumerable<Exception>)

Initializes a new instance of the AggregateException class with references to the inner exceptions that are the cause of this exception.

C#

```
public AggregateException
(System.Collections.Generic.IEnumerable<Exception> innerExceptions);
```

Parameters

`innerExceptions` IEnumerable<Exception>

The exceptions that are the cause of the current exception.

Exceptions

ArgumentNullException

The `innerExceptions` argument is null.

ArgumentException

An element of `innerExceptions` is null.

Applies to

UWP	10.0

AggregateException(String)

Initializes a new instance of the AggregateException class with a specified message that describes the error.

C#

```
public AggregateException (string? message);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of AggregateException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string specified in `message`.

UWP	10.0

AggregateException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the AggregateException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected AggregateException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` argument is null.

SerializationException

The exception could not be deserialized correctly.

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AggregateException(String, IEnumerable<Exception>)

Initializes a new instance of the AggregateException class with a specified error message and references to the inner exceptions that are the cause of this exception.

C#

```
public AggregateException (string? message,
System.Collections.Generic.IEnumerable<Exception> innerExceptions);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerExceptions` IEnumerable<Exception>

The exceptions that are the cause of the current exception.

Exceptions

ArgumentNullException

The `innerExceptions` argument is null.

ArgumentException

An element of `innerExceptions` is null.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

AggregateException(String, Exception)

Initializes a new instance of the AggregateException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public AggregateException (string? message, Exception innerException);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Exceptions

ArgumentNullException

The `innerException` argument is null.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of AggregateException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string specified in `message`.

AggregateException.InnerExceptions Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a read-only collection of the Exception instances that caused the current exception.

C#

```
public System.Collections.ObjectModel.ReadOnlyCollection<Exception>
InnerExceptions { get; }
```

Property Value

ReadOnlyCollection<Exception>

A read-only collection of the Exception instances that caused the current exception.

Applies to

Product	Versions

AggregateException.Flatten Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Flattens an AggregateException instances into a single, new instance.

C#

```
public AggregateException Flatten ();
```

Returns

AggregateException

A new, flattened AggregateException.

Examples

In the following example, nested AggregateException instances are flattened and handled in just one loop.

C#

```
using System;
using System.Threading.Tasks;

public class Example
{
   public static void Main()
   {
      var task1 = Task.Factory.StartNew(() => {
                      var child1 = Task.Factory.StartNew(() => {
                         var child2 = Task.Factory.StartNew(() => {
                             // This exception is nested inside three
AggregateExceptions.
                             throw new CustomException("Attached child2
faulted.");
                         }, TaskCreationOptions.AttachedToParent);

                         // This exception is nested inside two
```

```
AggregateExceptions.
                        throw new CustomException("Attached child1
faulted.");
                    }, TaskCreationOptions.AttachedToParent);
      });

      try {
         task1.Wait();
      }
      catch (AggregateException ae) {
         foreach (var e in ae.Flatten().InnerExceptions) {
            if (e is CustomException) {
               Console.WriteLine(e.Message);
            }
            else {
               throw;
            }
         }
      }
   }
}

public class CustomException : Exception
{
   public CustomException(String message) : base(message)
   {}
}
// The example displays the following output:
//    Attached child1 faulted.
//    Attached child2 faulted.
```

You can also use the AggregateException.Flatten method to rethrow the inner exceptions from multiple AggregateException instances thrown by multiple tasks in a single AggregateException instance, as the following example shows.

C#

```
using System;
using System.Collections.Generic;
using System.IO;
using System.Threading.Tasks;

public class Example2
{
   public static void Main()
   {
        try {
            ExecuteTasks();
        }
        catch (AggregateException ae) {
            foreach (var e in ae.InnerExceptions) {
                Console.WriteLine("{0}:\n   {1}", e.GetType().Name,
```

```
e.Message);
            }
        }
    }

    static void ExecuteTasks()
    {
        // Assume this is a user-entered String.
        String path = @"C:\";
        List<Task> tasks = new List<Task>();

        tasks.Add(Task.Run(() => {
                                // This should throw an
UnauthorizedAccessException.
                                return Directory.GetFiles(path, "*.txt",

SearchOption.AllDirectories);
                            }));

        tasks.Add(Task.Run(() => {
                                if (path == @"C:\")
                                   throw new ArgumentException("The system
root is not a valid path.");
                                return new String[] { ".txt", ".dll", ".exe",
".bin", ".dat" };
                            }));

        tasks.Add(Task.Run(() => {
                                 throw new NotImplementedException("This
operation has not been implemented.");
                            }));

        try {
            Task.WaitAll(tasks.ToArray());
        }
        catch (AggregateException ae) {
            throw ae.Flatten();
        }
    }
}
// The example displays the following output:
//       UnauthorizedAccessException:
//          Access to the path 'C:\Documents and Settings' is denied.
//       ArgumentException:
//          The system root is not a valid path.
//       NotImplementedException:
//          This operation has not been implemented.
```

Remarks

If a task has an attached child task that throws an exception, that exception is wrapped in an AggregateException exception before it is propagated to the parent task, which

wraps that exception in its own AggregateException exception before it propagates it back to the calling thread. In such cases, the InnerExceptions property of the AggregateException exception that is caught by the Task.Wait, Wait, Task.WaitAny or Task.WaitAll method contains one or more AggregateException instances, not the original exceptions that caused the fault. To avoid having to iterate over nested AggregateException exceptions, you can use the Flatten method to remove all the nested AggregateException exceptions, so that the InnerExceptions property of the returned AggregateException object contains the original exceptions.

This method recursively flattens all instances of AggregateException exceptions that are inner exceptions of the current AggregateException instance. The inner exceptions returned in the new AggregateException are the union of all the inner exceptions from exception tree rooted at the current AggregateException instance.

Applies to

AggregateException.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the AggregateException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` argument is null.

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AggregateException.Handle(Func<Exception,Boolean>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Invokes a handler on each Exception contained by this AggregateException.

```
C#
public void Handle (Func<Exception,bool> predicate);
```

Parameters

`predicate` Func<Exception,Boolean>

The predicate to execute for each exception. The predicate accepts as an argument the Exception to be processed and returns a Boolean to indicate whether the exception was handled.

Exceptions

ArgumentNullException

The `predicate` argument is null.

AggregateException

An exception contained by this AggregateException was not handled.

Examples

Ordinarily, an exception handler that catches an AggregateException exception uses a `foreach` loop (in C#) or `For Each` loop (in Visual Basic) to handle each exception in its InnerExceptions collection. Instead, the following example uses the Handle method to

handle each exception, and only rethrows exceptions that are not `CustomException` instances.

C#

```
using System;
using System.Threading.Tasks;

public class Example
{
   public static void Main()
   {
      var task1 = Task.Run( () => { throw new CustomException("This
exception is expected!"); } );

      try {
          task1.Wait();
      }
      catch (AggregateException ae)
      {
         // Call the Handle method to handle the custom exception,
         // otherwise rethrow the exception.
         ae.Handle(ex => { if (ex is CustomException)
                              Console.WriteLine(ex.Message);
                            return ex is CustomException;
                          });
      }
   }
}

public class CustomException : Exception
{
   public CustomException(String message) : base(message)
   {}
}
// The example displays the following output:
//        This exception is expected!
```

The following is a more complete example that uses the Handle method to provide special handling for an UnauthorizedAccessException when enumerating files.

C#

```
using System;
using System.IO;
using System.Threading.Tasks;

public class Example2
{
    public static void Main()
    {
        // This should throw an UnauthorizedAccessException.
```

```
        try {
            var files = GetAllFiles(@"C:\");
            if (files != null)
               foreach (var file in files)
                  Console.WriteLine(file);
         }
         catch (AggregateException ae) {
            foreach (var ex in ae.InnerExceptions)
                Console.WriteLine("{0}: {1}", ex.GetType().Name, ex.Message);
         }
         Console.WriteLine();

         // This should throw an ArgumentException.
         try {
            foreach (var s in GetAllFiles(""))
               Console.WriteLine(s);
         }
         catch (AggregateException ae) {
            foreach (var ex in ae.InnerExceptions)
                Console.WriteLine("{0}: {1}", ex.GetType().Name, ex.Message);
         }
     }

     static string[] GetAllFiles(string path)
     {
        var task1 = Task.Run( () => Directory.GetFiles(path, "*.txt",

SearchOption.AllDirectories));

        try {
           return task1.Result;
        }
        catch (AggregateException ae) {
           ae.Handle( x => { // Handle an UnauthorizedAccessException
                             if (x is UnauthorizedAccessException) {
                                 Console.WriteLine("You do not have
permission to access all folders in this path.");
                                 Console.WriteLine("See your network
administrator or try another path.");
                             }
                             return x is UnauthorizedAccessException;
                          });
           return Array.Empty<String>();
        }
    }
}
// The example displays the following output:
//       You do not have permission to access all folders in this path.
//       See your network administrator or try another path.
//
//       ArgumentException: The path is not of a legal form.
```

Remarks

Each invocation of the `predicate` returns true or false to indicate whether the Exception was handled. After all invocations, if any exceptions went unhandled, all unhandled exceptions will be put into a new AggregateException which will be thrown. Otherwise, the Handle method simply returns. If any invocations of the `predicate` throws an exception, it will halt the processing of any more exceptions and immediately propagate the thrown exception as-is.

AggregateException.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates and returns a string representation of the current AggregateException.

C#

```
public override string ToString ();
```

Returns

String

A string representation of the current exception.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppContext Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides members for setting and retrieving data about an application's context.

C#

```
public static class AppContext
```

Inheritance Object → AppContext

Remarks

For more information about this API, see Supplemental API remarks for AppContext.

Properties

Expand table

BaseDirectory	Gets the file path of the base directory that the assembly resolver uses to probe for assemblies.
TargetFrameworkName	Gets the name of the framework version targeted by the current application.

Methods

Expand table

GetData(String)	Returns the value of the named data element assigned to the current application domain.
SetData(String, Object)	Sets the value of the named data element assigned to the current application domain.

SetSwitch(String, Boolean)	Sets the value of a switch.
TryGetSwitch(String, Boolean)	Tries to get the value of a switch.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

AppContext.BaseDirectory Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the file path of the base directory that the assembly resolver uses to probe for assemblies.

C#

```
public static string BaseDirectory { get; }
```

Property Value

String

The file path of the base directory that the assembly resolver uses to probe for assemblies.

Remarks

This is a per-application domain property. Its value corresponds to the AppDomain.BaseDirectory property of the current application domain.

In .NET 5 and later versions, for bundled assemblies, the value returned is the containing directory of the host executable.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

AppContext.TargetFrameworkName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the framework version targeted by the current application.

C#

```
public static string? TargetFrameworkName { get; }
```

Property Value

String

The name of the framework version targeted by the current application.

Remarks

The name of the target framework version corresponds to the value of the TargetFrameworkAttribute.FrameworkName property. For a list of target framework names for .NET Framework, see the <supportedRuntime> Element element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.6, 2.0, 2.1

AppContext.GetData(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the value of the named data element assigned to the current application domain.

C#

```
public static object? GetData (string name);
```

Parameters

name String

The name of the data element.

Returns

Object

The value of `name`, if `name` identifies a named value; otherwise, `null`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.6, 2.0, 2.1

AppContext.SetData(String, Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sets the value of the named data element assigned to the current application domain.

C#

```
public static void SetData (string name, object? data);
```

Parameters

name String

The name of the data element

data Object

The value of `name`

Exceptions

ArgumentNullException

`name` is `null`.

Applies to

Product	Versions
.NET	7, 8, 9

AppContext.SetSwitch(String, Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sets the value of a switch.

```
C#
public static void SetSwitch (string switchName, bool isEnabled);
```

Parameters

`switchName` String

The name of the switch.

`isEnabled` Boolean

The value of the switch.

Exceptions

ArgumentNullException

`switchName` is `null`.

ArgumentException

`switchName` is Empty.

Examples

The following line of code sets a switch named `Switch.AmazingLib.ThrowOnException` to `true`, which enables a legacy behavior. The library can then check whether a library consumer has set the value of the switch by calling the TryGetSwitch method.

```
C#
```

```
AppContext.SetSwitch("Switch.AmazingLib.ThrowOnException", true);
```

Remarks

The AppContext class enables library writers to provide a uniform opt-out mechanism for new functionality for their users. It establishes a loosely coupled contract between components in order to communicate an opt-out request. This capability is typically important when a change is made to existing functionality. Conversely, there is already an implicit opt-in for new functionality.

The SetSwitch method is called by an application (or a library) to declare the value of a switch (which is always a Boolean value) that a dependent library defines. The switch is always implicitly `false`, which provides the new behavior. Setting the switch to `true` enables it, which provides the legacy behavior. Explicitly setting the switch to `false` also provides the new behavior. The dependent library can then check the value of the switch by calling the TryGetSwitch method.

> **Note**
>
> It's beneficial to use a consistent format for switch names, since they are a formal contract exposed by a library. The following are two obvious formats.
>
> - *Switch.namespace.switchname*
> - *Switch.library.switchname*

For applications running on .NET Framework, in addition to setting the value of a switch programmatically, it can also be set:

- By adding the switch name and value to the <AppContextSwitchOverrides> element in the <runtime> section of an application configuration file. For example, the following defines a switch named `Libraries.FPLibrary.UseExactFloatingPointComparison` whose value is `False`.

  XML

  ```
  <configuration>
     <runtime>
        <AppContextSwitchOverrides
  value="Libraries.FPLibrary.UseExactFloatingPointComparison=false" />
     </runtime>
  </configuration>
  ```

- By adding a string value whose name is the name of the switch to the **HKLM\SOFTWARE\Microsoft\.NETFramework\AppContext** (and **HKLM\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\AppContext**) subkeys in the registry. Its value must be the string representation of a Boolean that can be parsed by the Boolean.Parse method; that is, it must be "True", "true", "False", or "false".

If the registry entry exists, its value is overwritten by the `isEnabled` argument when SetSwitch is called. That is, the most recent call to the SetSwitch method overrides the value defined in the registry, in an app configuration file, or by previous calls to the SetSwitch method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

AppContext.TryGetSwitch(String, Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to get the value of a switch.

C#

```
public static bool TryGetSwitch (string switchName, out bool isEnabled);
```

Parameters

`switchName` String

The name of the switch.

`isEnabled` Boolean

When this method returns, contains the value of `switchName` if `switchName` was found, or `false` if `switchName` was not found. This parameter is passed uninitialized.

Returns

Boolean

`true` if `switchName` was set and the `isEnabled` argument contains the value of the switch; otherwise, `false`.

Exceptions

ArgumentNullException

`switchName` is `null`.

ArgumentException

`switchName` is Empty.

Examples

The following example determines whether a library consumer has set a switch named `Switch.AmazingLib.ThrowOnException`.

C#

```
public class AmazingLib
{
   private bool shouldThrow;

   public void PerformAnOperation()
   {
      if (!AppContext.TryGetSwitch("Switch.AmazingLib.ThrowOnException", out
shouldThrow)) {
         // This is the case where the switch value was not set by the
application.
         // The library can choose to get the value of shouldThrow by other
means.
         // If no overrides or default values are specified, the value
should be 'false'.
         // A false value implies the latest behavior.
      }

      // The library can use the value of shouldThrow to throw exceptions or
not.
      if (shouldThrow) {
         // old code
      }
      else {
          // new code
      }
   }
}
```

Remarks

The AppContext class enables library writers to provide a uniform opt-out mechanism for new functionality for their users. It establishes a loosely coupled contract between components in order to communicate an opt-out request. This capability is typically important when a change is made to existing functionality. Conversely, there is already an implicit opt-in for new functionality.

The common language runtime automatically populates the switches assigned to an AppContext instance by reading the registry and the application's configuration file. The value of these switches can then be overridden, and new switches added, by calling the SetSwitch method.

A library calls the TryGetSwitch method to check whether its consumers have declared the value of the switch and then act appropriately on it. By default, if the switch is not defined, the new functionality is enabled. If the switch is defined and its value is `false`, the new functionality is also enabled. If its value is `true`, the legacy behavior is enabled.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

AppDomain Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an application domain, which is an isolated environment where applications execute. This class cannot be inherited.

C#

```
public sealed class AppDomain : MarshalByRefObject
```

Inheritance Object → MarshalByRefObject → AppDomain

Examples

This example shows how to create a new AppDomain, instantiate a type in that new AppDomain, and communicate with that type's object. In addition, this example shows how to unload the AppDomain causing the object to be garbage collected.

C#

```
using System;
using System.Reflection;
using System.Threading;

class Module1
{
    public static void Main()
    {
        // Get and display the friendly name of the default AppDomain.
        string callingDomainName = Thread.GetDomain().FriendlyName;
        Console.WriteLine(callingDomainName);

        // Get and display the full name of the EXE assembly.
        string exeAssembly = Assembly.GetEntryAssembly().FullName;
        Console.WriteLine(exeAssembly);

        // Construct and initialize settings for a second AppDomain.
        AppDomainSetup ads = new AppDomainSetup();
        ads.ApplicationBase = AppDomain.CurrentDomain.BaseDirectory;
```

```
        ads.DisallowBindingRedirects = false;
        ads.DisallowCodeDownload = true;
        ads.ConfigurationFile =
            AppDomain.CurrentDomain.SetupInformation.ConfigurationFile;

        // Create the second AppDomain.
        AppDomain ad2 = AppDomain.CreateDomain("AD #2", null, ads);

        // Create an instance of MarshalbyRefType in the second AppDomain.
        // A proxy to the object is returned.
        MarshalByRefType mbrt =
            (MarshalByRefType) ad2.CreateInstanceAndUnwrap(
                exeAssembly,
                typeof(MarshalByRefType).FullName
            );

        // Call a method on the object via the proxy, passing the
        // default AppDomain's friendly name in as a parameter.
        mbrt.SomeMethod(callingDomainName);

        // Unload the second AppDomain. This deletes its object and
        // invalidates the proxy object.
        AppDomain.Unload(ad2);
        try
        {
            // Call the method again. Note that this time it fails
            // because the second AppDomain was unloaded.
            mbrt.SomeMethod(callingDomainName);
            Console.WriteLine("Sucessful call.");
        }
        catch(AppDomainUnloadedException)
        {
            Console.WriteLine("Failed call; this is expected.");
        }
    }
}

// Because this class is derived from MarshalByRefObject, a proxy
// to a MarshalByRefType object can be returned across an AppDomain
// boundary.
public class MarshalByRefType : MarshalByRefObject
{
    //  Call this method via a proxy.
    public void SomeMethod(string callingDomainName)
    {
        // Get this AppDomain's settings and display some of them.
        AppDomainSetup ads = AppDomain.CurrentDomain.SetupInformation;
        Console.WriteLine("AppName={0}, AppBase={1}, ConfigFile={2}",
            ads.ApplicationName,
            ads.ApplicationBase,
            ads.ConfigurationFile
        );

        // Display the name of the calling AppDomain and the name
```

```
        // of the second domain.
        // NOTE: The application's thread has transitioned between
        // AppDomains.
        Console.WriteLine("Calling from '{0}' to '{1}'.",
            callingDomainName,
            Thread.GetDomain().FriendlyName
        );
    }
}

/* This code produces output similar to the following:

AppDomainX.exe
AppDomainX, Version=1.0.0.0, Culture=neutral, PublicKeyToken=null
AppName=, AppBase=C:\AppDomain\bin,
ConfigFile=C:\AppDomain\bin\AppDomainX.exe.config
Calling from 'AppDomainX.exe' to 'AD #2'.
Failed call; this is expected.
 */
```

Remarks

Application domains, which are represented by AppDomain objects, help provide isolation, unloading, and security boundaries for executing managed code.

- Use application domains to isolate tasks that might bring down a process. If the state of the AppDomain that's executing a task becomes unstable, the AppDomain can be unloaded without affecting the process. This is important when a process must run for long periods without restarting. You can also use application domains to isolate tasks that should not share data.

- If an assembly is loaded into the default application domain, it cannot be unloaded from memory while the process is running. However, if you open a second application domain to load and execute the assembly, the assembly is unloaded when that application domain is unloaded. Use this technique to minimize the working set of long-running processes that occasionally use large DLLs.

> **Note**
>
> On .NET Core, the **AppDomain** implementation is limited by design and does not provide isolation, unloading, or security boundaries. For .NET Core, there is exactly one **AppDomain**. Isolation and unloading are provided through **AssemblyLoadContext**. Security boundaries should be provided by process boundaries and appropriate remoting techniques.

Multiple application domains can run in a single process; however, there is not a one-to-one correlation between application domains and threads. Several threads can belong to a single application domain, and while a given thread is not confined to a single application domain, at any given time, a thread executes in a single application domain.

Application domains are created using the CreateDomain method. AppDomain instances are used to load and execute assemblies (Assembly). When an AppDomain is no longer in use, it can be unloaded.

The AppDomain class implements a set of events that enable applications to respond when an assembly is loaded, when an application domain will be unloaded, or when an unhandled exception is thrown.

For more information on using application domains, see Application Domains.

This class implements the MarshalByRefObject, _AppDomain, and IEvidenceFactory interfaces.

You should never create a remotable wrapper for an AppDomain object. Doing so could publish a remote reference to that AppDomain, exposing methods such as CreateInstance to remote access and effectively destroying code access security for that AppDomain. Malicious clients connecting to the remoted AppDomain could obtain access to any resource the AppDomain itself has access to. Do not create remotable wrappers for any type that extends MarshalByRefObject and that implements methods that could be used by malicious clients to bypass the security system.

> **Caution**
>
> The default value for the **AppDomainSetup.DisallowCodeDownload** property is `false`. This setting is unsafe for services. To prevent services from downloading partially trusted code, set this property to `true`.

Properties

Expand table

BaseDirectory	Gets the base directory that the assembly resolver uses to probe for assemblies.
CurrentDomain	Gets the current application domain for the current Thread.
DynamicDirectory	Gets the directory that the assembly resolver uses to probe for

	dynamically created assemblies.
FriendlyName	Gets the friendly name of this application domain.
Id	Gets an integer that uniquely identifies the application domain within the process.
IsFullyTrusted	Gets a value that indicates whether assemblies that are loaded into the current application domain execute with full trust.
IsHomogenous	Gets a value that indicates whether the current application domain has a set of permissions that is granted to all assemblies that are loaded into the application domain.
MonitoringIsEnabled	Gets or sets a value that indicates whether CPU and memory monitoring of application domains is enabled for the current process. Once monitoring is enabled for a process, it cannot be disabled.
MonitoringSurvived MemorySize	Gets the number of bytes that survived the last collection and that are known to be referenced by the current application domain.
MonitoringSurvived ProcessMemorySize	Gets the total bytes that survived from the last collection for all application domains in the process.
MonitoringTotal AllocatedMemorySize	Gets the total size, in bytes, of all memory allocations that have been made by the application domain since it was created, without subtracting memory that has been collected.
MonitoringTotal ProcessorTime	Gets the total processor time that has been used by all threads while executing in the current application domain, since the process started.
PermissionSet	**Obsolete.** Gets the permission set of a sandboxed application domain.
RelativeSearchPath	Gets the path under the base directory where the assembly resolver should probe for private assemblies.
SetupInformation	Gets the application domain configuration information for this instance.
ShadowCopyFiles	Gets an indication whether the application domain is configured to shadow copy files.

Methods

Expand table

AppendPrivatePath(String)	**Obsolete.**

	Appends the specified directory name to the private path list.
ApplyPolicy(String)	Returns the assembly display name after policy has been applied.
ClearPrivatePath()	**Obsolete.** Resets the path that specifies the location of private assemblies to the empty string ("").
ClearShadowCopyPath()	**Obsolete.** Resets the list of directories containing shadow copied assemblies to the empty string ("").
CreateDomain(String)	**Obsolete.** Creates a new application domain with the specified name.
CreateInstance(String, String)	Creates a new instance of the specified type defined in the specified assembly.
CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly. Parameters specify a binder, binding flags, constructor arguments, culture-specific information used to interpret arguments, and optional activation attributes.
CreateInstance(String, String, Object[])	Creates a new instance of the specified type defined in the specified assembly. A parameter specifies an array of activation attributes.
CreateInstanceAndUnwrap(String, String)	Creates a new instance of the specified type. Parameters specify the assembly where the type is defined, and the name of the type.
CreateInstanceAndUnwrap(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly, specifying whether the case of the type name is ignored; the binding attributes and the binder that are used to select the type to be created; the arguments of the constructor; the culture; and the activation attributes.
CreateInstanceAndUnwrap(String, String, Object[])	Creates a new instance of the specified type. Parameters specify the assembly where the type is defined, the name of the type, and an array of activation attributes.
CreateInstanceFrom(String, String)	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFrom(String, String, Boolean, BindingFlags, Binder,	Creates a new instance of the specified type defined in the specified assembly file.

Object[], CultureInfo, Object[])	
CreateInstanceFrom(String, String, Object[])	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFromAnd Unwrap(String, String)	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFromAnd Unwrap(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly file, specifying whether the case of the type name is ignored; the binding attributes and the binder that are used to select the type to be created; the arguments of the constructor; the culture; and the activation attributes.
CreateInstanceFromAnd Unwrap(String, String, Object[])	Creates a new instance of the specified type defined in the specified assembly file.
CreateObjRef(Type)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. (Inherited from MarshalByRefObject)
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
ExecuteAssembly(String)	Executes the assembly contained in the specified file.
ExecuteAssembly(String, String[])	Executes the assembly contained in the specified file, using the specified arguments.
ExecuteAssembly(String, String[], Byte[], AssemblyHashAlgorithm)	**Obsolete.** Executes the assembly contained in the specified file, using the specified arguments, hash value, and hash algorithm.
ExecuteAssemblyByName(Assembly Name, String[])	Executes the assembly given an AssemblyName, using the specified arguments.
ExecuteAssemblyByName(String)	Executes an assembly given its display name.
ExecuteAssemblyByName(String, String[])	Executes the assembly given its display name, using the specified arguments.
GetAssemblies()	Gets the assemblies that have been loaded into the execution context of this application domain.
GetCurrentThreadId()	**Obsolete.** Gets the current thread identifier.

GetData(String)	Gets the value stored in the current application domain for the specified name.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetLifetimeService()	**Obsolete.** Retrieves the current lifetime service object that controls the lifetime policy for this instance. (Inherited from MarshalByRefObject)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeLifetimeService()	**Obsolete.** Obtains a lifetime service object to control the lifetime policy for this instance. (Inherited from MarshalByRefObject)
IsCompatibilitySwitchSet(String)	Gets a nullable Boolean value that indicates whether any compatibility switches are set, and if so, whether the specified compatibility switch is set.
IsDefaultAppDomain()	Returns a value that indicates whether the application domain is the default application domain for the process.
IsFinalizingForUnload()	Indicates whether this application domain is unloading, and the objects it contains are being finalized by the common language runtime.
Load(AssemblyName)	Loads an Assembly given its AssemblyName.
Load(Byte[])	Loads the Assembly with a common object file format (COFF) based image containing an emitted Assembly.
Load(Byte[], Byte[])	Loads the Assembly with a common object file format (COFF) based image containing an emitted Assembly. The raw bytes representing the symbols for the Assembly are also loaded.
Load(String)	Loads an Assembly given its display name.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
MemberwiseClone(Boolean)	Creates a shallow copy of the current MarshalByRefObject object. (Inherited from MarshalByRefObject)

ReflectionOnlyGetAssemblies()	Returns the assemblies that have been loaded into the reflection-only context of the application domain.
SetCachePath(String)	**Obsolete.** Establishes the specified directory path as the location where assemblies are shadow copied.
SetData(String, Object)	Assigns the specified value to the specified application domain property.
SetDynamicBase(String)	**Obsolete.** Establishes the specified directory path as the base directory for subdirectories where dynamically generated files are stored and accessed.
SetPrincipalPolicy(PrincipalPolicy)	Specifies how principal and identity objects should be attached to a thread if the thread attempts to bind to a principal while executing in this application domain.
SetShadowCopyFiles()	**Obsolete.** Turns on shadow copying.
SetShadowCopyPath(String)	**Obsolete.** Establishes the specified directory path as the location of assemblies to be shadow copied.
SetThreadPrincipal(IPrincipal)	Sets the default principal object to be attached to threads if they attempt to bind to a principal while executing in this application domain.
ToString()	Obtains a string representation that includes the friendly name of the application domain and any context policies.
Unload(AppDomain)	**Obsolete.** Unloads the specified application domain.

Events

Expand table

AssemblyLoad	Occurs when an assembly is loaded.
AssemblyResolve	Occurs when the resolution of an assembly fails.
DomainUnload	Occurs when an AppDomain is about to be unloaded.

FirstChance Exception	Occurs when an exception is thrown in managed code, before the runtime searches the call stack for an exception handler in the application domain.
ProcessExit	Occurs when the default application domain's parent process exits.
ReflectionOnly AssemblyResolve	Occurs when the resolution of an assembly fails in the reflection-only context.
ResourceResolve	Occurs when the resolution of a resource fails because the resource is not a valid linked or embedded resource in the assembly.
TypeResolve	Occurs when the resolution of a type fails.
UnhandledException	Occurs when an exception is not caught.

AppDomain.BaseDirectory Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the base directory that the assembly resolver uses to probe for assemblies.

C#

```
public string BaseDirectory { get; }
```

Property Value

String

The base directory that the assembly resolver uses to probe for assemblies.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following code example creates a new application domain, specifying a base directory to use when searching for assemblies to load into the domain. The example then uses the BaseDirectory property to obtain the base directory path, for display to the console.

C#

```
using System;
using System.IO;
using System.Reflection;
using System.Security.Policy;

class ADSetupSnippet
{
    public static void Main()
```

```
    {
        // Create application domain setup information
        var domaininfo = new AppDomainSetup();
        domaininfo.ConfigurationFile =
Path.Combine(System.Environment.CurrentDirectory, "ADSetup.exe.config");
        domaininfo.ApplicationBase = System.Environment.CurrentDirectory;

        //Create evidence for the new appdomain from evidence of the current
application domain
        Evidence adEvidence = AppDomain.CurrentDomain.Evidence;

        // Create appdomain
        AppDomain domain = AppDomain.CreateDomain("Domain2", adEvidence,
domaininfo);

        // Display application domain information.
        Console.WriteLine("Host domain: " +
AppDomain.CurrentDomain.FriendlyName);
        Console.WriteLine("Child domain: " + domain.FriendlyName);
        Console.WriteLine();
        Console.WriteLine("Configuration file: " +
domain.SetupInformation.ConfigurationFile);
        Console.WriteLine("Application Base Directory: " +
domain.BaseDirectory);

        AppDomain.Unload(domain);
    }
}
// The example displays output like the following:
//    Host domain: adsetup.exe
//    Child domain: Domain2
//
//    Configuration file: C:\Test\ADSetup.exe.config
//    Application Base Directory: C:\Test
```

Remarks

This property corresponds to the AppDomainSetup.ApplicationBase property. It can also be retrieved using the GetData method with the string "APPBASE".

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.CurrentDomain Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current application domain for the current Thread.

C#

```
public static AppDomain CurrentDomain { get; }
```

Property Value

AppDomain

The current application domain.

Examples

The following code example creates a new application domain. The CurrentDomain property is used to obtain an AppDomain object that represents the current application domain. The FriendlyName property provides the name of the current application domain, which is then displayed at the command line.

C#

```
using System;

class ADSetupInformation
{
    static void Main()
    {
        AppDomain root = AppDomain.CurrentDomain;

        AppDomainSetup setup = new AppDomainSetup();
        setup.ApplicationBase =
            root.SetupInformation.ApplicationBase + @"MyAppSubfolder\";

        AppDomain domain = AppDomain.CreateDomain("MyDomain", null, setup);

        Console.WriteLine("Application base of {0}:\r\n\t{1}",
```

```
            root.FriendlyName, root.SetupInformation.ApplicationBase);
        Console.WriteLine("Application base of {0}:\r\n\t{1}",
            domain.FriendlyName, domain.SetupInformation.ApplicationBase);

        AppDomain.Unload(domain);
    }
}

/* This example produces output similar to the following:

Application base of MyApp.exe:
        C:\Program Files\MyApp\
Application base of MyDomain:
        C:\Program Files\MyApp\MyAppSubfolder\
 */
```

Applies to

Product	Versions

AppDomain.DynamicDirectory Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the directory that the assembly resolver uses to probe for dynamically created assemblies.

C#

```
public string? DynamicDirectory { get; }
```

Property Value

String

The directory that the assembly resolver uses to probe for dynamically created assemblies.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following example creates an application domain with a directory for dynamic assemblies, emits a dynamic assembly and stores it in the dynamic directory, and then loads the assembly into the new application domain and uses it.

The example creates an AppDomainSetup object and sets its ApplicationName property to "Example" and its DynamicBase property to "C:\DynamicAssemblyDir". The example then displays the DynamicBase property, to show that the hash code of the application name has been appended as a subdirectory of the path that was originally assigned.

Note

The base directory in this example is intended to be outside the probing path for the example application. Be sure to compile the example in a different location. Delete the base directory and all its subdirectories each time you run the example.

The example creates a new application domain, using the AppDomainSetup object. The example uses the DynamicDirectory property to retrieve the name of the directory, so it can create the directory. (The example could just as easily create the directory beforehand by concatenating the original path, the hash code of the application name, and the application name.)

The example has a `GenerateDynamicAssembly` method that emits an assembly named `DynamicHelloWorld.dll` and stores it in the new application domain's dynamic directory. The dynamic assembly contains one type, `HelloWorld`, that has a static method (`Shared` method in Visual Basic) named `HelloFromAD`. Calling this method displays the name of the application domain.

The `Example` class derives from MarshalByRefObject, so the example can create an instance of the class in the new application domain and call its `Test` method. The `Test` method loads the dynamic assembly by its display name and calls the static `HelloFromAD` method.

You can show that the dynamic directory is searched after the normal probing paths by writing code for an assembly named `DynamicHelloWorld.dll` and compiling it in the same directory as this example. The assembly must have a class named `HelloWorld` with a static method named `HelloFromAD`. This method does not have to have the same functionality as the one in the example; it can simply display a string to the console. The assembly must also have an AssemblyVersionAttribute attribute that sets its version to 1.0.0.0. When you run the example, the assembly you compiled in the current directory is found before the dynamic directory is searched.

C#

```
using System;
using System.Reflection;
using System.Reflection.Emit;

public class AddDynamicBaseSnippet : MarshalByRefObject
{
   static void Main()
   {
      // Prepare to create a new application domain.
      AppDomainSetup setup = new AppDomainSetup();

      // Set the application name before setting the dynamic base.
```

```
      setup.ApplicationName = "Example";

      // Set the location of the base directory where assembly resolution
      // probes for dynamic assemblies. Note that the hash code of the
      // application name is concatenated to the base directory name you
      // supply.
      setup.DynamicBase = "C:\\DynamicAssemblyDir";
      Console.WriteLine("DynamicBase is set to '{0}'.", setup.DynamicBase);

      AppDomain ad = AppDomain.CreateDomain("MyDomain", null, setup);

      // The dynamic directory name is the dynamic base concatenated with
      // the application name: <DynamicBase>\<hash code>\<ApplicationName>
      string dynamicDir = ad.DynamicDirectory;
      Console.WriteLine("Dynamic directory is '{0}'.", dynamicDir);

      // The AssemblyBuilder won't create this directory automatically.
      if (!System.IO.Directory.Exists(dynamicDir))
      {
         Console.WriteLine("Creating the dynamic directory.");
         System.IO.Directory.CreateDirectory(dynamicDir);
      }

      // Generate a dynamic assembly and store it in the dynamic
      // directory.
      GenerateDynamicAssembly(dynamicDir);

      // Create an instance of the Example class in the application domain,
      // and call its Test method to load the dynamic assembly and use it.
      AddDynamicBaseSnippet ex = (AddDynamicBaseSnippet)
ad.CreateInstanceAndUnwrap(
         typeof(AddDynamicBaseSnippet).Assembly.FullName, "Example");
      ex.Test();
   }

   public void Test()
   {
      Assembly dynAssem = Assembly.Load(
         "DynamicHelloWorld, Version=1.0.0.0, Culture=neutral,
PublicKeyToken=null");

      Type myType = dynAssem.GetType("HelloWorld");
      myType.InvokeMember("HelloFromAD", BindingFlags.Public |
         BindingFlags.Static | BindingFlags.InvokeMethod,
         Type.DefaultBinder, null, null);
   }

   private static void GenerateDynamicAssembly(string location)
   {
      // Define the dynamic assembly and the module. There is only one
      // module in this assembly. Note that the call to
DefineDynamicAssembly
      // specifies the location where the assembly will be saved. The
      // assembly version is 1.0.0.0.
      //
```

```
        AssemblyName asmName = new AssemblyName("DynamicHelloWorld");
        asmName.Version = new Version("1.0.0.0");

        AssemblyBuilder ab =
           AppDomain.CurrentDomain.DefineDynamicAssembly(
              asmName, AssemblyBuilderAccess.Save, location);

        String moduleName = asmName.Name + ".exe";
        ModuleBuilder mb = ab.DefineDynamicModule(asmName.Name, moduleName);

        // Define the "HelloWorld" type, with one static method.
        TypeBuilder tb = mb.DefineType("HelloWorld", TypeAttributes.Public);
        MethodBuilder hello = tb.DefineMethod("HelloFromAD",
           MethodAttributes.Public | MethodAttributes.Static, null, null);

        // The method displays a message that contains the name of the
application
        // domain where the method is executed.
        ILGenerator il = hello.GetILGenerator();
        il.Emit(OpCodes.Ldstr, "Hello from '{0}'!");
        il.Emit(OpCodes.Call,
typeof(AppDomain).GetProperty("CurrentDomain").GetGetMethod());
        il.Emit(OpCodes.Call,
typeof(AppDomain).GetProperty("FriendlyName").GetGetMethod());
        il.Emit(OpCodes.Call, typeof(Console).GetMethod("WriteLine",
                                 new Type[] { typeof(String), typeof(String)
}));
        il.Emit(OpCodes.Ret);

        // Complete the HelloWorld type and save the assembly. The assembly
        // is placed in the location specified by DefineDynamicAssembly.
        Type myType = tb.CreateType();
        ab.Save(moduleName);
    }
}

/* This example produces output similar to the following:

DynamicBase is set to 'C:\DynamicAssemblyDir\5e4a7545'.
Dynamic directory is 'C:\DynamicAssemblyDir\5e4a7545\Example'.
Creating the dynamic directory.
Hello from 'MyDomain'!
 */
```

Remarks

To set the dynamic directory, assign a base directory path to the AppDomainSetup.DynamicBase property of the AppDomainSetup object that will be used to create the new application domain. The base directory path you assign to the property is modified by the addition of a subdirectory whose simple name is the hash code of the string you assign to the AppDomainSetup.ApplicationName property, so the

format of the base directory is *original path\hash code*. The dynamic directory is a subdirectory of this base directory. Its simple name is the value of the AppDomainSetup.ApplicationName property, so its format is *original path\hash code\application name*.

AppDomain.FriendlyName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the friendly name of this application domain.

C#

```
public string FriendlyName { get; }
```

Property Value

String

The friendly name of this application domain.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following code example uses the FriendlyName property to get the friendly name of the current application domain. For the default application domain, the friendly name is the name of the application's executable file. The code example also displays additional information about the application domain.

C#

```
using System;

class ADSetupInformation
{
    static void Main()
    {
        AppDomain root = AppDomain.CurrentDomain;
```

```
        AppDomainSetup setup = new AppDomainSetup();
        setup.ApplicationBase =
            root.SetupInformation.ApplicationBase + @"MyAppSubfolder\";

        AppDomain domain = AppDomain.CreateDomain("MyDomain", null, setup);

        Console.WriteLine("Application base of {0}:\r\n\t{1}",
            root.FriendlyName, root.SetupInformation.ApplicationBase);
        Console.WriteLine("Application base of {0}:\r\n\t{1}",
            domain.FriendlyName, domain.SetupInformation.ApplicationBase);

        AppDomain.Unload(domain);
    }
}

/* This example produces output similar to the following:

Application base of MyApp.exe:
        C:\Program Files\MyApp\
Application base of MyDomain:
        C:\Program Files\MyApp\MyAppSubfolder\
 */
```

Remarks

The friendly name of the default application domain is the file name of the process executable. For example, if the executable used to start the process is `"c:\MyAppDirectory\MyAssembly.exe"`, the friendly name of the default application domain is `"MyAssembly.exe"`.

Applies to

AppDomain.Id Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an integer that uniquely identifies the application domain within the process.

C#

```
public int Id { get; }
```

Property Value

Int32

An integer that identifies the application domain.

Examples

The following code example creates a second application domain and displays information about the default domain and the new domain.

C#

```
using System;
using System.Reflection;

public class AppDomainIdSnippet
{
    // The following attribute indicates to the loader that assemblies
    // in the global assembly cache should be shared across multiple
    // application domains.
    [LoaderOptimizationAttribute( LoaderOptimization.MultiDomainHost)]
    public static void Main()
    {
        // Show information for the default application domain.
        ShowDomainInfo();

        // Create a new application domain and display its information.
        AppDomain newDomain = AppDomain.CreateDomain("MyMultiDomain");
        newDomain.DoCallBack(new CrossAppDomainDelegate(ShowDomainInfo));
```

```
    }

    // This method has the same signature as the CrossAppDomainDelegate,
    // so that it can be executed easily in the new application domain.
    //
    public static void ShowDomainInfo()
    {
        AppDomain ad = AppDomain.CurrentDomain;
        Console.WriteLine();
        Console.WriteLine("FriendlyName: {0}", ad.FriendlyName);
        Console.WriteLine("Id: {0}", ad.Id);
        Console.WriteLine("IsDefaultAppDomain: {0}",
ad.IsDefaultAppDomain());
    }
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppDomain.IsFullyTrusted Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether assemblies that are loaded into the current application domain execute with full trust.

```
C#
public bool IsFullyTrusted { get; }
```

Property Value

Boolean

`true` if assemblies that are loaded into the current application domain execute with full trust; otherwise, `false`.

Examples

The following example demonstrates the IsFullyTrusted property and the Assembly.IsFullyTrusted property with fully trusted and partially trusted application domains. The fully trusted application domain is the default application domain for the application. The partially trusted application domain is created by using the AppDomain.CreateDomain(String, Evidence, AppDomainSetup, PermissionSet, StrongName[]) method overload.

The example uses a `Worker` class that derives from MarshalByRefObject, so it can be marshaled across application domain boundaries. The example creates a `Worker` object in the default application domain. It then calls the `TestIsFullyTrusted` method to display the property value for the application domain and for two assemblies that are loaded into the application domain: mscorlib, which is part of the .NET Framework, and the example assembly. The application domain is fully trusted, so both assemblies are fully trusted.

The example creates another `Worker` object in a sandboxed application domain and again calls the `TestIsFullyTrusted` method. Mscorlib is always trusted, even in a partially trusted application domain, but the example assembly is partially trusted.

C#

```
using System;

namespace SimpleSandboxing
{
    public class Worker : MarshalByRefObject
    {
        static void Main()
        {
            Worker w = new Worker();
            w.TestIsFullyTrusted();

            AppDomain adSandbox = GetInternetSandbox();
            w = (Worker) adSandbox.CreateInstanceAndUnwrap(
                                typeof(Worker).Assembly.FullName,
                                typeof(Worker).FullName);
            w.TestIsFullyTrusted();
        }

        public void TestIsFullyTrusted()
        {
            AppDomain ad = AppDomain.CurrentDomain;
            Console.WriteLine("\r\nApplication domain '{0}': IsFullyTrusted
= {1}",
                                        ad.FriendlyName, ad.IsFullyTrusted);

            Console.WriteLine("   IsFullyTrusted = {0} for the current
assembly",
                              typeof(Worker).Assembly.IsFullyTrusted);

            Console.WriteLine("   IsFullyTrusted = {0} for mscorlib",

typeof(int).Assembly.IsFullyTrusted);
        }

        // ------------ Helper method -------------------------------------
-
        static AppDomain GetInternetSandbox()
        {
            // Create the permission set to grant to all assemblies.
            System.Security.Policy.Evidence hostEvidence = new
System.Security.Policy.Evidence();
            hostEvidence.AddHostEvidence(new System.Security.Policy.Zone(

System.Security.SecurityZone.Internet));
            System.Security.PermissionSet pset =

System.Security.SecurityManager.GetStandardSandbox(hostEvidence);
```

```
            // Identify the folder to use for the sandbox.
            AppDomainSetup ads = new AppDomainSetup();
            ads.ApplicationBase = System.IO.Directory.GetCurrentDirectory();

            // Create the sandboxed application domain.
            return AppDomain.CreateDomain("Sandbox", hostEvidence, ads,
pset, null);
        }
    }
}

/* This example produces output similar to the following:

Application domain 'Example.exe': IsFullyTrusted = True
   IsFullyTrusted = True for the current assembly
   IsFullyTrusted = True for mscorlib

Application domain 'Sandbox': IsFullyTrusted = False
   IsFullyTrusted = False for the current assembly
   IsFullyTrusted = True for mscorlib
 */
```

Remarks

This method always returns `true` for the default application domain of an application that runs on the desktop. It returns `false` for a sandboxed application domain that was created by using the AppDomain.CreateDomain(String, Evidence, AppDomainSetup, PermissionSet, StrongName[]) method overload, unless the permissions that are granted to the application domain are equivalent to full trust.

AppDomain.IsHomogenous Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current application domain has a set of permissions that is granted to all assemblies that are loaded into the application domain.

```
C#

public bool IsHomogenous { get; }
```

Property Value

Boolean

`true` if the current application domain has a homogenous set of permissions; otherwise, `false`.

Remarks

This property returns `true` for sandboxed application domains that were created by using the AppDomain.CreateDomain(String, Evidence, AppDomainSetup, PermissionSet, StrongName[]) method overload. Sandboxed application domains have a homogenous set of permissions; that is, the same set of permissions is granted to all partially trusted assemblies that are loaded into the application domain. A sandboxed application domain optionally has a list of strong-named assemblies that are exempt from this permission set, and instead run with full trust.

Fully trusted code can use the PermissionSet property to determine the homogenous grant set of a sandboxed application domain.

This property also returns `true` for the default application domain of a desktop application, because that application domain grants full trust to all assemblies.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppDomain.MonitoringIsEnabled Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets a value that indicates whether CPU and memory monitoring of application domains is enabled for the current process. Once monitoring is enabled for a process, it cannot be disabled.

```
C#
public static bool MonitoringIsEnabled { get; set; }
```

Property Value

Boolean

`true` if monitoring is enabled; otherwise `false`.

Exceptions

ArgumentException

The current process attempted to assign the value `false` to this property.

Remarks

This `static` property (`Shared` property in Visual Basic) controls CPU and memory monitoring of all the application domains in the process.

If you attempt to set this property to `false`, a ArgumentException exception is thrown, even if the current value of the property is `false`.

Once monitoring is enabled, you can use the MonitoringSurvivedMemorySize, MonitoringSurvivedProcessMemorySize, MonitoringTotalAllocatedMemorySize, and

MonitoringTotalProcessorTime instance properties to monitor CPU and memory use of individual application domains.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.MonitoringSurvivedMemorySize Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of bytes that survived the last collection and that are known to be referenced by the current application domain.

```
C#

public long MonitoringSurvivedMemorySize { get; }
```

Property Value

Int64

The number of surviving bytes.

Exceptions

InvalidOperationException

The `static` (`Shared` in Visual Basic) MonitoringIsEnabled property is set to `false`.

Remarks

The statistics are updated with each garbage collection. However, they are guaranteed to be accurate only after a full, blocking collection; that is, a collection that includes all generations and that stops the application while collection occurs. For example, the GC.Collect() method overload performs a full, blocking collection. (Concurrent collection occurs in the background and does not block the application.)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.MonitoringSurvivedProcessMemorySize Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total bytes that survived from the last collection for all application domains in the process.

C#

```
public static long MonitoringSurvivedProcessMemorySize { get; }
```

Property Value

Int64

The total number of surviving bytes for the process.

Exceptions

InvalidOperationException

The `static` (`Shared` in Visual Basic) MonitoringIsEnabled property is set to `false`.

Remarks

After a full, blocking collection, this number represents the number of bytes currently held live on managed heaps. It should be close to the number reported by the GetTotalMemory method. After an ephemeral collection, this number represents the number of bytes currently held live in ephemeral generations.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.MonitoringTotalAllocatedMemorySize Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total size, in bytes, of all memory allocations that have been made by the application domain since it was created, without subtracting memory that has been collected.

C#

```
public long MonitoringTotalAllocatedMemorySize { get; }
```

Property Value

Int64

The total size of all memory allocations.

Exceptions

InvalidOperationException

The `static` (`Shared` in Visual Basic) MonitoringIsEnabled property is set to `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.MonitoringTotalProcessorTime Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total processor time that has been used by all threads while executing in the current application domain, since the process started.

```
C#

public TimeSpan MonitoringTotalProcessorTime { get; }
```

Property Value

TimeSpan

Total processor time for the current application domain.

Exceptions

InvalidOperationException

The `static` (`Shared` in Visual Basic) MonitoringIsEnabled property is set to `false`.

Remarks

The total time that is reported for an application domain includes the time each thread in the process spent executing in that application domain.

A thread that calls into unmanaged code is still associated with an application domain, and the processor time spent executing the unmanaged code is reported for the application domain where the call was made.

When a thread is blocked or sleeping, it does not consume processor time.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.PermissionSet Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Code Access Security is not supported or honored by the runtime.

Gets the permission set of a sandboxed application domain.

C#

```
[System.Obsolete("Code Access Security is not supported or honored by the runtime.", DiagnosticId="SYSLIB0003", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public System.Security.PermissionSet PermissionSet { get; }
```

Property Value

PermissionSet

The permission set of the sandboxed application domain.

Attributes ObsoleteAttribute

Remarks

> ⊗ **Caution**
>
> Code Access Security (CAS) has been deprecated across all versions of .NET Framework and .NET. Recent versions of .NET do not honor CAS annotations and produce errors if CAS-related APIs are used. Developers should seek alternative means of accomplishing security tasks.

Sandboxed application domains that were created by using the AppDomain.CreateDomain(String, Evidence, AppDomainSetup, PermissionSet, StrongName[]) method overload have a homogenous set of permissions; that is, the same set of permissions is granted to all partially trusted assemblies that are loaded into the application domain. A sandboxed application domain optionally has a list of strong-named assemblies that are exempt from this permission set, and instead run with full trust.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 3.0, Core 3.1 *(5, 6, 7, 8, 9)*
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.RelativeSearchPath Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the path under the base directory where the assembly resolver should probe for private assemblies.

C#

```
public string? RelativeSearchPath { get; }
```

Property Value

String

The path under the base directory where the assembly resolver should probe for private assemblies.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Remarks

Private assemblies are deployed in the same directory structure as the application. If the path specified by the RelativeSearchPath property is not under AppDomainSetup.ApplicationBase, it is ignored.

This property returns the value set using AppDomainSetup.PrivateBinPath.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.SetupInformation Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the application domain configuration information for this instance.

```
C#
public AppDomainSetup SetupInformation { get; }
```

Property Value

AppDomainSetup

The application domain initialization information.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.ShadowCopyFiles Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an indication whether the application domain is configured to shadow copy files.

C#

```
public bool ShadowCopyFiles { get; }
```

Property Value

Boolean

`true` if the application domain is configured to shadow copy files; otherwise, `false`.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Remarks

For more information, see AppDomainSetup.ShadowCopyFiles and Shadow Copying Assemblies.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.AppendPrivatePath(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.AppendPrivatePath has been deprecated and is not supported.

Appends the specified directory name to the private path list.

C#

```
[System.Obsolete("AppDomain.AppendPrivatePath has been deprecated and is not supported.")]
public void AppendPrivatePath (string? path);
```

Parameters

path String

The name of the directory to be appended to the private path.

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Remarks

The use of this property is not recommended, because it might change the probing path for assemblies after they have already been loaded. Use the

AppDomainSetup.PrivateBinPath property instead.

The private path, or relative search path, is the path relative to the base directory where the assembly resolver probes for private assemblies.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*

AppDomain.ApplyPolicy(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the assembly display name after policy has been applied.

C#

```
public string ApplyPolicy (string assemblyName);
```

Parameters

`assemblyName` String

The assembly display name, in the form provided by the FullName property.

Returns

String

A string containing the assembly display name after policy has been applied.

Remarks

The ApplyPolicy method takes an assembly display name and returns the post-policy display name. This is useful if you need to load an assembly using policy, because the reflection-only context does not apply policy.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

AppDomain.ClearPrivatePath Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.ClearPrivatePath has been deprecated and is not supported.

Resets the path that specifies the location of private assemblies to the empty string ("").

C#

```
[System.Obsolete("AppDomain.ClearPrivatePath has been deprecated and is not supported.")]
public void ClearPrivatePath ();
```

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following code example demonstrates how to use the ClearPrivatePath method to remove all entries from the list of private paths to search when assemblies are loaded.

This method is now obsolete, and should not be used for new development.

C#

```
using System;
using System.Reflection;
using System.Security.Policy;
```

```
class ADAppendPrivatePath
{
    public static void Main()
    {
        //Create evidence for new appdomain.
        Evidence adevidence = AppDomain.CurrentDomain.Evidence;

        //Create the new application domain.
        AppDomain domain = AppDomain.CreateDomain("MyDomain", adevidence);

        //Display the current relative search path.
        Console.WriteLine("Relative search path is: " +
domain.RelativeSearchPath);

        //Append the relative path.
        String Newpath = "www.code.microsoft.com";
        domain.AppendPrivatePath(Newpath);

        //Display the new relative search path.
        Console.WriteLine("Relative search path is: " +
domain.RelativeSearchPath);

        //Clear the private search path.
        domain.ClearPrivatePath();

        //Display the new relative search path.
        Console.WriteLine("Relative search path is now: " +
domain.RelativeSearchPath);

        AppDomain.Unload(domain);
    }
}
```

Remarks

The private path is a path relative to the base directory that the common language runtime searches to locate private assemblies.

For more information, see AppDomainSetup.PrivateBinPath.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

AppDomain.ClearShadowCopyPath Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.ClearShadowCopyPath has been deprecated and is not supported.

Resets the list of directories containing shadow copied assemblies to the empty string ("").

C#

```
[System.Obsolete("AppDomain.ClearShadowCopyPath has been deprecated and is not supported.")]
public void ClearShadowCopyPath ();
```

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Remarks

The shadow copy path is a list of directories where shadow copied assemblies are stored.

For more information, see AppDomainSetup.ShadowCopyDirectories and Shadow Copying Assemblies.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

AppDomain.CreateDomain Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new application domain.

Overloads

Expand table

CreateDomain(String)	**Obsolete.** Creates a new application domain with the specified name.

CreateDomain(String)

Caution

Creating and unloading AppDomains is not supported and throws an exception.

Creates a new application domain with the specified name.

C#

```
[System.Obsolete("Creating and unloading AppDomains is not supported and throws an exception.", DiagnosticId="SYSLIB0024", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public static AppDomain CreateDomain (string friendlyName);
```

Parameters

`friendlyName` String

The friendly name of the domain.

Returns

AppDomain

The newly created application domain.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`friendlyName` is `null`.

PlatformNotSupportedException

.NET Core and .NET 5+ only: In all cases.

Examples

The following sample demonstrates, in general, how to create a domain using one of the CreateDomain overloads.

C#

```
// Set up the AppDomainSetup
AppDomainSetup setup = new AppDomainSetup();
setup.ApplicationBase = "(some directory)";
setup.ConfigurationFile = "(some file)";

// Set up the Evidence
Evidence baseEvidence = AppDomain.CurrentDomain.Evidence;
Evidence evidence = new Evidence(baseEvidence);
evidence.AddAssembly("(some assembly)");
evidence.AddHost("(some host)");

// Create the AppDomain
AppDomain newDomain = AppDomain.CreateDomain("newDomain", evidence,
setup);
```

Remarks

The `friendlyName` parameter is intended to identify the domain in a manner that is meaningful to humans. This string should be suitable for display in user interfaces.

This method overload uses the AppDomainSetup information from the default application domain.

AppDomain.CreateInstance Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new instance of a specified type defined in a specified assembly.

Overloads

Expand table

CreateInstance(String, String)	Creates a new instance of the specified type defined in the specified assembly.
CreateInstance(String, String, Object[])	Creates a new instance of the specified type defined in the specified assembly. A parameter specifies an array of activation attributes.
CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly. Parameters specify a binder, binding flags, constructor arguments, culture-specific information used to interpret arguments, and optional activation attributes.

CreateInstance(String, String)

Creates a new instance of the specified type defined in the specified assembly.

C#

```
public System.Runtime.Remoting.ObjectHandle? CreateInstance (string
assemblyName, string typeName);
```

Parameters

assemblyName String

The display name of the assembly. See FullName.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

Returns

ObjectHandle

An object that is a wrapper for the new instance specified by `typeName`. The return value needs to be unwrapped to access the real object.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

ArgumentNullException

`assemblyName` or `typeName` is `null`.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

NullReferenceException

This instance is `null`.

Remarks

This method calls the parameterless constructor for `typeName`.

See AssemblyName for the format of `assemblyName`.

An attempt to call CreateInstance on a target application domain that is not the current application domain will result in a successful load of the assembly in the target application domain. Since an Assembly is not MarshalByRefObject, when this method attempts to return the Assembly for the loaded assembly to the current application domain, the common language runtime will try to load the assembly into the current application domain and the load might fail. The assembly that is loaded into the current application domain might be different from the assembly that was loaded first if the path settings for the two application domains are different.

See also

- CreateInstance(Type, BindingFlags, Binder, Object[], CultureInfo)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstance(String, String, Object[])

Creates a new instance of the specified type defined in the specified assembly. A parameter specifies an array of activation attributes.

C#

```
public System.Runtime.Remoting.ObjectHandle? CreateInstance (string
```

```
assemblyName, string typeName, object?[]? activationAttributes);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects.Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

An object that is a wrapper for the new instance specified by `typeName`. The return value needs to be unwrapped to access the real object.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

ArgumentNullException

`assemblyName` or `typeName` is `null`.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MissingMethodException

No matching public constructor was found.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

TypeLoadException

`typename` was not found in `assemblyName`.

NullReferenceException

This instance is `null`.

Remarks

This method calls the parameterless constructor for `typeName`.

See AssemblyName for the format of `assemblyName`.

An attempt to call CreateInstance on a target application domain that is not the current application domain will result in a successful load of the assembly in the target application domain. Since an Assembly is not MarshalByRefObject, when this method attempts to return the Assembly for the loaded assembly to the current application domain, the common language runtime will try to load the assembly into the current application domain and the load might fail. The assembly that is loaded into the current application domain might be different from the assembly that was loaded first if the path settings for the two application domains are different.

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstance(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates a new instance of the specified type defined in the specified assembly. Parameters specify a binder, binding flags, constructor arguments, culture-specific information used to interpret arguments, and optional activation attributes.

C#

```
public System.Runtime.Remoting.ObjectHandle? CreateInstance (string
assemblyName, string typeName, bool ignoreCase,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, object?[]? args, System.Globalization.CultureInfo? culture,
object?[]? activationAttributes);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`ignoreCase` Boolean

A Boolean value specifying whether to perform a case-sensitive search or not.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `typeName` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that enables the binding, coercion of argument types, invocation of members, and retrieval of MemberInfo objects using reflection. If `binder` is null, the default binder is used.

`args` Object[]

The arguments to pass to the constructor. This array of arguments must match in number, order, and type the parameters of the constructor to invoke. If the parameterless constructor is preferred, `args` must be an empty array or null.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `typeName` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

An object that is a wrapper for the new instance specified by `typeName`. The return value needs to be unwrapped to access the real object.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

ArgumentNullException

`assemblyName` or `typeName` is `null`.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

`assemblyName` was compiled with a later version of the common language runtime than the version that is currently loaded.

FileLoadException

An assembly or module was loaded twice with two different evidences.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

MissingMethodException

No matching constructor was found.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

TypeLoadException

`typename` was not found in `assemblyName`.

NullReferenceException

This instance is `null`.

Remarks

See AssemblyName for the format of `assemblyName`.

An attempt to call CreateInstance on a target application domain that is not the current application domain will result in a successful load of the assembly in the target application domain. Since an Assembly is not MarshalByRefObject, when this method attempts to return the Assembly for the loaded assembly to the current application domain, the common language runtime will try to load the assembly into the current application domain and the load might fail. The assembly that is loaded into the current application domain might be different from the assembly that was loaded first if the path settings for the two application domains are different.

AppDomain.CreateInstanceAndUnwrap Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new instance of a specified type.

Overloads

Expand table

CreateInstanceAndUnwrap(String, String)	Creates a new instance of the specified type. Parameters specify the assembly where the type is defined, and the name of the type.
CreateInstanceAndUnwrap(String, String, Object[])	Creates a new instance of the specified type. Parameters specify the assembly where the type is defined, the name of the type, and an array of activation attributes.
CreateInstanceAndUnwrap(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly, specifying whether the case of the type name is ignored; the binding attributes and the binder that are used to select the type to be created; the arguments of the constructor; the culture; and the activation attributes.

CreateInstanceAndUnwrap(String, String)

Creates a new instance of the specified type. Parameters specify the assembly where the type is defined, and the name of the type.

C#

```
public object? CreateInstanceAndUnwrap (string assemblyName, string
```

```
typeName);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

Returns

Object

An instance of the object specified by `typeName`.

Exceptions

ArgumentNullException

`assemblyName` or `typeName` is `null`.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Examples

The following code example shows the simplest way to execute code in another application domain. The example defines a class named `Worker` that inherits from MarshalByRefObject. The `Worker` class defines a method that displays the name of the application domain in which it is executing. The example creates instances of `Worker` in the default application domain and in a new application domain.

> **Note**
>
> The assembly that contains `Worker` must be loaded into both application domains, but it can load other assemblies that exist only in the new application domain.

C#

```
using System;
using System.Reflection;

public class CreateInstanceWorker : MarshalByRefObject
{
    public void PrintDomain()
    {
        Console.WriteLine("Object is executing in AppDomain \"{0}\"",
            AppDomain.CurrentDomain.FriendlyName);
    }
}

class CreateInstanceAndUnwrapSourceSnippet
{
    public static void Main()
    {
        // Create an ordinary instance in the current AppDomain
        CreateInstanceWorker localWorker = new CreateInstanceWorker();
        localWorker.PrintDomain();

        // Create a new application domain, create an instance
        // of Worker in the application domain, and execute code
        // there.
        AppDomain ad = AppDomain.CreateDomain("New domain");
```

```
        CreateInstanceWorker remoteWorker = (CreateInstanceWorker)
ad.CreateInstanceAndUnwrap(
            typeof(CreateInstanceWorker).Assembly.FullName,
            "Worker");
        remoteWorker.PrintDomain();
    }
}

/* This code produces output similar to the following:

Object is executing in AppDomain "source.exe"
Object is executing in AppDomain "New domain"
 */
```

Remarks

This is a convenience method that combines CreateInstance and ObjectHandle.Unwrap. This method calls the parameterless constructor for `typeName`.

See AssemblyName for the format of `assemblyName`. See the Type.FullName property for the format of `typeName`.

> **Note**
>
> If you make an early-bound call to a method `M` of an object of type `T1` that was returned by **CreateInstanceAndUnwrap**, and that method makes an early-bound call to a method of an object of type `T2` in an assembly `C` other than the current assembly or the assembly containing `T1`, assembly `C` is loaded into the current application domain. This loading occurs even if the early-bound call to `T1.M()` was made in the body of a **DynamicMethod**, or in other dynamically generated code. If the current domain is the default domain, assembly `C` cannot be unloaded until the process ends. If the current domain later attempts to load assembly `C`, the load might fail.

CreateInstanceAndUnwrap(String, String, Object[])

Creates a new instance of the specified type. Parameters specify the assembly where the type is defined, the name of the type, and an array of activation attributes.

C#

```
public object? CreateInstanceAndUnwrap (string assemblyName, string
typeName, object?[]? activationAttributes);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects.Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

Object

An instance of the object specified by `typeName`.

Exceptions

ArgumentNullException

`assemblyName` or `typeName` is `null`.

MissingMethodException

No matching public constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Examples

```
C#
```

```
using System;
using System.IO;
using System.Threading;
using System.Reflection;
using System.Reflection.Emit;
using System.Runtime.Remoting;

class ADDyno

{

   public static Type CreateADynamicAssembly(ref AppDomain myNewDomain,
                        string executableNameNoExe)
   {

    string executableName = executableNameNoExe + ".exe";

    AssemblyName myAsmName = new AssemblyName();
    myAsmName.Name = executableNameNoExe;
    myAsmName.CodeBase = Environment.CurrentDirectory;

    AssemblyBuilder myAsmBuilder =
myNewDomain.DefineDynamicAssembly(myAsmName,
                        AssemblyBuilderAccess.RunAndSave);
    Console.WriteLine("-- Dynamic Assembly instantiated.");

    myFCIL.Emit(OpCodes.Conv_I4);
    myFCIL.Emit(OpCodes.Blt_S, topOfForEachLabel);
    //foreach loop end here.

    myFCIL.Emit(OpCodes.Ldstr, "---");
```

```
    myFCIL.EmitCall(OpCodes.Call, writeLine0objMI, null);
    myFCIL.Emit(OpCodes.Ldstr, "There are {0} files in {1}.");
    myFCIL.Emit(OpCodes.Ldloc_S, v1);
    myFCIL.Emit(OpCodes.Box, typeof(int));
    myFCIL.Emit(OpCodes.Ldloc_S, v0);
    myFCIL.EmitCall(OpCodes.Call, writeLine2objMI, null);

    myFCIL.Emit(OpCodes.Ret);

    Type myType = myTypeBuilder.CreateType();

    myAsmBuilder.SetEntryPoint(myFCMethod);
    myAsmBuilder.Save(executableName);
    Console.WriteLine("-- Method generated, type completed, and assembly
saved to disk.");

    return myType;
   }

   public static void Main()
   {

    string domainDir, executableName = null;

    Console.Write("Enter a name for the file counting assembly: ");
    string executableNameNoExe = Console.ReadLine();
    executableName = executableNameNoExe + ".exe";
    Console.WriteLine("---");

    domainDir = Environment.CurrentDirectory;

    AppDomain curDomain = Thread.GetDomain();

    // Create a new AppDomain, with the current directory as the base.

    Console.WriteLine("Current Directory: {0}",
Environment.CurrentDirectory);
    AppDomainSetup mySetupInfo = new AppDomainSetup();
    mySetupInfo.ApplicationBase = domainDir;
    mySetupInfo.ApplicationName = executableNameNoExe;
    mySetupInfo.LoaderOptimization = LoaderOptimization.SingleDomain;

    AppDomain myDomain = AppDomain.CreateDomain(executableNameNoExe,
                    null, mySetupInfo);

    Console.WriteLine("Creating a new AppDomain '{0}'...",
                    executableNameNoExe);

    Console.WriteLine("-- Base Directory = '{0}'",
myDomain.BaseDirectory);
    Console.WriteLine("-- Shadow Copy? = '{0}'",
myDomain.ShadowCopyFiles);

    Console.WriteLine("---");
    Type myFCType = CreateADynamicAssembly(ref curDomain,
```

```
                    executableNameNoExe);

    Console.WriteLine("Loading '{0}' from '{1}'...", executableName,
              myDomain.BaseDirectory.ToString());

    BindingFlags bFlags = (BindingFlags.Public |
BindingFlags.CreateInstance |
                  BindingFlags.Instance);

    Object myObjInstance =
myDomain.CreateInstanceAndUnwrap(executableNameNoExe,
                executableNameNoExe, false, bFlags,
                null, null, null, null, null);

    Console.WriteLine("Executing method 'CountLocalFiles' in {0}...",
               myObjInstance.ToString());

    myFCType.InvokeMember("CountLocalFiles", BindingFlags.InvokeMethod,
null,
                myObjInstance, new object[] { });
   }
}
```

Remarks

This is a convenience method that combines CreateInstance and ObjectHandle.Unwrap. This method calls the parameterless constructor for `typeName`.

See AssemblyName for the format of `assemblyName`. See the Type.FullName property for the format of `typeName`.

> **Note**
>
> If you make an early-bound call to a method `M` of an object of type `T1` that was returned by **CreateInstanceAndUnwrap**, and that method makes an early-bound call to a method of an object of type `T2` in an assembly `C` other than the current assembly or the assembly containing `T1`, assembly `C` is loaded into the current application domain. This loading occurs even if the early-bound call to `T1.M()` was made in the body of a **DynamicMethod**, or in other dynamically generated code. If the current domain is the default domain, assembly `C` cannot be unloaded until the process ends. If the current domain later attempts to load assembly `C`, the load might fail.

.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstanceAndUnwrap(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates a new instance of the specified type defined in the specified assembly, specifying whether the case of the type name is ignored; the binding attributes and the binder that are used to select the type to be created; the arguments of the constructor; the culture; and the activation attributes.

C#

```
public object? CreateInstanceAndUnwrap (string assemblyName, string
typeName, bool ignoreCase, System.Reflection.BindingFlags bindingAttr,
System.Reflection.Binder? binder, object?[]? args,
System.Globalization.CultureInfo? culture, object?[]?
activationAttributes);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`ignoreCase` Boolean

A Boolean value specifying whether to perform a case-sensitive search or not.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `typeName` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that enables the binding, coercion of argument types, invocation of members, and retrieval of MemberInfo objects using reflection. If `binder` is null, the default binder is used.

`args` Object[]

The arguments to pass to the constructor. This array of arguments must match in number, order, and type the parameters of the constructor to invoke. If the parameterless constructor is preferred, `args` must be an empty array or null.

`culture` CultureInfo

A culture-specific object used to govern the coercion of types. If `culture` is `null`, the `CultureInfo` for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object. that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

Object

An instance of the object specified by `typeName`.

Exceptions

ArgumentNullException

`assemblyName` or `typeName` is `null`.

MissingMethodException

No matching constructor was found.

TypeLoadException

`typename` was not found in `assemblyName`.

FileNotFoundException

`assemblyName` was not found.

MethodAccessException

The caller does not have permission to call this constructor.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

`assemblyName` was compiled with a later version of the common language runtime than the version that is currently loaded.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Examples

The following sample demonstrates the use of the `ignoreCase` parameter.

C#

```
using System;
using System.Reflection;

class IgnoreCaseSnippet {

   static void Main() {
      InstantiateINT32(false);     // Failed!
      InstantiateINT32(true);      // OK!
```

```
    }

    static void InstantiateINT32(bool ignoreCase) {
        try {
            AppDomain currentDomain = AppDomain.CurrentDomain;
            object instance = currentDomain.CreateInstanceAndUnwrap(
                "mscorlib, Version=2.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089",
                "SYSTEM.INT32",
                ignoreCase,
                BindingFlags.Default,
                null,
                null,
                null,
                null,
                null
            );
            Console.WriteLine(instance.GetType());
        } catch (TypeLoadException e) {
            Console.WriteLine(e.Message);
        }
    }
}
```

Remarks

This is a convenience method that combines CreateInstance and ObjectHandle.Unwrap.

See AssemblyName for the format of `assemblyName`. See the Type.FullName property for the format of `typeName`.

> **Note**
>
> If you make an early-bound call to a method `M` of an object of type `T1` that was returned by **CreateInstanceAndUnwrap**, and that method makes an early-bound call to a method of an object of type `T2` in an assembly `C` other than the current assembly or the assembly containing `T1`, assembly `C` is loaded into the current application domain. This loading occurs even if the early-bound call to `T1.M()` was made in the body of a **DynamicMethod**, or in other dynamically generated code. If the current domain is the default domain, assembly `C` cannot be unloaded until the process ends. If the current domain later attempts to load assembly `C`, the load might fail.

AppDomain.CreateInstanceFrom Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new instance of a specified type defined in the specified assembly file.

Overloads

Expand table

CreateInstanceFrom(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFrom(String, String, Object[])	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFrom(String, String)	Creates a new instance of the specified type defined in the specified assembly file.

CreateInstanceFrom(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates a new instance of the specified type defined in the specified assembly file.

C#

```
public System.Runtime.Remoting.ObjectHandle? CreateInstanceFrom (string
assemblyFile, string typeName, bool ignoreCase,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
```

```
binder, object?[]? args, System.Globalization.CultureInfo? culture,
object?[]? activationAttributes);
```

Parameters

`assemblyFile` String

The name, including the path, of a file that contains an assembly that defines the requested type. The assembly is loaded using the LoadFrom(String) method.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`ignoreCase` Boolean

A Boolean value specifying whether to perform a case-sensitive search or not.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `typeName` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that enables the binding, coercion of argument types, invocation of members, and retrieval of MemberInfo objects through reflection. If `binder` is null, the default binder is used.

`args` Object[]

The arguments to pass to the constructor. This array of arguments must match in number, order, and type the parameters of the constructor to invoke. If the parameterless constructor is preferred, `args` must be an empty array or null.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `typeName` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required

to activate a remote object.

This parameter is related to client-activated objects. Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

An object that is a wrapper for the new instance, or `null` if `typeName` is not found. The return value needs to be unwrapped to access the real object.

Exceptions

ArgumentNullException

`assemblyFile` is `null`.

-or-

`typeName` is `null`.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileNotFoundException

`assemblyFile` was not found.

TypeLoadException

`typeName` was not found in `assemblyFile`.

MissingMethodException

No matching public constructor was found.

MethodAccessException

The caller does not have sufficient permission to call this constructor.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

`assemblyFile` was compiled with a later version of the common language runtime than the version that is currently loaded.

FileLoadException

An assembly or module was loaded twice with two different evidences.

NullReferenceException

This instance is `null`.

Remarks

For more information, see the Activator.CreateInstanceFrom method.

When the CreateInstanceFrom method is used to create an instance in a target application domain, other than the application domain from which the call is made, the assembly is loaded in the target application domain. However, if the instance is unwrapped in the calling application domain, using the unwrapped instance in certain ways can cause the assembly to be loaded into the calling application domain. For example, after the instance is unwrapped, its type information might be requested, in order to call its methods late-bound. When the assembly is loaded into the calling application domain, exceptions can occur.

- If another version of the same assembly was previously loaded into the calling application domain, or if the load path of the calling application domain is different from that of the target application domain, exceptions such as MissingMethodException can occur.
- If the calling application domain makes early-bound calls to the instance type, InvalidCastException can be thrown when an attempt is made to cast the instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstanceFrom(String, String, Object[])

Creates a new instance of the specified type defined in the specified assembly file.

C#

```
public System.Runtime.Remoting.ObjectHandle? CreateInstanceFrom (string
assemblyFile, string typeName, object?[]? activationAttributes);
```

Parameters

`assemblyFile` String

The name, including the path, of a file that contains an assembly that defines the requested type. The assembly is loaded using the LoadFrom(String) method.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects.Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

ObjectHandle

An object that is a wrapper for the new instance, or `null` if `typeName` is not found. The return value needs to be unwrapped to access the real object.

Exceptions

ArgumentNullException

`assemblyFile` is `null`.

FileNotFoundException

`assemblyFile` was not found.

TypeLoadException

`typeName` was not found in `assemblyFile`.

MethodAccessException

The caller does not have sufficient permission to call this constructor.

MissingMethodException

No matching public constructor was found.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyFile` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

NullReferenceException

This instance is `null`.

Remarks

The parameterless constructor for `typeName` is invoked.

For more information about this method, see the Activator.CreateInstanceFrom method.

When the CreateInstanceFrom method is used to create an instance in a target application domain, other than the application domain from which the call is made, the assembly is loaded in the target application domain. However, if the instance is unwrapped in the calling application domain, using the unwrapped instance in certain ways can cause the assembly to be loaded into the calling application domain. For example, after the instance is unwrapped, its type information might be requested, in order to call its methods late-bound. When the assembly is loaded into the calling application domain, exceptions can occur.

- If another version of the same assembly was previously loaded into the calling application domain, or if the load path of the calling application domain is different from that of the target application domain, exceptions such as MissingMethodException can occur.
- If the calling application domain makes early-bound calls to the instance type, InvalidCastException can be thrown when an attempt is made to cast the instance.

CreateInstanceFrom(String, String)

Creates a new instance of the specified type defined in the specified assembly file.

```C#
public System.Runtime.Remoting.ObjectHandle? CreateInstanceFrom (string assemblyFile, string typeName);
```

Parameters

`assemblyFile` String

The name, including the path, of a file that contains an assembly that defines the requested type. The assembly is loaded using the LoadFrom(String) method.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

Returns

ObjectHandle

An object that is a wrapper for the new instance, or `null` if `typeName` is not found. The return value needs to be unwrapped to access the real object.

Exceptions

ArgumentNullException

`assemblyFile` is `null`.

-or-

`typeName` is `null`.

FileNotFoundException

`assemblyFile` was not found.

TypeLoadException

`typeName` was not found in `assemblyFile`.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

MissingMethodException

No parameterless public constructor was found.

MethodAccessException

The caller does not have sufficient permission to call this constructor.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyFile` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

NullReferenceException

This instance is `null`.

Examples

The following example shows how to use the CreateInstanceFrom(String, String) method overload to create an instance of an object in a target application domain and call its methods.

The example defines the `MarshalableExample` class, which can be marshaled across application domain boundaries. The example builds a path to the currently executing assembly, creates a target application domain, and uses the CreateInstanceFrom(String, String) method overload to load the example assembly into the target application domain and create an instance of `MarshalableExample`.

> **Note**
>
> The path is absolute in this example, but a relative path would also work because the **Assembly.LoadFrom** method is used to load the assembly.

After unwrapping the object handle, the example demonstrates three ways to use an object in a target application domain:

- Invoking a method with late binding, using reflection. This requires type information, which causes the assembly to be loaded into the application domain of the caller. (In this example, it is already loaded.)
- Casting the object to an interface known to both the caller and the callee. If the interface is defined in the calling assembly or in a third assembly referenced by both the caller and the callee, the called assembly is not loaded into the application domain of the caller.
- Using the object directly when its type is known to the caller. The assembly must be loaded into the application domain of the caller.

Another way to avoid loading the called assembly into the application domain of the caller is for the caller to derive from the MarshalByRefObject class and to define a method that can be run in the target application domain. That method can use reflection to examine a target assembly, because the target assembly is already loaded into the target application domain. See the example for the DynamicDirectory property.

C#

```
using System;

public interface ITest
{
    void Test(string greeting);
}

public class MarshalableExample : MarshalByRefObject, ITest
{
    static void Main()
    {
        // Construct a path to the current assembly.
        string assemblyPath = Environment.CurrentDirectory + "\\" +
            typeof(MarshalableExample).Assembly.GetName().Name + ".exe";

        AppDomain ad = AppDomain.CreateDomain("MyDomain");

        System.Runtime.Remoting.ObjectHandle oh =
            ad.CreateInstanceFrom(assemblyPath, "MarshalableExample");

        object obj = oh.Unwrap();

        // Three ways to use the newly created object, depending on how
        // much is known about the type: Late bound, early bound through
        // a mutually known interface, or early binding of a known type.
        //
        obj.GetType().InvokeMember("Test",
            System.Reflection.BindingFlags.InvokeMethod,
            Type.DefaultBinder, obj, new object[] { "Hello" });
```

```
        ITest it = (ITest) obj;
        it.Test("Hi");

        MarshalableExample ex = (MarshalableExample) obj;
        ex.Test("Goodbye");
    }

    public void Test(string greeting)
    {
        Console.WriteLine("{0} from '{1}'!", greeting,
            AppDomain.CurrentDomain.FriendlyName);
    }
}

/* This example produces the following output:

Hello from 'MyDomain'!
Hi from 'MyDomain'!
Goodbye from 'MyDomain'!
 */
```

Remarks

The parameterless constructor for `typeName` is invoked.

For more information, see the Activator.CreateInstanceFrom method.

When the CreateInstanceFrom method is used to create an instance in a target application domain, other than the application domain from which the call is made, the assembly is loaded in the target application domain. However, if the instance is unwrapped in the calling application domain, using the unwrapped instance in certain ways can cause the assembly to be loaded into the calling application domain. For example, after the instance is unwrapped, its type information might be requested, in order to call its methods late-bound. When the assembly is loaded into the calling application domain, exceptions can occur.

- If another version of the same assembly was previously loaded into the calling application domain, or if the load path of the calling application domain is different from that of the target application domain, exceptions such as MissingMethodException can occur.

- If the calling application domain makes early-bound calls to the instance type, InvalidCastException can be thrown when an attempt is made to cast the instance.

AppDomain.CreateInstanceFromAndUnwrap Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new instance of a specified type defined in the specified assembly file.

Overloads

Expand table

CreateInstanceFromAndUnwrap(String, String)	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFromAndUnwrap(String, String, Object[])	Creates a new instance of the specified type defined in the specified assembly file.
CreateInstanceFromAndUnwrap(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])	Creates a new instance of the specified type defined in the specified assembly file, specifying whether the case of the type name is ignored; the binding attributes and the binder that are used to select the type to be created; the arguments of the constructor; the culture; and the activation attributes.

CreateInstanceFromAndUnwrap(String, String)

Creates a new instance of the specified type defined in the specified assembly file.

C#

```
public object? CreateInstanceFromAndUnwrap (string assemblyFile, string
typeName);
```

Parameters

`assemblyFile` String

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

Returns

Object

The requested object, or `null` if `typeName` is not found.

Exceptions

ArgumentNullException

`assemblyName` is `null`.

-or-

`typeName` is `null`.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileNotFoundException

`assemblyName` was not found.

TypeLoadException

`typeName` was not found in `assemblyName`.

MissingMethodException

No parameterless public constructor was found.

MethodAccessException

The caller does not have sufficient permission to call this constructor.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

FileLoadException
An assembly or module was loaded twice with two different evidences.

Remarks

This is a convenience method that combines CreateInstanceFrom and ObjectHandle.Unwrap. This method calls the parameterless constructor for `typeName`.

For more information, see the Activator.CreateInstanceFrom method.

.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CreateInstanceFromAndUnwrap(String, String, Object[])

Creates a new instance of the specified type defined in the specified assembly file.

C#

```
public object? CreateInstanceFromAndUnwrap (string assemblyFile, string
typeName, object?[]? activationAttributes);
```

Parameters

`assemblyFile` String

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly (see the FullName property).

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

This parameter is related to client-activated objects.Client activation is a legacy technology that is retained for backward compatibility but is not recommended for new development. Distributed applications should instead use Windows Communication Foundation.

Returns

Object

The requested object, or `null` if `typeName` is not found.

Exceptions

ArgumentNullException

`assemblyName` is `null`.

-or-

`typeName` is `null`.

NotSupportedException

The caller cannot provide activation attributes for an object that does not inherit from MarshalByRefObject.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileNotFoundException

`assemblyName` was not found.

TypeLoadException

`typeName` was not found in `assemblyName`.

MissingMethodException

No parameterless public constructor was found.

MethodAccessException

The caller does not have sufficient permission to call this constructor.

BadImageFormatException

`assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Remarks

This is a convenience method that combines CreateInstanceFrom and ObjectHandle.Unwrap. This method calls the parameterless constructor for `typeName`.

For more information about this method, see the Activator.CreateInstanceFrom method.

CreateInstanceFromAndUnwrap(String, String, Boolean, BindingFlags, Binder, Object[], CultureInfo, Object[])

Creates a new instance of the specified type defined in the specified assembly file, specifying whether the case of the type name is ignored; the binding attributes and the binder that are used to select the type to be created; the arguments of the constructor; the culture; and the activation attributes.

C#

```
public object? CreateInstanceFromAndUnwrap (string assemblyFile, string
typeName, bool ignoreCase, System.Reflection.BindingFlags bindingAttr,
System.Reflection.Binder? binder, object?[]? args,
System.Globalization.CultureInfo? culture, object?[]?
activationAttributes);
```

Parameters

`assemblyFile` String

The file name and path of the assembly that defines the requested type.

`typeName` String

The fully qualified name of the requested type, including the namespace but not the assembly, as returned by the FullName property.

`ignoreCase` Boolean

A Boolean value specifying whether to perform a case-sensitive search or not.

`bindingAttr` BindingFlags

A combination of zero or more bit flags that affect the search for the `typeName` constructor. If `bindingAttr` is zero, a case-sensitive search for public constructors is conducted.

`binder` Binder

An object that enables the binding, coercion of argument types, invocation of members, and retrieval of MemberInfo objects through reflection. If `binder` is null, the default binder is used.

`args` Object[]

The arguments to pass to the constructor. This array of arguments must match in number, order, and type the parameters of the constructor to invoke. If the parameterless constructor is preferred, `args` must be an empty array or null.

`culture` CultureInfo

Culture-specific information that governs the coercion of `args` to the formal types declared for the `typeName` constructor. If `culture` is `null`, the CultureInfo for the current thread is used.

`activationAttributes` Object[]

An array of one or more attributes that can participate in activation. Typically, an array that contains a single UrlAttribute object that specifies the URL that is required to activate a remote object.

AppDomain.ExecuteAssembly Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Executes the assembly contained in the specified file.

Overloads

Expand table

ExecuteAssembly(String, String[], Byte[], AssemblyHashAlgorithm)	**Obsolete.** Executes the assembly contained in the specified file, using the specified arguments, hash value, and hash algorithm.
ExecuteAssembly(String, String[])	Executes the assembly contained in the specified file, using the specified arguments.
ExecuteAssembly(String)	Executes the assembly contained in the specified file.

ExecuteAssembly(String, String[], Byte[], AssemblyHashAlgorithm)

Caution

Code Access Security is not supported or honored by the runtime.

Executes the assembly contained in the specified file, using the specified arguments, hash value, and hash algorithm.

C#

```
[System.Obsolete("Code Access Security is not supported or honored by the runtime.", DiagnosticId="SYSLIB0003", UrlFormat="https://aka.ms/dotnet-
```

```
warnings/{0}")]
public int ExecuteAssembly (string assemblyFile, string?[]? args, byte[]?
hashValue, System.Configuration.Assemblies.AssemblyHashAlgorithm
hashAlgorithm);
```

Parameters

`assemblyFile` String

The name of the file that contains the assembly to execute.

`args` String[]

The arguments to the entry point of the assembly.

`hashValue` Byte[]

Represents the value of the computed hash code.

`hashAlgorithm` AssemblyHashAlgorithm

Represents the hash algorithm used by the assembly manifest.

Returns

Int32

The value that is returned by the entry point of the assembly.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`assemblyFile` is `null`.

FileNotFoundException

`assemblyFile` is not found.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

`assemblyFile` was compiled with a later version of the common language runtime than the version that is currently loaded.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

MissingMethodException

The specified assembly has no entry point.

Examples

The following sample demonstrates using one of the overloads of ExecuteAssembly on two different domains.

C#

```
class ExecuteAssemblySnippet {
   public static void Main() {
      AppDomain currentDomain = AppDomain.CurrentDomain;
      AppDomain otherDomain = AppDomain.CreateDomain("otherDomain");

      currentDomain.ExecuteAssembly("MyExecutable.exe");
      // Prints "MyExecutable running on [default]"

      otherDomain.ExecuteAssembly("MyExecutable.exe");
      // Prints "MyExecutable running on otherDomain"
   }
}
```

Remarks

⊗ Caution

Code Access Security (CAS) has been deprecated across all versions of .NET Framework and .NET. Recent versions of .NET do not honor CAS annotations and produce errors if CAS-related APIs are used. Developers should seek alternative means of accomplishing security tasks.

The assembly begins executing at the entry point specified in the .NET Framework header.

This method does not create a new process or application domain, and it does not execute the entry point method on a new thread.

This method loads assemblies using the LoadFile method. You can also execute assemblies using the ExecuteAssemblyByName method, which loads assemblies using the Load method.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5 *(6, 7, 8, 9)*
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ExecuteAssembly(String, String[])

Executes the assembly contained in the specified file, using the specified arguments.

C#

```
public int ExecuteAssembly (string assemblyFile, string?[]? args);
```

Parameters

`assemblyFile` String

The name of the file that contains the assembly to execute.

`args` String[]

The arguments to the entry point of the assembly.

Returns

Int32

The value that is returned by the entry point of the assembly.

Exceptions

ArgumentNullException

`assemblyFile` is `null`.

FileNotFoundException

`assemblyFile` is not found.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

`assemblyFile` was compiled with a later version of the common language runtime than the version that is currently loaded.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

MissingMethodException

The specified assembly has no entry point.

Examples

The following sample demonstrates using one of the overloads of ExecuteAssembly on two different domains.

C#

```
class ExecuteAssemblySnippet {
   public static void Main() {
      AppDomain currentDomain = AppDomain.CurrentDomain;
      AppDomain otherDomain = AppDomain.CreateDomain("otherDomain");

      currentDomain.ExecuteAssembly("MyExecutable.exe");
      // Prints "MyExecutable running on [default]"

      otherDomain.ExecuteAssembly("MyExecutable.exe");
      // Prints "MyExecutable running on otherDomain"
   }
}
```

Remarks

The assembly begins executing at the entry point specified in the .NET Framework header.

This method does not create a new process or application domain, and it does not execute the entry point method on a new thread.

This method loads assemblies using the LoadFile method. You can also execute assemblies using the ExecuteAssemblyByName method, which loads assemblies using the Load method.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ExecuteAssembly(String)

Executes the assembly contained in the specified file.

C#

```
public int ExecuteAssembly (string assemblyFile);
```

Parameters

`assemblyFile` String

The name of the file that contains the assembly to execute.

Returns

Int32

The value returned by the entry point of the assembly.

Exceptions

ArgumentNullException

`assemblyFile` is `null`.

FileNotFoundException

`assemblyFile` is not found.

BadImageFormatException

`assemblyFile` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyFile` was compiled with a later version.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

MissingMethodException

The specified assembly has no entry point.

Examples

The following sample demonstrates using one of the overloads of ExecuteAssembly on two different domains.

C#

```
class ExecuteAssemblySnippet {
   public static void Main() {
      AppDomain currentDomain = AppDomain.CurrentDomain;
      AppDomain otherDomain = AppDomain.CreateDomain("otherDomain");

      currentDomain.ExecuteAssembly("MyExecutable.exe");
      // Prints "MyExecutable running on [default]"

      otherDomain.ExecuteAssembly("MyExecutable.exe");
      // Prints "MyExecutable running on otherDomain"
   }
}
```

Remarks

The assembly begins executing at the entry point specified in the .NET Framework header.

This method does not create a new process or application domain, and it does not execute the entry point method on a new thread.

This method loads assemblies using the LoadFile method. You can also execute assemblies using the ExecuteAssemblyByName method, which loads assemblies using the Load method.

To create the AppDomain to load and execute, use the CreateDomain method.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppDomain.ExecuteAssemblyByName Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Executes an assembly.

Overloads

Expand table

ExecuteAssemblyByName(String)	Executes an assembly given its display name.
ExecuteAssemblyByName(AssemblyName, String[])	Executes the assembly given an AssemblyName, using the specified arguments.
ExecuteAssemblyByName(String, String[])	Executes the assembly given its display name, using the specified arguments.

ExecuteAssemblyByName(String)

Executes an assembly given its display name.

C#

```
public int ExecuteAssemblyByName (string assemblyName);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

Returns

Int32

The value returned by the entry point of the assembly.

Exceptions

ArgumentNullException

`assemblyName` is `null`.

FileNotFoundException

The assembly specified by `assemblyName` is not found.

BadImageFormatException

The assembly specified by `assemblyName` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyName` was compiled with a later version.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

The assembly specified by `assemblyName` was found, but could not be loaded.

MissingMethodException

The specified assembly has no entry point.

Remarks

The ExecuteAssemblyByName method provides similar functionality to the ExecuteAssembly method, but specifies the assembly by display name or AssemblyName rather than by file location. Therefore, ExecuteAssemblyByName loads assemblies with the Load method rather than with the LoadFile method.

The assembly begins executing at the entry point specified in the .NET Framework header.

This method does not create a new process or application domain, and it does not execute the entry point method on a new thread.

To create the AppDomain to load and execute, use the CreateDomain method.

See also

- AssemblyName
- Load(String)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ExecuteAssemblyByName(AssemblyName, String[])

Executes the assembly given an AssemblyName, using the specified arguments.

C#

```
public int ExecuteAssemblyByName (System.Reflection.AssemblyName
assemblyName, params string?[]? args);
```

Parameters

`assemblyName` AssemblyName

An AssemblyName object representing the name of the assembly.

`args` String[]

Command-line arguments to pass when starting the process.

Returns

Int32

The value that is returned by the entry point of the assembly.

Exceptions

FileNotFoundException

The assembly specified by `assemblyName` is not found.

FileLoadException

The assembly specified by `assemblyName` was found, but could not be loaded.

BadImageFormatException

The assembly specified by `assemblyName` is not a valid assembly.

-or-

`assemblyName` was compiled with a later version of the common language runtime than the version that is currently loaded.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

MissingMethodException

The specified assembly has no entry point.

Remarks

The ExecuteAssemblyByName method provides similar functionality to the ExecuteAssembly method, but specifies the assembly by display name or AssemblyName rather than by file location. Therefore, ExecuteAssemblyByName loads assemblies with the Load method rather than with the LoadFile method.

The assembly begins executing at the entry point specified in the .NET Framework header.

This method does not create a new process or application domain, and it does not execute the entry point method on a new thread.

.NET Standard	2.0, 2.1

ExecuteAssemblyByName(String, String[])

Executes the assembly given its display name, using the specified arguments.

```
C#

public int ExecuteAssemblyByName (string assemblyName, params string?[]?
args);
```

Parameters

`assemblyName` String

The display name of the assembly. See FullName.

`args` String[]

Command-line arguments to pass when starting the process.

Returns

Int32

The value that is returned by the entry point of the assembly.

Exceptions

ArgumentNullException

`assemblyName` is `null`.

FileNotFoundException

The assembly specified by `assemblyName` is not found.

FileLoadException

The assembly specified by `assemblyName` was found, but could not be loaded.

BadImageFormatException

The assembly specified by `assemblyName` is not a valid assembly.

-or-

`assemblyName` was compiled with a later version of the common language runtime than the version that is currently loaded.

AppDomainUnloadedException
The operation is attempted on an unloaded application domain.

MissingMethodException
The specified assembly has no entry point.

Remarks

The ExecuteAssemblyByName method provides similar functionality to the ExecuteAssembly method, but specifies the assembly by display name or AssemblyName rather than by file location. Therefore, ExecuteAssemblyByName loads assemblies with the Load method rather than with the LoadFile method.

The assembly begins executing at the entry point specified in the .NET Framework header.

This method does not create a new process or application domain, and it does not execute the entry point method on a new thread.

AppDomain.GetAssemblies Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the assemblies that have been loaded into the execution context of this application domain.

C#

```
public System.Reflection.Assembly[] GetAssemblies ();
```

Returns

Assembly[]

An array of assemblies in this application domain.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following code example uses the GetAssemblies method to get a list of all assemblies that have been loaded into the application domain. The assemblies are then displayed to the console.

To run this code example, you need to create an assembly named `CustomLibrary.dll`, or change the assembly name that is passed to the GetAssemblies method.

C#

```
using System;
using System.Reflection;
using System.Security.Policy;

class ADGetAssemblies
```

```
{

    public static void Main()
    {
        AppDomain currentDomain = AppDomain.CurrentDomain;
        //Provide the current application domain evidence for the assembly.
        Evidence asEvidence = currentDomain.Evidence;
        //Load the assembly from the application directory using a simple
name.

        //Create an assembly called CustomLibrary to run this sample.
        currentDomain.Load("CustomLibrary",asEvidence);

        //Make an array for the list of assemblies.
        Assembly[] assems = currentDomain.GetAssemblies();

        //List the assemblies in the current application domain.
        Console.WriteLine("List of assemblies loaded in current
appdomain:");
            foreach (Assembly assem in assems)
                Console.WriteLine(assem.ToString());
    }
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppDomain.GetCurrentThreadId Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.GetCurrentThreadId has been deprecated because it does not provide a stable Id when managed threads are running on fibers (aka lightweight threads). To get a stable identifier for a managed thread, use the ManagedThreadId property on Thread instead.

Gets the current thread identifier.

C#

```
[System.Obsolete("AppDomain.GetCurrentThreadId has been deprecated because it does not provide a stable Id when managed threads are running on fibers (aka lightweight threads). To get a stable identifier for a managed thread, use the ManagedThreadId property on Thread instead.")]
public static int GetCurrentThreadId ();
```

Returns

Int32

A 32-bit signed integer that is the identifier of the current thread.

Attributes ObsoleteAttribute

Remarks

Use the Thread.ManagedThreadId property, which is stable even when the .NET Framework is hosted by an environment that supports fibers (that is, lightweight

threads).

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

AppDomain.GetData(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value stored in the current application domain for the specified name.

```
C#
public object? GetData (string name);
```

Parameters

name String

The name of a predefined application domain property, or the name of an application domain property you have defined.

Returns

Object

The value of the `name` property, or `null` if the property does not exist.

Exceptions

ArgumentNullException

`name` is `null`.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following example creates a new application domain, sets a system-provided value for the domain, and adds a new value pair for the domain. The example then demonstrates how to use the GetData method to retrieve the data from these value pairs and display them to the console.

C#

```
using System;
using System.Reflection;

class ADGetData
{
    public static void Main()
    {
        // appdomain setup information
        AppDomain currentDomain = AppDomain.CurrentDomain;

        //Create a new value pair for the appdomain
        currentDomain.SetData("ADVALUE", "Example value");

        //get the value specified in the setdata method
        Console.WriteLine("ADVALUE is: " +
currentDomain.GetData("ADVALUE"));

        //get a system value specified at appdomainsetup
        Console.WriteLine("System value for loader optimization: {0}",
            currentDomain.GetData("LOADER_OPTIMIZATION"));
    }
}

/* This code example produces the following output:

ADVALUE is: Example value
System value for loader optimization: NotSpecified
 */
```

Remarks

Use this method to retrieve the value of an entry in an internal cache of name-data pairs that describe properties of this instance of AppDomain. Note that the comparison of `name` with the name of key-value pairs is case-sensitive.

The cache automatically contains predefined system entries that are inserted when the application domain is created. You can inspect their values with the GetData method, or the equivalent AppDomainSetup properties.

You can insert or modify your own user defined name-data pairs with the SetData method and inspect their values with the GetData method.

The following table describes the `name` of each predefined system entry and its corresponding AppDomainSetup property.

Expand table

Value of 'name'	Property
"APPBASE"	AppDomainSetup.ApplicationBase
"APP_CONFIG_FILE"	AppDomainSetup.ConfigurationFile
"APP_LAUNCH_URL"	(no property) "APP_LAUNCH_URL" represents the URL originally requested by the user, before any redirection. It is available only when the application has been launched with a browser. Not all browsers provide this value.
"APP_NAME"	AppDomainSetup.ApplicationName
"BINPATH_PROBE_ONLY"	AppDomainSetup.PrivateBinPathProbe
"CACHE_BASE"	AppDomainSetup.CachePath
"CODE_DOWNLOAD_DISABLED"	AppDomainSetup.DisallowCodeDownload
"DEV_PATH"	(no property)
"DISALLOW_APP"	AppDomainSetup.DisallowPublisherPolicy
"DISALLOW_APP_BASE_PROBING"	AppDomainSetup.DisallowApplicationBaseProbing
"DISALLOW_APP_REDIRECTS"	AppDomainSetup.DisallowBindingRedirects
"DYNAMIC_BASE"	AppDomainSetup.DynamicBase
"FORCE_CACHE_INSTALL"	AppDomainSetup.ShadowCopyFiles
"LICENSE_FILE", or an application-specific string	AppDomainSetup.LicenseFile
"LOADER_OPTIMIZATION"	AppDomainSetup.LoaderOptimization
"LOCATION_URI"	(no property)
"PRIVATE_BINPATH"	AppDomainSetup.PrivateBinPath
"REGEX_DEFAULT_MATCH_TIMEOUT"	Regex.MatchTimeout "REGEX_DEFAULT_MATCH_TIMEOUT" is not a system entry, and its value can be set by calling the SetData method.
"SHADOW_COPY_DIRS"	AppDomainSetup.ShadowCopyDirectories

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.IsCompatibilitySwitchSet(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a nullable Boolean value that indicates whether any compatibility switches are set, and if so, whether the specified compatibility switch is set.

C#

```
public bool? IsCompatibilitySwitchSet (string value);
```

Parameters

`value` String

The compatibility switch to test.

Returns

Nullable<Boolean>

A null reference (`Nothing` in Visual Basic) if no compatibility switches are set; otherwise, a Boolean value that indicates whether the compatibility switch that is specified by `value` is set.

Remarks

This method tests whether the specified compatibility switch has been set for the current application domain. Compatibility switches typically restore a behavior (such as the way strings are sorted) that was changed between versions of the .NET Framework. They are set by calling the AppDomainSetup.SetCompatibilitySwitches method before creating an application domain.

The following table provides examples of compatibility switches that can be set to restore the behavior of earlier versions of the .NET Framework.

Expand table

Switch	Meaning
"NetFx40_LegacySecurityPolicy"	Code access security (CAS) for the .NET Framework 3.5 is enabled in this application domain. See <NetFx40_LegacySecurityPolicy> Element.
"NetFx40_Legacy20SortingBehavior"	String sorting defaults for the .NET Framework 3.5 are enabled in this application domain. Its success requires sort00001000.dll to be installed. See <CompatSortNLSVersion> Element.
"NetFx40_Legacy40SortingBehavior"	String sorting defaults for the .NET Framework 4and Unicode 5.0 are enabled in this application domain. Its success requires sort00060101.dll to be installed.
"NetFx40_TimeSpanLegacyFormatMode"	TimeSpan formatting behavior for the .NET Framework 3.5 is enabled in this application domain. See <TimeSpan_LegacyFormatMode> Element and the "Restoring Legacy TimeSpan Formatting" section of the TimeSpan topic.
"UseRandomizedStringHashAlgorithm"	The runtime calculates hash codes for strings on a per application domain basis instead of using a single hashing algorithm that produces a consistent hash code across application domains. See <UseRandomizedStringHashAlgorithm> Element.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.IsDefaultAppDomain Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the application domain is the default application domain for the process.

C#

```
public bool IsDefaultAppDomain ();
```

Returns

Boolean

`true` if the current AppDomain object represents the default application domain for the process; otherwise, `false`.

Examples

The following code example creates a second application domain and displays information about the default domain and the new domain.

C#

```
using System;
using System.Reflection;

public class AppDomainIdSnippet
{
    // The following attribute indicates to the loader that assemblies
    // in the global assembly cache should be shared across multiple
    // application domains.
    [LoaderOptimizationAttribute( LoaderOptimization.MultiDomainHost)]
    public static void Main()
    {
        // Show information for the default application domain.
```

```
        ShowDomainInfo();

        // Create a new application domain and display its information.
        AppDomain newDomain = AppDomain.CreateDomain("MyMultiDomain");
        newDomain.DoCallBack(new CrossAppDomainDelegate(ShowDomainInfo));
    }

    // This method has the same signature as the CrossAppDomainDelegate,
    // so that it can be executed easily in the new application domain.
    //
    public static void ShowDomainInfo()
    {
        AppDomain ad = AppDomain.CurrentDomain;
        Console.WriteLine();
        Console.WriteLine("FriendlyName: {0}", ad.FriendlyName);
        Console.WriteLine("Id: {0}", ad.Id);
        Console.WriteLine("IsDefaultAppDomain: {0}",
ad.IsDefaultAppDomain());
    }
}
```

Remarks

Every managed process has a default application domain. Execution begins in the default domain.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.IsFinalizingForUnload Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether this application domain is unloading, and the objects it contains are being finalized by the common language runtime.

C#

```
public bool IsFinalizingForUnload ();
```

Returns

Boolean

`true` if this application domain is unloading and the common language runtime has started invoking finalizers; otherwise, `false`.

Remarks

The finalization method for an object provides you an opportunity to perform any necessary cleanup operations before the object is garbage collected. After finalization, the object is accessible but in an invalid state and therefore unusable. Eventually, garbage collection completes and reclaims the object.

An object's finalization method is called in one of the following situations: during garbage collection, when the common language runtime is shutting down, or when the application domain that contains the object is unloaded. The IsFinalizingForUnload method returns `true` only in the last case; it does not return `true` if finalization results from routine garbage collection or from CLR shutdown.

Note

To determine whether finalization is due to CLR shutdown, use the **Environment.HasShutdownStarted** property. It returns `true` if finalization is due to an application domain being unloaded or to the CLR shutting down.

While executing in your finalization method during domain unloading, you might want to access another object that is referenced by a static field and has a finalization method. However, you cannot reliably do so because the accessed object might already have been finalized.

> **Note**
>
> An exception to this rule is the **Console** class, which contains static fields that reference stream objects, but is implemented specially so you can always write to the system console, even during domain unloading or system shutdown.

Use this method in an object's finalization method to determine whether the application domain that contains the object is unloading. If that is the case, you cannot reliably access any object that has a finalization method and is referenced by a static field.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.Load Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Loads an Assembly into this application domain.

Overloads

Expand table

Load(Byte[])	Loads the Assembly with a common object file format (COFF) based image containing an emitted Assembly.
Load(AssemblyName)	Loads an Assembly given its AssemblyName.
Load(String)	Loads an Assembly given its display name.
Load(Byte[], Byte[])	Loads the Assembly with a common object file format (COFF) based image containing an emitted Assembly. The raw bytes representing the symbols for the Assembly are also loaded.

Load(Byte[])

Loads the Assembly with a common object file format (COFF) based image containing an emitted Assembly.

C#

```
public System.Reflection.Assembly Load (byte[] rawAssembly);
```

Parameters

rawAssembly Byte[]

An array of type `byte` that is a COFF-based image containing an emitted assembly.

Returns

Assembly

The loaded assembly.

Exceptions

ArgumentNullException

`rawAssembly` is `null`.

BadImageFormatException

`rawAssembly` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `rawAssembly` was compiled with a later version.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Examples

The following sample demonstrates the use of loading a raw assembly.

For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.IO;
using System.Reflection;
using System.Reflection.Emit;

class LoadRawSnippet {
   public static void Main() {
      AppDomain currentDomain = AppDomain.CurrentDomain;

      InstantiateMyType(currentDomain);   // Failed!
```

```
      currentDomain.AssemblyResolve += new
ResolveEventHandler(MyResolver);

      InstantiateMyType(currentDomain);   // OK!
   }

   static void InstantiateMyType(AppDomain domain) {
      try {
     // You must supply a valid fully qualified assembly name here.
         domain.CreateInstance("Assembly text name, Version, Culture,
PublicKeyToken", "MyType");
      } catch (Exception e) {
         Console.WriteLine(e.Message);
      }
   }

   // Loads the content of a file to a byte array.
   static byte[] loadFile(string filename) {
      FileStream fs = new FileStream(filename, FileMode.Open);
      byte[] buffer = new byte[(int) fs.Length];
      fs.Read(buffer, 0, buffer.Length);
      fs.Close();

      return buffer;
   }

   static Assembly MyResolver(object sender, ResolveEventArgs args) {
      AppDomain domain = (AppDomain) sender;

      // Once the files are generated, this call is
      // actually no longer necessary.
      EmitAssembly(domain);

      byte[] rawAssembly = loadFile("temp.dll");
      byte[] rawSymbolStore = loadFile("temp.pdb");
      Assembly assembly = domain.Load(rawAssembly, rawSymbolStore);

      return assembly;
   }

   // Creates a dynamic assembly with symbol information
   // and saves them to temp.dll and temp.pdb
   static void EmitAssembly(AppDomain domain) {
      AssemblyName assemblyName = new AssemblyName();
      assemblyName.Name = "MyAssembly";

      AssemblyBuilder assemblyBuilder =
domain.DefineDynamicAssembly(assemblyName, AssemblyBuilderAccess.Save);
      ModuleBuilder moduleBuilder =
assemblyBuilder.DefineDynamicModule("MyModule", "temp.dll", true);
      TypeBuilder typeBuilder = moduleBuilder.DefineType("MyType",
TypeAttributes.Public);

      ConstructorBuilder constructorBuilder =
typeBuilder.DefineConstructor(MethodAttributes.Public,
```

```
CallingConventions.Standard, null);
      ILGenerator ilGenerator = constructorBuilder.GetILGenerator();
      ilGenerator.EmitWriteLine("MyType instantiated!");
      ilGenerator.Emit(OpCodes.Ret);

      typeBuilder.CreateType();

      assemblyBuilder.Save("temp.dll");
   }
}
```

Remarks

Beginning with the .NET Framework 4, the trust level of an assembly that is loaded by using this method is the same as the trust level of the application domain.

This method should be used only to load an assembly into the current application domain. This method is provided as a convenience for interoperability callers who cannot call the static Assembly.Load method. To load assemblies into other application domains, use a method such as CreateInstanceAndUnwrap.

For information that is common to all overloads of this method, see the Load(AssemblyName) method overload.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Load(AssemblyName)

Loads an Assembly given its AssemblyName.

C#

```
public System.Reflection.Assembly Load (System.Reflection.AssemblyName
```

```
assemblyRef);
```

Parameters

`assemblyRef` AssemblyName

An object that describes the assembly to load.

Returns

Assembly

The loaded assembly.

Exceptions

ArgumentNullException

`assemblyRef` is `null`.

FileNotFoundException

`assemblyRef` is not found.

BadImageFormatException

`assemblyRef` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyRef` was compiled with a later version.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Remarks

This method should be used only to load an assembly into the current application domain. This method is provided as a convenience for interoperability callers who cannot call the static Assembly.Load method. To load assemblies into other application domains, use a method such as CreateInstanceAndUnwrap.

If a version of the requested assembly is already loaded, this method returns the loaded assembly, even if a different version is requested.

Supplying a partial assembly name for `assemblyRef` is not recommended. (A partial name omits one or more of culture, version, or public key token. For overloads that take a string instead of an AssemblyName object, "MyAssembly, Version=1.0.0.0" is an example of a partial name and "MyAssembly, Version=1.0.0.0, Culture=neutral, PublicKeyToken=18ab3442da84b47" is an example of a full name.) Using partial names has a negative effect on performance. In addition, a partial assembly name can load an assembly from the global assembly cache only if there is an exact copy of the assembly in the application base directory (BaseDirectory or AppDomainSetup.ApplicationBase).

If the current AppDomain object represents application domain `A`, and the Load method is called from application domain `B`, the assembly is loaded into both application domains. For example, the following code loads `MyAssembly` into the new application domain `ChildDomain` and also into the application domain where the code executes:

```
C#

AppDomain ad = AppDomain.CreateDomain("ChildDomain");
ad.Load("MyAssembly");
```

The assembly is loaded into both domains because Assembly does not derive from MarshalByRefObject, and therefore the return value of the Load method cannot be marshaled. Instead, the common language runtime tries to load the assembly into the calling application domain. The assemblies that are loaded into the two application domains might be different if the path settings for the two application domains are different.

> **Note**
>
> If both the **AssemblyName.Name** property and the **AssemblyName.CodeBase** property are set, the first attempt to load the assembly uses the display name (including version, culture, and so on, as returned by the **Assembly.FullName** property). If the file is not found, the **CodeBase** property is used to search for the assembly. If the assembly is found using **CodeBase**, the display name is matched against the assembly. If the match fails, a **FileLoadException** is thrown.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

Load(String)

Loads an Assembly given its display name.

```
C#

public System.Reflection.Assembly Load (string assemblyString);
```

Parameters

`assemblyString` String

The display name of the assembly. See FullName.

Returns

Assembly

The loaded assembly.

Exceptions

ArgumentNullException

`assemblyString` is `null`

FileNotFoundException

`assemblyString` is not found.

BadImageFormatException

`assemblyString` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `assemblyString` was compiled with a later version.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Remarks

This method should be used only to load an assembly into the current application domain. This method is provided as a convenience for interoperability callers who cannot call the static Assembly.Load method. To load assemblies into other application domains, use a method such as CreateInstanceAndUnwrap.

For information that is common to all overloads of this method, see the Load(AssemblyName) method overload.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Load(Byte[], Byte[])

Loads the Assembly with a common object file format (COFF) based image containing an emitted Assembly. The raw bytes representing the symbols for the Assembly are also loaded.

C#

```
public System.Reflection.Assembly Load (byte[] rawAssembly, byte[]?
rawSymbolStore);
```

Parameters

`rawAssembly` Byte[]

An array of type `byte` that is a COFF-based image containing an emitted assembly.

`rawSymbolStore` Byte[]

An array of type `byte` containing the raw bytes representing the symbols for the assembly.

Returns

Assembly

The loaded assembly.

Exceptions

ArgumentNullException

`rawAssembly` is `null`.

BadImageFormatException

`rawAssembly` is not a valid assembly.

-or-

Version 2.0 or later of the common language runtime is currently loaded and `rawAssembly` was compiled with a later version.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

FileLoadException

An assembly or module was loaded twice with two different evidences.

Examples

The following sample demonstrates the use of loading a raw assembly.

For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

```
C#
```

```
using System;
using System.IO;
using System.Reflection;
using System.Reflection.Emit;

class LoadRawSnippet {
   public static void Main() {
      AppDomain currentDomain = AppDomain.CurrentDomain;

      InstantiateMyType(currentDomain);   // Failed!

      currentDomain.AssemblyResolve += new
ResolveEventHandler(MyResolver);

      InstantiateMyType(currentDomain);   // OK!
   }

   static void InstantiateMyType(AppDomain domain) {
      try {
     // You must supply a valid fully qualified assembly name here.
         domain.CreateInstance("Assembly text name, Version, Culture,
PublicKeyToken", "MyType");
      } catch (Exception e) {
         Console.WriteLine(e.Message);
      }
   }

   // Loads the content of a file to a byte array.
   static byte[] loadFile(string filename) {
      FileStream fs = new FileStream(filename, FileMode.Open);
      byte[] buffer = new byte[(int) fs.Length];
      fs.Read(buffer, 0, buffer.Length);
      fs.Close();

      return buffer;
   }

   static Assembly MyResolver(object sender, ResolveEventArgs args) {
      AppDomain domain = (AppDomain) sender;

      // Once the files are generated, this call is
      // actually no longer necessary.
      EmitAssembly(domain);

      byte[] rawAssembly = loadFile("temp.dll");
      byte[] rawSymbolStore = loadFile("temp.pdb");
      Assembly assembly = domain.Load(rawAssembly, rawSymbolStore);

      return assembly;
   }

   // Creates a dynamic assembly with symbol information
   // and saves them to temp.dll and temp.pdb
   static void EmitAssembly(AppDomain domain) {
```

```
        AssemblyName assemblyName = new AssemblyName();
        assemblyName.Name = "MyAssembly";

        AssemblyBuilder assemblyBuilder =
domain.DefineDynamicAssembly(assemblyName, AssemblyBuilderAccess.Save);
        ModuleBuilder moduleBuilder =
assemblyBuilder.DefineDynamicModule("MyModule", "temp.dll", true);
        TypeBuilder typeBuilder = moduleBuilder.DefineType("MyType",
TypeAttributes.Public);

        ConstructorBuilder constructorBuilder =
typeBuilder.DefineConstructor(MethodAttributes.Public,
CallingConventions.Standard, null);
        ILGenerator ilGenerator = constructorBuilder.GetILGenerator();
        ilGenerator.EmitWriteLine("MyType instantiated!");
        ilGenerator.Emit(OpCodes.Ret);

        typeBuilder.CreateType();

        assemblyBuilder.Save("temp.dll");
    }
}
```

Remarks

Beginning with the .NET Framework 4, the trust level of an assembly that is loaded by using this method is the same as the trust level of the application domain.

This method should be used only to load an assembly into the current application domain. This method is provided as a convenience for interoperability callers who cannot call the static Assembly.Load method. To load assemblies into other application domains, use a method such as CreateInstanceAndUnwrap.

AppDomain.ReflectionOnlyGetAssemblies Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the assemblies that have been loaded into the reflection-only context of the application domain.

C#

```
public System.Reflection.Assembly[] ReflectionOnlyGetAssemblies ();
```

Returns

Assembly[]

An array of Assembly objects that represent the assemblies loaded into the reflection-only context of the application domain.

Exceptions

AppDomainUnloadedException

An operation is attempted on an unloaded application domain.

Examples

The following code example loads the System.dll assembly into the execution context and then into the reflection-only context. The GetAssemblies and ReflectionOnlyGetAssemblies methods are used to display the assemblies loaded into each context.

C#

```
using System;
using System.Reflection;
using System.Timers;
```

```
public class ReflectionOnlySnippet
{
    public static void Main()
    {
        // Get the assembly display name for System.dll, the assembly
        // that contains System.Timers.Timer. Note that this causes
        // System.dll to be loaded into the execution context.
        //
        string displayName = typeof(Timer).Assembly.FullName;

        // Load System.dll into the reflection-only context. Note that
        // if you obtain the display name (for example, by running this
        // example program), and enter it as a literal string in the
        // preceding line of code, you can load System.dll into the
        // reflection-only context without loading it into the execution
        // context.
        Assembly.ReflectionOnlyLoad(displayName);

        // Display the assemblies loaded into the execution and
        // reflection-only contexts. System.dll appears in both contexts.
        //
        Console.WriteLine("------------- Execution Context --------------");
        foreach (Assembly a in AppDomain.CurrentDomain.GetAssemblies())
        {
            Console.WriteLine("\t{0}", a.GetName());
        }
        Console.WriteLine("------------- Reflection-only Context -----------
---");
        foreach (Assembly a in
AppDomain.CurrentDomain.ReflectionOnlyGetAssemblies())
        {
            Console.WriteLine("\t{0}", a.GetName());
        }
    }
}
```

Remarks

This method returns the assemblies that have been loaded into the reflection-only context. To get the assemblies that have been loaded for execution, use the GetAssemblies method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.SetCachePath(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.SetCachePath has been deprecated and is not supported.

Establishes the specified directory path as the location where assemblies are shadow copied.

C#

```
[System.Obsolete("AppDomain.SetCachePath has been deprecated and is not supported.")]
public void SetCachePath (string? path);
```

Parameters

path String

The fully qualified path to the shadow copy location.

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Remarks

The cache path is ignored if the ApplicationName property is not set. See the AppDomainSetup.CachePath property.

For more information on shadow copying see Shadow Copying Assemblies.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

AppDomain.SetData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Assigns a value to an application domain property.

Overloads

Expand table

SetData(String, Object)	Assigns the specified value to the specified application domain property.

SetData(String, Object)

Assigns the specified value to the specified application domain property.

C#

```
public void SetData (string name, object? data);
```

Parameters

`name` String

The name of a user-defined application domain property to create or change.

`data` Object

The value of the property.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following example demonstrates how to use the SetData(String, Object) method to create a new value pair. The example then uses the GetData method to retrieve the value, and displays it to the console.

C#

```
using System;
using System.Reflection;

class ADGetData
{
    public static void Main()
    {
        // appdomain setup information
        AppDomain currentDomain = AppDomain.CurrentDomain;

        //Create a new value pair for the appdomain
        currentDomain.SetData("ADVALUE", "Example value");

        //get the value specified in the setdata method
        Console.WriteLine("ADVALUE is: " +
currentDomain.GetData("ADVALUE"));

        //get a system value specified at appdomainsetup
        Console.WriteLine("System value for loader optimization: {0}",
            currentDomain.GetData("LOADER_OPTIMIZATION"));
    }
}

/* This code example produces the following output:

ADVALUE is: Example value
System value for loader optimization: NotSpecified
 */
```

Remarks

Use this method to insert an entry, or modify the value of an entry in an internal cache of name-data pairs that describe properties of this instance of AppDomain.

The cache automatically contains predefined system entries that are inserted when the application domain is created. You cannot insert or modify system entries with this method. A method call that attempts to modify a system entry has no effect; the method does not throw an exception. You can inspect the values of system entries with the GetData method, or the equivalent AppDomainSetup properties described in GetData.

You can call this method to set the value of the default timeout interval for evaluating regular expression patterns by supply "REGEX_DEFAULT_MATCH_TIMEOUT" as the value of the `name` argument and a TimeSpan value that represents the timeout interval as the value of the `data` argument. You can also insert or modify your own user defined name-data pairs with this method and inspect their values with the GetData method.

AppDomain.SetDynamicBase(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.SetDynamicBase has been deprecated and is not supported.

Establishes the specified directory path as the base directory for subdirectories where dynamically generated files are stored and accessed.

C#

```
[System.Obsolete("AppDomain.SetDynamicBase has been deprecated and is not supported.")]
public void SetDynamicBase (string? path);
```

Parameters

path String

The fully qualified path that is the base directory for subdirectories where dynamic assemblies are stored.

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

This method is now obsolete, and should not be used for new development. The following example shows how to use the non-obsolete alternative, the AppDomainSetup.DynamicBase property. For an explanation of this example, see the AppDomainSetup.DynamicBase property or the DynamicDirectory property.

C#

```
using System;
using System.Reflection;
using System.Reflection.Emit;

public class AddDynamicBaseSnippet : MarshalByRefObject
{
   static void Main()
   {
      // Prepare to create a new application domain.
      AppDomainSetup setup = new AppDomainSetup();

      // Set the application name before setting the dynamic base.
      setup.ApplicationName = "Example";

      // Set the location of the base directory where assembly resolution
      // probes for dynamic assemblies. Note that the hash code of the
      // application name is concatenated to the base directory name you
      // supply.
      setup.DynamicBase = "C:\\DynamicAssemblyDir";
      Console.WriteLine("DynamicBase is set to '{0}'.", setup.DynamicBase);

      AppDomain ad = AppDomain.CreateDomain("MyDomain", null, setup);

      // The dynamic directory name is the dynamic base concatenated with
      // the application name: <DynamicBase>\<hash code>\<ApplicationName>
      string dynamicDir = ad.DynamicDirectory;
      Console.WriteLine("Dynamic directory is '{0}'.", dynamicDir);

      // The AssemblyBuilder won't create this directory automatically.
      if (!System.IO.Directory.Exists(dynamicDir))
      {
         Console.WriteLine("Creating the dynamic directory.");
         System.IO.Directory.CreateDirectory(dynamicDir);
      }

      // Generate a dynamic assembly and store it in the dynamic
      // directory.
      GenerateDynamicAssembly(dynamicDir);

      // Create an instance of the Example class in the application domain,
      // and call its Test method to load the dynamic assembly and use it.
      AddDynamicBaseSnippet ex = (AddDynamicBaseSnippet)
ad.CreateInstanceAndUnwrap(
         typeof(AddDynamicBaseSnippet).Assembly.FullName, "Example");
      ex.Test();
   }
```

```
   public void Test()
   {
      Assembly dynAssem = Assembly.Load(
         "DynamicHelloWorld, Version=1.0.0.0, Culture=neutral,
PublicKeyToken=null");

      Type myType = dynAssem.GetType("HelloWorld");
      myType.InvokeMember("HelloFromAD", BindingFlags.Public |
         BindingFlags.Static | BindingFlags.InvokeMethod,
         Type.DefaultBinder, null, null);
   }

   private static void GenerateDynamicAssembly(string location)
   {
      // Define the dynamic assembly and the module. There is only one
      // module in this assembly. Note that the call to
DefineDynamicAssembly
      // specifies the location where the assembly will be saved. The
      // assembly version is 1.0.0.0.
      //
      AssemblyName asmName = new AssemblyName("DynamicHelloWorld");
      asmName.Version = new Version("1.0.0.0");

      AssemblyBuilder ab =
         AppDomain.CurrentDomain.DefineDynamicAssembly(
            asmName, AssemblyBuilderAccess.Save, location);

      String moduleName = asmName.Name + ".exe";
      ModuleBuilder mb = ab.DefineDynamicModule(asmName.Name, moduleName);

      // Define the "HelloWorld" type, with one static method.
      TypeBuilder tb = mb.DefineType("HelloWorld", TypeAttributes.Public);
      MethodBuilder hello = tb.DefineMethod("HelloFromAD",
         MethodAttributes.Public | MethodAttributes.Static, null, null);

      // The method displays a message that contains the name of the
application
      // domain where the method is executed.
      ILGenerator il = hello.GetILGenerator();
      il.Emit(OpCodes.Ldstr, "Hello from '{0}'!");
      il.Emit(OpCodes.Call,
typeof(AppDomain).GetProperty("CurrentDomain").GetGetMethod());
      il.Emit(OpCodes.Call,
typeof(AppDomain).GetProperty("FriendlyName").GetGetMethod());
      il.Emit(OpCodes.Call, typeof(Console).GetMethod("WriteLine",
                              new Type[] { typeof(String), typeof(String)
}));
      il.Emit(OpCodes.Ret);

      // Complete the HelloWorld type and save the assembly. The assembly
      // is placed in the location specified by DefineDynamicAssembly.
      Type myType = tb.CreateType();
      ab.Save(moduleName);
   }
```

```
}

/* This example produces output similar to the following:

DynamicBase is set to 'C:\DynamicAssemblyDir\5e4a7545'.
Dynamic directory is 'C:\DynamicAssemblyDir\5e4a7545\Example'.
Creating the dynamic directory.
Hello from 'MyDomain'!
 */
```

Remarks

This method sets the DynamicBase property of the internal AppDomainSetup associated with this instance.

AppDomain.SetPrincipalPolicy(PrincipalPolicy) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies how principal and identity objects should be attached to a thread if the thread attempts to bind to a principal while executing in this application domain.

C#

```
public void SetPrincipalPolicy (System.Security.Principal.PrincipalPolicy policy);
```

Parameters

policy PrincipalPolicy

One of the PrincipalPolicy values that specifies the type of the principal object to attach to threads.

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following example shows the effect on threads of using the SetPrincipalPolicy method to change the principal policy of the application domain. It also shows the effect of using the SetThreadPrincipal method to change the principal that is available for attaching to threads in the application domain.

C#

```
using System;
using System.Security.Principal;
using System.Threading;
```

```
class ADPrincipal
{
    static void Main(string[] args)
    {
        // Create a new thread with a generic principal.
        Thread t = new Thread(new ThreadStart(PrintPrincipalInformation));
        t.Start();
        t.Join();

        // Set the principal policy to WindowsPrincipal.
        AppDomain currentDomain = AppDomain.CurrentDomain;
        currentDomain.SetPrincipalPolicy(PrincipalPolicy.WindowsPrincipal);

        // The new thread will have a Windows principal representing the
        // current user.
        t = new Thread(new ThreadStart(PrintPrincipalInformation));
        t.Start();
        t.Join();

        // Create a principal to use for new threads.
        IIdentity identity = new GenericIdentity("NewUser");
        IPrincipal principal = new GenericPrincipal(identity, null);
        currentDomain.SetThreadPrincipal(principal);

        // Create a new thread with the principal created above.
        t = new Thread(new ThreadStart(PrintPrincipalInformation));
        t.Start();
        t.Join();

        // Wait for user input before terminating.
        Console.ReadLine();
    }

    static void PrintPrincipalInformation()
    {
        IPrincipal curPrincipal = Thread.CurrentPrincipal;
        if(curPrincipal != null)
        {
            Console.WriteLine("Type: " + curPrincipal.GetType().Name);
            Console.WriteLine("Name: " + curPrincipal.Identity.Name);
            Console.WriteLine("Authenticated: " +
                curPrincipal.Identity.IsAuthenticated);
            Console.WriteLine();
        }
    }
}
```

Remarks

Setting this value will only be effective if you set it before using the Thread.CurrentPrincipal property. For example, if you set Thread.CurrentPrincipal to a

given principal (for example, a generic principal) and then use the SetPrincipalPolicy method to set the PrincipalPolicy to WindowsPrincipal, the current principal will remain the generic principal.

AppDomain.SetShadowCopyFiles Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.SetShadowCopyFiles has been deprecated and is not supported.

Turns on shadow copying.

C#

```
[System.Obsolete("AppDomain.SetShadowCopyFiles has been deprecated and is not supported.")]
public void SetShadowCopyFiles ();
```

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

This method is now obsolete, and should not be used for new development.

C#

```
using System;
using System.Security.Policy;
namespace AppDomainSnippets
{
    class ADProperties
```

```
    {
        static void Main(string[] args)
        {

            AppDomainSetup setup = new AppDomainSetup();
            // Shadow copying will not work unless the application has a
name.
            setup.ApplicationName = "MyApplication";

            //Create evidence for the new application domain from evidence
of
            // current application domain.
            Evidence adevidence = AppDomain.CurrentDomain.Evidence;

            // Create a new application domain.
            AppDomain domain = AppDomain.CreateDomain("MyDomain",
adevidence, setup);

            // MyAssembly.dll is located in the Assemblies subdirectory.
            domain.AppendPrivatePath("Assemblies");
            // MyOtherAssembly.dll and MyThirdAssembly.dll are located in
the
            // MoreAssemblies subdirectory.
            domain.AppendPrivatePath("MoreAssemblies");
            // Display the relative search path.
            Console.WriteLine("RelativeSearchPath: " +
domain.RelativeSearchPath);
            // Because Load returns an Assembly object, the assemblies must
be
            // loaded into the current domain as well. This will fail unless
the
            // current domain also has these directories in its search path.
            AppDomain.CurrentDomain.AppendPrivatePath("Assemblies");
            AppDomain.CurrentDomain.AppendPrivatePath("MoreAssemblies");

            // Save shadow copies to C:\Cache
            domain.SetCachePath("C:\\Cache");
            // Shadow copy only the assemblies in the Assemblies directory.
            domain.SetShadowCopyPath(domain.BaseDirectory + "Assemblies");
            // Turn shadow copying on.
            domain.SetShadowCopyFiles();
            Console.WriteLine("ShadowCopyFiles turned on: " +
domain.ShadowCopyFiles);

            // This will be copied.
            // You must supply a valid fully qualified assembly name here.
            domain.Load("Assembly1 text name, Version, Culture,
PublicKeyToken");
            // This will not be copied.
            // You must supply a valid fully qualified assembly name here.
            domain.Load("Assembly2 text name, Version, Culture,
PublicKeyToken");

            // When the shadow copy path is cleared, the CLR will make
shadow copies
```

```
            // of all private assemblies.
            domain.ClearShadowCopyPath();
            // MoreAssemblies\MyThirdAssembly.dll should be shadow copied
this time.
            // You must supply a valid fully qualified assembly name here.
            domain.Load("Assembly3 text name, Version, Culture,
PublicKeyToken");

            // Unload the domain.
            AppDomain.Unload(domain);
        }
    }
}
```

Remarks

For more information on shadow copying, see Shadow Copying Assemblies.

Applies to

AppDomain.SetShadowCopyPath(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> AppDomain.SetShadowCopyPath has been deprecated and is not supported.

Establishes the specified directory path as the location of assemblies to be shadow copied.

C#

```
[System.Obsolete("AppDomain.SetShadowCopyPath has been deprecated and is not supported.")]
public void SetShadowCopyPath (string? path);
```

Parameters

path String

A list of directory names, where each name is separated by a semicolon.

Attributes ObsoleteAttribute

Exceptions

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

This method is now obsolete, and should not be used for new development.

C#

```
using System;
using System.Security.Policy;
namespace AppDomainSnippets
{
    class ADShadowCopy
    {
        static void Main(string[] args)
        {

            AppDomainSetup setup = new AppDomainSetup();
            // Shadow copying will not work unless the application has a
name.
            setup.ApplicationName = "MyApplication";

            //Create evidence for the new application domain from evidence
of
            // current application domain.
            Evidence adevidence = AppDomain.CurrentDomain.Evidence;

            // Create a new application domain.
            AppDomain domain = AppDomain.CreateDomain("MyDomain",
adevidence, setup);

            // MyAssembly.dll is located in the Assemblies subdirectory.
            domain.AppendPrivatePath("Assemblies");
            // MyOtherAssembly.dll and MyThirdAssembly.dll are located in
the
            // MoreAssemblies subdirectory.
            domain.AppendPrivatePath("MoreAssemblies");
            // Display the relative search path.
            Console.WriteLine("RelativeSearchPath: " +
domain.RelativeSearchPath);
            // Because Load returns an Assembly object, the assemblies must
be
            // loaded into the current domain as well. This will fail unless
the
            // current domain also has these directories in its search path.
            AppDomain.CurrentDomain.AppendPrivatePath("Assemblies");
            AppDomain.CurrentDomain.AppendPrivatePath("MoreAssemblies");

            // Save shadow copies to C:\Cache
            domain.SetCachePath("C:\\Cache");
            // Shadow copy only the assemblies in the Assemblies directory.
            domain.SetShadowCopyPath(domain.BaseDirectory + "Assemblies");
            // Turn shadow copying on.
            domain.SetShadowCopyFiles();

            // This will be copied.
            // You must supply a valid fully qualified assembly name here.
            domain.Load("Assembly1 text name, Version, Culture,
PublicKeyToken");
            // This will not be copied.
```

```
            // You must supply a valid fully qualified assembly name here.
            domain.Load("Assembly2 text name, Version, Culture,
PublicKeyToken");

            // When the shadow copy path is cleared, the CLR will make
shadow copies
            // of all private assemblies.
            domain.ClearShadowCopyPath();
            // MoreAssemblies\MyThirdAssembly.dll should be shadow copied
this time.
            // You must supply a valid fully qualified assembly name here.
            domain.Load("Assembly3 text name, Version, Culture,
PublicKeyToken");

            // Unload the domain.
            AppDomain.Unload(domain);
        }
    }
}
```

Remarks

By default, a shadow copy includes all assemblies found through probing. The SetShadowCopyPath method restricts the shadow copy to the assemblies in the directories specified by `path`.

The SetShadowCopyPath method does not specify additional directories to be searched for assemblies. Assemblies to be shadow-copied must already be located in the search path, for example under BaseDirectory. The SetShadowCopyPath method specifies which search paths are eligible to be shadow-copied.

This method sets the ShadowCopyDirectories property of the internal AppDomainSetup associated with this instance.

For more information on shadow copying, see Shadow Copying Assemblies.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*

AppDomain.SetThread Principal(IPrincipal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sets the default principal object to be attached to threads if they attempt to bind to a principal while executing in this application domain.

C#

```
public void SetThreadPrincipal (System.Security.Principal.IPrincipal
principal);
```

Parameters

principal IPrincipal

The principal object to attach to threads.

Exceptions

ArgumentNullException

`principal` is `null`.

PolicyException

The thread principal has already been set.

AppDomainUnloadedException

The operation is attempted on an unloaded application domain.

Examples

The following example shows the effect of using the SetThreadPrincipal method to change the principal that is available for attaching to threads that are executing in the application domain. It also shows the effect on threads of using the SetPrincipalPolicy method to change the principal policy of the application domain.

C#

```
using System;
using System.Security.Principal;
using System.Threading;

class ADPrincipal
{
    static void Main(string[] args)
    {
        // Create a new thread with a generic principal.
        Thread t = new Thread(new ThreadStart(PrintPrincipalInformation));
        t.Start();
        t.Join();

        // Set the principal policy to WindowsPrincipal.
        AppDomain currentDomain = AppDomain.CurrentDomain;
        currentDomain.SetPrincipalPolicy(PrincipalPolicy.WindowsPrincipal);

        // The new thread will have a Windows principal representing the
        // current user.
        t = new Thread(new ThreadStart(PrintPrincipalInformation));
        t.Start();
        t.Join();

        // Create a principal to use for new threads.
        IIdentity identity = new GenericIdentity("NewUser");
        IPrincipal principal = new GenericPrincipal(identity, null);
        currentDomain.SetThreadPrincipal(principal);

        // Create a new thread with the principal created above.
        t = new Thread(new ThreadStart(PrintPrincipalInformation));
        t.Start();
        t.Join();

        // Wait for user input before terminating.
        Console.ReadLine();
    }

    static void PrintPrincipalInformation()
    {
        IPrincipal curPrincipal = Thread.CurrentPrincipal;
        if(curPrincipal != null)
        {
            Console.WriteLine("Type: " + curPrincipal.GetType().Name);
            Console.WriteLine("Name: " + curPrincipal.Identity.Name);
            Console.WriteLine("Authenticated: " +
                curPrincipal.Identity.IsAuthenticated);
            Console.WriteLine();
        }
    }
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppDomain.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Obtains a string representation that includes the friendly name of the application domain and any context policies.

C#

```
public override string ToString ();
```

Returns

String

A string formed by concatenating the literal string "Name:", the friendly name of the application domain, and either string representations of the context policies or the string "There are no context policies."

Exceptions

AppDomainUnloadedException

The application domain represented by the current AppDomain has been unloaded.

Examples

The following code example displays the return value of the ToString method.

C#

```
using System;
using System.Reflection;
using System.Security.Policy;
class ADSetup
{
    public static void Main()
    {
        // Create application domain setup information
```

```
        AppDomainSetup domaininfo = new AppDomainSetup();

        //Create evidence for the new appdomain from evidence of the current
application domain
        Evidence adevidence = AppDomain.CurrentDomain.Evidence;

        // Create appdomain
        AppDomain domain = AppDomain.CreateDomain("MyDomain", adevidence,
domaininfo);

        // Write out application domain information
        Console.WriteLine("Host domain: " +
AppDomain.CurrentDomain.FriendlyName);
        Console.WriteLine("child domain: " + domain.FriendlyName);
        Console.WriteLine("child domain name using ToString:" +
domain.ToString());
        Console.WriteLine();

        AppDomain.Unload(domain);
    }
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.Unload(AppDomain) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Creating and unloading AppDomains is not supported and throws an exception.

Unloads the specified application domain.

C#

```
[System.Obsolete("Creating and unloading AppDomains is not supported and throws an exception.", DiagnosticId="SYSLIB0024", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public static void Unload (AppDomain domain);
```

Parameters

`domain` AppDomain

An application domain to unload.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`domain` is `null`.

CannotUnloadAppDomainException

.NET Core and .NET 5+ only: In all cases.

-or-

`domain` could not be unloaded.

Exception

An error occurred during the unload process.

Examples

The following code example shows how to unload an application domain.

C#

```
using System;
using System.Reflection;
using System.Security.Policy;
class ADUnload
{
    public static void Main()
    {

        //Create evidence for the new appdomain.
        Evidence adevidence = AppDomain.CurrentDomain.Evidence;

        // Create the new application domain.
        AppDomain domain = AppDomain.CreateDomain("MyDomain", adevidence);

                Console.WriteLine("Host domain: " +
AppDomain.CurrentDomain.FriendlyName);
                Console.WriteLine("child domain: " + domain.FriendlyName);
        // Unload the application domain.
        AppDomain.Unload(domain);

        try
        {
        Console.WriteLine();
        // Note that the following statement creates an exception because
the domain no longer exists.
                Console.WriteLine("child domain: " + domain.FriendlyName);
        }

        catch (AppDomainUnloadedException e)
        {
        Console.WriteLine("The appdomain MyDomain does not exist.");
        }
    }
}
```

Remarks

In .NET Framework version 2.0 and later, there is a thread dedicated to unloading application domains. This improves reliability, especially when .NET Framework is hosted. When a thread calls Unload, the target domain is marked for unloading. The dedicated thread attempts to unload the domain, and all threads in the domain are aborted. If a thread does not abort, for example because it is executing unmanaged code, or because it is executing a `finally` block, then after a period of time, a CannotUnloadAppDomainException is thrown in the thread that originally called Unload. If the thread that could not be aborted eventually ends, the target domain is not unloaded. Thus, in .NET Framework version 2.0 and later, `domain` is not guaranteed to unload, because it might not be possible to terminate executing threads.

> **Note**
>
> In some cases, calling **Unload** causes an immediate **CannotUnloadAppDomainException**, for example if it is called in a finalizer.

The threads in `domain` are terminated using the Abort method, which throws a ThreadAbortException in the thread. Although the thread should terminate promptly, it can continue executing for an unpredictable amount of time in a `finally` clause.

AppDomain.AssemblyLoad Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when an assembly is loaded.

C#

```
public event AssemblyLoadEventHandler? AssemblyLoad;
```

Event Type

AssemblyLoadEventHandler

Examples

The following sample demonstrates the AssemblyLoad event.

For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.Reflection;

class AssemblyLoadSnippet {

   public static void Main() {
      AppDomain currentDomain = AppDomain.CurrentDomain;
      currentDomain.AssemblyLoad += new
AssemblyLoadEventHandler(MyAssemblyLoadEventHandler);

      PrintLoadedAssemblies(currentDomain);
      // Lists mscorlib and this assembly

      // You must supply a valid fully qualified assembly name here.
      currentDomain.CreateInstance("System.Windows.Forms, Version, Culture,
PublicKeyToken", "System.Windows.Forms.TextBox");
```

```
        // Loads System, System.Drawing, System.Windows.Forms

        PrintLoadedAssemblies(currentDomain);
        // Lists all five assemblies
    }

    static void PrintLoadedAssemblies(AppDomain domain) {
        Console.WriteLine("LOADED ASSEMBLIES:");
        foreach (Assembly a in domain.GetAssemblies()) {
            Console.WriteLine(a.FullName);
        }
        Console.WriteLine();
    }

    static void MyAssemblyLoadEventHandler(object sender,
AssemblyLoadEventArgs args) {
        Console.WriteLine("ASSEMBLY LOADED: " + args.LoadedAssembly.FullName);
        Console.WriteLine();
    }
}
```

Remarks

The AssemblyLoadEventHandler delegate for this event indicates what assembly was loaded.

To register an event handler for this event, you must have the required permissions, or a SecurityException is thrown.

For more information about handling events, see Handling and Raising Events.

Applies to

AppDomain.AssemblyResolve Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when the resolution of an assembly fails.

C#

```
public event ResolveEventHandler? AssemblyResolve;
```

Event Type

ResolveEventHandler

Examples

The following sample demonstrates the AssemblyResolve event.

For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
public class MyType
{
    public MyType()
    {
        Console.WriteLine();
        Console.WriteLine("MyType instantiated!");
    }
}

class AssemblyResolveSnippet
{
    public static void Main()
    {
        AppDomain currentDomain = AppDomain.CurrentDomain;

        // This call will fail to create an instance of MyType since the
```

```
        // assembly resolver is not set
        InstantiateMyTypeFail(currentDomain);

        currentDomain.AssemblyResolve += new
ResolveEventHandler(MyResolveEventHandler);

        // This call will succeed in creating an instance of MyType since
the
        // assembly resolver is now set.
        InstantiateMyTypeFail(currentDomain);

        // This call will succeed in creating an instance of MyType since
the
        // assembly name is valid.
        InstantiateMyTypeSucceed(currentDomain);
    }

    private static void InstantiateMyTypeFail(AppDomain domain)
    {
        // Calling InstantiateMyType will always fail since the assembly
info
        // given to CreateInstance is invalid.
        try
        {
            // You must supply a valid fully qualified assembly name here.
            domain.CreateInstance("Assembly text name, Version, Culture,
PublicKeyToken", "MyType");
        }
        catch (Exception e)
        {
            Console.WriteLine();
            Console.WriteLine(e.Message);
        }
    }

    private static void InstantiateMyTypeSucceed(AppDomain domain)
    {
        try
        {
            string asmname = Assembly.GetCallingAssembly().FullName;
            domain.CreateInstance(asmname, "MyType");
        }
        catch (Exception e)
        {
            Console.WriteLine();
            Console.WriteLine(e.Message);
        }
    }

    private static Assembly MyResolveEventHandler(object sender,
ResolveEventArgs args)
    {
        Console.WriteLine("Resolving...");
        return typeof(MyType).Assembly;
```

```
    }
}
```

Remarks

It is the responsibility of the ResolveEventHandler for this event to return the assembly that is specified by the ResolveEventArgs.Name property, or to return null if the assembly is not recognized. The assembly must be loaded into an execution context; if it is loaded into the reflection-only context, the load that caused this event to be raised fails.

For guidance on the use of this event, see Resolving Assembly Loads.

Beginning with the .NET Framework 4, the ResolveEventArgs.RequestingAssembly property returns the assembly that requested the assembly load that could not be resolved. For example, the loader might be unable to load a dependency of the requesting assembly because the requesting assembly and its dependency are not in the probing path. Knowing the identity of the requesting assembly might be useful in locating the dependency or in identifying the correct version, if more than one version of the dependency is available. For more information, see ResolveEventArgs.RequestingAssembly.

> **ⓘ Important**
>
> Beginning with the .NET Framework 4, the **ResolveEventHandler** event is raised for all assemblies, including resource assemblies. In earlier versions, the event was not raised for resource assemblies. If the operating system is localized, the handler might be called multiple times: once for each culture in the fallback chain.

For this event, the ResolveEventArgs.Name property returns the assembly name before policy is applied.

> **ⓘ Important**
>
> If more than one event handler is registered for this event, the event handlers are called in order until an event handler returns a value that isn't `null`. Subsequent event handlers are ignored.

For more information about handling events, see Handling and Raising Events.

AppDomain.DomainUnload Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when an AppDomain is about to be unloaded.

```
C#
public event EventHandler? DomainUnload;
```

Event Type

EventHandler

Remarks

The EventHandler delegate for this event can perform any termination activities before the application domain is unloaded.

Each application domain that needs to perform processing when it is unloaded should register an event handler for this event. A shared event handler should not be used, because the EventHandler delegate does not identify the domain that is being unloaded.

> **Note**
>
> This event is never raised in the default application domain.

Do not make assumptions about the thread the event is raised on. The event can be raised on a different thread than the one that called the Unload method.

For more information about handling events, see Handling and Raising Events.

AppDomain.FirstChanceException Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when an exception is thrown in managed code, before the runtime searches the call stack for an exception handler in the application domain.

C#

```
public event
EventHandler<System.Runtime.ExceptionServices.FirstChanceExceptionEventArgs>
? FirstChanceException;
```

Event Type

EventHandler<FirstChanceExceptionEventArgs>

Examples

The following example creates a series of application domains named `AD0` through `AD3`, with a `Worker` object in each application domain. Each `Worker` object has a reference to the `Worker` object in the next application domain, except for the `Worker` in the last application domain. The FirstChanceException event is handled in all application domains except `AD1`.

> **Note**
>
> In addition to this example, which demonstrates first-chance exception notifications in multiple application domains, you can find simple use cases in **How to: Receive First-Chance Exception Notifications**.

When the application domains have been created, the default application domain calls the `TestException` method for the first application domain. Each `Worker` object calls the `TestException` method for the next application domain, until the last `Worker` throws an exception that is either handled or unhandled. Thus, the current thread passes through

all the application domains, and `TestException` is added to the stack in each application domain.

When the last `Worker` object handles the exception, the FirstChanceException event is raised only in the last application domain. The other application domains never get a chance to handle the exception, so the event is not raised.

When the last `Worker` object does not handle the exception, the FirstChanceException event is raised in each application domain that has an event handler. After each event handler has finished, the stack continues to unwind until the exception is caught by the default application domain.

> **Note**
>
> To see how the stack display grows as the event is raised closer and closer to the default application domain, change `e.Exception.Message` to `e.Exception` in the `FirstChanceHandler` event handlers. Notice that when `TestException` is called across application domain boundaries, it appears twice: once for the proxy and once for the stub.

C#

```
using System;
using System.Reflection;
using System.Runtime.ExceptionServices;

class FirstChanceExceptionSnippet
{
    static void Main()
    {
        AppDomain.CurrentDomain.FirstChanceException += FirstChanceHandler;

        // Create a set of application domains, with a Worker object in each
one.
        // Each Worker object creates the next application domain.
        AppDomain ad = AppDomain.CreateDomain("AD0");
        Worker w = (Worker) ad.CreateInstanceAndUnwrap(
                                typeof(Worker).Assembly.FullName, "Worker");
        w.Initialize(0, 3);

        Console.WriteLine("\r\nThe last application domain throws an
exception and catches it:");
        Console.WriteLine();
        w.TestException(true);

        try
        {
```

```
            Console.WriteLine(
                "\r\nThe last application domain throws an exception and
does not catch it:");
            Console.WriteLine();
            w.TestException(false);
        }
        catch (ArgumentException ex)
        {
            Console.WriteLine("ArgumentException caught in {0}: {1}",
                AppDomain.CurrentDomain.FriendlyName, ex.Message);
        }
    }

    static void FirstChanceHandler(object source,
FirstChanceExceptionEventArgs e)
    {
        Console.WriteLine("FirstChanceException event raised in {0}: {1}",
            AppDomain.CurrentDomain.FriendlyName, e.Exception.Message);
    }
}

public class Worker : MarshalByRefObject
{
    private AppDomain ad = null;
    private Worker w = null;

    public void Initialize(int count, int max)
    {
        // Handle the FirstChanceException event in all application domains
except
        // AD1.
        if (count != 1)
        {
            AppDomain.CurrentDomain.FirstChanceException +=
FirstChanceHandler;
        }

        // Create another application domain, until the maximum is reached.
        // Field w remains null in the last application domain, as a signal
        // to TestException().
        if (count < max)
        {
            int next = count + 1;
            ad = AppDomain.CreateDomain("AD" + next);
            w = (Worker) ad.CreateInstanceAndUnwrap(
                                typeof(Worker).Assembly.FullName, "Worker");
            w.Initialize(next, max);
        }
    }

    public void TestException(bool handled)
    {
        // As long as there is another application domain, call
TestException() on
        // its Worker object. When the last application domain is reached,
```

```
throw a
        // handled or unhandled exception.
        if (w != null)
        {
            w.TestException(handled);
        }
        else if (handled)
        {
            try
            {
                throw new ArgumentException("Thrown in " +
AppDomain.CurrentDomain.FriendlyName);
            }
            catch (ArgumentException ex)
            {
                Console.WriteLine("ArgumentException caught in {0}: {1}",
                    AppDomain.CurrentDomain.FriendlyName, ex.Message);
            }
        }
        else
        {
            throw new ArgumentException("Thrown in " +
AppDomain.CurrentDomain.FriendlyName);
        }
    }

    static void FirstChanceHandler(object source,
FirstChanceExceptionEventArgs e)
    {
        Console.WriteLine("FirstChanceException event raised in {0}: {1}",
            AppDomain.CurrentDomain.FriendlyName, e.Exception.Message);
    }
}

/* This example produces output similar to the following:

The last application domain throws an exception and catches it:

FirstChanceException event raised in AD3: Thrown in AD3
ArgumentException caught in AD3: Thrown in AD3

The last application domain throws an exception and does not catch it:

FirstChanceException event raised in AD3: Thrown in AD3
FirstChanceException event raised in AD2: Thrown in AD3
FirstChanceException event raised in AD0: Thrown in AD3
FirstChanceException event raised in Example.exe: Thrown in AD3
ArgumentException caught in Example.exe: Thrown in AD3
 */
```

Remarks

This event is only a notification. Handling this event does not handle the exception or affect subsequent exception handling in any way. After the event has been raised and event handlers have been invoked, the common language runtime (CLR) begins to search for a handler for the exception. FirstChanceException provides the application domain with a first chance to examine any managed exception.

The event can be handled per application domain. If a thread passes through multiple application domains while executing a call, the event is raised in each application domain that has registered an event handler, before the CLR begins searching for a matching exception handler in that application domain. After the event has been handled, a search is made for a matching exception handler in that application domain. If none is found, the event is raised in the next application domain.

You must handle all exceptions that occur in the event handler for the FirstChanceException event. Otherwise, FirstChanceException is raised recursively. This could result in a stack overflow and termination of the application. We recommend that you implement event handlers for this event as constrained execution regions (CERs), to keep infrastructure-related exceptions such as out-of-memory or stack overflow from affecting the virtual machine while the exception notification is being processed.

This event is not raised for exceptions that indicate corruption of process state, such as access violations, unless the event handler is security-critical and has the HandleProcessCorruptedStateExceptionsAttribute attribute.

The common language runtime suspends thread aborts while this notification event is being handled.

AppDomain.ProcessExit Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when the default application domain's parent process exits.

```
C#
public event EventHandler? ProcessExit;
```

Event Type

EventHandler

Remarks

The EventHandler for this event can perform termination activities, such as closing files, releasing storage and so on, before the process ends.

Beginning with the .NET Framework version 2.0, this event is raised in each application domain that registers an event handler.

> **Note**
>
> In .NET Framework, the total execution time of all **ProcessExit** event handlers is limited, just as the total execution time of all finalizers is limited at process shutdown. The default is two seconds. An unmanaged host can change this execution time by calling the **ICLRPolicyManager::SetTimeout** method with the **OPR_ProcessExit** enumeration value. This time limit does not exist in .NET Core.

In the .NET Framework versions 1.0 and 1.1, this event is raised only in the default application domain, and only if an event handler is registered in the default application domain.

To register an event handler for this event, you must have the required permissions, or a SecurityException is thrown.

For more information about handling events, see Handling and Raising Events.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

AppDomain.ReflectionOnlyAssemblyResolve Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when the resolution of an assembly fails in the reflection-only context.

C#

```
public event ResolveEventHandler? ReflectionOnlyAssemblyResolve;
```

Event Type

ResolveEventHandler

Remarks

In the reflection-only context, dependencies are not resolved automatically. They must be preloaded or returned by the handler for this event. This event is raised when an assembly has a dependency that is not already loaded into the reflection-only context. The missing dependency is specified by the ResolveEventArgs.Name property. The ResolveEventHandler for this event must return an assembly that satisfies the dependency. The assembly that is returned must be loaded into the reflection-only context.

> **Important**
>
> This event is raised only for missing dependencies of the assembly that you are loading into the reflection-only context (for example, by using the **Assembly.ReflectionOnlyLoad** method). It is not raised if the assembly that you are loading cannot be found.

Beginning with the .NET Framework 4, the ResolveEventArgs.RequestingAssembly property returns the assembly that requested the assembly load that could not be

resolved. Knowing the identity of the requesting assembly might be useful in identifying the correct version of the dependency, if more than one version is available. For more information, see ResolveEventArgs.RequestingAssembly.

For this event, the ResolveEventArgs.Name property returns the assembly name before policy is applied.

For more information about handling events, see Handling and Raising Events.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomain.ResourceResolve Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when the resolution of a resource fails because the resource is not a valid linked or embedded resource in the assembly.

```
C#
public event ResolveEventHandler? ResourceResolve;
```

Event Type

ResolveEventHandler

Remarks

The ResolveEventHandler for this event can attempt to locate the assembly containing the resource and return it.

> **Important**
>
> This event is not raised if resolution fails because no file can be found for a valid linked resource. It is raised if a manifest resource stream cannot be found, but it is not raised if an individual resource key cannot be found.

Beginning with the .NET Framework 4, the ResolveEventArgs.RequestingAssembly property contains the assembly that requested the resource. For more information, see ResolveEventArgs.RequestingAssembly.

To register an event handler for this event, you must have the required permissions, or a SecurityException is thrown.

For more information about handling events, see Handling and Raising Events.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomain.TypeResolve Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when the resolution of a type fails.

C#

```
public event ResolveEventHandler? TypeResolve;
```

Event Type

ResolveEventHandler

Examples

The following sample demonstrates the TypeResolve event.

For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.Reflection;
using System.Reflection.Emit;

class Test
{
    // For this code example, the following information needs to be
    // available to both Main and the HandleTypeResolve event
    // handler:
    private static AssemblyBuilder ab;
    private static string moduleName;

    public static void Main()
    {
        AppDomain currDom = AppDomain.CurrentDomain;
```

```
        // Create a dynamic assembly with one module, to be saved to
        // disk (AssemblyBuilderAccess.Save).
        //
        AssemblyName aName = new AssemblyName();
        aName.Name = "Transient";
        moduleName = aName.Name + ".dll";
        ab = currDom.DefineDynamicAssembly(aName,
            AssemblyBuilderAccess.Save);
        ModuleBuilder mb = ab.DefineDynamicModule(aName.Name, moduleName);

        // The dynamic assembly has just one dummy type, to demonstrate
        // type resolution.
        TypeBuilder tb = mb.DefineType("Example");
        tb.CreateType();

        // First, try to load the type without saving the dynamic
        // assembly and without hooking up the TypeResolve event. The
        // type cannot be loaded.
        try
        {
            Type temp = Type.GetType("Example", true);
            Console.WriteLine("Loaded type {0}.", temp);
        }
        catch (TypeLoadException)
        {
            Console.WriteLine("Loader could not resolve the type.");
        }

        // Hook up the TypeResolve event.
        //
        currDom.TypeResolve +=
            new ResolveEventHandler(HandleTypeResolve);

        // Now try to load the type again. The TypeResolve event is
        // raised, the dynamic assembly is saved, and the dummy type is
        // loaded successfully. Display it to the console, and create
        // an instance.
        Type t = Type.GetType("Example", true);
        Console.WriteLine("Loaded type \"{0}\".", t);
        Object o = Activator.CreateInstance(t);
    }

    static Assembly HandleTypeResolve(object sender, ResolveEventArgs args)
    {
        Console.WriteLine("TypeResolve event handler.");

        // Save the dynamic assembly, and then load it using its
        // display name. Return the loaded assembly.
        //
        ab.Save(moduleName);
        return Assembly.Load(ab.FullName);
    }
}

/* This code example produces the following output:
```

```
Loader could not resolve the type.
TypeResolve event handler.
Loaded type "Example".
 */
```

Remarks

The TypeResolve event occurs when the common language runtime is unable to determine the assembly that can create the requested type. This can occur if the type is defined in a dynamic assembly, or the type is not defined in a dynamic assembly but the runtime does not know which assembly the type is defined in. The latter situation can occur when Type.GetType is called with a type name that is not qualified with the assembly name.

The ResolveEventHandler for this event can attempt to locate and create the type.

However, the TypeResolve event does not occur if the runtime knows it is not possible to find a type in certain assemblies. For example, this event does not occur if the type is not found in a static assembly because the runtime knows types cannot be added dynamically to static assemblies.

Beginning with the .NET Framework 4, the ResolveEventArgs.RequestingAssembly property contains the assembly that requested the type. For more information, see ResolveEventArgs.RequestingAssembly.

To register an event handler for this event, you must have the required permissions, or a SecurityException is thrown.

For more information about handling events, see Handling and Raising Events.

AppDomain.UnhandledException Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Occurs when an exception is not caught.

C#

```
public event UnhandledExceptionEventHandler? UnhandledException;
```

Event Type

UnhandledExceptionEventHandler

Examples

The following example demonstrates the UnhandledException event. It defines an event handler, `MyHandler`, that is invoked whenever an unhandled exception is thrown in the default application domain. It then throws two exceptions. The first is handled by a **try/catch** block. The second is unhandled and invokes the `MyHandle` routine before the application terminates.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      AppDomain currentDomain = AppDomain.CurrentDomain;
      currentDomain.UnhandledException += new
UnhandledExceptionEventHandler(MyHandler);

      try {
         throw new Exception("1");
      } catch (Exception e) {
         Console.WriteLine("Catch clause caught : {0} \n", e.Message);
      }
```

```
        throw new Exception("2");
    }

    static void MyHandler(object sender, UnhandledExceptionEventArgs args)
    {
        Exception e = (Exception) args.ExceptionObject;
        Console.WriteLine("MyHandler caught : " + e.Message);
        Console.WriteLine("Runtime terminating: {0}", args.IsTerminating);
    }
}
// The example displays the following output:
//       Catch clause caught : 1
//
//       MyHandler caught : 2
//       Runtime terminating: True
//
//       Unhandled Exception: System.Exception: 2
//          at Example.Main()
```

Remarks

For more information about this API, see Supplemental API remarks for UnhandledException.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomainSetup Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents assembly binding information that can be added to an instance of AppDomain.

C#

```
public sealed class AppDomainSetup
```

Inheritance Object → AppDomainSetup

Remarks

Changing the properties of an AppDomainSetup instance does not affect any existing AppDomain. It can affect only the creation of a new AppDomain, when the CreateDomain method is called with the AppDomainSetup instance as a parameter.

This class implements the IAppDomainSetup interface.

> ⊗ **Caution**
>
> The default value for the **DisallowCodeDownload** property is false. This setting is unsafe for services. To help prevent services from downloading partially trusted code, set this property to true

Properties

Expand table

ApplicationBase	Gets the name of the directory containing the application.
TargetFrameworkName	Gets (or, in .NET Framework, sets) a string that specifies the target framework in a format that can be parsed by the FrameworkName(String) constructor.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomainSetup.ApplicationBase Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the directory containing the application.

C#

```
public string? ApplicationBase { get; }
```

Property Value

String

The name of the application base directory.

Examples

The following example demonstrates how to use the ApplicationBase property to set the location where the assembly loader begins probing for assemblies to load into a new application domain.

> **Note**
>
> You must ensure that the folder you specify exists.

C#

```
using System;

class ADSetupInformation
{
    static void Main()
    {
        AppDomain root = AppDomain.CurrentDomain;
```

```
        AppDomainSetup setup = new AppDomainSetup();
        setup.ApplicationBase =
            root.SetupInformation.ApplicationBase + @"MyAppSubfolder\";

        AppDomain domain = AppDomain.CreateDomain("MyDomain", null, setup);

        Console.WriteLine("Application base of {0}:\r\n\t{1}",
            root.FriendlyName, root.SetupInformation.ApplicationBase);
        Console.WriteLine("Application base of {0}:\r\n\t{1}",
            domain.FriendlyName, domain.SetupInformation.ApplicationBase);

        AppDomain.Unload(domain);
    }
}

/* This example produces output similar to the following:

Application base of MyApp.exe:
        C:\Program Files\MyApp\
Application base of MyDomain:
        C:\Program Files\MyApp\MyAppSubfolder\
 */
```

Remarks

The application base directory is where the assembly manager begins probing for assemblies.

The ApplicationBase property can influence which permissions are granted to an application domain. For example, an application domain originating from the local computer normally receives full trust based on its location of origin. However, if the ApplicationBase property of that AppDomain is set to the full name of an intranet directory, the ApplicationBase setting restricts the permissions granted to the application domain to a LocalIntranet grant even though the application domain actually originates from the local computer.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomainSetup.TargetFramework Name Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets (or, in .NET Framework, sets) a string that specifies the target framework in a format that can be parsed by the FrameworkName(String) constructor.

```
C#

public string? TargetFrameworkName { get; }
```

Property Value

String

The target framework of the executable that started the process.

Remarks

Set this property to tell the currently running version of the .NET Framework that the application domain will be used to load and run assemblies that have been compiled for the target version and profile. If the currently running version of the .NET Framework has optional behaviors that affect the compatibility of code that was compiled with the target version, it can enable or disable those behaviors, as appropriate, to improve compatibility. This can be useful when an application supports add-ins compiled with multiple versions of the .NET Framework by running them in separate application domains.

For client applications, the value of the TargetFrameworkName property is inferred from the TargetFrameworkAttribute attribute. In Visual Studio 2010 and later, this attribute is added to the assembly automatically based on the setting of the project's **Target Framework** property.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AppDomainUnloadedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt is made to access an unloaded application domain.

```
C#
public class AppDomainUnloadedException : SystemException
```

Inheritance Object → Exception → SystemException → AppDomainUnloadedException

Examples

This section contains two code examples. The first example demonstrates the effects of an AppDomainUnloadedException on various threads, and the second shows elementary application domain unloading.

Example 1

The following code example defines a `TestClass` class that can be marshaled across application domain boundaries and an `Example` class containing a `static` (`Shared` in Visual Basic) `ThreadProc` method. The `ThreadProc` method creates an application domain, creates a `TestClass` object in the domain, and calls a method of `TestClass` that unloads the executing domain, causing an AppDomainUnloadedException.

The `TestClass` method is executed without exception handling from a ThreadPool thread and from an ordinary thread, demonstrating that the unhandled exception terminates the task or thread but not the application. It is then executed with and without exception handling from the main application thread, demonstrating that it terminates the application if not handled.

```
C#
```

```
using System;
using System.Threading;
using System.Runtime.InteropServices;

public class Example
{
    public static void Main()
    {
        // 1. Queue ThreadProc as a task for a ThreadPool thread.
        ThreadPool.QueueUserWorkItem(ThreadProc, " from a ThreadPool
thread");
        Thread.Sleep(1000);

        // 2. Execute ThreadProc on an ordinary thread.
        Thread t = new Thread(ThreadProc);
        t.Start(" from an ordinary thread");
        t.Join();

        // 3. Execute ThreadProc on the main thread, with
        //    exception handling.
        try
        {
            ThreadProc(" from the main application thread (handled)");
        }
        catch (AppDomainUnloadedException adue)
        {
            Console.WriteLine("Main thread caught
AppDomainUnloadedException: {0}", adue.Message);
        }

        // 4. Execute ThreadProc on the main thread without
        //    exception handling.
        ThreadProc(" from the main application thread (unhandled)");

        Console.WriteLine("Main: This message is never displayed.");
    }

    private static void ThreadProc(object state)
    {
        // Create an application domain, and create an instance
        // of TestClass in the application domain. The first
        // parameter of CreateInstanceAndUnwrap is the name of
        // this executable. If you compile the example code using
        // any name other than "Sample.exe", you must change the
        // parameter appropriately.
        AppDomain ad = AppDomain.CreateDomain("TestDomain");
        TestClass tc = (TestClass)ad.CreateInstanceAndUnwrap("Sample",
"TestClass");

        // In the new application domain, execute a method that
        // unloads the AppDomain. The unhandled exception this
        // causes ends the current thread.
        tc.UnloadCurrentDomain(state);
```

```
        Console.WriteLine("ThreadProc: This message is never displayed.");
    }
}

// TestClass derives from MarshalByRefObject, so it can be marshaled
// across application domain boundaries.
//
public class TestClass : MarshalByRefObject
{
    public void UnloadCurrentDomain(object state)
    {
        Console.WriteLine("\nUnloading the current AppDomain{0}.", state);

        // Unload the current application domain. This causes
        // an AppDomainUnloadedException to be thrown.
        //
        AppDomain.Unload(AppDomain.CurrentDomain);
    }
}

/* This code example produces output similar to the following:
Unloading the current AppDomain from a ThreadPool thread.

Unloading the current AppDomain from an ordinary thread.

Unloading the current AppDomain from the main application thread (handled).
Main thread caught AppDomainUnloadedException: The application domain in
which the thread was running has been unloaded.

Unloading the current AppDomain from the main application thread
(unhandled).

Unhandled Exception: System.AppDomainUnloadedException: The application
domain in which the thread was running has been unloaded.
   at TestClass.UnloadCurrentDomain(Object state)
   at Example.ThreadProc(Object state)
   at Example.Main()
 */
```

Example 2

The following code example creates and unloads an application domain, and demonstrates that an AppDomainUnloadedException is thrown on a subsequent attempt to access the unloaded domain.

C#

```
using System;
using System.Reflection;
using System.Security.Policy;
class ADUnload
{
```

```
    public static void Main()
    {

        //Create evidence for the new appdomain.
        Evidence adevidence = AppDomain.CurrentDomain.Evidence;

        // Create the new application domain.
        AppDomain domain = AppDomain.CreateDomain("MyDomain", adevidence);

                Console.WriteLine("Host domain: " +
AppDomain.CurrentDomain.FriendlyName);
                Console.WriteLine("child domain: " + domain.FriendlyName);
        // Unload the application domain.
        AppDomain.Unload(domain);

        try
        {
        Console.WriteLine();
        // Note that the following statement creates an exception because
the domain no longer exists.
                Console.WriteLine("child domain: " + domain.FriendlyName);
        }

        catch (AppDomainUnloadedException e)
        {
        Console.WriteLine("The appdomain MyDomain does not exist.");
        }
    }
}
```

Remarks

In the .NET Framework version 2.0, an AppDomainUnloadedException that is not handled in user code has the following effect:

- If a thread was started in managed code, it is terminated. The unhandled exception is not allowed to terminate the application.
- If a task is executing on a ThreadPool thread, it is terminated and the thread is returned to the thread pool. The unhandled exception is not allowed to terminate the application.
- If a thread started in unmanaged code, such as the main application thread, it is terminated. The unhandled exception is allowed to proceed, and the operating system terminates the application.

AppDomainUnloadedException uses the HRESULT COR_E_APPDOMAINUNLOADED, which has the value 0x80131014.

For a list of initial property values for an instance of AppDomainUnloadedException, see the AppDomainUnloadedException constructors.

Constructors

Expand table

AppDomainUnloadedException()	Initializes a new instance of the AppDomainUnloadedException class.
AppDomainUnloadedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AppDomainUnloadedException class with serialized data.
AppDomainUnloadedException(String)	Initializes a new instance of the AppDomainUnloadedException class with a specified error message.
AppDomainUnloadedException(String, Exception)	Initializes a new instance of the AppDomainUnloadedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error.

	(Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception.

(Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomainUnloadedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the AppDomainUnloadedException class.

Overloads

Expand table

AppDomainUnloadedException()	Initializes a new instance of the AppDomainUnloadedException class.
AppDomainUnloadedException(String)	Initializes a new instance of the AppDomainUnloadedException class with a specified error message.
AppDomainUnloadedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the AppDomainUnloadedException class with serialized data.
AppDomainUnloadedException(String, Exception)	Initializes a new instance of the AppDomainUnloadedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

AppDomainUnloadedException()

Initializes a new instance of the AppDomainUnloadedException class.

C#

```
public AppDomainUnloadedException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The target application domain has been unloaded." This message takes into account the current system culture.

The following table shows the initial property values for an instance of AppDomainUnloadedException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomainUnloadedException(String)

Initializes a new instance of the AppDomainUnloadedException class with a specified error message.

C#

```
public AppDomainUnloadedException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of AppDomainUnloadedException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomainUnloadedException(SerializationInfo, StreamingContext)

> **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the AppDomainUnloadedException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected AppDomainUnloadedException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

AppDomainUnloadedException(String, Exception)

Initializes a new instance of the AppDomainUnloadedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public AppDomainUnloadedException (string? message, Exception?
innerException);
```

Parameters

`message` String

The message that describes the error.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of AppDomainUnloadedException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

ApplicationException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as the base class for application-defined exceptions.

C#

```
public class ApplicationException : Exception
```

Inheritance Object → Exception → ApplicationException

Derived Microsoft.JScript.BreakOutOfFinally
Microsoft.JScript.ContinueOutOfFinally
Microsoft.JScript.JScriptException
Microsoft.JScript.NoContextException
Microsoft.JScript.ReturnOutOfFinally
More...

Remarks

Important

You should derive custom exceptions from the **Exception** class rather than the **ApplicationException** class. You should not throw an **ApplicationException** exception in your code, and you should not catch an **ApplicationException** exception unless you intend to re-throw the original exception.

Constructors

Expand table

ApplicationException()	Initializes a new instance of the ApplicationException class.

ApplicationException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ApplicationException class with serialized data.
ApplicationException(String)	Initializes a new instance of the ApplicationException class with a specified error message.
ApplicationException(String, Exception)	Initializes a new instance of the ApplicationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

ApplicationException()	Initializes a new instance of the ApplicationException class.
ApplicationException(String)	Initializes a new instance of the ApplicationException class with a specified error message.
ApplicationException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ApplicationException class with serialized data.
ApplicationException(String, Exception)	Initializes a new instance of the ApplicationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

ApplicationException()

Initializes a new instance of the ApplicationException class.

C#

```
public ApplicationException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "An application error has occurred." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ApplicationException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationException(String)

Initializes a new instance of the ApplicationException class with a specified error message.

C#

```
public ApplicationException (string? message);
```

Parameters

`message` String

A message that describes the error.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

This message takes into account the current system culture.

The following table shows the initial property values for an instance of ApplicationException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
`Message`	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ApplicationException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ApplicationException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and Soap Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationException(String, Exception)

Initializes a new instance of the ApplicationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public ApplicationException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of ApplicationException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

See also

- Exception
- Handling and throwing exceptions in .NET

ApplicationId Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Contains information used to uniquely identify a manifest-based application. This class cannot be inherited.

C#

```
public sealed class ApplicationId
```

Inheritance Object → ApplicationId

Examples

The following code example displays the ApplicationId properties by obtaining the ApplicationId from an ApplicationSecurityInfo instance created using the ActivationContext for the currently executing manifest-based application.

C#

```
using System;
using System.Collections;
using System.Text;
using System.Security.Policy;
using System.Reflection;
using System.Security;

namespace ActivationContextSample
{
    public class Program : MarshalByRefObject
    {
        public static void Main(string[] args)
        {
            Console.WriteLine("Full name = " +

AppDomain.CurrentDomain.ActivationContext.Identity.FullName);
            Console.WriteLine("Code base = " +

AppDomain.CurrentDomain.ActivationContext.Identity.CodeBase);
```

```
            ApplicationSecurityInfo asi = new
ApplicationSecurityInfo(AppDomain.CurrentDomain.ActivationContext);

            Console.WriteLine("ApplicationId.Name property = " +
asi.ApplicationId.Name);
            if (asi.ApplicationId.Culture != null)
                Console.WriteLine("ApplicationId.Culture property = " +
asi.ApplicationId.Culture.ToString());
            Console.WriteLine("ApplicationId.ProcessorArchitecture property
= " + asi.ApplicationId.ProcessorArchitecture);
            Console.WriteLine("ApplicationId.Version property = " +
asi.ApplicationId.Version);
            // To display the value of the public key, enumerate the Byte
array for the property.
            Console.Write("ApplicationId.PublicKeyToken property = ");
            byte[] pk = asi.ApplicationId.PublicKeyToken;
            for (int i = 0; i < pk.GetLength(0); i++)
                Console.Write("{0:x}", pk[i]);

            Console.Read();
        }

        public void Run()
        {
            Main(new string[] { });
            Console.ReadLine();
        }
    }
}
```

Remarks

An application identity consists of the publisher's public key, the application name, the target processor architecture, the application culture, and the application version. The application identity properties values correspond to information contained in the application manifest. For more information about the application manifest, see ClickOnce Application Manifest.

ApplicationId is used by the ApplicationSecurityInfo class to identify a manifest-based application.

Constructors

Expand table

ApplicationId(Byte[], String, Version, String, String)	Initializes a new instance of the ApplicationId class.

Properties

Expand table

Culture	Gets a string representing the culture information for the application.
Name	Gets the name of the application.
ProcessorArchitecture	Gets the target processor architecture for the application.
PublicKeyToken	Gets the public key token for the application.
Version	Gets the version of the application.

Methods

Expand table

Copy()	Creates and returns an identical copy of the current application identity.
Equals(Object)	Determines whether the specified ApplicationId object is equivalent to the current ApplicationId.
GetHashCode()	Gets the hash code for the current application identity.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the application identity.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationId(Byte[], String, Version, String, String) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ApplicationId class.

C#

```
public ApplicationId (byte[] publicKeyToken, string name, Version version,
string? processorArchitecture, string? culture);
```

Parameters

publicKeyToken Byte[]

The array of bytes representing the raw public key data.

name String

The name of the application.

version Version

A Version object that specifies the version of the application.

processorArchitecture String

The processor architecture of the application.

culture String

The culture of the application.

Exceptions

ArgumentNullException

`name` is `null`.

-or-

`version` is `null`.

-or-

`publicKeyToken` is `null`.

ArgumentException

`name` is an empty string.

Remarks

The constructor initializes the Culture, Name, ProcessorArchitecture, PublicKeyToken, and Version properties of the ApplicationId.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationId.Culture Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a string representing the culture information for the application.

```
C#

public string? Culture { get; }
```

Property Value

String

The culture information for the application.

Examples

The following code example displays the Culture property by obtaining the ApplicationId from an ApplicationSecurityInfo instance created using the ActivationContext for the currently executing manifest-based application. This code example is part of a larger example provided for the ApplicationId class.

```
C#

if (asi.ApplicationId.Culture != null)
    Console.WriteLine("ApplicationId.Culture property = " +
asi.ApplicationId.Culture.ToString());
```

Remarks

The Culture value can include language information, for example, "en-US".

For information about culture values, see CultureInfo.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationId.Name Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the application.

C#

```
public string Name { get; }
```

Property Value

String

The name of the application.

Examples

The following code example displays the Name property by obtaining the ApplicationId from an ApplicationSecurityInfo instance created using the ActivationContext for the currently executing manifest-based application. This code example is part of a larger example provided for the ApplicationId class.

C#

```
ApplicationSecurityInfo asi = new
ApplicationSecurityInfo(AppDomain.CurrentDomain.ActivationContext);

Console.WriteLine("ApplicationId.Name property = " +
asi.ApplicationId.Name);
```

Remarks

Name is the simple, unencrypted name of the application.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationId.ProcessorArchitecture Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the target processor architecture for the application.

C#

```
public string? ProcessorArchitecture { get; }
```

Property Value

String

The processor architecture of the application.

Examples

The following code example displays the ProcessorArchitecture property by obtaining the ApplicationId from an ApplicationSecurityInfo instance created using the ActivationContext for the currently executing manifest-based application. This code example is part of a larger example provided for the ApplicationId class.

C#

```
Console.WriteLine("ApplicationId.ProcessorArchitecture property = " +
asi.ApplicationId.ProcessorArchitecture);
```

Remarks

Valid values include "msil", "x86", "ia64", and "amd64". The default is "msil", or Microsoft intermediate language, which means all your assemblies are platform independent, and the common language runtime will compile them when they are needed by your application.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ApplicationId.PublicKeyToken Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the public key token for the application.

C#

```
public byte[] PublicKeyToken { get; }
```

Property Value

Byte[]

A byte array containing the public key token for the application.

Examples

The following code example displays the PublicKeyToken property by obtaining the ApplicationId from an ApplicationSecurityInfo instance created using the ActivationContext for the currently executing manifest-based application. This code example is part of a larger example provided for the ApplicationId class.

C#

```
// To display the value of the public key, enumerate the Byte array for the
property.
Console.Write("ApplicationId.PublicKeyToken property = ");
byte[] pk = asi.ApplicationId.PublicKeyToken;
for (int i = 0; i < pk.GetLength(0); i++)
    Console.Write("{0:x}", pk[i]);
```

Remarks

The public key token is represented by the last 8 bytes of the SHA-1 hash of the public key under which the application is signed.

For more information, see AssemblyName.GetPublicKeyToken.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ApplicationId.Version Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the version of the application.

```
C#
public Version Version { get; }
```

Property Value

Version

A Version that specifies the version of the application.

Examples

The following code example displays the Version property by obtaining the ApplicationId from an ApplicationSecurityInfo instance created using the ActivationContext for the currently executing manifest-based application. This code example is part of a larger example provided for the ApplicationId class.

```
C#
Console.WriteLine("ApplicationId.Version property = " +
asi.ApplicationId.Version);
```

Remarks

For more information, see System.Version.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ApplicationId.Copy Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates and returns an identical copy of the current application identity.

C#

```
public ApplicationId Copy ();
```

Returns

ApplicationId

An ApplicationId object that represents an exact copy of the original.

Remarks

The copy returned by this method is equal to the original as substantiated by the Equals method. The hash codes for the original and the copy are also equal.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ApplicationId.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified ApplicationId object is equivalent to the current ApplicationId.

```
C#
public override bool Equals (object? o);
```

Parameters

o Object

The ApplicationId object to compare to the current ApplicationId.

Returns

Boolean

`true` if the specified ApplicationId object is equivalent to the current ApplicationId; otherwise, `false`.

Remarks

This method overrides the Object.Equals(Object) method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ApplicationId.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the hash code for the current application identity.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current application identity.

Remarks

This method generates the same hash code for two objects that have the same values for their Name and Version properties.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ApplicationId.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates and returns a string representation of the application identity.

C#

```
public override string ToString ();
```

Returns

String

A string representation of the application identity.

Remarks

This method overrides the Object.ToString method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArgIterator Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a variable-length argument list; that is, the parameters of a function that takes a variable number of arguments.

```
C#
public ref struct ArgIterator
```

Inheritance Object → ValueType → ArgIterator

Remarks

Developers who write compilers use the ArgIterator structure to enumerate the mandatory and optional arguments in an argument list. The ArgIterator structure is not generally useful for applications other than compilers.

The functionality in the ArgIterator structure is typically hidden in the syntax of a specific programming language. For example, in the C++ programming language you declare a variable-length argument list by specifying an ellipsis ("...") at the end of the argument list. The ArgIterator structure is useful primarily when a development language does not provide direct support for accessing variable-length parameters.

Constructors

Expand table

ArgIterator(RuntimeArgumentHandle)	Initializes a new instance of the ArgIterator structure using the specified argument list.
ArgIterator(RuntimeArgumentHandle, Void*)	Initializes a new instance of the ArgIterator structure using the specified argument list and a pointer to an item in the list.

Methods

Expand table

End()	Concludes processing of the variable-length argument list represented by this instance.
Equals(Object)	This method is not supported, and always throws NotSupportedException.
GetHashCode()	Returns the hash code of this object.
GetNextArg()	Returns the next argument in a variable-length argument list.
GetNextArg(RuntimeTypeHandle)	Returns the next argument in a variable-length argument list that has a specified type.
GetNextArgType()	Returns the type of the next argument.
GetRemainingCount()	Returns the number of arguments remaining in the argument list.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArgIterator structure.

Overloads

Expand table

ArgIterator(RuntimeArgumentHandle)	Initializes a new instance of the ArgIterator structure using the specified argument list.
ArgIterator(RuntimeArgumentHandle, Void*)	Initializes a new instance of the ArgIterator structure using the specified argument list and a pointer to an item in the list.

ArgIterator(RuntimeArgumentHandle)

Initializes a new instance of the ArgIterator structure using the specified argument list.

C#

```
public ArgIterator (RuntimeArgumentHandle arglist);
```

Parameters

`arglist` RuntimeArgumentHandle

An argument list consisting of mandatory and optional arguments.

Remarks

The new ArgIterator object enumerates the argument list starting from the first optional argument.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator(RuntimeArgumentHandle, Void*)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the ArgIterator structure using the specified argument list and a pointer to an item in the list.

C#

```
[System.CLSCompliant(false)]
public ArgIterator (RuntimeArgumentHandle arglist, void* ptr);
```

Parameters

`arglist` RuntimeArgumentHandle

An argument list consisting of mandatory and optional arguments.

`ptr` Void*

A pointer to the argument in `arglist` to access first, or the first mandatory argument in `arglist` if `ptr` is `null`.

Attributes CLSCompliantAttribute

Remarks

The new ArgIterator object enumerates the argument list starting from the argument specified by `ptr`, or the first mandatory argument if `ptr` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator.End Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Concludes processing of the variable-length argument list represented by this instance.

C#

```
public void End ();
```

Remarks

Conceptually, End concludes the processing of a variable-length argument list. However, this method has no actual implementation; the End method body is empty. You can use this method in your code as a marker to indicate where variable-length argument list processing logically ends.

The End method corresponds to the `va_end` method in the C standard library.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This method is not supported, and always throws NotSupportedException.

C#

```
public override bool Equals (object? o);
```

Parameters

o Object

An object to be compared to this instance.

Returns

Boolean

This comparison is not supported. No value is returned.

Exceptions

NotSupportedException

This method is not supported.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code of this object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator.GetNextArg Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the next argument in a variable-length argument list.

Overloads

Expand table

GetNextArg()	Returns the next argument in a variable-length argument list.
GetNextArg(RuntimeTypeHandle)	Returns the next argument in a variable-length argument list that has a specified type.

GetNextArg()

> Important
>
> This API is not CLS-compliant.

Returns the next argument in a variable-length argument list.

C#

```
[System.CLSCompliant(false)]
public TypedReference GetNextArg ();
```

Returns

TypedReference

The next argument as a TypedReference object.

Attributes CLSCompliantAttribute

Exceptions

InvalidOperationException

An attempt was made to read beyond the end of the list.

Remarks

The iterator is automatically advanced to the next argument.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

GetNextArg(RuntimeTypeHandle)

> Important
>
> This API is not CLS-compliant.

Returns the next argument in a variable-length argument list that has a specified type.

C#

```
[System.CLSCompliant(false)]
public TypedReference GetNextArg (RuntimeTypeHandle rth);
```

Parameters

`rth` RuntimeTypeHandle

A runtime type handle that identifies the type of the argument to retrieve.

Returns

TypedReference

The next argument as a TypedReference object.

Attributes CLSCompliantAttribute

Exceptions

InvalidOperationException

An attempt was made to read beyond the end of the list.

ArgumentNullException

The pointer to the remaining arguments is zero.

Remarks

The iterator is automatically advanced to the next argument.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator.GetNextArgType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the type of the next argument.

C#

```
public RuntimeTypeHandle GetNextArgType ();
```

Returns

RuntimeTypeHandle

The type of the next argument.

Remarks

This method does not advance the iterator to the next argument.

GetNextArgType returns the type of the argument as specified in the calling function. For example, if an argument is type String, but the calling function specifies the argument as type Object, GetNextArgType reports the argument as type Object.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgIterator.GetRemainingCount Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the number of arguments remaining in the argument list.

C#

```
public int GetRemainingCount ();
```

Returns

Int32

The number of remaining arguments.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgumentException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when one of the arguments provided to a method is not valid.

C#

```
public class ArgumentException : SystemException
```

Inheritance Object → Exception → SystemException → ArgumentException

Derived System.ArgumentNullException
System.ArgumentOutOfRangeException
System.ComponentModel.InvalidAsynchronousStateException
System.ComponentModel.InvalidEnumArgumentException
System.DuplicateWaitObjectException
More...

Examples

The following example demonstrates how to throw and catch an ArgumentException. It uses the ArgumentException.GetType().Name property to display the name of the exception object, and also uses the Message property to display the text of the exception message.

C#

```
using System;

public class Example
{
    static void Main()
    {
        // Define some integers for a division operation.
        int[] values = { 10, 7 };
        foreach (var value in values) {
```

```
            try {
               Console.WriteLine("{0} divided by 2 is {1}", value,
DivideByTwo(value));
            }
            catch (ArgumentException e) {
               Console.WriteLine("{0}: {1}", e.GetType().Name, e.Message);
            }
            Console.WriteLine();
        }
    }

    static int DivideByTwo(int num)
    {
        // If num is an odd number, throw an ArgumentException.
        if ((num & 1) == 1)
            throw new ArgumentException(String.Format("{0} is not an even
number", num),
                                        "num");

        // num is even, return half of its value.
        return num / 2;
    }
}
// This example displays the following output:
//     10 divided by 2 is 5
//
//     ArgumentException: 7 is not an even number
//     Parameter name: num
```

Remarks

ArgumentException is thrown when a method is invoked and at least one of the passed arguments does not meet the parameter specification of the called method. The ParamName property identifies the invalid argument.

Most commonly, an ArgumentException is thrown by the common language runtime or another class library and indicates developer error. If you throw an ArgumentException from your code, you should ensure that the exception's Message property includes a meaningful error message that describes the invalid argument and the expected range of values for the argument.

The primary derived classes of ArgumentException are ArgumentNullException and ArgumentOutOfRangeException. These derived classes should be used instead of ArgumentException, except in situations where neither of the derived classes is acceptable. For example, exceptions should be thrown by:

- ArgumentNullException whenever `null` is passed to a method that does not accept it as a valid argument.

- ArgumentOutOfRangeException when the value of an argument is outside the range of acceptable values; for example, when the value "46" is passed as the month argument during the creation of a DateTime.

If the method call does not have any argument or if the failure does not involve the arguments themselves, then InvalidOperationException should be used.

ArgumentException uses the HRESULT COR_E_ARGUMENT, which has the value 0x80070057.

For a list of initial property values for an instance of ArgumentException, see the ArgumentException constructors.

In F#, you can use the invalidArg function to generate and raise an ArgumentException.

Constructors

Expand table

ArgumentException()	Initializes a new instance of the ArgumentException class.
ArgumentException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArgumentException class with serialized data.
ArgumentException(String)	Initializes a new instance of the ArgumentException class with a specified error message.
ArgumentException(String, Exception)	Initializes a new instance of the ArgumentException class with a specified error message and a reference to the inner exception that is the cause of this exception.
ArgumentException(String, String)	Initializes a new instance of the ArgumentException class with a specified error message and the name of the parameter that causes this exception.
ArgumentException(String, String, Exception)	Initializes a new instance of the ArgumentException class with a specified error message, the parameter name, and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message and the parameter name, or only the error message if no parameter name is set.
ParamName	Gets the name of the parameter that causes this exception.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the parameter name and additional exception information.
GetType()	Gets the runtime type of the current instance.

	(Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ThrowIfNullOrEmpty(String, String)	Throws an exception if `argument` is `null` or empty.
ThrowIfNullOrWhiteSpace(String, String)	Throws an exception if `argument` is `null`, empty, or consists only of white-space characters.
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArgumentException class.

Overloads

Expand table

ArgumentException()	Initializes a new instance of the ArgumentException class.
ArgumentException(String)	Initializes a new instance of the ArgumentException class with a specified error message.
ArgumentException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArgumentException class with serialized data.
ArgumentException(String, Exception)	Initializes a new instance of the ArgumentException class with a specified error message and a reference to the inner exception that is the cause of this exception.
ArgumentException(String, String)	Initializes a new instance of the ArgumentException class with a specified error message and the name of the parameter that causes this exception.
ArgumentException(String, String, Exception)	Initializes a new instance of the ArgumentException class with a specified error message, the parameter name, and a reference to the inner exception that is the cause of this exception.

ArgumentException()

Initializes a new instance of the ArgumentException class.

```
C#
```

```
public ArgumentException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "An invalid argument was specified." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ArgumentException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException(String)

Initializes a new instance of the ArgumentException class with a specified error message.

C#

```
public ArgumentException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "An invalid argument was specified." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ArgumentException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ArgumentException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ArgumentException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArgumentException(String, Exception)

Initializes a new instance of the ArgumentException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public ArgumentException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

This constructor initializes the Message property of the new instance using the value of the `message` parameter. The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of ArgumentException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The localized error message string.

See also

- Exception
- Handling and Throwing Exceptions

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException(String, String)

Initializes a new instance of the ArgumentException class with a specified error message and the name of the parameter that causes this exception.

C#

```
public ArgumentException (string? message, string? paramName);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`paramName` String

The name of the parameter that caused the current exception.

Examples

The following code example demonstrates how to call the ArgumentException constructor. This code example is part of a larger example provided for the ArgumentException class.

C#

```
static int DivideByTwo(int num)
{
    // If num is an odd number, throw an ArgumentException.
    if ((num & 1) == 1)
        throw new ArgumentException("Number must be even", "num");

    // num is even, return half of its value.
    return num / 2;
}
```

Remarks

This constructor initializes the Message property of the new instance using the value of the `message` parameter. The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

This constructor initializes the ParamName property of the new instance using `paramName`. The content of `paramName` is intended to be understood by humans.

The following table shows the initial property values for an instance of ArgumentException.

Expand table

Property	Value
Message	The error message string.
ParamName	The parameter name string.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException(String, String, Exception)

Initializes a new instance of the ArgumentException class with a specified error message, the parameter name, and a reference to the inner exception that is the cause of this exception.

C#

```
public ArgumentException (string? message, string? paramName, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`paramName` String

The name of the parameter that caused the current exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

This constructor initializes the Message property of the new instance using the value of the `message` parameter. The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

This constructor initializes the ParamName property of the new instance using `paramName`. The content of `paramName` is intended to be understood by humans.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

ArgumentException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the error message and the parameter name, or only the error message if no parameter name is set.

C#

```
public override string Message { get; }
```

Property Value

String

A text string describing the details of the exception. The value of this property takes one of two forms:

Expand table

Condition	Value
The `paramName` is a null reference (`Nothing` in Visual Basic) or of zero length.	The `message` string passed to the constructor.
The `paramName` is not null reference (`Nothing` in Visual Basic) and it has a length greater than zero.	The `message` string appended with the name of the invalid parameter.

Remarks

This property overrides Message. The error message should be localized.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException.ParamName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the parameter that causes this exception.

```
C#
public virtual string? ParamName { get; }
```

Property Value

String

The parameter name.

Remarks

Every ArgumentException should carry the name of the parameter that causes this exception.

This property is read-only, and returns the same value as was passed into the constructor. Overriding methods should be used solely to customize the format of the parameter name.

The parameter name should not be translated for localization purposes.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentException.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the parameter name and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` object is a null reference (`Nothing` in Visual Basic).

Remarks

GetObjectData sets a SerializationInfo with all the exception object data targeted for serialization. During deserialization, the exception object is reconstituted from the SerializationInfo transmitted over the stream.

For more information, see SerializationInfo.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArgumentException.ThrowIfNullOrEmpty(String, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an exception if `argument` is `null` or empty.

```
C#

public static void ThrowIfNullOrEmpty (string? argument, string? paramName =
default);
```

Parameters

`argument` String

The string argument to validate as non-`null` and non-empty.

`paramName` String

The name of the parameter with which `argument` corresponds.

Exceptions

ArgumentNullException

`argument` is `null`.

ArgumentException

`argument` is empty.

Applies to

Product	Versions
.NET	7, 8, 9

ArgumentException.ThrowIfNullOrWhiteSpace(String, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an exception if `argument` is `null`, empty, or consists only of white-space characters.

```
C#

public static void ThrowIfNullOrWhiteSpace (string? argument, string?
paramName = default);
```

Parameters

`argument` String

The string argument to validate.

`paramName` String

The name of the parameter with which `argument` corresponds.

Exceptions

ArgumentNullException

`argument` is `null`.

ArgumentException

`argument` is empty or consists only of white-space characters.

Applies to

Product	Versions
.NET	8, 9

ArgumentNullException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a null reference (`Nothing` in Visual Basic) is passed to a method that does not accept it as a valid argument.

C#

```
public class ArgumentNullException : ArgumentException
```

Inheritance Object → Exception → SystemException → ArgumentException → ArgumentNullException

Remarks

An ArgumentNullException exception is thrown when a method is invoked and at least one of the passed arguments is `null` but should never be `null`.

An ArgumentNullException exception is thrown at run time in the following two major circumstances, both of which reflect developer error:

- An uninstantiated object is passed to a method. To prevent the error, instantiate the object.
- An object returned from a method call is then passed as an argument to a second method, but the value of the original returned object is `null`. To prevent the error, check for a return value that is `null` and call the second method only if the return value is not `null`.

ArgumentNullException behaves identically to ArgumentException. It is provided so that application code can differentiate between exceptions caused by `null` arguments and exceptions caused by arguments that are not null. For errors caused by arguments that are not null, see ArgumentOutOfRangeException.

ArgumentNullException uses the HRESULT E_POINTER, which has the value 0x80004003.

For a list of initial property values for an instance of ArgumentNullException, see the ArgumentNullException constructors.

Constructors

Expand table

ArgumentNullException()	Initializes a new instance of the ArgumentNullException class.
ArgumentNullException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArgumentNullException class with serialized data.
ArgumentNullException(String)	Initializes a new instance of the ArgumentNullException class with the name of the parameter that causes this exception.
ArgumentNullException(String, Exception)	Initializes a new instance of the ArgumentNullException class with a specified error message and the exception that is the cause of this exception.
ArgumentNullException(String, String)	Initializes an instance of the ArgumentNullException class with a specified error message and the name of the parameter that causes this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message and the parameter name, or only the error message if no parameter name is set.

	(Inherited from ArgumentException)
ParamName	Gets the name of the parameter that causes this exception. (Inherited from ArgumentException)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the parameter name and additional exception information. (Inherited from ArgumentException)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ThrowIfNull(Object, String)	Throws an ArgumentNullException if `argument` is `null`.
ThrowIfNull(Void*, String)	Throws an ArgumentNullException if `argument` is `null`.
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentNullException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArgumentNullException class.

Overloads

Expand table

ArgumentNullException()	Initializes a new instance of the ArgumentNullException class.
ArgumentNullException(String)	Initializes a new instance of the ArgumentNullException class with the name of the parameter that causes this exception.
ArgumentNullException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArgumentNullException class with serialized data.
ArgumentNullException(String, Exception)	Initializes a new instance of the ArgumentNullException class with a specified error message and the exception that is the cause of this exception.
ArgumentNullException(String, String)	Initializes an instance of the ArgumentNullException class with a specified error message and the name of the parameter that causes this exception.

ArgumentNullException()

Initializes a new instance of the ArgumentNullException class.

```
C#
```

```
public ArgumentNullException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Value cannot be null." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ArgumentNullException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	A localized error message string, such as "Value cannot be null." for the English language.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentNullException(String)

Initializes a new instance of the ArgumentNullException class with the name of the parameter that causes this exception.

C#

```
public ArgumentNullException (string? paramName);
```

Parameters

paramName String

The name of the parameter that caused the exception.

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error and includes the parameter name. This message takes into account the current system culture.

This constructor initializes the ParamName property of the new instance using the `paramName` parameter. The content of `paramName` is intended to be understood by humans.

The following table shows the initial property values for an instance of ArgumentNullException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	A localized error message string that identifies the null argument. For example, if the `paramName` argument is "arg1", the English language message string is: On .NET 5+ and .NET Core: `Value cannot be null. (Parameter name: 'arg1')` On .NET Framework: `Value cannot be null.\r\nParameter name: arg1`
ParamName	The parameter name string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentNullException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ArgumentNullException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ArgumentNullException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

An object that describes the source or destination of the serialized data.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArgumentNullException(String, Exception)

Initializes a new instance of the ArgumentNullException class with a specified error message and the exception that is the cause of this exception.

C#

```
public ArgumentNullException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for this exception.

`innerException` Exception

The exception that is the cause of the current exception, or a null reference (`Nothing` in Visual Basic) if no inner exception is specified.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentNullException(String, String)

Initializes an instance of the ArgumentNullException class with a specified error message and the name of the parameter that causes this exception.

C#

```
public ArgumentNullException (string? paramName, string? message);
```

Parameters

`paramName` String

The name of the parameter that caused the exception.

`message` String

A message that describes the error.

Remarks

This constructor initializes the Message property of the new instance using the value of the `message` parameter. The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

This constructor initializes the ParamName property of the new instance using the `paramName` parameter. The content of `paramName` is intended to be understood by

humans.

The following table shows the initial property values for an instance of ArgumentNullException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.
ParamName	The parameter name string.

Applies to

ArgumentNullException.ThrowIfNull Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ThrowIfNull(Object, String)	Throws an ArgumentNullException if `argument` is `null`.
ThrowIfNull(Void*, String)	Throws an ArgumentNullException if `argument` is `null`.

ThrowIfNull(Object, String)

Throws an ArgumentNullException if `argument` is `null`.

C#

```
public static void ThrowIfNull (object? argument, string? paramName =
default);
```

Parameters

`argument` Object

The reference type argument to validate as non-null.

`paramName` String

The name of the parameter with which `argument` corresponds. If you omit this parameter, the name of `argument` is used.

Exceptions

ArgumentNullException

`argument` is `null`.

Remarks

The `paramName` parameter is included to support the CallerArgumentExpressionAttribute attribute. It's recommended that you don't pass a value for this parameter and let the name of `argument` be used instead.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ThrowIfNull(Void*, String)

> Important
>
> This API is not CLS-compliant.

Throws an ArgumentNullException if `argument` is `null`.

C#

```
[System.CLSCompliant(false)]
public static void ThrowIfNull (void* argument, string? paramName =
default);
```

Parameters

`argument` Void*

The pointer argument to validate as non-null.

`paramName` String

The name of the parameter with which `argument` corresponds.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ArgumentOutOfRangeException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when the value of an argument is outside the allowable range of values as defined by the invoked method.

C#

```
public class ArgumentOutOfRangeException : ArgumentException
```

Inheritance Object → Exception → SystemException → ArgumentException → ArgumentOutOfRangeException

Examples

The following example defines a class to contain information about an invited guest. If the guest is younger than 21, an ArgumentOutOfRangeException exception is thrown.

C#

```
using System;
using static System.Console;

public class Program
{
    public static void Main(string[] args)
    {
        try
        {
            var guest1 = new Guest("Ben", "Miller", 17);
            WriteLine(guest1.GuestInfo);
        }
        catch (ArgumentOutOfRangeException argumentOutOfRangeException)
        {
            WriteLine($"Error: {argumentOutOfRangeException.Message}");
        }
    }
}
```

```
class Guest
{
    private const int minimumRequiredAge = 21;

    private string firstName;
    private string lastName;
    private int age;

    public Guest(string firstName, string lastName, int age)
    {
        if (age < minimumRequiredAge)
            throw new ArgumentOutOfRangeException(nameof(age), $"All guests
must be {minimumRequiredAge}-years-old or older.");

        this.firstName = firstName;
        this.lastName = lastName;
        this.age = age;
    }

    public string GuestInfo => $"{firstName} {lastName}, {age}";
}
```

Remarks

An ArgumentOutOfRangeException exception is thrown when a method is invoked and at least one of the arguments passed to the method is not `null` and contains an invalid value that is not a member of the set of values expected for the argument. The ParamName property identifies the invalid argument, and the ActualValue property, if a value is present, identifies the invalid value.

Typically, an ArgumentOutOfRangeException results from developer error. Instead of handling the exception in a `try`/`catch` block, you should eliminate the cause of the exception or, if the argument is returned by a method call or input by the user before being passed to the method that throws the exception, you should validate arguments before passing them to the method.

ArgumentOutOfRangeException is used extensively by:

- Classes in the System.Collections and System.IO namespaces.
- The Array class.
- String manipulation methods in the String class.

The conditions in which an ArgumentOutOfRangeException exception is thrown include the following:

- You are retrieving the member of a collection by its index number, and the index number is invalid.

  This is the most common cause of an ArgumentOutOfRangeException exception. Typically, the index number is invalid for one of four reasons:

  1. The collection has no members, and your code assumes that it does. The following example attempts to retrieve the first element of a collection that has no elements:

     C#

     ```
     using System;
     using System.Collections.Generic;

     public class Example4
     {
        public static void Main()
        {
           var list = new List<string>();
           Console.WriteLine("Number of items: {0}", list.Count);
           try {
              Console.WriteLine("The first item: '{0}'", list[0]);
           }
           catch (ArgumentOutOfRangeException e) {
              Console.WriteLine(e.Message);
           }
        }
     }
     // The example displays the following output:
     //   Number of items: 0
     //   Index was out of range. Must be non-negative and less than
     the size of the collection.
     //   Parameter name: index
     ```

     To prevent the exception, check whether the collection's `Count` property is greater than zero before attempting to retrieve any members, as the following code fragment does.

     C#

     ```
     if (list.Count > 0)
        Console.WriteLine("The first item: '{0}'", list[0]);
     ```

  2. In some cases, the exception may occur because you are attempting to add a member to a collection by using an index that does not exist, rather than by calling the method, such as `Add`, that exists for this purpose. The following

example attempts to add an element to a collection by using a non-existent index rather than calling the List<T>.Add method.

```
C#

using System;
using System.Collections.Generic;

public class Example13
{
   public static void Main()
   {
      var numbers = new List<int>();
      numbers.AddRange( new int[] { 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
20 } );

      var squares = new List<int>();
      for (int ctr = 0; ctr < numbers.Count; ctr++)
         squares[ctr] = (int) Math.Pow(numbers[ctr], 2);
   }
}
// The example displays the following output:
//    Unhandled Exception: System.ArgumentOutOfRangeException:
Index was out of range. Must be non-negative and less than the
size of the collection.
//    Parameter name: index
//       at
System.ThrowHelper.ThrowArgumentOutOfRangeException(ExceptionArgum
ent argument, ExceptionResource resource)
//       at Example.Main()
```

The following code fragment corrects this error:

```
C#

var squares = new List<int>();
for (int ctr = 0; ctr < numbers.Count; ctr++)
   squares.Add((int) Math.Pow(numbers[ctr], 2));
```

3. You're attempting to retrieve an item whose index is negative. This usually occurs because you've searched a collection for the index of a particular element and have erroneously assumed that the search is successful. In the following example, the call to the List<T>.FindIndex(Predicate<T>) method fails to find a string equal to "Z" and so returns -1. However, this is an invalid index value.

```
C#
```

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      var list = new List<string>();
      list.AddRange( new String[] { "A", "B", "C" } );
      // Get the index of the element whose value is "Z".
      int index = list.FindIndex((new
StringSearcher("Z")).FindEquals);
      try {
         Console.WriteLine("Index {0} contains '{1}'", index,
list[index]);
      }
      catch (ArgumentOutOfRangeException e) {
         Console.WriteLine(e.Message);
      }
   }
}

internal class StringSearcher
{
   string value;

   public StringSearcher(string value)
   {
      this.value = value;
   }

   public bool FindEquals(string s)
   {
      return s.Equals(value, StringComparison.InvariantCulture);
   }
}
// The example displays the following output:
//   Index was out of range. Must be non-negative and less than
the size of the collection.
//   Parameter name: index
```

To prevent the exception, check that the search is successful by making sure that the returned index is greater than or equal to zero before attempting to retrieve the item from the collection, as the following code fragment does.

C#

```
// Get the index of the element whose value is "Z".
int index = list.FindIndex((new StringSearcher("Z")).FindEquals);
if (index >= 0)
   Console.WriteLine("'Z' is found at index {0}", list[index]);
```

4. You're attempting to retrieve an element whose index is equal to the value of the collection's `Count` property, as the following example illustrates.

C#

```
using System;
using System.Collections.Generic;

public class Example8
{
   public static void Main()
   {
      var list = new List<string>();
      list.AddRange( new String[] { "A", "B", "C" } );
      try {
         // Display the elements in the list by index.
         for (int ctr = 0; ctr <= list.Count; ctr++)
            Console.WriteLine("Index {0}: {1}", ctr, list[ctr]);
      }
      catch (ArgumentOutOfRangeException e) {
         Console.WriteLine(e.Message);
      }
   }
}
// The example displays the following output:
//   Index 0: A
//   Index 1: B
//   Index 2: C
//   Index was out of range. Must be non-negative and less than
the size of the collection.
//   Parameter name: index
```

Because collections in .NET use zero-based indexing, the first element of the collection is at index 0, and the last element is at index `Count` - 1. You can eliminate the error by ensuring that you access the last element at index `Count` - 1, as the following code does.

C#

```
// Display the elements in the list by index.
for (int ctr = 0; ctr < list.Count; ctr++)
   Console.WriteLine("Index {0}: {1}", ctr, list[ctr]);
```

- You are attempting to perform a string operation by calling a string manipulation method, and the starting index does not exist in the string.

  Overloads of methods such as such as String.Compare, String.CompareOrdinal, String.IndexOf, IndexOfAny, String.Insert, String.LastIndexOf, String.LastIndexOfAny,

Remove, or String.Substring that allow you to specify the starting index of the operation require that the index be a valid position within the string. Valid indexes range from 0 to String.Length - 1.

There are four common causes of this ArgumentOutOfRangeException exception:

1. You are working with an empty string, or String.Empty. Because its String.Length property returns 0, any attempt to manipulate it by index throws an ArgumentOutOfRangeException exception. The following example, defines a `GetFirstCharacter` method that returns the first character of a string. If the string is empty, as the final string passed to the method is, the method throws an ArgumentOutOfRangeException exception.

   C#

   ```
   using System;

   public class Example1
   {
       public static void Main()
       {
           String[] words = { "the", "today", "tomorrow", " ", "" };
           foreach (var word in words)
               Console.WriteLine("First character of '{0}': '{1}'",
                                 word, GetFirstCharacter(word));
       }

       private static char GetFirstCharacter(string s)
       {
           return s[0];
       }
   }
   // The example displays the following output:
   //    First character of //the//: //t//
   //    First character of //today//: //t//
   //    First character of //tomorrow//: //t//
   //    First character of // //: // //
   //
   //    Unhandled Exception: System.IndexOutOfRangeException: Index
   was outside the bounds of the array.
   //       at Example.Main()
   ```

   You can eliminate the exception by testing whether the string's String.Length is greater than zero or by calling the IsNullOrEmpty method to ensure that the string is not `null` or empty. The following code fragment does the latter. In this case, if the string is `null` or empty, the `GetFirstCharacter` method returns U+0000.

C#

```
static char GetFirstCharacter(string s)
{
    if (string.IsNullOrEmpty(s))
        return '\u0000';
    else
        return s[0];
}
```

2. You're manipulating a string based on the position of a substring within that string, and you've failed to determine whether the substring was actually found.

   The following example extracts the second word of a two-word phrase. It throws an ArgumentOutOfRangeException exception if the phrase consists of only one word, and therefore does not contain an embedded space character. This occurs because the call to the String.IndexOf(String) method returns -1 to indicate that the search failed, and this invalid value is then passed to the String.Substring(Int32) method.

C#

```
using System;

public class Example17
{
   public static void Main()
   {
      String[] phrases = { "ocean blue", "concerned citizen",
                           "runOnPhrase" };
      foreach (var phrase in phrases)
         Console.WriteLine("Second word is {0}",
GetSecondWord(phrase));
   }

   static string GetSecondWord(string s)
   {
      int pos = s.IndexOf(" ");
      return s.Substring(pos).Trim();
   }
}
// The example displays the following output:
//    Second word is blue
//    Second word is citizen
//
//    Unhandled Exception: System.ArgumentOutOfRangeException:
StartIndex cannot be less than zero.
//    Parameter name: startIndex
//       at System.String.Substring(Int32 startIndex, Int32
```

```
length)
//       at Example17.GetSecondWord(String s)
//       at Example17.Main()
```

To eliminate the exception, validate the value returned by the string search method before calling the string manipulation method.

C#

```
using System;

public class Example18
{
   public static void Main()
   {
      String[] phrases = { "ocean blue", "concerned citizen",
                           "runOnPhrase" };
      foreach (var phrase in phrases) {
         string word = GetSecondWord(phrase);
         if (! string.IsNullOrEmpty(word))
            Console.WriteLine("Second word is {0}", word);
      }
   }

   static string GetSecondWord(string s)
   {
      int pos = s.IndexOf(" ");
      if (pos >= 0)
         return s.Substring(pos).Trim();
      else
         return string.Empty;
   }
}
// The example displays the following output:
//       Second word is blue
//       Second word is citizen
```

3. You've attempted to extract a substring that is outside the range of the current string.

   The methods that extract substrings all require that you specify the starting position of the substring and, for substrings that do not continue to the end of the string, the number of characters in the substring. Note that this is not the *index* of the last character in the substring.

   An ArgumentOutOfRangeException exception is typically thrown in this case because you've incorrectly calculated the number of characters in the substring. If you are using a search method like String.IndexOf to identify the starting and ending positions of a substring:

- If the character in the ending position returned by String.IndexOf is to be included in the substring, the ending position of the substring is given by the formula

```
endIndex - startIndex + 1
```

- If the character in the ending position returned by String.IndexOf is to be excluded from the substring, the ending position of the substring is given by the formula

```
endIndex - startIndex
```

The following example defines a `FindWords` method that uses the String.IndexOfAny(Char[], Int32) method to identify space characters and punctuation marks in a string and returns an array that contains the words found in the string.

C#

```
using System;
using System.Collections.Generic;

public class Example19
{
   public static void Main()
   {
      string sentence = "This is a simple, short sentence.";
      Console.WriteLine("Words in '{0}':", sentence);
      foreach (var word in FindWords(sentence))
         Console.WriteLine("   '{0}'", word);
   }

   static String[] FindWords(string s)
   {
      int start = 0, end = 0;
      Char[] delimiters = { ' ', '.', ',', ';', ':', '(', ')'
};
      var words = new List<string>();

      while (end >= 0) {
         end = s.IndexOfAny(delimiters, start);
         if (end >= 0) {
            if (end - start > 0)
               words.Add(s.Substring(start, end - start));
```

```
            start = end + 1;
         }
         else {
            if (start < s.Length - 1)
               words.Add(s.Substring(start));
         }
      }
      return words.ToArray();
   }
}
// The example displays the following output:
//       Words in 'This is a simple, short sentence.':
//          'This'
//          'is'
//          'a'
//          'simple'
//          'short'
//          'sentence'
```

- You have passed a negative number to a method with an argument that requires only positive numbers and zero, or you have passed either a negative number or zero to a method with an argument that requires only positive numbers.

  For example, the Array.CreateInstance(Type, Int32, Int32, Int32) method requires that you specify the number of elements in each dimension of a two-dimensional array; valid values for each dimension can range from 0 to Int32.MaxValue. But because the dimension argument in the following example has a negative value, the method throws an ArgumentOutOfRangeException exception.

C#

```
using System;

public class Example01
{
    public static void Main()
    {
        int dimension1 = 10;
        int dimension2 = -1;
        try
        {
            Array arr = Array.CreateInstance(typeof(string),
                                             dimension1, dimension2);
        }
        catch (ArgumentOutOfRangeException e)
        {
            if (e.ActualValue != null)
                Console.WriteLine("{0} is an invalid value for {1}: ",
e.ActualValue, e.ParamName);
            Console.WriteLine(e.Message);
```

```
        }
    }
}
// The example displays the following output:
//     Non-negative number required.
//     Parameter name: length2
```

To correct the error, ensure that the value of the invalid argument is non-negative. You can do this by providing a valid value, as the following code fragment does.

```C#
int dimension1 = 10;
int dimension2 = 10;
Array arr = Array.CreateInstance(typeof(string),
                                 dimension1, dimension2);
```

You can also validate the input and, if it is invalid, take some action. The following code fragment displays an error message instead of calling the method.

```C#
if (dimension1 < 0 || dimension2 < 0)
{
    Console.WriteLine("Unable to create the array.");
    Console.WriteLine("Specify non-negative values for the two
dimensions.");
}
else
{
    arr = Array.CreateInstance(typeof(string),
                               dimension1, dimension2);
}
```

- A race condition exists in an app that is multithreaded or has tasks that execute asynchronously and that updates an array or collection.

  The following example uses a List<T> object to populate a collection of `Continent` objects. It throws an ArgumentOutOfRangeException if the example attempts to display the seven items in the collection before the collection is fully populated.

```C#
using System;
using System.Collections.Generic;
using System.Threading;

public class Continent
```

```
{
   public string? Name { get; set; }
   public int Population { get; set; }
   public Decimal Area { get; set; }
}

public class Example11
{
   static List<Continent> continents = new List<Continent>();
   static string? s_msg;

   public static void Main()
   {
      String[] names = { "Africa", "Antarctica", "Asia",
                         "Australia", "Europe", "North America",
                         "South America" };
      // Populate the list.
      foreach (var name in names) {
         var th = new Thread(PopulateContinents);
         th.Start(name);
      }
      Console.WriteLine(s_msg);
      Console.WriteLine();

      // Display the list.
      for (int ctr = 0; ctr < names.Length; ctr++) {
         var continent = continents[ctr];
         Console.WriteLine("{0}: Area: {1}, Population {2}",
                           continent.Name, continent.Population,
                           continent.Area);
      }
   }

   private static void PopulateContinents(Object? obj)
   {
      string? name = obj?.ToString();
      s_msg += string.Format("Adding '{0}' to the list.\n", name);
      var continent = new Continent();
      continent.Name = name;
      // Sleep to simulate retrieving remaining data.
      Thread.Sleep(50);
      continents.Add(continent);
   }
}
// The example displays output like the following:
//    Adding //Africa// to the list.
//    Adding //Antarctica// to the list.
//    Adding //Asia// to the list.
//    Adding //Australia// to the list.
//    Adding //Europe// to the list.
//    Adding //North America// to the list.
//    Adding //South America// to the list.
//
//
//
```

```
//    Unhandled Exception: System.ArgumentOutOfRangeException: Index
was out of range. Must be non-negative and less than the size of the
collection.
//    Parameter name: index
//       at
System.ThrowHelper.ThrowArgumentOutOfRangeException(ExceptionArgument
argument, ExceptionResource resource)
//       at Example.Main()
```

In this case, two resources are accessed from multiple threads:

- The `continents` collection. Its List<T>.Add method is called from multiple threads. In addition, the main or primary thread assumes the collection is fully populated with seven elements when it iterates its members.
- The `msg` string, which is concatenated from multiple threads.

To correct the error, ensure that shared state is accessed in a thread-safe way, as follows.

- if your app uses an array or collection object, consider using a thread-safe collection class, such as the types in the System.Collections.Concurrent namespace or the System.Collections.Immutable out-of-band release.
- Ensure that shared state (that is, resources that can be accessed by multiple threads) is accessed in a thread-safe way, so that only one thread at a time has exclusive access to the resources. A large number of classes, such as CountdownEvent, Interlocked, Monitor, and Mutex, are available to synchronize access to resources. For more information, see Threading. In addition, language support is available through the lock statement in C# and the SyncLock construct in Visual Basic.

The following example addresses the ArgumentOutOfRangeException and the other issues from the previous example. It replaces the List<T> object with a ConcurrentBag<T> object to ensure that access to the collection is thread-safe, uses a CountdownEvent object to ensure that the application thread continues only after other threads have executed, and uses a lock to ensure that only one thread can access the `msg` variable at a time.

C#

```
using System;
using System.Collections.Concurrent;
using System.Threading;

public class ContinentD
```

```
{
   public string? Name { get; set; }
   public int Population { get; set; }
   public Decimal Area { get; set; }
}

public class Example12
{
   static ConcurrentBag<ContinentD> ContinentDs = new
ConcurrentBag<ContinentD>();
   static CountdownEvent? gate;
   static string msg = string.Empty;

   public static void Main()
   {
      String[] names = { "Africa", "Antarctica", "Asia",
                         "Australia", "Europe", "North America",
                         "South America" };
      gate = new CountdownEvent(names.Length);

      // Populate the list.
      foreach (var name in names) {
         var th = new Thread(PopulateContinentDs);
         th.Start(name);
      }

      // Display the list.
      gate.Wait();
      Console.WriteLine(msg);
      Console.WriteLine();

      var arr = ContinentDs.ToArray();
      for (int ctr = 0; ctr < names.Length; ctr++) {
         var ContinentD = arr[ctr];
         Console.WriteLine("{0}: Area: {1}, Population {2}",
                           ContinentD.Name, ContinentD.Population,
                           ContinentD.Area);
      }
   }

   private static void PopulateContinentDs(Object? obj)
   {
      string? name = obj?.ToString();
      lock(msg) {
         msg += string.Format("Adding '{0}' to the list.\n", name);
      }
      var ContinentD = new ContinentD();
      ContinentD.Name = name;
      // Sleep to simulate retrieving remaining data.
      Thread.Sleep(25);
      ContinentDs.Add(ContinentD);
      gate?.Signal();
   }
}
// The example displays output like the following:
```

```
//       Adding 'Africa' to the list.
//       Adding 'Antarctica' to the list.
//       Adding 'Asia' to the list.
//       Adding 'Australia' to the list.
//       Adding 'Europe' to the list.
//       Adding 'North America' to the list.
//       Adding 'South America' to the list.
//
//
//       Africa: Area: 0, Population 0
//       Antarctica: Area: 0, Population 0
//       Asia: Area: 0, Population 0
//       Australia: Area: 0, Population 0
//       Europe: Area: 0, Population 0
//       North America: Area: 0, Population 0
//       South America: Area: 0, Population 0
```

ArgumentOutOfRangeException uses the HRESULT COR_E_ARGUMENTOUTOFRANGE, which has the value 0x80131502.

For a list of initial property values for an instance of ArgumentOutOfRangeException, see the ArgumentOutOfRangeException constructors.

Constructors

Expand table

ArgumentOutOfRangeException()	Initializes a new instance of the ArgumentOutOfRangeException class.
ArgumentOutOfRange Exception(SerializationInfo, Streaming Context)	**Obsolete.** Initializes a new instance of the ArgumentOutOfRangeException class with serialized data.
ArgumentOutOfRange Exception(String)	Initializes a new instance of the ArgumentOutOfRangeException class with the name of the parameter that causes this exception.
ArgumentOutOfRange Exception(String, Exception)	Initializes a new instance of the ArgumentOutOfRangeException class with a specified error message and the exception that is the cause of this exception.
ArgumentOutOfRange Exception(String, Object, String)	Initializes a new instance of the ArgumentOutOfRangeException class with the parameter name, the value of the argument, and a specified error message.

ArgumentOutOfRangeException(String, String)	Initializes a new instance of the ArgumentOutOfRangeException class with the name of the parameter that causes this exception and a specified error message.

Properties

Expand table

ActualValue	Gets the argument value that causes this exception.
Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message and the string representation of the invalid argument value, or only the error message if the argument value is null.
ParamName	Gets the name of the parameter that causes this exception. (Inherited from ArgumentException)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object.

	(Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the invalid argument value and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ThrowIfEqual<T>(T, T, String)	Throws an ArgumentOutOfRangeException if `value` is equal to `other`.
ThrowIfGreaterThan<T>(T, T, String)	Throws an ArgumentOutOfRangeException if `value` is greater than `other`.
ThrowIfGreaterThanOrEqual<T>(T, T, String)	Throws an ArgumentOutOfRangeException if `value` is greater than or equal to `other`.
ThrowIfLessThan<T>(T, T, String)	Throws an ArgumentOutOfRangeException if `value` is less than `other`.
ThrowIfLessThanOrEqual<T>(T, T, String)	Throws an ArgumentOutOfRangeException if `value` is less than or equal to `other`.
ThrowIfNegative<T>(T, String)	Throws an ArgumentOutOfRangeException if `value` is negative.
ThrowIfNegativeOrZero<T>(T, String)	Throws an ArgumentOutOfRangeException if `value` is negative or zero.
ThrowIfNotEqual<T>(T, T, String)	Throws an ArgumentOutOfRangeException if `value` is not equal to `other`.
ThrowIfZero<T>(T, String)	Throws an ArgumentOutOfRangeException if `value` is zero.
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

ArgumentOutOfRangeException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArgumentOutOfRangeException class.

Overloads

Expand table

ArgumentOutOfRangeException()	Initializes a new instance of the ArgumentOutOfRangeException class.
ArgumentOutOfRangeException(String)	Initializes a new instance of the ArgumentOutOfRangeException class with the name of the parameter that causes this exception.
ArgumentOutOfRangeException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArgumentOutOfRangeException class with serialized data.
ArgumentOutOfRangeException(String, Exception)	Initializes a new instance of the ArgumentOutOfRangeException class with a specified error message and the exception that is the cause of this exception.
ArgumentOutOfRangeException(String, String)	Initializes a new instance of the ArgumentOutOfRangeException class with the name of the parameter that causes this exception and a specified error message.
ArgumentOutOfRangeException(String, Object, String)	Initializes a new instance of the ArgumentOutOfRangeException class with the parameter name, the value of the argument, and a specified error message.

ArgumentOutOfRangeException()

Initializes a new instance of the ArgumentOutOfRangeException class.

C#

```
public ArgumentOutOfRangeException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Nonnegative number required." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ArgumentOutOfRangeException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentOutOfRangeException(String)

Initializes a new instance of the ArgumentOutOfRangeException class with the name of the parameter that causes this exception.

```
C#

public ArgumentOutOfRangeException (string? paramName);
```

Parameters

paramName String

The name of the parameter that causes this exception.

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Nonnegative number required." This message takes into account the current system culture.

This constructor initializes the ParamName property of the new instance using the `paramName` parameter. The content of `paramName` is intended to be understood by humans.

The following table shows the initial property values for an instance of ArgumentOutOfRangeException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The empty string ("").
ParamName	The parameter name string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentOutOfRangeException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ArgumentOutOfRangeException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ArgumentOutOfRangeException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

An object that describes the source or destination of the serialized data.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArgumentOutOfRangeException(String, Exception)

Initializes a new instance of the ArgumentOutOfRangeException class with a specified error message and the exception that is the cause of this exception.

C#

```
public ArgumentOutOfRangeException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for this exception.

`innerException` Exception

The exception that is the cause of the current exception, or a null reference (`Nothing` in Visual Basic) if no inner exception is specified.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentOutOfRangeException(String, String)

Initializes a new instance of the ArgumentOutOfRangeException class with the name of the parameter that causes this exception and a specified error message.

C#

```
public ArgumentOutOfRangeException (string? paramName, string? message);
```

Parameters

`paramName` String

The name of the parameter that caused the exception.

`message` String

The message that describes the error.

Remarks

This constructor initializes the Message property of the new instance using the value of the `message` parameter. The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

This constructor initializes the ParamName property of the new instance using the `paramName` parameter. The content of `paramName` is intended to be understood by

humans.

The following table shows the initial property values for an instance of ArgumentOutOfRangeException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string.
ParamName	The parameter name string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentOutOfRangeException(String, Object, String)

Initializes a new instance of the ArgumentOutOfRangeException class with the parameter name, the value of the argument, and a specified error message.

C#

```
public ArgumentOutOfRangeException (string? paramName, object?
actualValue, string? message);
```

Parameters

`paramName` String

The name of the parameter that caused the exception.

`actualValue` Object

The value of the argument that causes this exception.

`message` String

The message that describes the error.

Remarks

This constructor initializes the ParamName property of the new instance using the `paramName` parameter, the ActualValue property using the `actualValue` parameter, and the Message property using the `message` parameter. The content of the `paramName` and `message` parameters is intended to be understood by humans. The caller of this constructor is required to ensure that these strings have been localized for the current system culture.

The `actualValue` parameter is not used within the .NET class library. However, apps can use the ActualValue property to obtain the available argument value.

The `actualValue` parameter contains the invalid value that was passed to the method and caused this exception to be thrown. This value is stored in the ActualValue property and its string representation is appended to the message string held in the Message property.

The following table shows the initial property values for an instance of ArgumentOutOfRangeException.

Expand table

Property	Value
ActualValue	The argument value.
InnerException	The null reference (`Nothing` in Visual Basic).
Message	The error message string.
ParamName	The parameter name string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArgumentOutOfRangeException.ActualValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the argument value that causes this exception.

```
C#
public virtual object? ActualValue { get; }
```

Property Value

Object

The value of the parameter that caused the current Exception.

Remarks

Use this property to retrieve the invalid argument.

The `ActualValue` property returns the same value that was passed to the constructor, or `null` if no value was supplied.

The ActualValue property is assigned a value at the time of object construction. If the ActualValue property value is not `null`, a string representation of the value is appended to the message string held by the Message property.

The ActualValue property is not used within the .NET class library. It carries a null value in all the ArgumentOutOfRangeException objects thrown by the .NET class library. The ActualValue property is provided so that applications can use the available argument value.

This property is read-only and should be overridden only to customize the content or format of the value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArgumentOutOfRangeException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the error message and the string representation of the invalid argument value, or only the error message if the argument value is null.

C#

```
public override string Message { get; }
```

Property Value

String

The text message for this exception. The value of this property takes one of two forms, as follows.

Expand table

Condition	Value
The `actualValue` is `null`.	The `message` string passed to the constructor.
The `actualValue` is not `null`.	The `message` string appended with the string representation of the invalid argument value.

Remarks

This property overrides Message.

The error message should describe the expected values of the parameter that causes this exception. The error message should be localized.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArgumentOutOfRangeException.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the invalid argument value and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

An object that describes the source or destination of the serialized data.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` object is `null`.

Remarks

GetObjectData sets a SerializationInfo object with all the exception object data targeted for serialization. During deserialization, the exception object is reconstituted from the SerializationInfo transmitted over the stream.

For more information, see SerializationInfo.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArgumentOutOfRangeException.ThrowIfEqual<T>(T, T, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an ArgumentOutOfRangeException if `value` is equal to `other`.

```
C#

public static void ThrowIfEqual<T> (T value, T other, string? paramName =
default) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the objects to validate.

Parameters

`value` T

The argument to validate as not equal to `other`.

`other` T

The value to compare with `value`.

`paramName` String

The name of the parameter with which `value` corresponds.

Applies to

Product	Versions
.NET	8, 9

ArgumentOutOfRangeException.ThrowIfGreaterThan<T>(T, T, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an ArgumentOutOfRangeException if `value` is greater than `other`.

```
C#

public static void ThrowIfGreaterThan<T> (T value, T other, string?
paramName = default) where T : IComparable<T>;
```

Type Parameters

`T`

The type of the objects to validate.

Parameters

`value` T

The argument to validate as less than or equal to `other`.

`other` T

The value to compare with `value`.

`paramName` String

The name of the parameter with which `value` corresponds.

Applies to

Product	Versions
.NET	8, 9

ArgumentOutOfRangeException.ThrowIfGreaterThanOrEqual<T> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an ArgumentOutOfRangeException if `value` is greater than or equal to `other`.

C#

```
public static void ThrowIfGreaterThanOrEqual<T> (T value, T other, string?
paramName = default) where T : IComparable<T>;
```

Type Parameters

`T`

The type of the objects to validate.

Parameters

`value` T

The argument to validate as less than `other`.

`other` T

The value to compare with `value`.

`paramName` String

The name of the parameter with which `value` corresponds.

ArgumentOutOfRangeException.ThrowIfLessThan<T>(T, T, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an ArgumentOutOfRangeException if `value` is less than `other`.

```
C#

public static void ThrowIfLessThan<T> (T value, T other, string? paramName =
default) where T : IComparable<T>;
```

Type Parameters

T

The type of the objects to validate.

Parameters

value T

The argument to validate as greater than or equal to `other`.

other T

The value to compare with `value`.

paramName String

The name of the parameter with which `value` corresponds.

Applies to

Product	Versions
.NET	8, 9

ArgumentOutOfRangeException.ThrowIfNegative<T>(T, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws an ArgumentOutOfRangeException if `value` is negative.

```
C#

public static void ThrowIfNegative<T> (T value, string? paramName = default)
where T : System.Numerics.INumberBase<T>;
```

Type Parameters

T

The type of the object to validate.

Parameters

value T

The argument to validate as non-negative.

paramName String

The name of the parameter with which `value` corresponds.

ArithmeticException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown for errors in an arithmetic, casting, or conversion operation.

```
C#
public class ArithmeticException : SystemException
```

Inheritance Object → Exception → SystemException → ArithmeticException

Derived System.DivideByZeroException
System.NotFiniteNumberException
System.OverflowException

Remarks

ArithmeticException is the base class for the following exceptions:

- DivideByZeroException, which is thrown in integer division when the divisor is 0. For example, attempting to divide 10 by 0 throws a DivideByZeroException exception.
- NotFiniteNumberException, which is thrown when an operation is performed on or returns Double.NaN, Double.NegativeInfinity, Double.PositiveInfinity, Single.NaN, Single.NegativeInfinity, Single.PositiveInfinity, and the programming language used does not support those values.
- OverflowException, which is thrown when the result of an operation is outside the bounds of the target data type. That is, it is less than a number's `MinValue` property or greater than its `MaxValue` property. For example, attempting to assign 200 + 200 to a Byte value throws an OverflowException exception, since 400 greater than 256, the upper bound of the Byte data type.

Your code should not handle or throw this exception. Instead, you should either handle or throw one of its derived classes, since it more precisely indicates the exact nature of the error.

For a list of initial property values for an instance of ArithmeticException, see the ArithmeticException constructors.

ArithmeticException uses the HRESULT COR_E_ARITHMETIC, which has the value 0x80070216.

Constructors

Expand table

ArithmeticException()	Initializes a new instance of the ArithmeticException class.
ArithmeticException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArithmeticException class with serialized data.
ArithmeticException(String)	Initializes a new instance of the ArithmeticException class with a specified error message.
ArithmeticException(String, Exception)	Initializes a new instance of the ArithmeticException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)

Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArithmeticException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArithmeticException class.

Overloads

Expand table

ArithmeticException()	Initializes a new instance of the ArithmeticException class.
ArithmeticException(String)	Initializes a new instance of the ArithmeticException class with a specified error message.
ArithmeticException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArithmeticException class with serialized data.
ArithmeticException(String, Exception)	Initializes a new instance of the ArithmeticException class with a specified error message and a reference to the inner exception that is the cause of this exception.

ArithmeticException()

Initializes a new instance of the ArithmeticException class.

C#

```
public ArithmeticException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The arithmetic operation is not allowed." This message takes into account the current system culture.

The following table shows initial property values for an instance of ArithmeticException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArithmeticException(String)

Initializes a new instance of the ArithmeticException class with a specified error message.

C#

```
public ArithmeticException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows initial property values for an instance of ArithmeticException.

Expand table

Property	Value
InnerException	The null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArithmeticException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ArithmeticException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ArithmeticException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArithmeticException(String, Exception)

Initializes a new instance of the ArithmeticException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public ArithmeticException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows initial property values for an instance of ArithmeticException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Array Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides methods for creating, manipulating, searching, and sorting arrays, thereby serving as the base class for all arrays in the common language runtime.

C#

```
public abstract class Array : ICloneable, System.Collections.IList,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable
```

Inheritance Object → Array

Implements ICollection , IEnumerable , IList , IStructuralComparable , IStructuralEquatable , ICloneable

Examples

The following code example shows how Array.Copy copies elements between an array of type integer and an array of type Object.

C#

```
using System;
public class SamplesArray
{

    public static void Main()
    {

        // Creates and initializes a new integer array and a new Object
array.
        int[] myIntArray = new int[5] { 1, 2, 3, 4, 5 };
        Object[] myObjArray = new Object[5] { 26, 27, 28, 29, 30 };

        // Prints the initial values of both arrays.
        Console.WriteLine("Initially,");
```

```
        Console.Write("integer array:");
        PrintValues(myIntArray);
        Console.Write("Object array: ");
        PrintValues(myObjArray);

        // Copies the first two elements from the integer array to the
Object array.
        System.Array.Copy(myIntArray, myObjArray, 2);

        // Prints the values of the modified arrays.
        Console.WriteLine("\nAfter copying the first two elements of the
integer array to the Object array,");
        Console.Write("integer array:");
        PrintValues(myIntArray);
        Console.Write("Object array: ");
        PrintValues(myObjArray);

        // Copies the last two elements from the Object array to the integer
array.
        System.Array.Copy(myObjArray, myObjArray.GetUpperBound(0) - 1,
myIntArray, myIntArray.GetUpperBound(0) - 1, 2);

        // Prints the values of the modified arrays.
        Console.WriteLine("\nAfter copying the last two elements of the
Object array to the integer array,");
        Console.Write("integer array:");
        PrintValues(myIntArray);
        Console.Write("Object array: ");
        PrintValues(myObjArray);
    }

    public static void PrintValues(Object[] myArr)
    {
        foreach (Object i in myArr)
        {
            Console.Write("\t{0}", i);
        }
        Console.WriteLine();
    }

    public static void PrintValues(int[] myArr)
    {
        foreach (int i in myArr)
        {
            Console.Write("\t{0}", i);
        }
        Console.WriteLine();
    }
}
/*
This code produces the following output.

Initially,
integer array:  1       2       3       4       5
Object array:   26      27      28      29      30
```

```
After copying the first two elements of the integer array to the Object
array,
integer array:  1       2       3       4       5
Object array:   1       2       28      29      30

After copying the last two elements of the Object array to the integer
array,
integer array:  1       2       3       29      30
Object array:   1       2       28      29      30
*/
```

The following code example creates and initializes an Array and displays its properties and its elements.

C#

```
// Creates and initializes a new three-dimensional Array of type int.
Array myArr = Array.CreateInstance(typeof(int), 2, 3, 4);
for (int i = myArr.GetLowerBound(0); i <= myArr.GetUpperBound(0); i++)
{
    for (int j = myArr.GetLowerBound(1); j <= myArr.GetUpperBound(1); j++)
    {
        for (int k = myArr.GetLowerBound(2); k <= myArr.GetUpperBound(2);
k++)
        {
            myArr.SetValue((i * 100) + (j * 10) + k, i, j, k);
        }
    }
}

// Displays the properties of the Array.
Console.WriteLine("The Array has {0} dimension(s) and a total of {1}
elements.", myArr.Rank, myArr.Length);
Console.WriteLine("\tLength\tLower\tUpper");
for (int i = 0; i < myArr.Rank; i++)
{
    Console.Write("{0}:\t{1}", i, myArr.GetLength(i));
    Console.WriteLine("\t{0}\t{1}", myArr.GetLowerBound(i),
myArr.GetUpperBound(i));
}

// Displays the contents of the Array.
Console.WriteLine("The Array contains the following values:");
PrintValues(myArr);

void PrintValues(Array myArray)
{
    System.Collections.IEnumerator myEnumerator = myArray.GetEnumerator();
    int i = 0;
    int cols = myArray.GetLength(myArray.Rank - 1);
    while (myEnumerator.MoveNext())
    {
```

```
        if (i < cols)
        {
            i++;
        }
        else
        {
            Console.WriteLine();
            i = 1;
        }
        Console.Write("\t{0}", myEnumerator.Current);
    }
    Console.WriteLine();
}
// This code produces the following output.

// The Array has 3 dimension(s) and a total of 24 elements.
//     Length    Lower    Upper
// 0:  2    0    1
// 1:  3    0    2
// 2:  4    0    3
//
// The Array contains the following values:
//    0      1      2      3
//    10     11     12     13
//    20     21     22     23
//    100    101    102    103
//    110    111    112    113
//    120    121    122    123
```

Remarks

The Array class is not part of the System.Collections namespaces. However, it is still considered a collection because it is based on the IList interface.

The Array class is the base class for language implementations that support arrays. However, only the system and compilers can derive explicitly from the Array class. Users should employ the array constructs provided by the language.

An element is a value in an Array. The length of an Array is the total number of elements it can contain. The lower bound of an Array is the index of its first element. An Array can have any lower bound, but it has a lower bound of zero by default. A different lower bound can be defined when creating an instance of the Array class using CreateInstance. A multidimensional Array can have different bounds for each dimension. An array can have a maximum of 32 dimensions.

Unlike the classes in the System.Collections namespaces, Array has a fixed capacity. To increase the capacity, you must create a new Array object with the required capacity, copy the elements from the old Array object to the new one, and delete the old Array.

The array size is limited to a total of 4 billion elements, and to a maximum index of 0X7FEFFFFF in any given dimension (0X7FFFFFC7 for byte arrays and arrays of single-byte structures).

.NET Framework only: By default, the maximum size of an Array is 2 gigabytes (GB). In a 64-bit environment, you can avoid the size restriction by setting the `enabled` attribute of the gcAllowVeryLargeObjects configuration element to `true` in the run-time environment.

Single-dimensional arrays implement the System.Collections.Generic.IList<T>, System.Collections.Generic.ICollection<T>, System.Collections.Generic.IEnumerable<T>, System.Collections.Generic.IReadOnlyList<T> and System.Collections.Generic.IReadOnlyCollection<T> generic interfaces. The implementations are provided to arrays at run time, and as a result, the generic interfaces do not appear in the declaration syntax for the Array class. In addition, there are no reference topics for interface members that are accessible only by casting an array to the generic interface type (explicit interface implementations). The key thing to be aware of when you cast an array to one of these interfaces is that members which add, insert, or remove elements throw NotSupportedException.

Type objects provide information about array type declarations. Array objects with the same array type share the same Type object.

Type.IsArray and Type.GetElementType might not return the expected results with Array because if an array is cast to the type Array, the result is an object, not an array. That is, `typeof(System.Array).IsArray` returns `false`, and `typeof(System.Array).GetElementType` returns `null`.

The Array.Copy method copies elements not only between arrays of the same type but also between standard arrays of different types; it handles type casting automatically.

Some methods, such as CreateInstance, Copy, CopyTo, GetValue, and SetValue, provide overloads that accept 64-bit integers as parameters to accommodate large capacity arrays. LongLength and GetLongLength return 64-bit integers indicating the length of the array.

The Array is not guaranteed to be sorted. You must sort the Array prior to performing operations (such as BinarySearch) that require the Array to be sorted.

Using an Array object of pointers in native code is not supported and will throw a NotSupportedException for several methods.

Properties

Expand table

IsFixedSize	Gets a value indicating whether the Array has a fixed size.
IsReadOnly	Gets a value indicating whether the Array is read-only.
Is Synchronized	Gets a value indicating whether access to the Array is synchronized (thread safe).
Length	Gets the total number of elements in all the dimensions of the Array.
LongLength	Gets a 64-bit integer that represents the total number of elements in all the dimensions of the Array.
MaxLength	Gets the maximum number of elements that may be contained in an array.
Rank	Gets the rank (number of dimensions) of the Array. For example, a one-dimensional array returns 1, a two-dimensional array returns 2, and so on.
SyncRoot	Gets an object that can be used to synchronize access to the Array.

Methods

Expand table

AsReadOnly<T>(T[])	Returns a read-only wrapper for the specified array.
BinarySearch(Array, Int32, Int32, Object)	Searches a range of elements in a one-dimensional sorted array for a value, using the IComparable interface implemented by each element of the array and by the specified value.
BinarySearch(Array, Int32, Int32, Object, IComparer)	Searches a range of elements in a one-dimensional sorted array for a value, using the specified IComparer interface.
BinarySearch(Array, Object)	Searches an entire one-dimensional sorted array for a specific element, using the IComparable interface implemented by each element of the array and by the specified object.
BinarySearch(Array, Object, IComparer)	Searches an entire one-dimensional sorted array for a value using the specified IComparer interface.
BinarySearch<T>(T[], Int32, Int32, T)	Searches a range of elements in a one-dimensional sorted array for a value, using the IComparable<T> generic

	interface implemented by each element of the Array and by the specified value.
BinarySearch<T>(T[], Int32, Int32, T, IComparer<T>)	Searches a range of elements in a one-dimensional sorted array for a value, using the specified IComparer<T> generic interface.
BinarySearch<T>(T[], T)	Searches an entire one-dimensional sorted array for a specific element, using the IComparable<T> generic interface implemented by each element of the Array and by the specified object.
BinarySearch<T>(T[], T, IComparer<T>)	Searches an entire one-dimensional sorted array for a value using the specified IComparer<T> generic interface.
Clear(Array)	Clears the contents of an array.
Clear(Array, Int32, Int32)	Sets a range of elements in an array to the default value of each element type.
Clone()	Creates a shallow copy of the Array.
ConstrainedCopy(Array, Int32, Array, Int32, Int32)	Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. Guarantees that all changes are undone if the copy does not succeed completely.
ConvertAll<TInput,TOutput>(TInput[], Converter<TInput,TOutput>)	Converts an array of one type to an array of another type.
Copy(Array, Array, Int32)	Copies a range of elements from an Array starting at the first element and pastes them into another Array starting at the first element. The length is specified as a 32-bit integer.
Copy(Array, Array, Int64)	Copies a range of elements from an Array starting at the first element and pastes them into another Array starting at the first element. The length is specified as a 64-bit integer.
Copy(Array, Int32, Array, Int32, Int32)	Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. The length and the indexes are specified as 32-bit integers.
Copy(Array, Int64, Array, Int64, Int64)	Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. The length and the indexes are specified as 64-bit integers.

CopyTo(Array, Int32)	Copies all the elements of the current one-dimensional array to the specified one-dimensional array starting at the specified destination array index. The index is specified as a 32-bit integer.
CopyTo(Array, Int64)	Copies all the elements of the current one-dimensional array to the specified one-dimensional array starting at the specified destination array index. The index is specified as a 64-bit integer.
CreateInstance(Type, Int32)	Creates a one-dimensional Array of the specified Type and length, with zero-based indexing.
CreateInstance(Type, Int32, Int32)	Creates a two-dimensional Array of the specified Type and dimension lengths, with zero-based indexing.
CreateInstance(Type, Int32, Int32, Int32)	Creates a three-dimensional Array of the specified Type and dimension lengths, with zero-based indexing.
CreateInstance(Type, Int32[])	Creates a multidimensional Array of the specified Type and dimension lengths, with zero-based indexing. The dimension lengths are specified in an array of 32-bit integers.
CreateInstance(Type, Int32[], Int32[])	Creates a multidimensional Array of the specified Type and dimension lengths, with the specified lower bounds.
CreateInstance(Type, Int64[])	Creates a multidimensional Array of the specified Type and dimension lengths, with zero-based indexing. The dimension lengths are specified in an array of 64-bit integers.
Empty<T>()	Returns an empty array.
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
Exists<T>(T[], Predicate<T>)	Determines whether the specified array contains elements that match the conditions defined by the specified predicate.
Fill<T>(T[], T)	Assigns the given `value` of type `T` to each element of the specified `array`.
Fill<T>(T[], T, Int32, Int32)	Assigns the given `value` of type `T` to the elements of the specified `array` which are within the range of `startIndex` (inclusive) and the next `count` number of indices.
Find<T>(T[], Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the first

	occurrence within the entire Array.
FindAll<T>(T[], Predicate<T>)	Retrieves all the elements that match the conditions defined by the specified predicate.
FindIndex<T>(T[], Int32, Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the range of elements in the Array that starts at the specified index and contains the specified number of elements.
FindIndex<T>(T[], Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the range of elements in the Array that extends from the specified index to the last element.
FindIndex<T>(T[], Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the entire Array.
FindLast<T>(T[], Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the last occurrence within the entire Array.
FindLastIndex<T>(T[], Int32, Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the range of elements in the Array that contains the specified number of elements and ends at the specified index.
FindLastIndex<T>(T[], Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the range of elements in the Array that extends from the first element to the specified index.
FindLastIndex<T>(T[], Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the entire Array.
ForEach<T>(T[], Action<T>)	Performs the specified action on each element of the specified array.
GetEnumerator()	Returns an IEnumerator for the Array.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetLength(Int32)	Gets a 32-bit integer that represents the number of elements in the specified dimension of the Array.

GetLongLength(Int32)	Gets a 64-bit integer that represents the number of elements in the specified dimension of the Array.
GetLowerBound(Int32)	Gets the index of the first element of the specified dimension in the array.
GetType()	Gets the Type of the current instance. (Inherited from Object)
GetUpperBound(Int32)	Gets the index of the last element of the specified dimension in the array.
GetValue(Int32)	Gets the value at the specified position in the one-dimensional Array. The index is specified as a 32-bit integer.
GetValue(Int32, Int32)	Gets the value at the specified position in the two-dimensional Array. The indexes are specified as 32-bit integers.
GetValue(Int32, Int32, Int32)	Gets the value at the specified position in the three-dimensional Array. The indexes are specified as 32-bit integers.
GetValue(Int32[])	Gets the value at the specified position in the multidimensional Array. The indexes are specified as an array of 32-bit integers.
GetValue(Int64)	Gets the value at the specified position in the one-dimensional Array. The index is specified as a 64-bit integer.
GetValue(Int64, Int64)	Gets the value at the specified position in the two-dimensional Array. The indexes are specified as 64-bit integers.
GetValue(Int64, Int64, Int64)	Gets the value at the specified position in the three-dimensional Array. The indexes are specified as 64-bit integers.
GetValue(Int64[])	Gets the value at the specified position in the multidimensional Array. The indexes are specified as an array of 64-bit integers.
IndexOf(Array, Object)	Searches for the specified object and returns the index of its first occurrence in a one-dimensional array.
IndexOf(Array, Object, Int32)	Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of its first occurrence. The range extends from a specified index to the end of the array.

IndexOf(Array, Object, Int32, Int32)	Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of ifs first occurrence. The range extends from a specified index for a specified number of elements.
IndexOf<T>(T[], T)	Searches for the specified object and returns the index of its first occurrence in a one-dimensional array.
IndexOf<T>(T[], T, Int32)	Searches for the specified object in a range of elements of a one dimensional array, and returns the index of its first occurrence. The range extends from a specified index to the end of the array.
IndexOf<T>(T[], T, Int32, Int32)	Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of its first occurrence. The range extends from a specified index for a specified number of elements.
Initialize()	Initializes every element of the value-type Array by calling the parameterless constructor of the value type.
LastIndexOf(Array, Object)	Searches for the specified object and returns the index of the last occurrence within the entire one-dimensional Array.
LastIndexOf(Array, Object, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the one-dimensional Array that extends from the first element to the specified index.
LastIndexOf(Array, Object, Int32, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the one-dimensional Array that contains the specified number of elements and ends at the specified index.
LastIndexOf<T>(T[], T)	Searches for the specified object and returns the index of the last occurrence within the entire Array.
LastIndexOf<T>(T[], T, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the Array that extends from the first element to the specified index.
LastIndexOf<T>(T[], T, Int32, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the Array that contains the specified number of elements and ends at the specified index.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)

Resize<T>(T[], Int32)	Changes the number of elements of a one-dimensional array to the specified new size.
Reverse(Array)	Reverses the sequence of the elements in the entire one-dimensional Array.
Reverse(Array, Int32, Int32)	Reverses the sequence of a subset of the elements in the one-dimensional Array.
Reverse<T>(T[])	Reverses the sequence of the elements in the one-dimensional generic array.
Reverse<T>(T[], Int32, Int32)	Reverses the sequence of a subset of the elements in the one-dimensional generic array.
SetValue(Object, Int32)	Sets a value to the element at the specified position in the one-dimensional Array. The index is specified as a 32-bit integer.
SetValue(Object, Int32, Int32)	Sets a value to the element at the specified position in the two-dimensional Array. The indexes are specified as 32-bit integers.
SetValue(Object, Int32, Int32, Int32)	Sets a value to the element at the specified position in the three-dimensional Array. The indexes are specified as 32-bit integers.
SetValue(Object, Int32[])	Sets a value to the element at the specified position in the multidimensional Array. The indexes are specified as an array of 32-bit integers.
SetValue(Object, Int64)	Sets a value to the element at the specified position in the one-dimensional Array. The index is specified as a 64-bit integer.
SetValue(Object, Int64, Int64)	Sets a value to the element at the specified position in the two-dimensional Array. The indexes are specified as 64-bit integers.
SetValue(Object, Int64, Int64, Int64)	Sets a value to the element at the specified position in the three-dimensional Array. The indexes are specified as 64-bit integers.
SetValue(Object, Int64[])	Sets a value to the element at the specified position in the multidimensional Array. The indexes are specified as an array of 64-bit integers.
Sort(Array)	Sorts the elements in an entire one-dimensional Array using the IComparable implementation of each element of the Array.

Sort(Array, Array)	Sorts a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable implementation of each key.
Sort(Array, Array, IComparer)	Sorts a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer.
Sort(Array, Array, Int32, Int32)	Sorts a range of elements in a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable implementation of each key.
Sort(Array, Array, Int32, Int32, IComparer)	Sorts a range of elements in a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer.
Sort(Array, IComparer)	Sorts the elements in a one-dimensional Array using the specified IComparer.
Sort(Array, Int32, Int32)	Sorts the elements in a range of elements in a one-dimensional Array using the IComparable implementation of each element of the Array.
Sort(Array, Int32, Int32, IComparer)	Sorts the elements in a range of elements in a one-dimensional Array using the specified IComparer.
Sort<T>(T[])	Sorts the elements in an entire Array using the IComparable<T> generic interface implementation of each element of the Array.
Sort<T>(T[], Comparison<T>)	Sorts the elements in an Array using the specified Comparison<T>.
Sort<T>(T[], IComparer<T>)	Sorts the elements in an Array using the specified IComparer<T> generic interface.
Sort<T>(T[], Int32, Int32)	Sorts the elements in a range of elements in an Array using the IComparable<T> generic interface implementation of each element of the Array.
Sort<T>(T[], Int32, Int32, IComparer<T>)	Sorts the elements in a range of elements in an Array using the specified IComparer<T> generic interface.
Sort<TKey,TValue>(TKey[], TValue[])	Sorts a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the

	keys in the first Array using the IComparable<T> generic interface implementation of each key.
Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>)	Sorts a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer<T> generic interface.
Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32)	Sorts a range of elements in a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable<T> generic interface implementation of each key.
Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>)	Sorts a range of elements in a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer<T> generic interface.
ToString()	Returns a string that represents the current object. (Inherited from Object)
TrueForAll<T>(T[], Predicate<T>)	Determines whether every element in the array matches the conditions defined by the specified predicate.

Explicit Interface Implementations

Expand table

ICollection.Count	Gets the number of elements contained in the Array.
IList.Add(Object)	Calling this method always throws a NotSupportedException exception.
IList.Clear()	Removes all items from the IList.
IList.Contains(Object)	Determines whether an element is in the IList.
IList.IndexOf(Object)	Determines the index of a specific item in the IList.
IList.Insert(Int32, Object)	Inserts an item to the IList at the specified index.
IList.Item[Int32]	Gets or sets the element at the specified index.
IList.Remove(Object)	Removes the first occurrence of a specific object from the IList.
IList.RemoveAt(Int32)	Removes the IList item at the specified index.

IStructuralComparable.CompareTo(Object, IComparer)	Determines whether the current collection object precedes, occurs in the same position as, or follows another object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Determines whether an object is equal to the current instance.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Returns a hash code for the current instance.

Extension Methods

Expand table

Cast<TResult>(IEnumerable)	Casts the elements of an IEnumerable to the specified type.
OfType<TResult>(IEnumerable)	Filters the elements of an IEnumerable based on a specified type.
AsParallel(IEnumerable)	Enables parallelization of a query.
AsQueryable(IEnumerable)	Converts an IEnumerable to an IQueryable.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

Public static (`Shared` in Visual Basic) members of this type are thread safe. Any instance members are not guaranteed to be thread safe.

This implementation does not provide a synchronized (thread safe) wrapper for an Array; however, .NET classes based on Array provide their own synchronized version of the collection using the SyncRoot property.

Enumerating through a collection is intrinsically not a thread-safe procedure. Even when a collection is synchronized, other threads can still modify the collection, which causes the enumerator to throw an exception. To guarantee thread safety during enumeration, you can either lock the collection during the entire enumeration or catch the exceptions resulting from changes made by other threads.

Array.IsFixedSize Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Array has a fixed size.

```
C#
public bool IsFixedSize { get; }
```

Property Value

Boolean

This property is always `true` for all arrays.

Implements

IsFixedSize

Remarks

Array implements the IsFixedSize property because it is required by the System.Collections.IList interface.

An array with a fixed size does not allow the addition or removal of elements after the array is created, but it allows the modification of existing elements.

Retrieving the value of this property is an O(1) operation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Array.IsReadOnly Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Array is read-only.

C#

```
public bool IsReadOnly { get; }
```

Property Value

Boolean

This property is always `false` for all arrays.

Implements

IsReadOnly

Remarks

Array implements the IsReadOnly property because it is required by the System.Collections.IList interface. An array that is read-only does not allow the addition, removal, or modification of elements after the array is created.

If you require a read-only collection, use a System.Collections class that implements the System.Collections.IList interface.

If you cast or convert an array to an IList interface object, the IList.IsReadOnly property returns `false`. However, if you cast or convert an array to a IList<T> interface, the `IsReadOnly` property returns `true`.

Retrieving the value of this property is an O(1) operation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Array.IsSynchronized Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether access to the Array is synchronized (thread safe).

C#

```
public bool IsSynchronized { get; }
```

Property Value

Boolean

This property is always `false` for all arrays.

Implements

IsSynchronized

Examples

The following code example shows how to lock an array during the entire enumeration by using the SyncRoot property.

C#

```
Array myArray = new int[] { 1, 2, 4 };
lock(myArray.SyncRoot)
{
    foreach (Object item in myArray)
        Console.WriteLine(item);
}
```

Remarks

Array implements the IsSynchronized property because it is required by the System.Collections.ICollection interface.

.NET classes based on Array provide their own synchronized version of the collection using the SyncRoot property.

Classes that use arrays can also implement their own synchronization using the SyncRoot property. The synchronizing code must perform operations on the `SyncRoot` of the collection, not directly on the collection. This ensures proper operation of collections that are derived from other objects. Specifically, it maintains proper synchronization with other threads that might be simultaneously modifying the collection. Note that some implementations of SyncRoot might return the Array itself.

Enumerating through a collection is intrinsically not a thread safe procedure. Even when a collection is synchronized, other threads can still modify the collection, which causes the enumerator to throw an exception. To guarantee thread safety during enumeration, you can either lock the collection during the entire enumeration or catch the exceptions resulting from changes made by other threads.

Retrieving the value of this property is an O(1) operation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total number of elements in all the dimensions of the Array.

C#

```
public int Length { get; }
```

Property Value

Int32

The total number of elements in all the dimensions of the Array; zero if there are no elements in the array.

Exceptions

OverflowException

The array is multidimensional and contains more than Int32.MaxValue elements.

Examples

The following example uses the Length property to get the total number of elements in an array. It also uses the GetUpperBound method to determine the number of elements in each dimension of a multidimensional array.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        // Declare a single-dimensional string array
        String[] array1d = { "zero", "one", "two", "three" };
```

```
        ShowArrayInfo(array1d);

        // Declare a two-dimensional string array
        String[,] array2d = { { "zero", "0" }, { "one", "1" },
                              { "two", "2" }, { "three", "3"},
                              { "four", "4" }, { "five", "5" } };
        ShowArrayInfo(array2d);

        // Declare a three-dimensional integer array
        int[, ,] array3d = new int[,,] { { { 1, 2, 3 }, { 4, 5, 6 } },
                                         { { 7, 8, 9 }, { 10, 11, 12 } } };
        ShowArrayInfo(array3d);
    }

    private static void ShowArrayInfo(Array arr)
    {
        Console.WriteLine("Length of Array:      {0,3}", arr.Length);
        Console.WriteLine("Number of Dimensions: {0,3}", arr.Rank);
        // For multidimensional arrays, show number of elements in each
dimension.
        if (arr.Rank > 1) {
            for (int dimension = 1; dimension <= arr.Rank; dimension++)
                Console.WriteLine("   Dimension {0}: {1,3}", dimension,
                                  arr.GetUpperBound(dimension - 1) + 1);
        }
        Console.WriteLine();
    }
}
// The example displays the following output:
//       Length of Array:        4
//       Number of Dimensions:   1
//
//       Length of Array:       12
//       Number of Dimensions:   2
//          Dimension 1:   6
//          Dimension 2:   2
//
//       Length of Array:       12
//       Number of Dimensions:   3
//          Dimension 1:   2
//          Dimension 2:   2
//          Dimension 3:   3
```

Remarks

Retrieving the value of this property is an O(1) operation.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Array.LongLength Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a 64-bit integer that represents the total number of elements in all the dimensions of the Array.

C#

```
public long LongLength { get; }
```

Property Value

Int64

A 64-bit integer that represents the total number of elements in all the dimensions of the Array.

Remarks

Retrieving the value of this property is an O(1) operation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.MaxLength Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum number of elements that may be contained in an array.

C#

```
public static int MaxLength { get; }
```

Property Value

Int32

The maximum count of elements allowed in any array.

Remarks

This property represents a runtime limitation, the maximum number of elements (not bytes) the runtime will allow in an array. There is no guarantee that an allocation under this length will succeed, but all attempts to allocate a larger array will fail.

This property only applies to single-dimension, zero-bound (SZ) arrays. Length property may return larger value than this property for multi-dimensional arrays.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Array.Rank Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the rank (number of dimensions) of the Array. For example, a one-dimensional array returns 1, a two-dimensional array returns 2, and so on.

C#

```
public int Rank { get; }
```

Property Value

Int32

The rank (number of dimensions) of the Array.

Examples

The following example initializes a one-dimensional array, a two-dimensional array, and a jagged array, and retrieves the Rank property of each.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int[] array1 = new int[10];
      int[,] array2= new int[10,3];
      int[][] array3 = new int[10][];

      Console.WriteLine("{0}: {1} dimension(s)",
                        array1.ToString(), array1.Rank);
      Console.WriteLine("{0}: {1} dimension(s)",
                        array2.ToString(), array2.Rank);
      Console.WriteLine("{0}: {1} dimension(s)",
                        array3.ToString(), array3.Rank);
```

```
    }
}
// The example displays the following output:
//       System.Int32[]: 1 dimension(s)
//       System.Int32[,]: 2 dimension(s)
//       System.Int32[][]: 1 dimension(s)
```

Remarks

For example, the following code creates an array of three dimensions with a Rank property whose value is 3.

C#

```
int[,,] TDArray = new int[1,1,1];
```

A jagged array (an array of arrays) is a one-dimensional array; the value of its Rank property is 1.

Retrieving the value of this property is an O(1) operation.

Array.SyncRoot Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an object that can be used to synchronize access to the Array.

C#

```
public object SyncRoot { get; }
```

Property Value

Object

An object that can be used to synchronize access to the Array.

Implements

SyncRoot

Examples

The following code example shows how to lock an array during the entire enumeration by using the SyncRoot property.

C#

```
Array myArray = new int[] { 1, 2, 4 };
lock(myArray.SyncRoot)
{
    foreach (Object item in myArray)
        Console.WriteLine(item);
}
```

Remarks

This property implements the System.Collections.ICollection interface.

.NET classes based on Array provide their own synchronized version of the collection using the SyncRoot property.

Classes that use arrays can also implement their own synchronization using the SyncRoot property. The synchronizing code must perform operations on the `SyncRoot` of the collection, not directly on the collection. This ensures proper operation of collections that are derived from other objects. Specifically, it maintains proper synchronization with other threads that might be simultaneously modifying the collection. Note that some implementations of SyncRoot might return the Array itself.

Enumerating through a collection is intrinsically not a thread safe procedure. Even when a collection is synchronized, other threads can still modify the collection, which causes the enumerator to throw an exception. To guarantee thread safety during enumeration, you can either lock the collection during the entire enumeration or catch the exceptions resulting from changes made by other threads.

Retrieving the value of this property is an O(1) operation.

Array.AsReadOnly<T>(T[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a read-only wrapper for the specified array.

C#

```
public static System.Collections.ObjectModel.ReadOnlyCollection<T>
AsReadOnly<T> (T[] array);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based array to wrap in a read-only ReadOnlyCollection<T> wrapper.

Returns

ReadOnlyCollection<T>

A read-only ReadOnlyCollection<T> wrapper for the specified array.

Exceptions

ArgumentNullException

`array` is `null`.

Examples

The following example wraps an array in a read-only ReadOnlyCollection<T>.

C#

```
using System;
using System.Collections.Generic;

public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new string array.
      String[] myArr = { "The", "quick", "brown", "fox" };

      // Display the values of the array.
      Console.WriteLine( "The string array initially contains the following
values:" );
      PrintIndexAndValues( myArr );

      // Create a read-only IList wrapper around the array.
      IList<string> myList = Array.AsReadOnly( myArr );

      // Display the values of the read-only IList.
      Console.WriteLine( "The read-only IList contains the following
values:" );
      PrintIndexAndValues( myList );

      // Attempt to change a value through the wrapper.
      try  {
         myList[3] = "CAT";
      }
      catch ( NotSupportedException e )  {
         Console.WriteLine( "{0} - {1}", e.GetType(), e.Message );
         Console.WriteLine();
      }

      // Change a value in the original array.
      myArr[2] = "RED";

      // Display the values of the array.
      Console.WriteLine( "After changing the third element, the string array
contains the following values:" );
      PrintIndexAndValues( myArr );

      // Display the values of the read-only IList.
      Console.WriteLine( "After changing the third element, the read-only
IList contains the following values:" );
      PrintIndexAndValues( myList );
   }

   public static void PrintIndexAndValues( String[] myArr )  {
      for ( int i = 0; i < myArr.Length; i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, myArr[i] );
      }
      Console.WriteLine();
   }
```

```
    public static void PrintIndexAndValues( IList<string> myList )  {
        for ( int i = 0; i < myList.Count; i++ )  {
            Console.WriteLine( "   [{0}] : {1}", i, myList[i] );
        }
        Console.WriteLine();
    }
}

/*
This code produces the following output.

The string array initially contains the following values:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox

The read-only IList contains the following values:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox

System.NotSupportedException - Collection is read-only.

After changing the third element, the string array contains the following
values:
   [0] : The
   [1] : quick
   [2] : RED
   [3] : fox

After changing the third element, the read-only IList contains the following
values:
   [0] : The
   [1] : quick
   [2] : RED
   [3] : fox

*/
```

Remarks

To prevent any modifications to the array, expose the array only through this wrapper.

A collection that is read-only is simply a collection with a wrapper that prevents modifying the collection; therefore, if changes are made to the underlying collection, the read-only collection reflects those changes.

This method is an O(1) operation.

Array.BinarySearch Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches a one-dimensional sorted Array for a value, using a binary search algorithm.

Overloads

Expand table

BinarySearch(Array, Object)	Searches an entire one-dimensional sorted array for a specific element, using the IComparable interface implemented by each element of the array and by the specified object.
BinarySearch(Array, Object, IComparer)	Searches an entire one-dimensional sorted array for a value using the specified IComparer interface.
BinarySearch(Array, Int32, Int32, Object)	Searches a range of elements in a one-dimensional sorted array for a value, using the IComparable interface implemented by each element of the array and by the specified value.
BinarySearch(Array, Int32, Int32, Object, IComparer)	Searches a range of elements in a one-dimensional sorted array for a value, using the specified IComparer interface.
BinarySearch<T>(T[], T)	Searches an entire one-dimensional sorted array for a specific element, using the IComparable<T> generic interface implemented by each element of the Array and by the specified object.
BinarySearch<T>(T[], T, IComparer<T>)	Searches an entire one-dimensional sorted array for a value using the specified IComparer<T> generic interface.
BinarySearch<T>(T[], Int32, Int32, T)	Searches a range of elements in a one-dimensional sorted array for a value, using the IComparable<T> generic interface implemented by each element of the Array and by the specified value.
BinarySearch<T>(T[], Int32, Int32, T, IComparer<T>)	Searches a range of elements in a one-dimensional sorted array for a value, using the specified IComparer<T> generic interface.

BinarySearch(Array, Object)

Searches an entire one-dimensional sorted array for a specific element, using the IComparable interface implemented by each element of the array and by the specified object.

```
C#
public static int BinarySearch (Array array, object? value);
```

Parameters

`array` Array

The sorted one-dimensional Array to search.

`value` Object

The object to search for.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentException

`value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`value` does not implement the IComparable interface, and the search encounters an element that does not implement the IComparable interface.

Examples

The following code example shows how to use BinarySearch to locate a specific object in an Array.

> **Note**
>
> The array is created with its elements in ascending sort order. The **BinarySearch** method requires the array to be sorted in ascending order.

C#

```
using System;

public class SamplesArray
{
    public static void Main()
    {
        // Creates and initializes a new Array.
        Array myIntArray = Array.CreateInstance(typeof(int), 5);

        myIntArray.SetValue(8, 0);
        myIntArray.SetValue(2, 1);
        myIntArray.SetValue(6, 2);
        myIntArray.SetValue(3, 3);
        myIntArray.SetValue(7, 4);

        // Do the required sort first
        Array.Sort(myIntArray);

        // Displays the values of the Array.
        Console.WriteLine( "The int array contains the following:" );
        PrintValues(myIntArray);

        // Locates a specific object that does not exist in the Array.
        object myObjectOdd = 1;
        FindMyObject( myIntArray, myObjectOdd );

        // Locates an object that exists in the Array.
        object myObjectEven = 6;
        FindMyObject(myIntArray, myObjectEven);
    }
```

```
    public static void FindMyObject(Array myArr, object myObject)
    {
        int myIndex=Array.BinarySearch(myArr, myObject);
        if (myIndex < 0)
        {
            Console.WriteLine("The object to search for ({0}) is not
found. The next larger object is at index {1}.", myObject, ~myIndex );
        }
        else
        {
            Console.WriteLine("The object to search for ({0}) is at index
{1}.", myObject, myIndex );
        }
    }

    public static void PrintValues(Array myArr)
    {
        int i = 0;
        int cols = myArr.GetLength(myArr.Rank - 1);
        foreach (object o in myArr)
        {
            if ( i < cols )
            {
                i++;
            }
            else
            {
                Console.WriteLine();
                i = 1;
            }
            Console.Write( "\t{0}", o);
        }
        Console.WriteLine();
    }
}
// This code produces the following output.
//
//The int array contains the following:
//        2       3       6       7       8
//The object to search for (1) is not found. The next larger object is at
index 0
//
//The object to search for (6) is at index 2.
```

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the Array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is one greater than the upper bound of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

Either `value` or every element of `array` must implement the IComparable interface, which is used for comparisons. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable implementation; otherwise, the result might be incorrect.

> ⓘ **Note**
>
> If `value` does not implement the **IComparable** interface, the elements of `array` are not tested for **IComparable** before the search begins. An exception is thrown if the search encounters an element that does not implement **IComparable**.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception.

> ⓘ **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable** implementation, even if `value` is `null`. That is, the **IComparable** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is the Length of `array`.

UWP	10.0

BinarySearch(Array, Object, IComparer)

Searches an entire one-dimensional sorted array for a value using the specified IComparer interface.

C#

```
public static int BinarySearch (Array array, object? value,
System.Collections.IComparer? comparer);
```

Parameters

`array` Array

The sorted one-dimensional Array to search.

`value` Object

The object to search for.

`comparer` IComparer

The IComparer implementation to use when comparing elements.

-or-

`null` to use the IComparable implementation of each element.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentException

`comparer` is `null`, and `value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`comparer` is `null`, `value` does not implement the IComparable interface, and the search encounters an element that does not implement the IComparable interface.

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the Array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is one greater than the upper bound of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

The comparer customizes how the elements are compared. For example, you can use a System.Collections.CaseInsensitiveComparer as the comparer to perform case-

insensitive string searches.

If `comparer` is not `null`, the elements of `array` are compared to the specified value using the specified IComparer implementation. The elements of `array` must already be sorted in increasing value according to the sort order defined by `comparer`; otherwise, the result might be incorrect.

If `comparer` is `null`, the comparison is done using the IComparable implementation provided by the element itself or by the specified value. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable implementation; otherwise, the result might be incorrect.

> ⓘ **Note**
>
> If `comparer` is `null` and `value` does not implement the **IComparable** interface, the elements of `array` are not tested for **IComparable** before the search begins. An exception is thrown if the search encounters an element that does not implement **IComparable**.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception.

> ⓘ **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable** implementation, even if `value` is `null`. That is, the **IComparable** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is the Length of `array`.

BinarySearch(Array, Int32, Int32, Object)

Searches a range of elements in a one-dimensional sorted array for a value, using the IComparable interface implemented by each element of the array and by the specified value.

C#

```
public static int BinarySearch (Array array, int index, int length,
object? value);
```

Parameters

`array` Array

The sorted one-dimensional Array to search.

`index` Int32

The starting index of the range to search.

`length` Int32

The length of the range to search.

`value` Object

The object to search for.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

-or-

`value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`value` does not implement the IComparable interface, and the search encounters an element that does not implement the IComparable interface.

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the Array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is one greater than the upper bound of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

Either `value` or every element of `array` must implement the IComparable interface, which is used for comparisons. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable implementation; otherwise, the result might be incorrect.

> ⓘ **Note**
>
> If `value` does not implement the **IComparable** interface, the elements of `array` are not tested for **IComparable** before the search begins. An exception is thrown if the search encounters an element that does not implement **IComparable**.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception.

> ⓘ **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable** implementation, even if `value` is `null`. That is, the **IComparable** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is `length`.

BinarySearch(Array, Int32, Int32, Object, IComparer)

Searches a range of elements in a one-dimensional sorted array for a value, using the specified IComparer interface.

C#

```
public static int BinarySearch (Array array, int index, int length,
object? value, System.Collections.IComparer? comparer);
```

Parameters

`array` Array

The sorted one-dimensional Array to search.

`index` Int32

The starting index of the range to search.

`length` Int32

The length of the range to search.

`value` Object

The object to search for.

`comparer` IComparer

The IComparer implementation to use when comparing elements.

-or-

`null` to use the IComparable implementation of each element.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

-or-

`comparer` is `null`, and `value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`comparer` is `null`, `value` does not implement the IComparable interface, and the search encounters an element that does not implement the IComparable interface.

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the Array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is one greater than the upper bound of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

The comparer customizes how the elements are compared. For example, you can use a System.Collections.CaseInsensitiveComparer as the comparer to perform case-insensitive string searches.

If `comparer` is not `null`, the elements of `array` are compared to the specified value using the specified IComparer implementation. The elements of `array` must already be sorted in increasing value according to the sort order defined by `comparer`; otherwise, the result might be incorrect.

If `comparer` is `null`, the comparison is done using the IComparable implementation provided by the element itself or by the specified value. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable implementation; otherwise, the result might be incorrect.

> **Note**
>
> If `comparer` is `null` and `value` does not implement the **IComparable** interface, the elements of `array` are not tested for **IComparable** before the search begins. An exception is thrown if the search encounters an element that does not implement **IComparable**.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception when using IComparable.

> **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable** implementation, even if `value` is `null`. That is, the **IComparable** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is `length`.

BinarySearch<T>(T[], T)

Searches an entire one-dimensional sorted array for a specific element, using the IComparable<T> generic interface implemented by each element of the Array and by the specified object.

C#

```
public static int BinarySearch<T> (T[] array, T value);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The sorted one-dimensional, zero-based Array to search.

`value` T

The object to search for.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

InvalidOperationException

`T` does not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<T>(T[]) generic method overload and the BinarySearch<T>(T[], T) generic method overload. An array of strings is created, in no particular order.

The array is displayed, sorted, and displayed again. Arrays must be sorted in order to use the BinarySearch method.

> **Note**
>
> The calls to the **Sort** and **BinarySearch** generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, F#, C#, and C++ infer the type of the generic type parameter from the type of the first argument. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

The BinarySearch<T>(T[], T) generic method overload is then used to search for two strings, one that is not in the array and one that is. The array and the return value of the BinarySearch method are passed to the `ShowWhere` generic method (the `showWhere` function in the F# example), which displays the index value if the string is found, and otherwise the elements the search string would fall between if it were in the array. The index is negative if the string is not in the array, so the `ShowWhere` method takes the bitwise complement (the ~ operator in C# and Visual C++, the ~~~ operator in F#, `Xor`-1 in Visual Basic) to obtain the index of the first element in the list that is larger than the search string.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {"Pachycephalosaurus",
                              "Amargasaurus",
                              "Tyrannosaurus",
                              "Mamenchisaurus",
                              "Deinonychus",
                              "Edmontosaurus"};

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nSort");
        Array.Sort(dinosaurs);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
```

```
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nBinarySearch for 'Coelophysis':");
        int index = Array.BinarySearch(dinosaurs, "Coelophysis");
        ShowWhere(dinosaurs, index);

        Console.WriteLine("\nBinarySearch for 'Tyrannosaurus':");
        index = Array.BinarySearch(dinosaurs, "Tyrannosaurus");
        ShowWhere(dinosaurs, index);
    }

    private static void ShowWhere<T>(T[] array, int index)
    {
        if (index<0)
        {
            // If the index is negative, it represents the bitwise
            // complement of the next larger element in the array.
            //
            index = ~index;

            Console.Write("Not found. Sorts between: ");

            if (index == 0)
                Console.Write("beginning of array and ");
            else
                Console.Write("{0} and ", array[index-1]);

            if (index == array.Length)
                Console.WriteLine("end of array.");
            else
                Console.WriteLine("{0}.", array[index]);
        }
        else
        {
            Console.WriteLine("Found at index {0}.", index);
        }
    }
}

/* This code example produces the following output:

Pachycephalosaurus
Amargasaurus
Tyrannosaurus
Mamenchisaurus
Deinonychus
Edmontosaurus

Sort

Amargasaurus
Deinonychus
Edmontosaurus
Mamenchisaurus
```

```
Pachycephalosaurus
Tyrannosaurus

BinarySearch for 'Coelophysis':
Not found. Sorts between: Amargasaurus and Deinonychus.

BinarySearch for 'Tyrannosaurus':
Found at index 5.
 */
```

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If `array` does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is equal to the size of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

`T` must implement the IComparable<T> generic interface, which is used for comparisons. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable<T> implementation; otherwise, the result might be incorrect.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception.

> **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable<T>** implementation, even if `value` is `null`. That is, the **IComparable<T>** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is the Length of `array`.

BinarySearch<T>(T[], T, IComparer<T>)

Searches an entire one-dimensional sorted array for a value using the specified IComparer<T> generic interface.

C#

```
public static int BinarySearch<T> (T[] array, T value,
System.Collections.Generic.IComparer<T>? comparer);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The sorted one-dimensional, zero-based Array to search.

`value` T

The object to search for.

`comparer` IComparer<T>

The IComparer<T> implementation to use when comparing elements.

-or-

`null` to use the IComparable<T> implementation of each element.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentException

`comparer` is `null`, and `value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`comparer` is `null`, and `T` does not implement the IComparable<T> generic interface

Examples

The following example demonstrates the Sort<T>(T[], IComparer<T>) generic method overload and the BinarySearch<T>(T[], T, IComparer<T>) generic method overload.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls

the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The array is displayed, sorted, and displayed again. Arrays must be sorted in order to use the BinarySearch method.

> ⓘ **Note**
>
> The calls to the **Sort<T>(T[], IComparer<T>)** and **BinarySearch<T>(T[], T, IComparer<T>)** generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, C#, and C++ infer the type of the generic type parameter from the type of the first argument. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

The BinarySearch<T>(T[], T, IComparer<T>) generic method overload is then used to search for two strings, one that is not in the array and one that is. The array and the return value of the BinarySearch<T>(T[], T, IComparer<T>) method are passed to the `ShowWhere` generic method (the `showWhere` function in the F# example), which displays the index value if the string is found, and otherwise the elements the search string would fall between if it were in the array. The index is negative if the string is not n the array, so the `ShowWhere` method takes the bitwise complement (the ~ operator in C# and Visual C++, the ~~~ operator in F#, `Xor` -1 in Visual Basic) to obtain the index of the first element in the list that is larger than the search string.

C#

```
using System;
using System.Collections.Generic;

public class ReverseComparer: IComparer<string>
{
    public int Compare(string x, string y)
    {
        // Compare y and x in reverse order.
        return y.CompareTo(x);
    }
}

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {"Pachycephalosaurus",
                              "Amargasaurus",
                              "Tyrannosaurus",
```

```
                                "Mamenchisaurus",
                                "Deinonychus",
                                "Edmontosaurus"};

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        ReverseComparer rc = new ReverseComparer();

        Console.WriteLine("\nSort");
        Array.Sort(dinosaurs, rc);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nBinarySearch for 'Coelophysis':");
        int index = Array.BinarySearch(dinosaurs, "Coelophysis", rc);
        ShowWhere(dinosaurs, index);

        Console.WriteLine("\nBinarySearch for 'Tyrannosaurus':");
        index = Array.BinarySearch(dinosaurs, "Tyrannosaurus", rc);
        ShowWhere(dinosaurs, index);
    }

    private static void ShowWhere<T>(T[] array, int index)
    {
        if (index<0)
        {
            // If the index is negative, it represents the bitwise
            // complement of the next larger element in the array.
            //
            index = ~index;

            Console.Write("Not found. Sorts between: ");

            if (index == 0)
                Console.Write("beginning of array and ");
            else
                Console.Write("{0} and ", array[index-1]);

            if (index == array.Length)
                Console.WriteLine("end of array.");
            else
                Console.WriteLine("{0}.", array[index]);
        }
        else
        {
            Console.WriteLine("Found at index {0}.", index);
        }
```

```
    }
}

/* This code example produces the following output:

Pachycephalosaurus
Amargasaurus
Tyrannosaurus
Mamenchisaurus
Deinonychus
Edmontosaurus

Sort

Tyrannosaurus
Pachycephalosaurus
Mamenchisaurus
Edmontosaurus
Deinonychus
Amargasaurus

BinarySearch for 'Coelophysis':
Not found. Sorts between: Deinonychus and Amargasaurus.

BinarySearch for 'Tyrannosaurus':
Found at index 0.
 */
```

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the Array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is equal to the size of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

The comparer customizes how the elements are compared. For example, you can use a System.Collections.CaseInsensitiveComparer as the comparer to perform case-insensitive string searches.

If `comparer` is not `null`, the elements of `array` are compared to the specified value using the specified IComparer<T> generic interface implementation. The elements of `array` must already be sorted in increasing value according to the sort order defined by `comparer`; otherwise, the result might be incorrect.

If `comparer` is `null`, the comparison is done using the IComparable<T> generic interface implementation provided by `T`. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable<T> implementation; otherwise, the result might be incorrect.

> **Note**
>
> If `comparer` is `null` and `value` does not implement the **IComparable<T>** generic interface, the elements of `array` are not tested for **IComparable<T>** before the search begins. An exception is thrown if the search encounters an element that does not implement **IComparable<T>**.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception.

> **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable<T>** implementation, even if `value` is `null`. That is, the **IComparable<T>** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is the Length of `array`.

BinarySearch<T>(T[], Int32, Int32, T)

Searches a range of elements in a one-dimensional sorted array for a value, using the IComparable<T> generic interface implemented by each element of the Array and by the specified value.

C#

```
public static int BinarySearch<T> (T[] array, int index, int length, T
value);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The sorted one-dimensional, zero-based Array to search.

`index` Int32

The starting index of the range to search.

`length` Int32

The length of the range to search.

`value` T

The object to search for.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

-or-

`value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`T` does not implement the IComparable<T> generic interface.

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual

Basic) to the negative result to produce an index. If this index is equal to the size of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

`T` must implement the IComparable<T> generic interface, which is used for comparisons. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable<T> implementation; otherwise, the result might be incorrect.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception.

> ⓘ **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable<T>** implementation, even if `value` is `null`. That is, the **IComparable<T>** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is `length`.

BinarySearch<T>(T[], Int32, Int32, T, IComparer<T>)

Searches a range of elements in a one-dimensional sorted array for a value, using the specified IComparer<T> generic interface.

C#

```
public static int BinarySearch<T> (T[] array, int index, int length, T
value, System.Collections.Generic.IComparer<T>? comparer);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The sorted one-dimensional, zero-based Array to search.

`index` Int32

The starting index of the range to search.

`length` Int32

The length of the range to search.

`value` T

The object to search for.

`comparer` IComparer<T>

The IComparer<T> implementation to use when comparing elements.

-or-

`null` to use the IComparable<T> implementation of each element.

Returns

Int32

The index of the specified `value` in the specified `array`, if `value` is found; otherwise, a negative number. If `value` is not found and `value` is less than one or more elements in `array`, the negative number returned is the bitwise complement of the index of the first element that is larger than `value`. If `value` is not found and `value` is greater than all elements in `array`, the negative number returned is the bitwise complement of (the index of the last element plus 1). If this method is called with a non-sorted `array`, the return value can be incorrect and a negative number could be returned, even if `value` is present in `array`.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

-or-

`comparer` is `null`, and `value` is of a type that is not compatible with the elements of `array`.

InvalidOperationException

`comparer` is `null`, and `T` does not implement the IComparable<T> generic interface.

Remarks

This method does not support searching arrays that contain negative indexes. `array` must be sorted before calling this method.

If the array does not contain the specified value, the method returns a negative integer. You can apply the bitwise complement operator (~ in C#, `Not` in Visual Basic) to the negative result to produce an index. If this index is equal to the size of the array, there are no elements larger than `value` in the array. Otherwise, it is the index of the first element that is larger than `value`.

The comparer customizes how the elements are compared. For example, you can use a System.Collections.CaseInsensitiveComparer as the comparer to perform case-insensitive string searches.

If `comparer` is not `null`, the elements of `array` are compared to the specified value using the specified IComparer<T> generic interface implementation. The elements of `array` must already be sorted in increasing value according to the sort order defined by `comparer`; otherwise, the result might be incorrect.

If `comparer` is `null`, the comparison is done using the IComparable<T> generic interface implementation provided for type `T`. The elements of `array` must already be sorted in increasing value according to the sort order defined by the IComparable<T> implementation; otherwise, the result might be incorrect.

Duplicate elements are allowed. If the Array contains more than one element equal to `value`, the method returns the index of only one of the occurrences, and not necessarily the first one.

`null` can always be compared with any other reference type; therefore, comparisons with `null` do not generate an exception when using IComparable<T>.

> **Note**
>
> For every element tested, `value` is passed to the appropriate **IComparable<T>** implementation, even if `value` is `null`. That is, the **IComparable<T>** implementation determines how a given element compares to `null`.

This method is an O(log `n`) operation, where `n` is `length`.

Array.Clear Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Clear(Array)	Clears the contents of an array.
Clear(Array, Int32, Int32)	Sets a range of elements in an array to the default value of each element type.

Clear(Array)

Clears the contents of an array.

C#

```
public static void Clear (Array array);
```

Parameters

`array` Array

The array to clear.

Exceptions

ArgumentNullException

`array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Clear(Array, Int32, Int32)

Sets a range of elements in an array to the default value of each element type.

```
C#
public static void Clear (Array array, int index, int length);
```

Parameters

`array` Array

The array whose elements need to be cleared.

`index` Int32

The starting index of the range of elements to clear.

`length` Int32

The number of elements to clear.

Exceptions

ArgumentNullException

`array` is `null`.

IndexOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

-or-

The sum of `index` and `length` is greater than the size of `array`.

Examples

The following example uses the Clear method to reset integer values in a one-dimensional, two-dimensional, and three-dimensional array.

C#

```
using System;

class Example
{
    public static void Main()
    {
        Console.WriteLine("One dimension (Rank=1):");
        int[] numbers1 = { 1, 2, 3, 4, 5, 6, 7, 8, 9 };

        for (int i = 0; i < 9; i++)
        {
            Console.Write("{0} ", numbers1[i]);
        }
        Console.WriteLine();
        Console.WriteLine();

        Console.WriteLine("Array.Clear(numbers1, 2, 5)");
        Array.Clear(numbers1, 2, 5);

        for (int i = 0; i < 9; i++)
        {
            Console.Write("{0} ", numbers1[i]);
        }
        Console.WriteLine();
        Console.WriteLine();

        Console.WriteLine("Two dimensions (Rank=2):");
        int[,] numbers2 = { { 1, 2, 3 }, { 4, 5, 6 }, { 7, 8, 9 } };

        for (int i = 0; i < 3; i++)
        {
            for (int j = 0; j < 3; j++)
            {
                Console.Write("{0} ", numbers2[i, j]);
            }
            Console.WriteLine();
        }

        Console.WriteLine();
        Console.WriteLine("Array.Clear(numbers2, 2, 5)");
        Array.Clear(numbers2, 2, 5);

        for (int i = 0; i < 3; i++)
        {
            for (int j = 0; j < 3; j++)
            {
                Console.Write("{0} ", numbers2[i, j]);
            }
            Console.WriteLine();
```

```
        }

        Console.WriteLine("Three dimensions (Rank=3):");
        int[, ,] numbers3 = {{{1, 2}, {3, 4}},
                             {{5, 6}, {7, 8}},
                             {{9, 10}, {11, 12}}};

        for (int i = 0; i < 2; i++)
        {
            for (int j = 0; j < 2; j++)
            {
                for (int k = 0; k < 2; k++)
                {
                    Console.Write("{0} ", numbers3[i, j, k]);
                }
                Console.WriteLine();
            }
            Console.WriteLine();
        }

        Console.WriteLine("Array.Clear(numbers3, 2, 5)");
        Array.Clear(numbers3, 2, 5);

        for (int i = 0; i < 2; i++)
        {
            for (int j = 0; j < 2; j++)
            {
                for (int k = 0; k < 2; k++)
                {
                    Console.Write("{0} ", numbers3[i, j, k]);
                }
                Console.WriteLine();
            }
            Console.WriteLine();
        }
    }
}
/*  This code example produces the following output:
 *
 * One dimension (Rank=1):
 * 1 2 3 4 5 6 7 8 9
 *
 * Array.Clear(numbers1, 2, 5)
 * 1 2 0 0 0 0 0 8 9
 *
 * Two dimensions (Rank=2):
 * 1 2 3
 * 4 5 6
 * 7 8 9
 *
 * Array.Clear(numbers2, 2, 5)
 * 1 2 0
 * 0 0 0
 * 0 8 9
 *
```

```
 * Three dimensions (Rank=3):
 * 1 2
 * 3 4
 *
 * 5 6
 * 7 8
 *
 * Array.Clear(numbers3, 2, 5)
 * 1 2
 * 0 0
 *
 * 0 0
 * 0 8
 */
```

The following example defines a `TimeZoneTime` structure that includes a TimeZoneInfo field and a DateTimeOffset field. It then calls the Clear method to clear one element in a two-element array of `TimeZoneTime` values. The method sets the value of the cleared element to the default value of a TimeZoneInfo object, which is `null`, and the default value of a DateTimeOffset object, which is DateTimeOffset.MinValue.

C#

```
using System;

public struct TimeZoneTime
{
   private DateTimeOffset dt;
   private TimeZoneInfo tz;

   public TimeZoneTime(DateTimeOffset dateTime, TimeZoneInfo timeZone)
   {
      dt = dateTime;
      tz = timeZone;
   }

   public DateTimeOffset DateTime
   { get { return dt; } }

   public TimeZoneInfo TimeZone
   { get { return tz; } }
}

public class Example
{
   public static void Main()
   {
      // Declare an array with two elements.
      TimeZoneTime[] timeZoneTimes = { new TimeZoneTime(DateTime.Now,
TimeZoneInfo.Local),
```

```
                                        new TimeZoneTime(DateTime.Now,
TimeZoneInfo.Utc) };
      foreach (var timeZoneTime in timeZoneTimes)
         Console.WriteLine("{0}: {1:G}",
                           timeZoneTime.TimeZone == null ? "<null>" :
timeZoneTime.TimeZone.ToString(),
                           timeZoneTime.DateTime);
      Console.WriteLine();

      Array.Clear(timeZoneTimes, 1, 1);
      foreach (var timeZoneTime in timeZoneTimes)
         Console.WriteLine("{0}: {1:G}",
                           timeZoneTime.TimeZone == null ? "<null>" :
timeZoneTime.TimeZone.ToString(),
                           timeZoneTime.DateTime);
   }
}
// The example displays the following output:
//       (UTC-08:00) Pacific Time (US & Canada): 1/20/2014 12:11:00 PM
//       UTC: 1/20/2014 12:11:00 PM
//
//       (UTC-08:00) Pacific Time (US & Canada): 1/20/2014 12:11:00 PM
//       <null>: 1/1/0001 12:00:00 AM
```

Remarks

This method resets each element in an array to the element type's default value. It sets elements of reference types (including String elements) to `null`, and sets elements of value types to the default values shown in the following table.

Expand table

Type	Value
Boolean	`false`
All integral and floating point numeric types	0 (zero)
DateTime	DateTime.MinValue
Other value types	Default value of the type's fields

The range of cleared elements wrap from row to row in a multi-dimensional array.

This method only clears the values of the elements; it does not delete the elements themselves. An array has a fixed size; therefore, elements cannot be added or removed.

This method is an O(`n`) operation, where `n` is `length`.

Array.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a shallow copy of the Array.

C#

```
public object Clone ();
```

Returns

Object

A shallow copy of the Array.

Implements

Clone()

Examples

The following code example clones a System.Globalization.CultureInfo array and demonstrates the behavior of a shallow copy.

C#

```
using System;
using System.Globalization;
public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new CultureInfo array.
      CultureInfo ci0 = new CultureInfo( "ar-SA", false );
      CultureInfo ci1 = new CultureInfo( "en-US", false );
      CultureInfo ci2 = new CultureInfo( "fr-FR", false );
      CultureInfo ci3 = new CultureInfo( "ja-JP", false );
      CultureInfo[] arrCI = new CultureInfo[] { ci0, ci1, ci2, ci3 };
```

```
      // Create a clone of the CultureInfo array.
      CultureInfo[] arrCIClone = (CultureInfo[]) arrCI.Clone();

      // Replace an element in the clone array.
      CultureInfo ci4 = new CultureInfo( "th-TH", false );
      arrCIClone[0] = ci4;

      // Display the contents of the original array.
      Console.WriteLine( "The original array contains the following values:"
);
      PrintIndexAndValues( arrCI );

      // Display the contents of the clone array.
      Console.WriteLine( "The clone array contains the following values:" );
      PrintIndexAndValues( arrCIClone );

      // Display the DateTimeFormatInfo.DateSeparator for the fourth element
in both arrays.
      Console.WriteLine( "Before changes to the clone:" );
      Console.WriteLine( "   Original: The DateTimeFormatInfo.DateSeparator
for {0} is {1}.", arrCI[3].Name, arrCI[3].DateTimeFormat.DateSeparator );
      Console.WriteLine( "      Clone: The DateTimeFormatInfo.DateSeparator
for {0} is {1}.", arrCIClone[3].Name,
arrCIClone[3].DateTimeFormat.DateSeparator );

      // Replace the DateTimeFormatInfo.DateSeparator for the fourth element
in the clone array.
      arrCIClone[3].DateTimeFormat.DateSeparator = "-";

      // Display the DateTimeFormatInfo.DateSeparator for the fourth element
in both arrays.
      Console.WriteLine( "After changes to the clone:" );
      Console.WriteLine( "   Original: The DateTimeFormatInfo.DateSeparator
for {0} is {1}.", arrCI[3].Name, arrCI[3].DateTimeFormat.DateSeparator );
      Console.WriteLine( "      Clone: The DateTimeFormatInfo.DateSeparator
for {0} is {1}.", arrCIClone[3].Name,
arrCIClone[3].DateTimeFormat.DateSeparator );
   }

   public static void PrintIndexAndValues( Array myArray )  {
      for ( int i = myArray.GetLowerBound(0); i <= myArray.GetUpperBound(0);
i++ )
         Console.WriteLine( "\t[{0}]:\t{1}", i, myArray.GetValue( i ) );
   }
}

/*
This code produces the following output.

The original array contains the following values:
        [0]:    ar-SA
        [1]:    en-US
        [2]:    fr-FR
```

```
        [3]:    ja-JP
The clone array contains the following values:
        [0]:    th-TH
        [1]:    en-US
        [2]:    fr-FR
        [3]:    ja-JP
Before changes to the clone:
   Original: The DateTimeFormatInfo.DateSeparator for ja-JP is /.
      Clone: The DateTimeFormatInfo.DateSeparator for ja-JP is /.
After changes to the clone:
   Original: The DateTimeFormatInfo.DateSeparator for ja-JP is -.
      Clone: The DateTimeFormatInfo.DateSeparator for ja-JP is -.

*/
```

Remarks

A shallow copy of an Array copies only the elements of the Array, whether they are reference types or value types, but it does not copy the objects that the references refer to. The references in the new Array point to the same objects that the references in the original Array point to.

In contrast, a deep copy of an Array copies the elements and everything directly or indirectly referenced by the elements.

The clone is of the same Type as the original Array.

This method is an O(`n`) operation, where `n` is Length.

Array.ConstrainedCopy(Array, Int32, Array, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. Guarantees that all changes are undone if the copy does not succeed completely.

```
C#

public static void ConstrainedCopy (Array sourceArray, int sourceIndex,
Array destinationArray, int destinationIndex, int length);
```

Parameters

`sourceArray` Array

The Array that contains the data to copy.

`sourceIndex` Int32

A 32-bit integer that represents the index in the `sourceArray` at which copying begins.

`destinationArray` Array

The Array that receives the data.

`destinationIndex` Int32

A 32-bit integer that represents the index in the `destinationArray` at which storing begins.

`length` Int32

A 32-bit integer that represents the number of elements to copy.

Exceptions

ArgumentNullException

`sourceArray` is `null`.

-or-

`destinationArray` is `null`.

RankException

`sourceArray` and `destinationArray` have different ranks.

ArrayTypeMismatchException

The `sourceArray` type is neither the same as nor derived from the `destinationArray` type.

InvalidCastException

At least one element in `sourceArray` cannot be cast to the type of `destinationArray`.

ArgumentOutOfRangeException

`sourceIndex` is less than the lower bound of the first dimension of `sourceArray`.

-or-

`destinationIndex` is less than the lower bound of the first dimension of `destinationArray`.

-or-

`length` is less than zero.

ArgumentException

`length` is greater than the number of elements from `sourceIndex` to the end of `sourceArray`.

-or-

`length` is greater than the number of elements from `destinationIndex` to the end of `destinationArray`.

Remarks

The `sourceArray` and `destinationArray` parameters must have the same number of dimensions. The `sourceArray` type must be the same as or derived from the `destinationArray` type; otherwise, an ArrayTypeMismatchException is thrown. Unlike

Copy, ConstrainedCopy verifies the compatibility of the array types before performing any operation.

When copying between multidimensional arrays, the array behaves like a long one-dimensional array, where the rows (or columns) are conceptually laid end-to-end. For example, if an array has three rows (or columns) with four elements each, copying six elements from the beginning of the array would copy all four elements of the first row (or column) and the first two elements of the second row (or column). To start copying from the second element of the third row (or column), `sourceIndex` must be the upper bound of the first row (or column) plus the length of the second row (or column) plus two.

If `sourceArray` and `destinationArray` overlap, this method behaves as if the original values of `sourceArray` were preserved in a temporary location before `destinationArray` is overwritten.

[C++]

This method is equivalent to the standard C/C++ function `memmove`, not `memcpy`.

The arrays can be reference-type arrays or value-type arrays. If `sourceArray` and `destinationArray` are both reference-type arrays or are both arrays of type Object, a shallow copy is performed. A shallow copy of an Array is a new Array containing references to the same elements as the original Array. The elements themselves or anything referenced by the elements are not copied. In contrast, a deep copy of an Array copies the elements and everything directly or indirectly referenced by the elements.

If this method throws an exception while copying, the `destinationArray` remains unchanged; therefore, ConstrainedCopy can be used within a constrained execution region (Cer).

This method is an O(`n`) operation, where `n` is `length`.

Array.ConvertAll<TInput,TOutput> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts an array of one type to an array of another type.

C#

```
public static TOutput[] ConvertAll<TInput,TOutput> (TInput[] array,
Converter<TInput,TOutput> converter);
```

Type Parameters

TInput

The type of the elements of the source array.

TOutput

The type of the elements of the target array.

Parameters

array TInput[]

The one-dimensional, zero-based Array to convert to a target type.

converter Converter<TInput,TOutput>

A Converter<TInput,TOutput> that converts each element from one type to another type.

Returns

TOutput[]

An array of the target type containing the converted elements from the source array.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`converter` is `null`.

Examples

The following code example defines a method named `PointFToPoint` that converts a PointF structure to a Point structure. The example then creates an array of PointF structures, creates a `Converter<PointF, Point>` delegate (`Converter(Of PointF, Point)` in Visual Basic) to represent the `PointFToPoint` method, and passes the delegate to the ConvertAll method. The ConvertAll method passes each element of the input list to the `PointFToPoint` method and puts the converted elements into a new list of Point structures. In the F# example, the `pointFToPoint` function is implicitly casted to the `Converter<PointF, Point>` delegate. Both lists are displayed.

C#

```
using System;
using System.Drawing;
using System.Collections.Generic;

public class Example
{
    public static void Main()
    {
        // Create an array of PointF objects.
        PointF[] apf = {
            new PointF(27.8F, 32.62F),
            new PointF(99.3F, 147.273F),
            new PointF(7.5F, 1412.2F) };

        // Display each element in the PointF array.
        Console.WriteLine();
        foreach( PointF p in apf )
            Console.WriteLine(p);

        // Convert each PointF element to a Point object.
        Point[] ap = Array.ConvertAll(apf,
            new Converter<PointF, Point>(PointFToPoint));

        // Display each element in the Point array.
        Console.WriteLine();
        foreach( Point p in ap )
```

```
        {
            Console.WriteLine(p);
        }
    }

    public static Point PointFToPoint(PointF pf)
    {
        return new Point(((int) pf.X), ((int) pf.Y));
    }
}

/* This code example produces the following output:

{X=27.8, Y=32.62}
{X=99.3, Y=147.273}
{X=7.5, Y=1412.2}

{X=27,Y=32}
{X=99,Y=147}
{X=7,Y=1412}
 */
```

Remarks

The Converter<TInput,TOutput> is a delegate to a method that converts an object to the target type. The elements of `array` are individually passed to the Converter<TInput,TOutput>, and the converted elements are saved in the new array.

The source `array` remains unchanged.

This method is an O(`n`) operation, where `n` is the Length of `array`.

In F#, the Array.map function is generally used instead.

Applies to

Array.Copy Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies a range of elements in one Array to another Array and performs type casting and boxing as required.

Overloads

Expand table

Copy(Array, Int64, Array, Int64, Int64)	Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. The length and the indexes are specified as 64-bit integers.
Copy(Array, Int32, Array, Int32, Int32)	Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. The length and the indexes are specified as 32-bit integers.
Copy(Array, Array, Int32)	Copies a range of elements from an Array starting at the first element and pastes them into another Array starting at the first element. The length is specified as a 32-bit integer.
Copy(Array, Array, Int64)	Copies a range of elements from an Array starting at the first element and pastes them into another Array starting at the first element. The length is specified as a 64-bit integer.

Examples

The following code example shows how to copy from one Array of type Object to another Array of type integer.

C#

```
using System;
public class SamplesArray  {

   public static void Main()  {
```

```
      // Creates and initializes a new Array of type int.
      Array myIntArray=Array.CreateInstance( typeof(System.Int32), 5 );
      for ( int i = myIntArray.GetLowerBound(0); i <=
myIntArray.GetUpperBound(0); i++ )
         myIntArray.SetValue( i+1, i );

      // Creates and initializes a new Array of type Object.
      Array myObjArray = Array.CreateInstance( typeof(System.Object), 5 );
      for ( int i = myObjArray.GetLowerBound(0); i <=
myObjArray.GetUpperBound(0); i++ )
         myObjArray.SetValue( i+26, i );

      // Displays the initial values of both arrays.
      Console.WriteLine( "int array:" );
      PrintValues( myIntArray );
      Console.WriteLine( "Object array:" );
      PrintValues( myObjArray );

      // Copies the first element from the int array to the Object array.
      Array.Copy( myIntArray, myIntArray.GetLowerBound(0), myObjArray,
myObjArray.GetLowerBound(0), 1 );

      // Copies the last two elements from the Object array to the int
array.
      Array.Copy( myObjArray, myObjArray.GetUpperBound(0) - 1, myIntArray,
myIntArray.GetUpperBound(0) - 1, 2 );

      // Displays the values of the modified arrays.
      Console.WriteLine( "int array - Last two elements should now be the
same as Object array:" );
      PrintValues( myIntArray );
      Console.WriteLine( "Object array - First element should now be the
same as int array:" );
      PrintValues( myObjArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator = myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
      while ( myEnumerator.MoveNext() )  {
         if ( i < cols )  {
            i++;
         } else  {
            Console.WriteLine();
            i = 1;
         }
         Console.Write( "\t{0}", myEnumerator.Current );
      }
      Console.WriteLine();
   }
}
/*
This code produces the following output.
```

```
int array:
    1    2    3    4    5
Object array:
    26    27    28    29    30
int array - Last two elements should now be the same as Object array:
    1    2    3    29    30
Object array - First element should now be the same as int array:
    1    27    28    29    30
*/
```

Copy(Array, Int64, Array, Int64, Int64)

Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. The length and the indexes are specified as 64-bit integers.

C#

```
public static void Copy (Array sourceArray, long sourceIndex, Array
destinationArray, long destinationIndex, long length);
```

Parameters

`sourceArray` Array

The Array that contains the data to copy.

`sourceIndex` Int64

A 64-bit integer that represents the index in the `sourceArray` at which copying begins.

`destinationArray` Array

The Array that receives the data.

`destinationIndex` Int64

A 64-bit integer that represents the index in the `destinationArray` at which storing begins.

`length` Int64

A 64-bit integer that represents the number of elements to copy. The integer must be between zero and Int32.MaxValue, inclusive.

Exceptions

ArgumentNullException

`sourceArray` is `null`.

-or-

`destinationArray` is `null`.

RankException

`sourceArray` and `destinationArray` have different ranks.

ArrayTypeMismatchException

`sourceArray` and `destinationArray` are of incompatible types.

InvalidCastException

At least one element in `sourceArray` cannot be cast to the type of `destinationArray`.

ArgumentOutOfRangeException

`sourceIndex` is outside the range of valid indexes for the `sourceArray`.

-or-

`destinationIndex` is outside the range of valid indexes for the `destinationArray`.

-or-

`length` is less than 0 or greater than Int32.MaxValue.

ArgumentException

`length` is greater than the number of elements from `sourceIndex` to the end of `sourceArray`.

-or-

`length` is greater than the number of elements from `destinationIndex` to the end of `destinationArray`.

Remarks

The `sourceArray` and `destinationArray` parameters must have the same number of dimensions. In addition, `destinationArray` must already have been dimensioned and

must have a sufficient number of elements starting from the `destinationIndex` position to accommodate the copied data.

When copying between multidimensional arrays, the array behaves like a long one-dimensional array, where the rows (or columns) are conceptually laid end-to-end. For example, if an array has three rows (or columns) with four elements each, copying six elements from the beginning of the array would copy all four elements of the first row (or column) and the first two elements of the second row (or column). To start copying from the second element of the third row (or column), `sourceIndex` must be the upper bound of the first row (or column) plus the length of the second row (or column) plus two.

If `sourceArray` and `destinationArray` overlap, this method behaves as if the original values of `sourceArray` were preserved in a temporary location before `destinationArray` is overwritten.

[C++]

This method is equivalent to the standard C/C++ function `memmove`, not `memcpy`.

The arrays can be reference-type arrays or value-type arrays. Type downcasting is performed, as required.

- When copying from a reference-type array to a value-type array, each element is unboxed and then copied. When copying from a value-type array to a reference-type array, each element is boxed and then copied.
- When copying from a reference-type or value-type array to an Object array, an Object is created to hold each value or reference and then copied. When copying from an Object array to a reference-type or value-type array and the assignment is not possible, an InvalidCastException is thrown.
- If `sourceArray` and `destinationArray` are both reference-type arrays or are both arrays of type Object, a shallow copy is performed. A shallow copy of an Array is a new Array containing references to the same elements as the original Array. The elements themselves or anything referenced by the elements are not copied. In contrast, a deep copy of an Array copies the elements and everything directly or indirectly referenced by the elements.

An ArrayTypeMismatchException is thrown if the arrays are of incompatible types. Type compatibility is defined as follows:

- A type is compatible with itself.

- A value type is compatible with Object and with an interface type implemented by that value type. A value type is considered connected to an interface only if it implements that interface directly. Disconnected types are not compatible.
- Two intrinsic (predefined) value types are compatible if copying from the source type to the destination type is a widening conversion. A widening conversion never loses information, whereas a narrowing conversion can lose information. For example, converting a 32-bit signed integer to a 64-bit signed integer is a widening conversion, and converting a 64-bit signed integer to a 32-bit signed integer is a narrowing conversion. For more information about conversions, see Convert.
- A nonintrinsic (user-defined) value type is compatible only with itself.
- Enumerations have an implicit conversion to Enum and to their underlying type.

If every element in `sourceArray` requires a downcast (for example, from a base class to a derived class or from an interface to an object) and one or more elements cannot be cast to the corresponding type in `destinationArray`, an InvalidCastException is thrown.

If this method throws an exception while copying, the state of `destinationArray` is undefined.

This method is an O(`n`) operation, where `n` is `length`.

.NET Standard	2.0, 2.1

Copy(Array, Int32, Array, Int32, Int32)

Copies a range of elements from an Array starting at the specified source index and pastes them to another Array starting at the specified destination index. The length and the indexes are specified as 32-bit integers.

```
C#

public static void Copy (Array sourceArray, int sourceIndex, Array
destinationArray, int destinationIndex, int length);
```

Parameters

`sourceArray` Array

The Array that contains the data to copy.

`sourceIndex` Int32

A 32-bit integer that represents the index in the `sourceArray` at which copying begins.

`destinationArray` Array

The Array that receives the data.

`destinationIndex` Int32

A 32-bit integer that represents the index in the `destinationArray` at which storing begins.

`length` Int32

A 32-bit integer that represents the number of elements to copy.

Exceptions

ArgumentNullException

`sourceArray` is `null`.

-or-

`destinationArray` is `null`.

RankException

`sourceArray` and `destinationArray` have different ranks.

ArrayTypeMismatchException

`sourceArray` and `destinationArray` are of incompatible types.

InvalidCastException

At least one element in `sourceArray` cannot be cast to the type of `destinationArray`.

ArgumentOutOfRangeException

`sourceIndex` is less than the lower bound of the first dimension of `sourceArray`.

-or-

`destinationIndex` is less than the lower bound of the first dimension of `destinationArray`.

-or-

`length` is less than zero.

ArgumentException

`length` is greater than the number of elements from `sourceIndex` to the end of `sourceArray`.

-or-

`length` is greater than the number of elements from `destinationIndex` to the end of `destinationArray`.

Remarks

The `sourceArray` and `destinationArray` parameters must have the same number of dimensions. In addition, `destinationArray` must already have been dimensioned and must have a sufficient number of elements starting from the `destinationIndex` position to accommodate the copied data.

When copying between multidimensional arrays, the array behaves like a long one-dimensional array, where the rows (or columns) are conceptually laid end-to-end. For example, if an array has three rows (or columns) with four elements each, copying six elements from the beginning of the array would copy all four elements of the first row (or column) and the first two elements of the second row (or column). To start copying from the second element of the third row (or column), `sourceIndex` must be the upper bound of the first row (or column) plus the length of the second row (or column) plus two.

If `sourceArray` and `destinationArray` overlap, this method behaves as if the original values of `sourceArray` were preserved in a temporary location before `destinationArray` is overwritten.

[C++]

This method is equivalent to the standard C/C++ function `memmove`, not `memcpy`.

The arrays can be reference-type arrays or value-type arrays. Type downcasting is performed, as required.

- When copying from a reference-type array to a value-type array, each element is unboxed and then copied. When copying from a value-type array to a reference-type array, each element is boxed and then copied.
- When copying from a reference-type or value-type array to an Object array, an Object is created to hold each value or reference and then copied. When copying from an Object array to a reference-type or value-type array and the assignment is not possible, an InvalidCastException is thrown.
- If `sourceArray` and `destinationArray` are both reference-type arrays or are both arrays of type Object, a shallow copy is performed. A shallow copy of an Array is a new Array containing references to the same elements as the original Array. The elements themselves or anything referenced by the elements are not copied. In contrast, a deep copy of an Array copies the elements and everything directly or indirectly referenced by the elements.

An ArrayTypeMismatchException is thrown if the arrays are of incompatible types. Type compatibility is defined as follows:

- A type is compatible with itself.
- A value type is compatible with Object and with an interface type implemented by that value type. A value type is considered connected to an interface only if it implements that interface directly. Disconnected types are not compatible.
- Two intrinsic (predefined) value types are compatible if copying from the source type to the destination type is a widening conversion. Copy(Array, Array, Int64)

Copies a range of elements from an Array starting at the first element and pastes them into another Array starting at the first element. The length is specified as a 64-bit integer.

```
C#

public static void Copy (Array sourceArray, Array destinationArray, long
length);
```

Parameters

`sourceArray` Array

The Array that contains the data to copy.

`destinationArray` Array

The Array that receives the data.

`length` Int64

A 64-bit integer that represents the number of elements to copy. The integer must be between zero and Int32.MaxValue, inclusive.

Exceptions

ArgumentNullException

`sourceArray` is `null`.

-or-

`destinationArray` is `null`.

RankException

`sourceArray` and `destinationArray` have different ranks.

ArrayTypeMismatchException

`sourceArray` and `destinationArray` are of incompatible types.

InvalidCastException

At least one element in `sourceArray` cannot be cast to the type of `destinationArray`.

ArgumentOutOfRangeException

`length` is less than 0 or greater than Int32.MaxValue.

ArgumentException

`length` is greater than the number of elements in `sourceArray`.

-or-

`length` is greater than the number of elements in `destinationArray`.

Remarks

The `sourceArray` and `destinationArray` parameters must have the same number of dimensions. In addition, `destinationArray` must already have been dimensioned and must have a sufficient number of elements to accommodate the copied data.

When copying between multidimensional arrays, the array behaves like a long one-dimensional array, where the rows (or columns) are conceptually laid end to end. For example, if an array has three rows (or columns) with four elements each, copying six elements from the beginning of the array would copy all four elements of the first row (or column) and the first two elements of the second row (or column).

If `sourceArray` and `destinationArray` overlap, this method behaves as if the original values of `sourceArray` were preserved in a temporary location before `destinationArray` is overwritten.

[C++]

This method is equivalent to the standard C/C++ function `memmove`, not `memcpy`.

The arrays can be reference-type arrays or value-type arrays. Type downcasting is performed, as required.

- When copying from a reference-type array to a value-type array, each element is unboxed and then copied. When copying from a value-type array to a reference-type array, each element is boxed and then copied.
- When copying from a reference-type or value-type array to an Object array, an Object is created to hold each value or reference and then copied. When

copying from an Object array to a reference-type or value-type array and the assignment is not possible, an InvalidCastException is thrown.

- If `sourceArray` and `destinationArray` are both reference-type arrays or are both arrays of type Object, a shallow copy is performed. A shallow copy of an Array is a new Array containing references to the same elements as the original Array. The elements themselves or anything referenced by the elements are not copied. In contrast, a deep copy of an Array copies the elements and everything directly or indirectly referenced by the elements.

An ArrayTypeMismatchException is thrown if the arrays are of incompatible types. Type compatibility is defined as follows:

- A type is compatible with itself.
- A value type is compatible with Object and with an interface type implemented by that value type. A value type is considered connected to an interface only if it implements that interface directly. Disconnected types are not compatible.
- Two intrinsic (predefined) value types are compatible if copying from the source type to the destination type is a widening conversion. A widening conversion never loses information, whereas a narrowing conversion can lose information. For example, converting a 32-bit signed integer to a 64-bit signed integer is a widening conversion, and converting a 64-bit signed integer to a 32-bit signed integer is a narrowing conversion. For more information about conversions, see Convert.
- A nonintrinsic (user-defined) value type is compatible only with itself.
- Enumerations have an implicit conversion to Enum and to their underlying type.

If every element in `sourceArray` requires a downcast (for example, from a base class to a derived class or from an interface to an object) and one or more elements cannot be cast to the corresponding type in `destinationArray`, an InvalidCastException is thrown.

If this method throws an exception while copying, the state of `destinationArray` is undefined.

This method is an O(`n`) operation, where `n` is `length`.

Array.CopyTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies all the elements of the current one-dimensional array to the specified one-dimensional array.

Overloads

Expand table

CopyTo(Array, Int32)	Copies all the elements of the current one-dimensional array to the specified one-dimensional array starting at the specified destination array index. The index is specified as a 32-bit integer.
CopyTo(Array, Int64)	Copies all the elements of the current one-dimensional array to the specified one-dimensional array starting at the specified destination array index. The index is specified as a 64-bit integer.

Examples

The following code example shows how to copy an Array to another Array.

C#

```
using System;

public class SamplesArray
{

   public static void Main()
   {

      // Creates and initializes two new Arrays.
      Array mySourceArray=Array.CreateInstance(typeof(string), 6);
      mySourceArray.SetValue("three", 0);
      mySourceArray.SetValue("napping", 1);
      mySourceArray.SetValue("cats", 2);
      mySourceArray.SetValue("in", 3);
      mySourceArray.SetValue("the", 4);
```

```
      mySourceArray.SetValue("barn", 5);
      Array myTargetArray=Array.CreateInstance(typeof(string), 15);
      myTargetArray.SetValue("The", 0);
      myTargetArray.SetValue("quick", 1);
      myTargetArray.SetValue("brown", 2);
      myTargetArray.SetValue("fox", 3);
      myTargetArray.SetValue("jumps", 4);
      myTargetArray.SetValue("over", 5);
      myTargetArray.SetValue("the", 6);
      myTargetArray.SetValue("lazy", 7);
      myTargetArray.SetValue("dog", 8);

      // Displays the values of the Array.
      Console.WriteLine("The target Array contains the following (before and
after copying):");
      PrintValues(myTargetArray, ' ');

      // Copies the source Array to the target Array, starting at index 6.
      mySourceArray.CopyTo(myTargetArray, 6);

      // Displays the values of the Array.
      PrintValues(myTargetArray, ' ');
   }

   public static void PrintValues(Array myArr, char mySeparator)
   {

      System.Collections.IEnumerator myEnumerator = myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength(myArr.Rank - 1);
      while (myEnumerator.MoveNext())
      {
         if (i < cols)
         {
            i++;
         }
         else
         {
             Console.WriteLine();
             i = 1;
         }
         Console.Write("{0}{1}", mySeparator, myEnumerator.Current);
      }
      Console.WriteLine();
   }
}
/*
This code produces the following output.

The target Array contains the following (before and after copying):
 The quick brown fox jumps over the lazy dog
 The quick brown fox jumps over three napping cats in the barn
*/
```

The following code example shows how to copy an Array to another Array with a nonzero lower bound. Note that the entire source Array is copied, including empty elements that overwrite existing elements in the target Array.

C#

```
using System;

public class SamplesArray2
{

   public static void Main()
   {
      // Creates and initializes the source Array.
      Array myArrayZero=Array.CreateInstance(typeof(string), 3);
      myArrayZero.SetValue("zero", 0);
      myArrayZero.SetValue("one", 1);

      // Displays the source Array.
      Console.WriteLine("The array with lower bound=0 contains:");
      PrintIndexAndValues(myArrayZero);

      // Creates and initializes the target Array.
      int[] myArrLen = { 4 };
      int[] myArrLow = { 2 };
      Array myArrayTwo=Array.CreateInstance(typeof(string), myArrLen,
myArrLow);
      myArrayTwo.SetValue("two", 2);
      myArrayTwo.SetValue("three", 3);
      myArrayTwo.SetValue("four", 4);
      myArrayTwo.SetValue("five", 5);

      // Displays the target Array.
      Console.WriteLine("The array with lower bound=2 contains:");
      PrintIndexAndValues(myArrayTwo);

      // Copies from the array with lower bound=0 to the array with lower
bound=2.
      myArrayZero.CopyTo(myArrayTwo, 3);

      // Displays the modified target Array.
      Console.WriteLine("\nAfter copying to the target array from index
3:");
      PrintIndexAndValues(myArrayTwo);
   }

   public static void PrintIndexAndValues(Array myArray)
   {
      for (int i = myArray.GetLowerBound(0); i <= myArray.GetUpperBound(0);
i++)
         Console.WriteLine("\t[{0}]:\t{1}", i, myArray.GetValue(i));
   }
}
```

```
/*
This code produces the following output.

The array with lower bound=0 contains:
    [0]:    zero
    [1]:    one
    [2]:
The array with lower bound=2 contains:
    [2]:    two
    [3]:    three
    [4]:    four
    [5]:    five

After copying to the target array from index 3:
    [2]:    two
    [3]:    zero
    [4]:    one
    [5]:
*/
```

CopyTo(Array, Int32)

Copies all the elements of the current one-dimensional array to the specified one-dimensional array starting at the specified destination array index. The index is specified as a 32-bit integer.

```
C#

public void CopyTo (Array array, int index);
```

Parameters

`array` Array

The one-dimensional array that is the destination of the elements copied from the current array.

`index` Int32

A 32-bit integer that represents the index in `array` at which copying begins.

Implements

CopyTo(Array, Int32)

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

ArgumentException

`array` is multidimensional.

-or-

The number of elements in the source array is greater than the available number of elements from `index` to the end of the destination `array`.

ArrayTypeMismatchException

The type of the source Array cannot be cast automatically to the type of the destination `array`.

RankException

The source array is multidimensional.

InvalidCastException

At least one element in the source Array cannot be cast to the type of destination `array`.

Remarks

This method copies all the elements of the current array instance to the `array` destination array, starting at index `index`. The `array` destination array must already have been dimensioned and must have a sufficient number of elements to accommodate the copied elements. Otherwise, the method throws an exception.

This method supports the System.Collections.ICollection interface. If implementing System.Collections.ICollection is not explicitly required, use Copy to avoid an extra indirection.

If this method throws an exception while copying, the state of `array` is undefined.

This method is an O(`n`) operation, where `n` is Length. It performs a shallow copy only.

UWP	10.0

CopyTo(Array, Int64)

Copies all the elements of the current one-dimensional array to the specified one-dimensional array starting at the specified destination array index. The index is specified as a 64-bit integer.

C#

```
public void CopyTo (Array array, long index);
```

Parameters

`array` Array

The one-dimensional array that is the destination of the elements copied from the current array.

`index` Int64

A 64-bit integer that represents the index in `array` at which copying begins.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is outside the range of valid indexes for `array`.

ArgumentException

`array` is multidimensional.

-or-

The number of elements in the source array is greater than the available number of elements from `index` to the end of the destination `array`.

ArrayTypeMismatchException

The type of the source Array cannot be cast automatically to the type of the destination `array`.

RankException

The source Array is multidimensional.

InvalidCastException

At least one element in the source Array cannot be cast to the type of destination `array`.

Remarks

This method copies all the elements of the current array instance to the `array` destination array, starting at index `index`. The `array` destination array must already have been dimensioned and must have a sufficient number of elements to accommodate the copied elements. Otherwise, the method throws an exception.

This method supports the System.Collections.ICollection interface. If implementing System.Collections.ICollection is not explicitly required, use Copy to avoid an extra indirection.

If this method throws an exception while copying, the state of `array` is undefined.

This method is an O(`n`) operation, where `n` is Length. It performs a shallow copy only.

Array.CreateInstance Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Array class.

Overloads

Expand table

CreateInstance(Type, Int32)	Creates a one-dimensional Array of the specified Type and length, with zero-based indexing.
CreateInstance(Type, Int32[])	Creates a multidimensional Array of the specified Type and dimension lengths, with zero-based indexing. The dimension lengths are specified in an array of 32-bit integers.
CreateInstance(Type, Int64[])	Creates a multidimensional Array of the specified Type and dimension lengths, with zero-based indexing. The dimension lengths are specified in an array of 64-bit integers.
CreateInstance(Type, Int32, Int32)	Creates a two-dimensional Array of the specified Type and dimension lengths, with zero-based indexing.
CreateInstance(Type, Int32[], Int32[])	Creates a multidimensional Array of the specified Type and dimension lengths, with the specified lower bounds.
CreateInstance(Type, Int32, Int32, Int32)	Creates a three-dimensional Array of the specified Type and dimension lengths, with zero-based indexing.

CreateInstance(Type, Int32)

Creates a one-dimensional Array of the specified Type and length, with zero-based indexing.

C#

```
public static Array CreateInstance (Type elementType, int length);
```

Parameters

`elementType` Type

The Type of the Array to create.

`length` Int32

The size of the Array to create.

Returns

Array

A new one-dimensional Array of the specified Type with the specified length, using zero-based indexing.

Exceptions

ArgumentNullException

`elementType` is `null`.

ArgumentException

`elementType` is not a valid Type.

NotSupportedException

`elementType` is not supported. For example, Void is not supported.

-or-

`elementType` is an open generic type.

ArgumentOutOfRangeException

`length` is less than zero.

Examples

The following code example shows how to create and initialize a one-dimensional Array.

C#

```
using System;
public class SamplesArray  {

   public static void Main()  {
```

```
      // Creates and initializes a one-dimensional Array of type int.
      Array my1DArray=Array.CreateInstance( typeof(int), 5 );
      for ( int i = my1DArray.GetLowerBound(0); i <=
my1DArray.GetUpperBound(0); i++ )
         my1DArray.SetValue( i+1, i );

      // Displays the values of the Array.
      Console.WriteLine( "The one-dimensional Array contains the
following values:" );
      PrintValues( my1DArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator =
myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
      while ( myEnumerator.MoveNext() )  {
         if ( i < cols )  {
            i++;
         } else  {
            Console.WriteLine();
            i = 1;
         }
         Console.Write( "\t{0}", myEnumerator.Current );
      }
      Console.WriteLine();
   }
}
/*
This code produces the following output.

The one-dimensional Array contains the following values:
    1    2    3    4    5
*/
```

Remarks

Unlike most classes, Array provides the CreateInstance method, instead of public constructors, to allow for late bound access.

Reference-type elements are initialized to `null`. Value-type elements are initialized to zero.

This method is an O(`n`) operation, where `n` is `length`.

In F#, the Array.zeroCreate function is usually used instead.

CreateInstance(Type, Int32[])

Creates a multidimensional Array of the specified Type and dimension lengths, with zero-based indexing. The dimension lengths are specified in an array of 32-bit integers.

C#

```
public static Array CreateInstance (Type elementType, params int[]
lengths);
```

Parameters

`elementType` Type

The Type of the Array to create.

`lengths` Int32[]

An array of 32-bit integers that represent the size of each dimension of the Array to create.

Returns

Array

A new multidimensional Array of the specified Type with the specified length for each dimension, using zero-based indexing.

Exceptions

ArgumentNullException

`elementType` is `null`.

-or-

`lengths` is `null`.

ArgumentException

`elementType` is not a valid Type.

-or-

The `lengths` array contains less than one element.

NotSupportedException

`elementType` is not supported. For example, Void is not supported.

-or-

`elementType` is an open generic type.

ArgumentOutOfRangeException

Any value in `lengths` is less than zero.

Examples

The following code example shows how to create and initialize a multidimensional Array.

C#

```
using System;
public class SamplesArray3  {

   public static void Main()  {

      // Creates and initializes a multidimensional Array of type string.
      int[] myLengthsArray = new int[4] { 2, 3, 4, 5 };
      Array my4DArray=Array.CreateInstance( typeof(string),
myLengthsArray );
      for ( int i = my4DArray.GetLowerBound(0); i <=
my4DArray.GetUpperBound(0); i++ )
         for ( int j = my4DArray.GetLowerBound(1); j <=
my4DArray.GetUpperBound(1); j++ )
            for ( int k = my4DArray.GetLowerBound(2); k <=
my4DArray.GetUpperBound(2); k++ )
               for ( int l = my4DArray.GetLowerBound(3); l <=
```

```
my4DArray.GetUpperBound(3); l++ )  {
                  int[] myIndicesArray = new int[4] { i, j, k, l };
                  my4DArray.SetValue( Convert.ToString(i) + j + k + l,
myIndicesArray );
               }

      // Displays the values of the Array.
      Console.WriteLine( "The four-dimensional Array contains the
following values:" );
      PrintValues( my4DArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator =
myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
      while ( myEnumerator.MoveNext() )  {
         if ( i < cols )  {
            i++;
         } else  {
            Console.WriteLine();
            i = 1;
         }
         Console.Write( "\t{0}", myEnumerator.Current );
      }
      Console.WriteLine();
   }
}
/*
This code produces the following output.

The four-dimensional Array contains the following values:
    0000    0001    0002    0003    0004
    0010    0011    0012    0013    0014
    0020    0021    0022    0023    0024
    0030    0031    0032    0033    0034
    0100    0101    0102    0103    0104
    0110    0111    0112    0113    0114
    0120    0121    0122    0123    0124
    0130    0131    0132    0133    0134
    0200    0201    0202    0203    0204
    0210    0211    0212    0213    0214
    0220    0221    0222    0223    0224
    0230    0231    0232    0233    0234
    1000    1001    1002    1003    1004
    1010    1011    1012    1013    1014
    1020    1021    1022    1023    1024
    1030    1031    1032    1033    1034
    1100    1101    1102    1103    1104
    1110    1111    1112    1113    1114
    1120    1121    1122    1123    1124
    1130    1131    1132    1133    1134
    1200    1201    1202    1203    1204
    1210    1211    1212    1213    1214
```

```
    1220    1221    1222    1223    1224
    1230    1231    1232    1233    1234
*/
```

Remarks

Unlike most classes, Array provides the CreateInstance method, instead of public constructors, to allow for late bound access.

The number of elements in the `lengths` array must equal the number of dimensions in the new Array. Each element of the `lengths` array must specify the length of the corresponding dimension in the new Array.

Reference-type elements are initialized to `null`. Value-type elements are initialized to zero.

This method is an O(`n`) operation, where `n` is the product of all values in `lengths`.

CreateInstance(Type, Int64[])

Creates a multidimensional Array of the specified Type and dimension lengths, with zero-based indexing. The dimension lengths are specified in an array of 64-bit integers.

C#

```
public static Array CreateInstance (Type elementType, params long[]
```

```
lengths);
```

Parameters

`elementType` Type

The Type of the Array to create.

`lengths` Int64[]

An array of 64-bit integers that represent the size of each dimension of the Array to create. Each integer in the array must be between zero and Int32.MaxValue, inclusive.

Returns

Array

A new multidimensional Array of the specified Type with the specified length for each dimension, using zero-based indexing.

Exceptions

ArgumentNullException

`elementType` is `null`.

-or-

`lengths` is `null`.

ArgumentException

`elementType` is not a valid Type.

-or-

The `lengths` array contains less than one element.

NotSupportedException

`elementType` is not supported. For example, Void is not supported.

-or-

`elementType` is an open generic type.

ArgumentOutOfRangeException

Any value in `lengths` is less than zero or greater than Int32.MaxValue.

Examples

The following code example shows how to create and initialize a multidimensional Array.

C#

```
using System;
public class SamplesArray3  {

   public static void Main()  {

      // Creates and initializes a multidimensional Array of type string.
      int[] myLengthsArray = new int[4] { 2, 3, 4, 5 };
      Array my4DArray=Array.CreateInstance( typeof(string),
myLengthsArray );
      for ( int i = my4DArray.GetLowerBound(0); i <=
my4DArray.GetUpperBound(0); i++ )
         for ( int j = my4DArray.GetLowerBound(1); j <=
my4DArray.GetUpperBound(1); j++ )
            for ( int k = my4DArray.GetLowerBound(2); k <=
my4DArray.GetUpperBound(2); k++ )
               for ( int l = my4DArray.GetLowerBound(3); l <=
my4DArray.GetUpperBound(3); l++ )  {
                  int[] myIndicesArray = new int[4] { i, j, k, l };
                  my4DArray.SetValue( Convert.ToString(i) + j + k + l,
myIndicesArray );
               }

      // Displays the values of the Array.
      Console.WriteLine( "The four-dimensional Array contains the
following values:" );
      PrintValues( my4DArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator =
myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
      while ( myEnumerator.MoveNext() )  {
         if ( i < cols )  {
            i++;
         } else  {
            Console.WriteLine();
            i = 1;
         }
         Console.Write( "\t{0}", myEnumerator.Current );
      }
      Console.WriteLine();
   }
}
/*
```

```
This code produces the following output.

The four-dimensional Array contains the following values:
    0000    0001    0002    0003    0004
    0010    0011    0012    0013    0014

    0100    0101    0102    0103    0104
    0110    0111    0112    0113    0114
    0120    0121    0122    0123    0124
    0130    0131    0132    0133    0134
    0200    0201    0202    0203    0204
    0210    0211    0212    0213    0214
    0220    0221    0222    0223    0224
    0230    0231    0232    0233    0234
    1000    1001    1002    1003    1004
    1010    1011    1012    1013    1014
    1020    1021    1022    1023    1024
    1030    1031    1032    1033    1034
    1100    1101    1102    1103    1104
    1110    1111    1112    1113    1114
    1120    1121    1122    1123    1124
    1130    1131    1132    1133    1134
    1200    1201    1202    1203    1204
    1210    1211    1212    1213    1214
    1220    1221    1222    1223    1224
    1230    1231    1232    1233    1234
*/
```

Remarks

Unlike most classes, Array provides the CreateInstance method, instead of public constructors, to allow for late bound access.

The number of elements in the `lengths` array must equal the number of dimensions in the new Array. Each element of the `lengths` array must specify the length of the corresponding dimension in the new Array.

Reference-type elements are initialized to `null`. Value-type elements are initialized to zero.

This method is an O(`n`) operation, where `n` is the product of all values in `lengths`.

CreateInstance(Type, Int32, Int32)

Creates a two-dimensional Array of the specified Type and dimension lengths, with zero-based indexing.

C#

```
public static Array CreateInstance (Type elementType, int length1, int
length2);
```

Parameters

`elementType` Type

The Type of the Array to create.

`length1` Int32

The size of the first dimension of the Array to create.

`length2` Int32

The size of the second dimension of the Array to create.

Returns

Array

A new two-dimensional Array of the specified Type with the specified length for each dimension, using zero-based indexing.

Exceptions

ArgumentNullException

`elementType` is `null`.

ArgumentException

`elementType` is not a valid Type.

NotSupportedException

`elementType` is not supported. For example, Void is not supported.

-or-

`elementType` is an open generic type.

ArgumentOutOfRangeException

`length1` is less than zero.

-or-

`length2` is less than zero.

Examples

The following code example shows how to create and initialize a two-dimensional Array.

C#

```
using System;
public class SamplesArray1  {

   public static void Main()  {

      // Creates and initializes a two-dimensional Array of type string.
      Array my2DArray=Array.CreateInstance( typeof(string), 2, 3 );
      for ( int i = my2DArray.GetLowerBound(0); i <=
my2DArray.GetUpperBound(0); i++ )
         for ( int j = my2DArray.GetLowerBound(1); j <=
my2DArray.GetUpperBound(1); j++ )
            my2DArray.SetValue( "abc" + i + j, i, j );

      // Displays the values of the Array.
      Console.WriteLine( "The two-dimensional Array contains the
following values:" );
      PrintValues( my2DArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator =
myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
```

```
        while ( myEnumerator.MoveNext() )  {
           if ( i < cols )  {
              i++;
           } else  {
              Console.WriteLine();
              i = 1;
           }
           Console.Write( "\t{0}", myEnumerator.Current );
        }
        Console.WriteLine();
    }
}
/*
This code produces the following output.

The two-dimensional Array contains the following values:
    abc00    abc01    abc02
    abc10    abc11    abc12
*/
```

Remarks

Unlike most classes, Array provides the CreateInstance method, instead of public constructors, to allow for late bound access.

Reference-type elements are initialized to `null`. Value-type elements are initialized to zero.

This method is an O(`n`) operation, where `n` is the product of `length1` and `length2`.

In F#, the Array2D.zeroCreate function can be used instead.

CreateInstance(Type, Int32[], Int32[])

Creates a multidimensional Array of the specified Type and dimension lengths, with the specified lower bounds.

```
C#

public static Array CreateInstance (Type elementType, int[] lengths,
int[] lowerBounds);
```

Parameters

`elementType` Type

The Type of the Array to create.

`lengths` Int32[]

A one-dimensional array that contains the size of each dimension of the Array to create.

`lowerBounds` Int32[]

A one-dimensional array that contains the lower bound (starting index) of each dimension of the Array to create.

Returns

Array

A new multidimensional Array of the specified Type with the specified length and lower bound for each dimension.

Exceptions

ArgumentNullException

`elementType` is `null`.

-or-

`lengths` is `null`.

-or-

`lowerBounds` is `null`.

ArgumentException

`elementType` is not a valid Type.

-or-

The `lengths` array contains less than one element.

-or-

The `lengths` and `lowerBounds` arrays do not contain the same number of elements.

NotSupportedException

`elementType` is not supported. For example, Void is not supported.

-or-

`elementType` is an open generic type.

ArgumentOutOfRangeException

Any value in `lengths` is less than zero.

-or-

Any value in `lowerBounds` is very large, such that the sum of a dimension's lower bound and length is greater than Int32.MaxValue.

Examples

The following code example shows how to create and initialize a multidimensional Array with specified lower bounds.

C#

```
using System;
public class SamplesArray4  {

   public static void Main()  {

      // Creates and initializes a multidimensional Array of type string.
      int[] myLengthsArray = new int[2] { 3, 5 };
      int[] myBoundsArray = new int[2] { 2, 3 };
      Array myArray=Array.CreateInstance( typeof(string), myLengthsArray,
myBoundsArray );
      for ( int i = myArray.GetLowerBound(0); i <=
myArray.GetUpperBound(0); i++ )
         for ( int j = myArray.GetLowerBound(1); j <=
myArray.GetUpperBound(1); j++ )  {
            int[] myIndicesArray = new int[2] { i, j };
            myArray.SetValue( Convert.ToString(i) + j, myIndicesArray );
         }
```

```
      // Displays the lower bounds and the upper bounds of each
dimension.
      Console.WriteLine( "Bounds:\tLower\tUpper" );
      for ( int i = 0; i < myArray.Rank; i++ )
         Console.WriteLine( "{0}:\t{1}\t{2}", i,
myArray.GetLowerBound(i), myArray.GetUpperBound(i) );

      // Displays the values of the Array.
      Console.WriteLine( "The Array contains the following values:" );
      PrintValues( myArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator =
myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
      while ( myEnumerator.MoveNext() )  {
         if ( i < cols )  {
            i++;
         } else  {
            Console.WriteLine();
            i = 1;
         }
         Console.Write( "\t{0}", myEnumerator.Current );
      }
      Console.WriteLine();
   }
}
/*
This code produces the following output.

Bounds:    Lower    Upper
0:    2    4
1:    3    7
The Array contains the following values:
    23    24    25    26    27
    33    34    35    36    37
    43    44    45    46    47
*/
```

Remarks

Unlike most classes, Array provides the CreateInstance method, instead of public constructors, to allow for late bound access.

The `lengths` and `lowerBounds` arrays must have the same number of elements. The number of elements in the `lengths` array must equal the number of dimensions in the new Array.

Each element of the `lengths` array must specify the length of the corresponding dimension in the new Array.

Each element of the `lowerBounds` array must specify the lower bound of the corresponding dimension in the new Array. Generally, the .NET class library and many programming languages do not handle non-zero lower bounds.

Reference-type elements are initialized to `null`. Value-type elements are initialized to zero.

This method is an O(`n`) operation, where `n` is the product of all values in `lengths`.

> **Note**
>
> Not all languages support arrays with non-zero lower bounds, and therefore you may not be able to cast instances of non-zero based **Array** to the language's array type. For example, you cannot cast a 1-dimensional integer array with the lower bound 6 to C#'s `int[]` type. This results in **InvalidCastException** during runtime with the message "Unable to cast object of type 'System.Int32[*]' to type 'System.Int32[]'.", where the asterisk (*) means non-zero based index. However, you can cast zero based arrays of any rank created with **CreateInstance(Type, Int32[], Int32[])** to the language's array. For example, you can cast a 2-dimensional zero based integer array created with this method to C#'s `int[,]` type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CreateInstance(Type, Int32, Int32, Int32)

Creates a three-dimensional Array of the specified Type and dimension lengths, with zero-based indexing.

```
C#

public static Array CreateInstance (Type elementType, int length1, int
length2, int length3);
```

Parameters

elementType Type

The Type of the Array to create.

length1 Int32

The size of the first dimension of the Array to create.

length2 Int32

The size of the second dimension of the Array to create.

length3 Int32

The size of the third dimension of the Array to create.

Returns

Array

A new three-dimensional Array of the specified Type with the specified length for each dimension, using zero-based indexing.

Exceptions

ArgumentNullException

`elementType` is `null`.

ArgumentException

`elementType` is not a valid Type.

NotSupportedException

`elementType` is not supported. For example, Void is not supported.

-or-

`elementType` is an open generic type.

ArgumentOutOfRangeException

`length1` is less than zero.

-or-

`length2` is less than zero.

-or-

`length3` is less than zero.

Examples

The following code example shows how to create and initialize a three-dimensional Array.

C#

```
using System;
public class SamplesArray2  {

   public static void Main()  {

      // Creates and initializes a three-dimensional Array of type
Object.
      Array my3DArray=Array.CreateInstance( typeof(Object), 2, 3, 4 );
      for ( int i = my3DArray.GetLowerBound(0); i <=
my3DArray.GetUpperBound(0); i++ )
         for ( int j = my3DArray.GetLowerBound(1); j <=
my3DArray.GetUpperBound(1); j++ )
            for ( int k = my3DArray.GetLowerBound(2); k <=
my3DArray.GetUpperBound(2); k++ )
               my3DArray.SetValue( "abc" + i + j + k, i, j, k );

      // Displays the values of the Array.
      Console.WriteLine( "The three-dimensional Array contains the
following values:" );
      PrintValues( my3DArray );
   }

   public static void PrintValues( Array myArr )  {
      System.Collections.IEnumerator myEnumerator =
myArr.GetEnumerator();
      int i = 0;
      int cols = myArr.GetLength( myArr.Rank - 1 );
      while ( myEnumerator.MoveNext() )  {
         if ( i < cols )  {
            i++;
```

```
            } else  {
               Console.WriteLine();
               i = 1;
            }
            Console.Write( "\t{0}", myEnumerator.Current );
         }
         Console.WriteLine();
      }
   }
   /*
   This code produces the following output.

   The three-dimensional Array contains the following values:
       abc000    abc001    abc002    abc003
       abc010    abc011    abc012    abc013
       abc020    abc021    abc022    abc023
       abc100    abc101    abc102    abc103
       abc110    abc111    abc112    abc113
       abc120    abc121    abc122    abc123
   */
```

Remarks

Unlike most classes, Array provides the CreateInstance method, instead of public constructors, to allow for late bound access.

Reference-type elements are initialized to `null`. Value-type elements are initialized to zero.

This method is an O(`n`) operation, where `n` is the product of `length1`, `length2`, and `length3`.

In F#, the Array3D.zeroCreate function can be used instead.

Array.Empty<T> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an empty array.

C#

```
public static T[] Empty<T> ();
```

Type Parameters

T

The type of the elements of the array.

Returns

T[]

An empty array.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Array.Exists<T>(T[], Predicate<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified array contains elements that match the conditions defined by the specified predicate.

```
C#

public static bool Exists<T> (T[] array, Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the elements to search for.

Returns

Boolean

`true` if `array` contains one or more elements that match the conditions defined by the specified predicate; otherwise, `false`.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Examples

The following example specifies the match conditions for the Exists method using lambda expressions to check whether a planet starts with a given letter or whether the planet is found on the given array.

C#

```
using System;

namespace Example
{
    class Program
    {
        static void Main(string[] args)
        {
            string[] planets = { "Mercury", "Venus",
                "Earth", "Mars", "Jupiter",
                "Saturn", "Uranus", "Neptune" };

            Console.WriteLine("One or more planets begin with 'M': {0}",
                Array.Exists(planets, element => element.StartsWith("M")));

            Console.WriteLine("One or more planets begin with 'T': {0}",
                Array.Exists(planets, element => element.StartsWith("T")));

            Console.WriteLine("Is Pluto one of the planets? {0}",
                Array.Exists(planets, element => element == "Pluto"));
        }
    }
}
// The example displays the following output:
//       One or more planets begin with 'M': True
//       One or more planets begin with 'T': False
//       Is Pluto one of the planets? False
```

The following example uses the Exists method to indicate whether any names in a string array begin with a specified character. The example instantiates a `StringSearcher` object by passing the string to search for to its class constructor. The `StringSearcher.StartsWith` method has same signature as the Predicate<T> delegate. When the Exists method is called, each member of the array is passed to the delegate until it returns `true` or iterates all the elements in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] names = { "Adam", "Adel", "Bridgette", "Carla",
                         "Charles", "Daniel", "Elaine", "Frances",
                         "George", "Gillian", "Henry", "Irving",
                         "James", "Janae", "Lawrence", "Miguel",
                         "Nicole", "Oliver", "Paula", "Robert",
                         "Stephen", "Thomas", "Vanessa",
                         "Veronica", "Wilberforce" };
      Char[] charsToFind = { 'A', 'K', 'W', 'Z' };

      foreach (var charToFind in charsToFind)
         Console.WriteLine("One or more names begin with '{0}': {1}",
                           charToFind,
                           Array.Exists(names, (new
StringSearcher(charToFind)).StartsWith));
   }
}

public class StringSearcher
{
   char firstChar;

   public StringSearcher(char firstChar)
   {
      this.firstChar = char.ToUpper(firstChar);
   }

   public bool StartsWith(string s)
   {
      if (string.IsNullOrEmpty(s)) return false;

      if(s.Substring(0, 1).ToUpper() == firstChar.ToString())
         return true;
      else
         return false;
   }
}
// The example displays the following output:
//       One or more names begin with 'A': True
//       One or more names begin with 'K': False
//       One or more names begin with 'W': True
//       One or more names begin with 'Z': False
```

You can also use a lambda expression rather than explicitly define a method whose signature corresponds to that of the delegate. The following example replaces the

`StringSearcher` class and its `StartsWith` method with a lambda expression.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] names = { "Adam", "Adel", "Bridgette", "Carla",
                         "Charles", "Daniel", "Elaine", "Frances",
                         "George", "Gillian", "Henry", "Irving",
                         "James", "Janae", "Lawrence", "Miguel",
                         "Nicole", "Oliver", "Paula", "Robert",
                         "Stephen", "Thomas", "Vanessa",
                         "Veronica", "Wilberforce" };
      Char[] charsToFind = { 'A', 'K', 'W', 'Z' };

      foreach (var charToFind in charsToFind)
         Console.WriteLine("One or more names begin with '{0}': {1}",
                           charToFind,
                           Array.Exists(names,
                                        s => { if (string.IsNullOrEmpty(s))
                                                   return false;

                                               if (s.Substring(0,
1).ToUpper() == charToFind.ToString())
                                                   return true;
                                               else
                                                   return false;
                                             } ));
   }
}
// The example displays the following output:
//       One or more names begin with 'A': True
//       One or more names begin with 'K': False
//       One or more names begin with 'W': True
//       One or more names begin with 'Z': False
```

Remarks

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>, and processing is stopped when a match is found.

ⓘ **Note**

In C# and Visual Basic, it is not necessary to create the **Predicate<T>** delegate explicitly. These languages infer the correct delegate from context and create it automatically. In F#, functions and lambda expressions are implicitly converted.

This method is an O(`n`) operation, where `n` is the Length of `array`.

Array.Fill Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Fill<T>(T[], T)	Assigns the given `value` of type `T` to each element of the specified `array`.
Fill<T>(T[], T, Int32, Int32)	Assigns the given `value` of type `T` to the elements of the specified `array` which are within the range of `startIndex` (inclusive) and the next `count` number of indices.

Fill<T>(T[], T)

Assigns the given `value` of type `T` to each element of the specified `array`.

C#

```
public static void Fill<T> (T[] array, T value);
```

Type Parameters

T

The type of the elements in the array.

Parameters

array T[]

The array to be filled.

value T

The value to assign to each array element.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Fill<T>(T[], T, Int32, Int32)

Assigns the given `value` of type `T` to the elements of the specified `array` which are within the range of `startIndex` (inclusive) and the next `count` number of indices.

```
C#

public static void Fill<T> (T[] array, T value, int startIndex, int
count);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The Array to be filled.

`value` T

The new value for the elements in the specified range.

`startIndex` Int32

A 32-bit integer that represents the index in the Array at which filling begins.

`count` Int32

The number of elements to copy.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Array.Find<T>(T[], Predicate<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for an element that matches the conditions defined by the specified predicate, and returns the first occurrence within the entire Array.

```
C#

public static T? Find<T> (T[] array, Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based array to search.

`match` Predicate<T>

The predicate that defines the conditions of the element to search for.

Returns

T

The first element that matches the conditions defined by the specified predicate, if found; otherwise, the default value for type `T`.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Examples

The following example uses a Predicate<T> delegate with the Find generic method to search an array of Point structures. The method the delegate represents, `ProductGT10`, returns `true` if the product of the X and Y fields is greater than 100,000. The Find method calls the delegate for each element of the array, returning the first point that meets the test condition.

> **Note**
>
> Visual Basic, C#, and F# users do not have to create the delegate explicitly or specify the type argument of the generic method. The compilers determine the necessary types from the method arguments you supply.

C#

```
using System;
using System.Drawing;

public class Example
{
    public static void Main()
    {
        // Create an array of five Point structures.
        Point[] points = { new Point(100, 200),
            new Point(150, 250), new Point(250, 375),
            new Point(275, 395), new Point(295, 450) };

        // Find the first Point structure for which X times Y
        // is greater than 100000.
        Point first = Array.Find(points, ProductGT10);

        // Display the first structure found.
        Console.WriteLine("Found: X = {0}, Y = {1}", first.X, first.Y);
    }

    // Return true if X times Y is greater than 100000.
    private static bool ProductGT10(Point p)
    {
        return p.X * p.Y > 100000;
    }
```

```
}
// The example displays the following output:
//       Found: X = 275, Y = 395
```

Rather than explicitly defining a method with the necessary signature, instantiating a Predicate<T> delegate, and passing the delegate to the Find method, it is customary to use a lambda expression. The following example is identical to the previous one, except that it uses a lambda expression as the `match` argument.

C#

```
using System;
using System.Drawing;

public class Example
{
    public static void Main()
    {
        // Create an array of five Point structures.
        Point[] points = { new Point(100, 200),
            new Point(150, 250), new Point(250, 375),
            new Point(275, 395), new Point(295, 450) };

        // Find the first Point structure for which X times Y
        // is greater than 100000.
        Point first = Array.Find(points, p => p.X * p.Y > 100000);

        // Display the first structure found.
        Console.WriteLine("Found: X = {0}, Y = {1}", first.X, first.Y);
    }
}
// The example displays the following output:
//       Found: X = 275, Y = 395
```

Remarks

The Predicate<T> is a delegate to a method or a lambda expression that returns `true` if the object passed to it matches the conditions defined in the delegate or lambda expression. The elements of `array` are individually passed to the Predicate<T>, starting with the first element and ending with the last element. Processing is stopped when a match is found.

This method is an O(`n`) operation, where `n` is the Length of `array`.

In F#, the Array.find function can be used instead.

Array.FindAll<T>(T[], Predicate<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves all the elements that match the conditions defined by the specified predicate.

C#

```
public static T[] FindAll<T> (T[] array, Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the elements to search for.

Returns

T[]

An Array containing all the elements that match the conditions defined by the specified predicate, if found; otherwise, an empty Array.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Examples

The following example creates an array of 50 random numbers with values that can range from 0 to 1,000. It then calls the FindAll method with a lambda expression that returns the values that range from 300 to 600. Note that the lambda expression is passed a parameter named `x`; this represents the individual array member that is passed to the Predicate<T>. Also note that the local `lBound` and `uBound` variables are accessible within the lambda expression.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      // Get an array of n random integers.
      int[] values = GetArray(50, 0, 1000);
      int lBound = 300;
      int uBound = 600;
      int[] matchedItems = Array.FindAll(values, x =>
                                         x >= lBound && x <= uBound);
      for (int ctr = 0; ctr < matchedItems.Length; ctr++) {
         Console.Write("{0}  ", matchedItems[ctr]);
         if ((ctr + 1) % 12 == 0)
            Console.WriteLine();
      }
   }

   private static int[] GetArray(int n, int lower, int upper)
   {
      Random rnd = new Random();
      List<int> list = new List<int>();
      for (int ctr = 1; ctr <= n; ctr++)
         list.Add(rnd.Next(lower, upper + 1));

      return list.ToArray();
   }
}
// The example displays output similar to the following:
//       542  398  356  351  348  301  562  599  575  400  569  306
//       535  416  393  385
```

The following code example demonstrates the Find, FindLast, and FindAll generic methods. An array of strings is created, containing 8 dinosaur names, two of which (at positions 1 and 5) end with "saurus". The code example also defines a search predicate method named `EndsWithSaurus`, which accepts a string parameter and returns a Boolean value indicating whether the input string ends in "saurus".

The Find generic method traverses the array from the beginning, passing each element in turn to the `EndsWithSaurus` method. The search stops when the `EndsWithSaurus` method returns `true` for the element "Amargasaurus".

> **Note**
>
> In C#, F#, and Visual Basic, it is not necessary to create the `Predicate<string>` delegate (`Predicate(Of String)` in Visual Basic) explicitly. These languages infer the correct delegate from context and create it automatically.

The FindLast generic method is used to search the array backward from the end. It finds the element "Dilophosaurus" at position 5. The FindAll generic method is used to return an array containing all the elements that end in "saurus". The elements are displayed.

The code example also demonstrates the Exists and TrueForAll generic methods.

C#

```
using System;

public class DinoDiscoverySet
{
    public static void Main()
    {
        string[] dinosaurs =
        {
            "Compsognathus", "Amargasaurus", "Oviraptor",
            "Velociraptor",  "Deinonychus",  "Dilophosaurus",
            "Gallimimus",    "Triceratops"
        };

        DinoDiscoverySet GoMesozoic = new DinoDiscoverySet(dinosaurs);

        GoMesozoic.DiscoverAll();
        GoMesozoic.DiscoverByEnding("saurus");
    }

    private string[] dinosaurs;

    public DinoDiscoverySet(string[] items)
    {
```

```
        dinosaurs = items;
    }

    public void DiscoverAll()
    {
        Console.WriteLine();
        foreach(string dinosaur in dinosaurs)
        {
            Console.WriteLine(dinosaur);
        }
    }

    public void DiscoverByEnding(string Ending)
    {
        Predicate<string> dinoType;

        switch (Ending.ToLower())
        {
            case "raptor":
                dinoType = EndsWithRaptor;
                break;
            case "tops":
                dinoType = EndsWithTops;
                break;
            case "saurus":
            default:
                dinoType = EndsWithSaurus;
                break;
        }
        Console.WriteLine(
            "\nArray.Exists(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.Exists(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.TrueForAll(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.TrueForAll(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.Find(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.Find(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.FindLast(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.FindLast(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.FindAll(dinosaurs, \"{0}\"):", Ending);

        string[] subArray =
            Array.FindAll(dinosaurs, dinoType);
```

```
        foreach(string dinosaur in subArray)
        {
            Console.WriteLine(dinosaur);
        }
    }

    // Search predicate returns true if a string ends in "saurus".
    private bool EndsWithSaurus(string s)
    {
        if ((s.Length > 5) &&
            (s.Substring(s.Length - 6).ToLower() == "saurus"))
        {
            return true;
        }
        else
        {
            return false;
        }
    }

    // Search predicate returns true if a string ends in "raptor".
    private bool EndsWithRaptor(String s)
    {
        if ((s.Length > 5) &&
            (s.Substring(s.Length - 6).ToLower() == "raptor"))
        {
            return true;
        }
        else
        {
            return false;
        }
    }

    // Search predicate returns true if a string ends in "tops".
    private bool EndsWithTops(String s)
    {
        if ((s.Length > 3) &&
            (s.Substring(s.Length - 4).ToLower() == "tops"))
        {
            return true;
        }
        else
        {
            return false;
        }
    }
}

/* This code example produces the following output:

Compsognathus
Amargasaurus
Oviraptor
Velociraptor
```

```
Deinonychus
Dilophosaurus
Gallimimus
Triceratops

Array.Exists(dinosaurs, "saurus"): True

Array.TrueForAll(dinosaurs, "saurus"): False

Array.Find(dinosaurs, "saurus"): Amargasaurus

Array.FindLast(dinosaurs, "saurus"): Dilophosaurus

Array.FindAll(dinosaurs, "saurus"):
Amargasaurus
Dilophosaurus
*/
```

Remarks

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>, and the elements that match the conditions are saved in the returned array.

This method is an O(`n`) operation, where `n` is the Length of `array`.

In F#, the Array.filter function may be used instead.

Array.FindIndex Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for an element that matches the conditions defined by a specified predicate, and returns the zero-based index of the first occurrence within an Array or a portion of it.

Overloads

Expand table

FindIndex<T>(T[], Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the entire Array.
FindIndex<T>(T[], Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the range of elements in the Array that extends from the specified index to the last element.
FindIndex<T>(T[], Int32, Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the range of elements in the Array that starts at the specified index and contains the specified number of elements.

Examples

The following code example demonstrates all three overloads of the FindIndex generic method. An array of strings is created, containing 8 dinosaur names, two of which (at positions 1 and 5) end with "saurus". The code example also defines a search predicate method named `EndsWithSaurus`, which accepts a string parameter and returns a Boolean value indicating whether the input string ends in "saurus".

The FindIndex<T>(T[], Predicate<T>) method overload traverses the array from the beginning, passing each element in turn to the `EndsWithSaurus` method. The search stops when the `EndsWithSaurus` method returns `true` for the element at position 1.

> **Note**
>
> In C#, F#, and Visual Basic, it is not necessary to create the `Predicate<string>` delegate (`Predicate(Of String)` in Visual Basic) explicitly. These languages infer the correct delegate from context and create it automatically.

The FindIndex<T>(T[], Int32, Predicate<T>) method overload is used to search the array beginning at position 2 and continuing to the end of the array. It finds the element at position 5. Finally, the FindIndex<T>(T[], Int32, Int32, Predicate<T>) method overload is used to search the range of three elements beginning at position 2. It returns -1 because there are no dinosaur names in that range that end with "saurus".

C#

```
using System;

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = { "Compsognathus",
            "Amargasaurus",   "Oviraptor",      "Velociraptor",
            "Deinonychus",    "Dilophosaurus",  "Gallimimus",
            "Triceratops" };

        Console.WriteLine();
        foreach(string dinosaur in dinosaurs)
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine(
            "\nArray.FindIndex(dinosaurs, EndsWithSaurus): {0}",
            Array.FindIndex(dinosaurs, EndsWithSaurus));

        Console.WriteLine(
            "\nArray.FindIndex(dinosaurs, 2, EndsWithSaurus): {0}",
            Array.FindIndex(dinosaurs, 2, EndsWithSaurus));

        Console.WriteLine(

            Array.FindIndex(dinosaurs, 2, 3, EndsWithSaurus));
    }

    // Search predicate returns true if a string ends in "saurus".
    private static bool EndsWithSaurus(String s)
    {
        if ((s.Length > 5) &&
            (s.Substring(s.Length - 6).ToLower() == "saurus"))
        {
```

```
            return true;
        }
        else
        {
            return false;
        }
    }
}

/* This code example produces the following output:

Compsognathus
Amargasaurus
Oviraptor
Velociraptor
Deinonychus
Dilophosaurus
Gallimimus
Triceratops

Array.FindIndex(dinosaurs, EndsWithSaurus): 1

Array.FindIndex(dinosaurs, 2, EndsWithSaurus): 5

Array.FindIndex(dinosaurs, 2, 3, EndsWithSaurus): -1
 */
```

FindIndex<T>(T[], Predicate<T>)

Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the entire Array.

C#

```
public static int FindIndex<T> (T[] array, Predicate<T> match);
```

Type Parameters

T

The type of the elements of the array.

Parameters

array T[]

The one-dimensional, zero-based Array to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

Int32

The zero-based index of the first occurrence of an element that matches the conditions defined by `match`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Remarks

The Array is searched forward starting at the first element and ending at the last element.

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>.

This method is an O(`n`) operation, where `n` is the Length of `array`.

FindIndex<T>(T[], Int32, Predicate<T>)

Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the range of elements in the Array that extends from the specified index to the last element.

C#

```
public static int FindIndex<T> (T[] array, int startIndex, Predicate<T>
match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`startIndex` Int32

The zero-based starting index of the search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

Int32

The zero-based index of the first occurrence of an element that matches the conditions defined by `match`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

Remarks

The Array is searched forward starting at `startIndex` and ending at the last element.

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>.

This method is an O(`n`) operation, where `n` is the number of elements from `startIndex` to the end of `array`.

FindIndex<T>(T[], Int32, Int32, Predicate<T>)

Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the first occurrence within the range of elements in the Array that starts at the specified index and contains the specified number of elements.

C#

```
public static int FindIndex<T> (T[] array, int startIndex, int count,
Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`startIndex` Int32

The zero-based starting index of the search.

`count` Int32

The number of elements in the section to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

Int32

The zero-based index of the first occurrence of an element that matches the conditions defined by `match`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

-or-

`count` is less than zero.

-or-

`startIndex` and `count` do not specify a valid section in `array`.

Remarks

The Array is searched forward starting at `startIndex` and ending at `startIndex` plus `count` minus 1, if `count` is greater than 0.

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>.

This method is an O(`n`) operation, where `n` is `count`.

Array.FindLast<T>(T[], Predicate<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for an element that matches the conditions defined by the specified predicate, and returns the last occurrence within the entire Array.

```
C#

public static T? FindLast<T> (T[] array, Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

T

The last element that matches the conditions defined by the specified predicate, if found; otherwise, the default value for type `T`.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Examples

The following code example demonstrates the Find, FindLast, and FindAll generic methods. An array of strings is created, containing 8 dinosaur names, two of which (at positions 1 and 5) end with "saurus". The code example also defines a search predicate method named `EndsWithSaurus`, which accepts a string parameter and returns a Boolean value indicating whether the input string ends in "saurus".

The Find generic method traverses the array from the beginning, passing each element in turn to the `EndsWithSaurus` method. The search stops when the `EndsWithSaurus` method returns `true` for the element "Amargasaurus".

> **Note**
>
> In C# and Visual Basic, it is not necessary to create the `Predicate<string>` delegate (`Predicate(Of String)` in Visual Basic) explicitly. These languages infer the correct delegate from context and create it automatically.

The FindLast generic method is used to search the array backward from the end. It finds the element "Dilophosaurus" at position 5. The FindAll generic method is used to return an array containing all the elements that end in "saurus". The elements are displayed.

The code example also demonstrates the Exists and TrueForAll generic methods.

C#

```
using System;

public class DinoDiscoverySet
{
    public static void Main()
    {
        string[] dinosaurs =
        {
            "Compsognathus", "Amargasaurus", "Oviraptor",
            "Velociraptor",  "Deinonychus",  "Dilophosaurus",
            "Gallimimus",    "Triceratops"
        };
```

```
        DinoDiscoverySet GoMesozoic = new DinoDiscoverySet(dinosaurs);

        GoMesozoic.DiscoverAll();
        GoMesozoic.DiscoverByEnding("saurus");
    }

    private string[] dinosaurs;

    public DinoDiscoverySet(string[] items)
    {
        dinosaurs = items;
    }

    public void DiscoverAll()
    {
        Console.WriteLine();
        foreach(string dinosaur in dinosaurs)
        {
            Console.WriteLine(dinosaur);
        }
    }

    public void DiscoverByEnding(string Ending)
    {
        Predicate<string> dinoType;

        switch (Ending.ToLower())
        {
            case "raptor":
                dinoType = EndsWithRaptor;
                break;
            case "tops":
                dinoType = EndsWithTops;
                break;
            case "saurus":
            default:
                dinoType = EndsWithSaurus;
                break;
        }
        Console.WriteLine(
            "\nArray.Exists(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.Exists(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.TrueForAll(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.TrueForAll(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.Find(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.Find(dinosaurs, dinoType));

        Console.WriteLine(
```

```
            "\nArray.FindLast(dinosaurs, \"{0}\"): {1}",
            Ending,
            Array.FindLast(dinosaurs, dinoType));

        Console.WriteLine(
            "\nArray.FindAll(dinosaurs, \"{0}\"):", Ending);

        string[] subArray =
            Array.FindAll(dinosaurs, dinoType);

        foreach(string dinosaur in subArray)
        {
            Console.WriteLine(dinosaur);
        }
    }

    // Search predicate returns true if a string ends in "saurus".
    private bool EndsWithSaurus(string s)
    {
        if ((s.Length > 5) &&
            (s.Substring(s.Length - 6).ToLower() == "saurus"))
        {
            return true;
        }
        else
        {
            return false;
        }
    }

    // Search predicate returns true if a string ends in "raptor".
    private bool EndsWithRaptor(String s)
    {
        if ((s.Length > 5) &&
            (s.Substring(s.Length - 6).ToLower() == "raptor"))
        {
            return true;
        }
        else
        {
            return false;
        }
    }

    // Search predicate returns true if a string ends in "tops".
    private bool EndsWithTops(String s)
    {
        if ((s.Length > 3) &&
            (s.Substring(s.Length - 4).ToLower() == "tops"))
        {
            return true;
        }
        else
        {
            return false;
```

```
        }
    }
}

/* This code example produces the following output:

Compsognathus
Amargasaurus
Oviraptor
Velociraptor
Deinonychus
Dilophosaurus
Gallimimus
Triceratops

Array.Exists(dinosaurs, "saurus"): True

Array.TrueForAll(dinosaurs, "saurus"): False

Array.Find(dinosaurs, "saurus"): Amargasaurus

Array.FindLast(dinosaurs, "saurus"): Dilophosaurus

Array.FindAll(dinosaurs, "saurus"):
Amargasaurus
Dilophosaurus
*/
```

Remarks

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>, moving backward in the Array, starting with the last element and ending with the first element. Processing is stopped when a match is found.

This method is an O(`n`) operation, where `n` is the Length of `array`.

Array.FindLastIndex Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for an element that matches the conditions defined by a specified predicate, and returns the zero-based index of the last occurrence within an Array or a portion of it.

Overloads

Expand table

FindLastIndex<T>(T[], Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the entire Array.
FindLastIndex<T>(T[], Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the range of elements in the Array that extends from the first element to the specified index.
FindLastIndex<T>(T[], Int32, Int32, Predicate<T>)	Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the range of elements in the Array that contains the specified number of elements and ends at the specified index.

Examples

The following code example demonstrates all three overloads of the FindLastIndex generic method. An array of strings is created, containing 8 dinosaur names, two of which (at positions 1 and 5) end with "saurus". The code example also defines a search predicate method named `EndsWithSaurus`, which accepts a string parameter and returns a Boolean value indicating whether the input string ends in "saurus".

The FindLastIndex<T>(T[], Predicate<T>) method overload traverses the array backward from the end, passing each element in turn to the `EndsWithSaurus` method. The search stops when the `EndsWithSaurus` method returns `true` for the element at position 5.

> **Note**
>
> In C#, F# and Visual Basic, it is not necessary to create the `Predicate<string>` delegate (`Predicate(Of String)` in Visual Basic) explicitly. These languages infer the correct delegate from context and create it automatically.

The FindLastIndex<T>(T[], Int32, Predicate<T>) method overload is used to search the array beginning at position 4 and continuing backward to the beginning of the array. It finds the element at position 1. Finally, the FindLastIndex<T>(T[], Int32, Int32, Predicate<T>) method overload is used to search the range of three elements beginning at position 4 and working backward (that is, elements 4, 3, and 2). It returns -1 because there are no dinosaur names in that range that end with "saurus".

C#

```
using System;

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = { "Compsognathus",
            "Amargasaurus",   "Oviraptor",      "Velociraptor",
            "Deinonychus",    "Dilophosaurus",  "Gallimimus",
            "Triceratops" };

        Console.WriteLine();
        foreach(string dinosaur in dinosaurs)
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine(
            "\nArray.FindLastIndex(dinosaurs, EndsWithSaurus): {0}",
            Array.FindLastIndex(dinosaurs, EndsWithSaurus));

        Console.WriteLine(
            "\nArray.FindLastIndex(dinosaurs, 4, EndsWithSaurus): {0}",
            Array.FindLastIndex(dinosaurs, 4, EndsWithSaurus));

        Console.WriteLine(
            "\nArray.FindLastIndex(dinosaurs, 4, 3, EndsWithSaurus): {0}",
            Array.FindLastIndex(dinosaurs, 4, 3, EndsWithSaurus));
    }

    // Search predicate returns true if a string ends in "saurus".
    private static bool EndsWithSaurus(String s)
    {
        if ((s.Length > 5) &&
```

```
            (s.Substring(s.Length - 6).ToLower() == "saurus"))
        {
            return true;
        }
        else
        {
            return false;
        }
    }
}

/* This code example produces the following output:

Compsognathus
Amargasaurus
Oviraptor
Velociraptor
Deinonychus
Dilophosaurus
Gallimimus
Triceratops

Array.FindLastIndex(dinosaurs, EndsWithSaurus): 5

Array.FindLastIndex(dinosaurs, 4, EndsWithSaurus): 1

Array.FindLastIndex(dinosaurs, 4, 3, EndsWithSaurus): -1
 */
```

FindLastIndex<T>(T[], Predicate<T>)

Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the entire Array.

C#

```
public static int FindLastIndex<T> (T[] array, Predicate<T> match);
```

Type Parameters

T

The type of the elements of the array.

Parameters

array T[]

The one-dimensional, zero-based Array to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

Int32

The zero-based index of the last occurrence of an element that matches the conditions defined by `match`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Remarks

The Array is searched backward starting at the last element and ending at the first element.

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>.

This method is an O(`n`) operation, where `n` is the Length of `array`.

FindLastIndex<T>(T[], Int32, Predicate<T>)

Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the range of elements in the Array that extends from the first element to the specified index.

C#

```
public static int FindLastIndex<T> (T[] array, int startIndex,
Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`startIndex` Int32

The zero-based starting index of the backward search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

Int32

The zero-based index of the last occurrence of an element that matches the conditions defined by `match`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

Remarks

The Array is searched backward starting at `startIndex` and ending at the first element.

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>.

This method is an O(`n`) operation, where `n` is the number of elements from the beginning of `array` to `startIndex`.

UWP	10.0

FindLastIndex<T>(T[], Int32, Int32, Predicate<T>)

Searches for an element that matches the conditions defined by the specified predicate, and returns the zero-based index of the last occurrence within the range of elements in the Array that contains the specified number of elements and ends at the specified index.

C#

```
public static int FindLastIndex<T> (T[] array, int startIndex, int count,
Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`startIndex` Int32

The zero-based starting index of the backward search.

`count` Int32

The number of elements in the section to search.

`match` Predicate<T>

The Predicate<T> that defines the conditions of the element to search for.

Returns

Int32

The zero-based index of the last occurrence of an element that matches the conditions defined by `match`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

-or-

`count` is less than zero.

-or-

`startIndex` and `count` do not specify a valid section in `array`.

Remarks

The Array is searched backward starting at `startIndex` and ending at `startIndex` minus `count` plus 1, if `count` is greater than 0.

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>.

This method is an O(`n`) operation, where `n` is `count`.

Array.ForEach<T>(T[], Action<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Performs the specified action on each element of the specified array.

```
C#
public static void ForEach<T> (T[] array, Action<T> action);
```

Type Parameters

T

The type of the elements of the array.

Parameters

array T[]

The one-dimensional, zero-based Array on whose elements the action is to be performed.

action Action<T>

The Action<T> to perform on each element of `array`.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`action` is `null`.

Examples

The following example shows how to use ForEach to display the squares of each element in an integer array.

C#

```
using System;

public class SamplesArray
{
    public static void Main()
    {
        // create a three element array of integers
        int[] intArray = new int[] {2, 3, 4};

        // set a delegate for the ShowSquares method
        Action<int> action = new Action<int>(ShowSquares);

        Array.ForEach(intArray, action);
    }

    private static void ShowSquares(int val)
    {
        Console.WriteLine("{0:d} squared = {1:d}", val, val*val);
    }
}

/*
This code produces the following output:

2 squared = 4
3 squared = 9
4 squared = 16
*/
```

Remarks

The Action<T> is a delegate to a method that performs an action on the object passed to it. The elements of `array` are individually passed to the Action<T>.

This method is an O(`n`) operation, where `n` is the Length of `array`.

In F#, the Array.iter function can be used instead.

Array.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an IEnumerator for the Array.

C#

```
public System.Collections.IEnumerator GetEnumerator ();
```

Returns

IEnumerator

An IEnumerator for the Array.

Implements

GetEnumerator()

Examples

The following code example shows how to use GetEnumerator to list the elements of an array.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Creates and initializes a new Array.
      String[] myArr = new String[10];
      myArr[0] = "The";
      myArr[1] = "quick";
      myArr[2] = "brown";
      myArr[3] = "fox";
```

```
        myArr[4] = "jumps";
        myArr[5] = "over";
        myArr[6] = "the";
        myArr[7] = "lazy";
        myArr[8] = "dog";

        // Displays the values of the Array.
        int i = 0;
        System.Collections.IEnumerator myEnumerator = myArr.GetEnumerator();
        Console.WriteLine( "The Array contains the following values:" );
        while (( myEnumerator.MoveNext() ) && ( myEnumerator.Current != null
))
           Console.WriteLine( "[{0}] {1}", i++, myEnumerator.Current );
    }
}

/*
This code produces the following output.

The Array contains the following values:
[0] The
[1] quick
[2] brown
[3] fox
[4] jumps
[5] over
[6] the
[7] lazy
[8] dog

*/
```

Remarks

The `foreach` statement of the C# language (`for each` in C++, `For Each` in Visual Basic) hides the complexity of the enumerators. Therefore, using `foreach` is recommended, instead of directly manipulating the enumerator.

Enumerators can be used to read the data in the collection, but they cannot be used to modify the underlying collection.

Initially, the enumerator is positioned before the first element in the collection. Reset also brings the enumerator back to this position. At this position, Current is undefined. Therefore, you must call MoveNext to advance the enumerator to the first element of the collection before reading the value of Current.

Current returns the same object until either MoveNext or Reset is called. MoveNext sets Current to the next element.

If MoveNext passes the end of the collection, the enumerator is positioned after the last element in the collection and MoveNext returns `false`. When the enumerator is at this position, subsequent calls to MoveNext also return `false`. If the last call to MoveNext returned `false`, Current is undefined. To set Current to the first element of the collection again, you can call Reset followed by MoveNext.

An enumerator remains valid as long as the collection remains unchanged. If changes are made to the collection, such as adding, modifying, or deleting elements, the enumerator is irrecoverably invalidated and its behavior is undefined.

The enumerator does not have exclusive access to the collection; therefore, enumerating through a collection is intrinsically not a thread safe procedure. To guarantee thread safety during enumeration, you can lock the collection during the entire enumeration. To allow the collection to be accessed by multiple threads for reading and writing, you must implement your own synchronization.

This method is an O(1) operation.

Array.GetLength(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a 32-bit integer that represents the number of elements in the specified dimension of the Array.

C#

```
public int GetLength (int dimension);
```

Parameters

`dimension` Int32

A zero-based dimension of the Array whose length needs to be determined.

Returns

Int32

A 32-bit integer that represents the number of elements in the specified dimension.

Exceptions

IndexOutOfRangeException

`dimension` is less than zero.

-or-

`dimension` is equal to or greater than Rank.

Examples

The following example shows how to use GetLength to display the dimensions of two arrays with different ranks.

C#

```
using System;

public class SamplesArray
{
    public static void Main()
    {
        // make a single dimension array
        Array MyArray1 = Array.CreateInstance(typeof(int), 5);

        // make a 3 dimensional array
        Array MyArray2 = Array.CreateInstance(typeof(int), 5, 3, 2);

        // make an array container
        Array BossArray = Array.CreateInstance(typeof(Array), 2);
        BossArray.SetValue(MyArray1, 0);
        BossArray.SetValue(MyArray2, 1);

        int i = 0, j, rank;
        foreach (Array anArray in BossArray)
        {
            rank = anArray.Rank;
            if (rank > 1)
            {
                Console.WriteLine("Lengths of {0:d} dimension array[{1:d}]",
rank, i);
                // show the lengths of each dimension
                for (j = 0; j < rank; j++)
                {
                    Console.WriteLine("    Length of dimension({0:d}) =
{1:d}", j, anArray.GetLength(j));
                }
            }
            else
            {
                Console.WriteLine("Lengths of single dimension
array[{0:d}]", i);
            }
            // show the total length of the entire array or all dimensions
            Console.WriteLine("    Total length of the array = {0:d}",
anArray.Length);
            Console.WriteLine();
            i++;
        }
    }
}

/*
This code produces the following output:

Lengths of single dimension array[0]
    Total length of the array = 5

Lengths of 3 dimension array[1]
    Length of dimension(0) = 5
```

```
    Length of dimension(1) = 3
    Length of dimension(2) = 2
    Total length of the array = 30
*/
```

Remarks

An example of GetLength is `GetLength(0)`, which returns the number of elements in the first dimension of the Array.

This method is an O(1) operation.

Array.GetLongLength(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a 64-bit integer that represents the number of elements in the specified dimension of the Array.

```
C#
public long GetLongLength (int dimension);
```

Parameters

dimension Int32

A zero-based dimension of the Array whose length needs to be determined.

Returns

Int64

A 64-bit integer that represents the number of elements in the specified dimension.

Exceptions

IndexOutOfRangeException

`dimension` is less than zero.

-or-

`dimension` is equal to or greater than Rank.

Remarks

An example of GetLongLength is `GetLongLength(0)`, which returns the number of elements in the first dimension of the Array.

This method is an O(1) operation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Array.GetLowerBound(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the index of the first element of the specified dimension in the array.

```
C#
public int GetLowerBound (int dimension);
```

Parameters

`dimension` Int32

A zero-based dimension of the array whose starting index needs to be determined.

Returns

Int32

The index of the first element of the specified dimension in the array.

Exceptions

IndexOutOfRangeException

`dimension` is less than zero.

-or-

`dimension` is equal to or greater than Rank.

Examples

The following example uses the GetLowerBound and GetUpperBound methods to display the bounds of a one-dimensional and two-dimensional array and to display the values of their array elements.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      // Create a one-dimensional integer array.
      int[] integers = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
      // Get the upper and lower bound of the array.
      int upper = integers.GetUpperBound(0);
      int lower = integers.GetLowerBound(0);
      Console.WriteLine($"Elements from index {lower} to {upper}:");
      // Iterate the array.
      for (int ctr = lower; ctr <= upper; ctr++)
        Console.Write($"{(ctr == lower ?"    " : "")}{integers[ctr]}" +
                      $"{(ctr < upper ? ", " : Environment.NewLine)}");

      Console.WriteLine();

      // Create a two-dimensional integer array.
      int[,] integers2d= { {2, 4}, {3, 9}, {4, 16}, {5, 25},
                           {6, 36}, {7, 49}, {8, 64}, {9, 81} };
      // Get the number of dimensions.
      int rank = integers2d.Rank;
      Console.WriteLine($"Number of dimensions: {rank}");
      for (int ctr = 0; ctr < rank; ctr++)
        Console.WriteLine($"   Dimension {ctr}: " +
                          $"from {integers2d.GetLowerBound(ctr)} to
{integers2d.GetUpperBound(ctr)}");

      // Iterate the 2-dimensional array and display its values.
      Console.WriteLine("   Values of array elements:");
      for (int outer = integers2d.GetLowerBound(0); outer <=
integers2d.GetUpperBound(0);
           outer++)
        for (int inner = integers2d.GetLowerBound(1); inner <=
integers2d.GetUpperBound(1);
             inner++)
           Console.WriteLine($"      {'\u007b'}{outer}, {inner}{'\u007d'} =
" +
                             $"{integers2d.GetValue(outer, inner)}");
   }
}
// The example displays the following output:
//       Elements from index 0 to 9:
//          2, 4, 6, 8, 10, 12, 14, 16, 18, 20
//
//       Number of dimensions: 2
//          Dimension 0: from 0 to 7
//          Dimension 1: from 0 to 1
//          Values of array elements:
//             {0, 0} = 2
//             {0, 1} = 4
//             {1, 0} = 3
```

```
//              {1, 1} = 9
//              {2, 0} = 4
//              {2, 1} = 16
//              {3, 0} = 5
//              {3, 1} = 25
//              {4, 0} = 6
//              {4, 1} = 36
//              {5, 0} = 7
//              {5, 1} = 49
//              {6, 0} = 8
//              {6, 1} = 64
//              {7, 0} = 9
//              {7, 1} = 81
```

Remarks

`GetLowerBound(0)` returns the starting index of the first dimension of the array, and `GetLowerBound(Rank - 1)` returns the starting index of the last dimension of the array.

The GetLowerBound method always returns a value that indicates the index of the lower bound of the array, even if the array is empty.

Note that, although most arrays in .NET are zero-based (that is, the GetLowerBound method returns zero for each dimension of an array), .NET does support arrays that are not zero-based. Such arrays can be created with the CreateInstance(Type, Int32[], Int32[]) method, and can also be returned from unmanaged code.

This method is an O(1) operation.

Array.GetUpperBound(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the index of the last element of the specified dimension in the array.

```
C#
public int GetUpperBound (int dimension);
```

Parameters

`dimension` Int32

A zero-based dimension of the array whose upper bound needs to be determined.

Returns

Int32

The index of the last element of the specified dimension in the array, or -1 if the specified dimension is empty.

Exceptions

IndexOutOfRangeException

`dimension` is less than zero.

-or-

`dimension` is equal to or greater than Rank.

Examples

The following example uses the GetLowerBound and GetUpperBound methods to display the bounds of a one-dimensional and two-dimensional array and to display the values of their array elements.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Create a one-dimensional integer array.
      int[] integers = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
      // Get the upper and lower bound of the array.
      int upper = integers.GetUpperBound(0);
      int lower = integers.GetLowerBound(0);
      Console.WriteLine($"Elements from index {lower} to {upper}:");
      // Iterate the array.
      for (int ctr = lower; ctr <= upper; ctr++)
        Console.Write($"{(ctr == lower ?"    " : "")}{integers[ctr]}" +
                      $"{(ctr < upper ? ", " : Environment.NewLine)}");

      Console.WriteLine();

      // Create a two-dimensional integer array.
      int[,] integers2d= { {2, 4}, {3, 9}, {4, 16}, {5, 25},
                           {6, 36}, {7, 49}, {8, 64}, {9, 81} };
      // Get the number of dimensions.
      int rank = integers2d.Rank;
      Console.WriteLine($"Number of dimensions: {rank}");
      for (int ctr = 0; ctr < rank; ctr++)
        Console.WriteLine($"   Dimension {ctr}: " +
                          $"from {integers2d.GetLowerBound(ctr)} to
{integers2d.GetUpperBound(ctr)}");

      // Iterate the 2-dimensional array and display its values.
      Console.WriteLine("   Values of array elements:");
      for (int outer = integers2d.GetLowerBound(0); outer <=
integers2d.GetUpperBound(0);
           outer++)
        for (int inner = integers2d.GetLowerBound(1); inner <=
integers2d.GetUpperBound(1);
             inner++)
           Console.WriteLine($"      {'\u007b'}{outer}, {inner}{'\u007d'} =
" +
                             $"{integers2d.GetValue(outer, inner)}");
   }
}
// The example displays the following output:
//       Elements from index 0 to 9:
//          2, 4, 6, 8, 10, 12, 14, 16, 18, 20
//
//       Number of dimensions: 2
//          Dimension 0: from 0 to 7
//          Dimension 1: from 0 to 1
//          Values of array elements:
//             {0, 0} = 2
```

```
//              {0, 1} = 4
//              {1, 0} = 3
//              {1, 1} = 9
//              {2, 0} = 4
//              {2, 1} = 16
//              {3, 0} = 5
//              {3, 1} = 25
//              {4, 0} = 6
//              {4, 1} = 36
//              {5, 0} = 7
//              {5, 1} = 49
//              {6, 0} = 8
//              {6, 1} = 64
//              {7, 0} = 9
//              {7, 1} = 81
```

Remarks

`GetUpperBound(0)` returns the last index in the first dimension of the array, and `GetUpperBound(Rank - 1)` returns the last index of the last dimension of the array.

This method is an O(1) operation.

Array.GetValue Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified element in the current Array.

Overloads

Expand table

GetValue(Int32)	Gets the value at the specified position in the one-dimensional Array. The index is specified as a 32-bit integer.
GetValue(Int32[])	Gets the value at the specified position in the multidimensional Array. The indexes are specified as an array of 32-bit integers.
GetValue(Int64)	Gets the value at the specified position in the one-dimensional Array. The index is specified as a 64-bit integer.
GetValue(Int64[])	Gets the value at the specified position in the multidimensional Array. The indexes are specified as an array of 64-bit integers.
GetValue(Int32, Int32)	Gets the value at the specified position in the two-dimensional Array. The indexes are specified as 32-bit integers.
GetValue(Int64, Int64)	Gets the value at the specified position in the two-dimensional Array. The indexes are specified as 64-bit integers.
GetValue(Int32, Int32, Int32)	Gets the value at the specified position in the three-dimensional Array. The indexes are specified as 32-bit integers.
GetValue(Int64, Int64, Int64)	Gets the value at the specified position in the three-dimensional Array. The indexes are specified as 64-bit integers.

Examples

The following code example demonstrates how to set and get a specific value in a one-dimensional or multidimensional array.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Creates and initializes a one-dimensional array.
      String[] myArr1 = new String[5];

      // Sets the element at index 3.
      myArr1.SetValue( "three", 3 );
      Console.WriteLine( "[3]:   {0}", myArr1.GetValue( 3 ) );

      // Creates and initializes a two-dimensional array.
      String[,] myArr2 = new String[5,5];

      // Sets the element at index 1,3.
      myArr2.SetValue( "one-three", 1, 3 );
      Console.WriteLine( "[1,3]:   {0}", myArr2.GetValue( 1, 3 ) );

      // Creates and initializes a three-dimensional array.
      String[,,] myArr3 = new String[5,5,5];

      // Sets the element at index 1,2,3.
      myArr3.SetValue( "one-two-three", 1, 2, 3 );
      Console.WriteLine( "[1,2,3]:   {0}", myArr3.GetValue( 1, 2, 3 ) );

      // Creates and initializes a seven-dimensional array.
      String[,,,,,,] myArr7 = new String[5,5,5,5,5,5,5];

      // Sets the element at index 1,2,3,0,1,2,3.
      int[] myIndices = new int[7] { 1, 2, 3, 0, 1, 2, 3 };
      myArr7.SetValue( "one-two-three-zero-one-two-three", myIndices );
      Console.WriteLine( "[1,2,3,0,1,2,3]:   {0}", myArr7.GetValue(
myIndices ) );
   }
}

/*
This code produces the following output.

[3]:   three
[1,3]:   one-three
[1,2,3]:   one-two-three
[1,2,3,0,1,2,3]:   one-two-three-zero-one-two-three

*/
```

GetValue(Int32)

Gets the value at the specified position in the one-dimensional Array. The index is specified as a 32-bit integer.

```
C#

public object? GetValue (int index);
```

Parameters

`index` Int32

A 32-bit integer that represents the position of the Array element to get.

Returns

Object

The value at the specified position in the one-dimensional Array.

Exceptions

ArgumentException

The current Array does not have exactly one dimension.

IndexOutOfRangeException

`index` is outside the range of valid indexes for the current Array.

Remarks

The GetLowerBound and GetUpperBound methods can determine whether the value of `index` is out of bounds.

This method is an O(1) operation.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetValue(Int32[])

Gets the value at the specified position in the multidimensional Array. The indexes are specified as an array of 32-bit integers.

```
C#

public object? GetValue (params int[] indices);
```

Parameters

`indices` Int32[]

A one-dimensional array of 32-bit integers that represent the indexes specifying the position of the Array element to get.

Returns

Object

The value at the specified position in the multidimensional Array.

Exceptions

ArgumentNullException

`indices` is `null`.

ArgumentException

The number of dimensions in the current Array is not equal to the number of elements in `indices`.

IndexOutOfRangeException

Any element in `indices` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

The number of elements in `indices` must equal the number of dimensions in the Array. All elements in the `indices` array must collectively specify the position of the desired element in the multidimensional Array.

The GetLowerBound and GetUpperBound methods can determine whether any of the indexes is out of bounds.

This method is an O(1) operation.

A 32-bit integer that represents the first-dimension index of the Array element to get.

`index2` Int32

A 32-bit integer that represents the second-dimension index of the Array element to get.

Returns

Object

The value at the specified position in the two-dimensional Array.

Exceptions

ArgumentException

The current Array does not have exactly two dimensions.

IndexOutOfRangeException

Either `index1` or `index2` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

The GetLowerBound and GetUpperBound methods can determine whether any of the indexes is out of bounds.

This method is an O(1) operation.

.NET Standard	2.0, 2.1

GetValue(Int64, Int64)

Gets the value at the specified position in the two-dimensional Array. The indexes are specified as 64-bit integers.

C#

```
public object? GetValue (long index1, long index2);
```

Parameters

`index1` Int64

A 64-bit integer that represents the first-dimension index of the Array element to get.

`index2` Int64

A 64-bit integer that represents the second-dimension index of the Array element to get.

Returns

Object

The value at the specified position in the two-dimensional Array.

Exceptions

ArgumentException

The current Array does not have exactly two dimensions.

ArgumentOutOfRangeException

Either `index1` or `index2` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

The GetLowerBound and GetUpperBound methods can determine whether any of the indexes is out of bounds.

This method is an O(1) operation.

.NET Standard	2.0, 2.1

GetValue(Int32, Int32, Int32)

Gets the value at the specified position in the three-dimensional Array. The indexes are specified as 32-bit integers.

C#

```
public object? GetValue (int index1, int index2, int index3);
```

Parameters

`index1` Int32

A 32-bit integer that represents the first-dimension index of the Array element to get.

`index2` Int32

A 32-bit integer that represents the second-dimension index of the Array element to get.

`index3` Int32

A 32-bit integer that represents the third-dimension index of the Array element to get.

Returns

Object

The value at the specified position in the three-dimensional Array.

Exceptions

ArgumentException

The current Array does not have exactly three dimensions.

IndexOutOfRangeException

`index1` or `index2` or `index3` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

The GetLowerBound and GetUpperBound methods can determine whether any of the indexes is out of bounds.

This method is an O(1) operation.

Array.IndexOf Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for the specified object and returns the index of its first occurrence in a one-dimensional array or in a range of elements in the array.

Overloads

Expand table

IndexOf(Array, Object)	Searches for the specified object and returns the index of its first occurrence in a one-dimensional array.
IndexOf(Array, Object, Int32)	Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of its first occurrence. The range extends from a specified index to the end of the array.
IndexOf(Array, Object, Int32, Int32)	Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of ifs first occurrence. The range extends from a specified index for a specified number of elements.
IndexOf<T>(T[], T, Int32)	Searches for the specified object in a range of elements of a one dimensional array, and returns the index of its first occurrence. The range extends from a specified index to the end of the array.
IndexOf<T>(T[], T, Int32, Int32)	Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of its first occurrence. The range extends from a specified index for a specified number of elements.
IndexOf<T>(T[], T)	Searches for the specified object and returns the index of its first occurrence in a one-dimensional array.

IndexOf(Array, Object)

Searches for the specified object and returns the index of its first occurrence in a one-dimensional array.

```
C#

public static int IndexOf (Array array, object? value);
```

Parameters

`array` Array

The one-dimensional array to search.

`value` Object

The object to locate in `array`.

Returns

Int32

The index of the first occurrence of `value` in `array`, if found; otherwise, the lower bound of the array minus 1.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

Examples

The example calls the following three overloads of the IndexOf method to find the index of a string in a string array:

- IndexOf(Array, Object), to determine the first occurrence of the string "the" in a string array.
- IndexOf(Array, Object, Int32), to determine the first occurrence of the string "the" in the fourth to the last elements of a string array.
- IndexOf(Array, Object, Int32, Int32), to determine the first occurrence of the string "the" in a string array from the element that follows the last successful match to the end of the array.

C#

```
// Create a string array with 3 elements having the same value.
String[] strings = { "the", "quick", "brown", "fox", "jumps",
                     "over", "the", "lazy", "dog", "in", "the",
                     "barn" };

// Display the elements of the array.
Console.WriteLine("The array contains the following values:");
for (int i = strings.GetLowerBound(0); i <= strings.GetUpperBound(0);
i++)
   Console.WriteLine("   [{0,2}]: {1}", i, strings[i]);

// Search for the first occurrence of the duplicated value.
string searchString = "the";
int index = Array.IndexOf(strings, searchString);
Console.WriteLine("The first occurrence of \"{0}\" is at index {1}.",
                  searchString, index);

// Search for the first occurrence of the duplicated value in the last
section of the array.
index = Array.IndexOf(strings, searchString, 4);
Console.WriteLine("The first occurrence of \"{0}\" between index 4 and
the end is at index {1}.",
                  searchString, index);

// Search for the first occurrence of the duplicated value in a section
of the array.
int position = index + 1;
index = Array.IndexOf(strings, searchString, position,
strings.GetUpperBound(0) - position + 1);
Console.WriteLine("The first occurrence of \"{0}\" between index {1} and
index {2} is at index {3}.",
                  searchString, position, strings.GetUpperBound(0),
index);

// The example displays the following output:
//    The array contains the following values:
//       [ 0]: the
//       [ 1]: quick
//       [ 2]: brown
//       [ 3]: fox
//       [ 4]: jumps
//       [ 5]: over
//       [ 6]: the
//       [ 7]: lazy
//       [ 8]: dog
//       [ 9]: in
//       [10]: the
//       [11]: barn
//    The first occurrence of "the" is at index 0.
//    The first occurrence of "the" between index 4 and the end is at
index 6.
```

```
//    The first occurrence of "the" between index 7 and index 11 is at
index 10.
```

Remarks

This method searches all the elements of a one-dimensional array for `value`. To determine whether `value` exists in `array`, the method performs an equality comparison by calling each element's `Equals` method until it finds a match. This means that if the element overrides the Object.Equals(Object) method, that override is called.

Because most arrays have a lower bound of zero, this method generally returns -1 if `value` isn't found. In the rare case that the lower bound of the array is equal to Int32.MinValue(0x80000000) and `value` isn't found, this method returns Int32.MaxValue (0x7FFFFFFF).

This method is an O(`n`) operation, where `n` is the Length of `array`.

IndexOf(Array, Object, Int32)

Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of its first occurrence. The range extends from a specified

index to the end of the array.

```
C#
public static int IndexOf (Array array, object? value, int startIndex);
```

Parameters

`array` Array

The one-dimensional array to search.

`value` Object

The object to locate in `array`.

`startIndex` Int32

The starting index of the search. 0 (zero) is valid in an empty array.

Returns

Int32

The index of the first occurrence of `value`, if it's found, within the range of elements in `array` that extends from `startIndex` to the last element; otherwise, the lower bound of the array minus 1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

RankException

`array` is multidimensional.

Examples

The example calls the following three overloads of the IndexOf method to find the index of a string in a string array:

- IndexOf(Array, Object), to determine the first occurrence of the string "the" in a string array.
- IndexOf(Array, Object, Int32), to determine the first occurrence of the string "the" in the fourth to the last elements of a string array.
- IndexOf(Array, Object, Int32, Int32), to determine the first occurrence of the string "the" in a string array from the element that follows the last successful match to the end of the array.

C#

```
// Create a string array with 3 elements having the same value.
String[] strings = { "the", "quick", "brown", "fox", "jumps",
                     "over", "the", "lazy", "dog", "in", "the",
                     "barn" };

// Display the elements of the array.
Console.WriteLine("The array contains the following values:");
for (int i = strings.GetLowerBound(0); i <= strings.GetUpperBound(0);
i++)
   Console.WriteLine("   [{0,2}]: {1}", i, strings[i]);

// Search for the first occurrence of the duplicated value.
string searchString = "the";
int index = Array.IndexOf(strings, searchString);
Console.WriteLine("The first occurrence of \"{0}\" is at index {1}.",
                  searchString, index);

// Search for the first occurrence of the duplicated value in the last
section of the array.
index = Array.IndexOf(strings, searchString, 4);
Console.WriteLine("The first occurrence of \"{0}\" between index 4 and
the end is at index {1}.",
                  searchString, index);

// Search for the first occurrence of the duplicated value in a section
of the array.
int position = index + 1;
index = Array.IndexOf(strings, searchString, position,
strings.GetUpperBound(0) - position + 1);
Console.WriteLine("The first occurrence of \"{0}\" between index {1} and
index {2} is at index {3}.",
                  searchString, position, strings.GetUpperBound(0),
index);

// The example displays the following output:
//    The array contains the following values:
//       [ 0]: the
//       [ 1]: quick
//       [ 2]: brown
//       [ 3]: fox
```

```
//       [ 4]: jumps
//       [ 5]: over
//       [ 6]: the
//       [ 7]: lazy
//       [ 8]: dog
//       [ 9]: in
//       [10]: the
//       [11]: barn
//    The first occurrence of "the" is at index 0.
//    The first occurrence of "the" between index 4 and the end is at
index 6.
//    The first occurrence of "the" between index 7 and index 11 is at
index 10.
```

Remarks

This method searches a one-dimensional array from the element at index `startIndex` to the last element. To determine whether `value` exists in `array`, the method performs an equality comparison by calling the `Equals` method of every element until it finds a match. This means that if the element overrides the Object.Equals(Object) method, that override is called.

Because most arrays have a lower bound of zero, this method generally returns -1 if `value` isn't found. In the rare case that the lower bound of the array is equal to Int32.MinValue(0x80000000) and `value` isn't found, this method returns Int32.MaxValue (0x7FFFFFFF).

If `startIndex` equals Array.Length,the method returns -1. If `startIndex` is greater than Array.Length, the method throws an ArgumentOutOfRangeException.

This method is an O(`n`) operation, where `n` is the number of elements from `startIndex` to the end of `array`.

IndexOf(Array, Object, Int32, Int32)

Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of ifs first occurrence. The range extends from a specified index for a specified number of elements.

C#

```
public static int IndexOf (Array array, object? value, int startIndex,
int count);
```

Parameters

`array` Array

The one-dimensional array to search.

`value` Object

The object to locate in `array`.

`startIndex` Int32

The starting index of the search. 0 (zero) is valid in an empty array.

`count` Int32

The number of elements to search.

Returns

Int32

The index of the first occurrence of `value`, if it's found in the `array` from index `startIndex` to `startIndex` + `count` - 1; otherwise, the lower bound of the array minus 1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

-or-

`count` is less than zero.

-or-

`startIndex` and `count` do not specify a valid section in `array`.

RankException

`array` is multidimensional.

Examples

The example calls the following three overloads of the IndexOf method to find the index of a string in a string array:

- IndexOf(Array, Object), to determine the first occurrence of the string "the" in a string array.
- IndexOf(Array, Object, Int32), to determine the first occurrence of the string "the" in the fourth to the last elements of a string array.
- IndexOf(Array, Object, Int32, Int32), to determine the first occurrence of the string "the" in a string array from the element that follows the last successful match to the end of the array. To determine the value of the `count` argument, it subtracts the upper bound of the array from the starting index and adds one.

C#

```
// Create a string array with 3 elements having the same value.
String[] strings = { "the", "quick", "brown", "fox", "jumps",
                     "over", "the", "lazy", "dog", "in", "the",
```

```
                      "barn" };

// Display the elements of the array.
Console.WriteLine("The array contains the following values:");
for (int i = strings.GetLowerBound(0); i <= strings.GetUpperBound(0);
i++)
   Console.WriteLine("   [{0,2}]: {1}", i, strings[i]);

// Search for the first occurrence of the duplicated value.
string searchString = "the";
int index = Array.IndexOf(strings, searchString);
Console.WriteLine("The first occurrence of \"{0}\" is at index {1}.",
                  searchString, index);

// Search for the first occurrence of the duplicated value in the last
section of the array.
index = Array.IndexOf(strings, searchString, 4);
Console.WriteLine("The first occurrence of \"{0}\" between index 4 and
the end is at index {1}.",
                  searchString, index);

// Search for the first occurrence of the duplicated value in a section
of the array.
int position = index + 1;
index = Array.IndexOf(strings, searchString, position,
strings.GetUpperBound(0) - position + 1);
Console.WriteLine("The first occurrence of \"{0}\" between index {1} and
index {2} is at index {3}.",
                  searchString, position, strings.GetUpperBound(0),
index);

// The example displays the following output:
//    The array contains the following values:
//       [ 0]: the
//       [ 1]: quick
//       [ 2]: brown
//       [ 3]: fox
//       [ 4]: jumps
//       [ 5]: over
//       [ 6]: the
//       [ 7]: lazy
//       [ 8]: dog
//       [ 9]: in
//       [10]: the
//       [11]: barn
//    The first occurrence of "the" is at index 0.
//    The first occurrence of "the" between index 4 and the end is at
index 6.
//    The first occurrence of "the" between index 7 and index 11 is at
index 10.
```

Remarks

This method searches the elements of a one-dimensional array from `startIndex` to `startIndex` plus `count` minus 1, if `count` is greater than 0. To determine whether `value` exists in `array`, the method performs an equality comparison by calling the `Equals` method of every element until it finds a match. This means that if the element overrides the Object.Equals method, that override is called.

Because most arrays have a lower bound of zero, this method generally returns -1 when `value` isn't found. In the rare case that the lower bound of the array is equal to Int32.MinValue (0x80000000) and `value` isn't found, this method returns Int32.MaxValue (0x7FFFFFFF).

If `startindex` equals Array.Length, the method returns -1. If `startIndex` is greater than Array.Length, the method throws an ArgumentOutOfRangeException.

This method is an O(`n`) operation, where `n` is `count`.

UWP	10.0

IndexOf<T>(T[], T, Int32)

Searches for the specified object in a range of elements of a one dimensional array, and returns the index of its first occurrence. The range extends from a specified index to the end of the array.

```
C#
public static int IndexOf<T> (T[] array, T value, int startIndex);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based array to search.

`value` T

The object to locate in `array`.

`startIndex` Int32

The zero-based starting index of the search. 0 (zero) is valid in an empty array.

Returns

Int32

The zero-based index of the first occurrence of `value` within the range of elements in `array` that extends from `startIndex` to the last element, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

Examples

The following example demonstrates all three generic overloads of the IndexOf method. An array of strings is created, with one entry that appears twice, at index location 0 and index location 5. The IndexOf<T>(T[], T) method overload searches the array from the beginning, and finds the first occurrence of the string. The

IndexOf<T>(T[], T, Int32) method overload is used to search the array beginning with index location 3 and continuing to the end of the array, and finds the second occurrence of the string. Finally, the IndexOf<T>(T[], T, Int32, Int32) method overload is used to search a range of two entries, beginning at index location two; it returns -1 because there are no instances of the search string in that range.

C#

```
string[] dinosaurs = { "Tyrannosaurus",
    "Amargasaurus",
    "Mamenchisaurus",
    "Brachiosaurus",
    "Deinonychus",
    "Tyrannosaurus",
    "Compsognathus" };

Console.WriteLine();
foreach(string dinosaur in dinosaurs)
{
    Console.WriteLine(dinosaur);
}

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\"): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus"));

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\", 3): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus", 3));

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\", 2, 2): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus", 2, 2));

/* This code example produces the following output:

Tyrannosaurus
Amargasaurus
Mamenchisaurus
Brachiosaurus
Deinonychus
Tyrannosaurus
Compsognathus

Array.IndexOf(dinosaurs, "Tyrannosaurus"): 0

Array.IndexOf(dinosaurs, "Tyrannosaurus", 3): 5

Array.IndexOf(dinosaurs, "Tyrannosaurus", 2, 2): -1
*/
```

Remarks

This method searches a one-dimensional array from the element at `startIndex` to the end of the array. To determine whether `value` exists in `array`, the method performs an equality comparison by calling the `T.Equals` method on every element. This means that if `T` overrides the Equals method, that override is called.

If `startIndex` equals Length,the method returns -1. If `startIndex` is greater than Array.Length, the method throws an ArgumentOutOfRangeException.

This method is an O(`n`) operation, where `n` is the number of elements from `startIndex` to the end of `array`.

IndexOf<T>(T[], T, Int32, Int32)

Searches for the specified object in a range of elements of a one-dimensional array, and returns the index of its first occurrence. The range extends from a specified index for a specified number of elements.

```
C#
```

```
public static int IndexOf<T> (T[] array, T value, int startIndex, int
count);
```

Type Parameters

T

The type of the elements of the array.

Parameters

array T[]

The one-dimensional, zero-based array to search.

value T

The object to locate in `array`.

startIndex Int32

The zero-based starting index of the search. 0 (zero) is valid in an empty array.

count Int32

The number of elements in the section to search.

Returns

Int32

The zero-based index of the first occurrence of `value` within the range of elements in `array` that starts at `startIndex` and contains the number of elements specified in `count`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

-or-

`count` is less than zero.

-or-

`startIndex` and `count` do not specify a valid section in `array`.

Examples

The following example demonstrates all three generic overloads of the IndexOf method. An array of strings is created, with one entry that appears twice, at index location 0 and index location 5. The IndexOf<T>(T[], T) method overload searches the array from the beginning, and finds the first occurrence of the string. The IndexOf<T>(T[], T, Int32) method overload is used to search the array beginning with index location 3 and continuing to the end of the array, and finds the second occurrence of the string. Finally, the IndexOf<T>(T[], T, Int32, Int32) method overload is used to search a range of two entries, beginning at index location two; it returns -1 because there are no instances of the search string in that range.

C#

```
string[] dinosaurs = { "Tyrannosaurus",
    "Amargasaurus",
    "Mamenchisaurus",
    "Brachiosaurus",
    "Deinonychus",
    "Tyrannosaurus",
    "Compsognathus" };

Console.WriteLine();
foreach(string dinosaur in dinosaurs)
{
    Console.WriteLine(dinosaur);
}

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\"): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus"));

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\", 3): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus", 3));

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\", 2, 2): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus", 2, 2));

/* This code example produces the following output:

Tyrannosaurus
Amargasaurus
Mamenchisaurus
```

```
Brachiosaurus
Deinonychus
Tyrannosaurus
Compsognathus

Array.IndexOf(dinosaurs, "Tyrannosaurus"): 0

Array.IndexOf(dinosaurs, "Tyrannosaurus", 3): 5

Array.IndexOf(dinosaurs, "Tyrannosaurus", 2, 2): -1
*/
```

Remarks

This method searches the elements of a one-dimensional array from `startIndex` to `startIndex` plus `count` minus 1, if `count` is greater than 0. To determine whether `value` exists in `array`, the method performs an equality comparison by calling the `T.Equals` method on every element. This means that if `T` overrides the Equals method, that override is called.

If `startIndex` equals Array.Length, the method returns -1. If `startIndex` is greater than Array.Length, the method throws an ArgumentOutOfRangeException.

This method is an O(`n`) operation, where `n` is `count`.

UWP	10.0

IndexOf<T>(T[], T)

Searches for the specified object and returns the index of its first occurrence in a one-dimensional array.

```
C#

public static int IndexOf<T> (T[] array, T value);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based array to search.

`value` T

The object to locate in `array`.

Returns

Int32

The zero-based index of the first occurrence of `value` in the entire `array`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

Examples

The following example demonstrates all three generic overloads of the IndexOf method. An array of strings is created, with one entry that appears twice, at index location 0 and index location 5. The IndexOf<T>(T[], T) method overload searches the array from the beginning, and finds the first occurrence of the string. The IndexOf<T>(T[], T, Int32) method overload is used to search the array beginning with

index location 3 and continuing to the end of the array, and finds the second occurrence of the string. Finally, the IndexOf<T>(T[], T, Int32, Int32) method overload is used to search a range of two entries, beginning at index location two; it returns -1 because there are no instances of the search string in that range.

C#

```
string[] dinosaurs = { "Tyrannosaurus",
    "Amargasaurus",
    "Mamenchisaurus",
    "Brachiosaurus",
    "Deinonychus",
    "Tyrannosaurus",
    "Compsognathus" };

Console.WriteLine();
foreach(string dinosaur in dinosaurs)
{
    Console.WriteLine(dinosaur);
}

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\"): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus"));

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\", 3): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus", 3));

Console.WriteLine(
    "\nArray.IndexOf(dinosaurs, \"Tyrannosaurus\", 2, 2): {0}",
    Array.IndexOf(dinosaurs, "Tyrannosaurus", 2, 2));

/* This code example produces the following output:

Tyrannosaurus
Amargasaurus
Mamenchisaurus
Brachiosaurus
Deinonychus
Tyrannosaurus
Compsognathus

Array.IndexOf(dinosaurs, "Tyrannosaurus"): 0

Array.IndexOf(dinosaurs, "Tyrannosaurus", 3): 5

Array.IndexOf(dinosaurs, "Tyrannosaurus", 2, 2): -1
*/
```

Remarks

This method searches all the elements of a one-dimensional array for `value`. To determine whether `value` exists in `array`, the method performs an equality comparison by calling the `T.Equals` method on every element. This means that if `T` overrides the Equals method, that override is called.

This method is an O(`n`) operation, where `n` is the Length of `array`.

Array.Initialize Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes every element of the value-type Array by calling the parameterless constructor of the value type.

C#

```
public void Initialize ();
```

Remarks

This method is designed to help compilers support value-type arrays; most users do not need this method. It must not be used on reference-type arrays.

If the Array is not a value-type Array or if the value type does not have a parameterless constructor, the Array is not modified.

The value-type Array can have any lower bound and any number of dimensions.

This method is an O(`n`) operation, where `n` is Length.

Array.LastIndexOf Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the index of the last occurrence of a value in a one-dimensional Array or in a portion of the Array.

Overloads

Expand table

LastIndexOf(Array, Object)	Searches for the specified object and returns the index of the last occurrence within the entire one-dimensional Array.
LastIndexOf(Array, Object, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the one-dimensional Array that extends from the first element to the specified index.
LastIndexOf(Array, Object, Int32, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the one-dimensional Array that contains the specified number of elements and ends at the specified index.
LastIndexOf<T>(T[], T)	Searches for the specified object and returns the index of the last occurrence within the entire Array.
LastIndexOf<T>(T[], T, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the Array that extends from the first element to the specified index.
LastIndexOf<T>(T[], T, Int32, Int32)	Searches for the specified object and returns the index of the last occurrence within the range of elements in the Array that contains the specified number of elements and ends at the specified index.

LastIndexOf(Array, Object)

Searches for the specified object and returns the index of the last occurrence within the entire one-dimensional Array.

```C#
public static int LastIndexOf (Array array, object? value);
```

Parameters

`array` Array

The one-dimensional Array to search.

`value` Object

The object to locate in `array`.

Returns

Int32

The index of the last occurrence of `value` within the entire `array`, if found; otherwise, the lower bound of the array minus 1.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

Examples

The following code example shows how to determine the index of the last occurrence of a specified element in an array.

```C#
// Creates and initializes a new Array with three elements of the same value.
Array myArray=Array.CreateInstance( typeof(string), 12 );
myArray.SetValue( "the", 0 );
myArray.SetValue( "quick", 1 );
myArray.SetValue( "brown", 2 );
myArray.SetValue( "fox", 3 );
myArray.SetValue( "jumps", 4 );
myArray.SetValue( "over", 5 );
myArray.SetValue( "the", 6 );
```

```
myArray.SetValue( "lazy", 7 );
myArray.SetValue( "dog", 8 );
myArray.SetValue( "in", 9 );
myArray.SetValue( "the", 10 );
myArray.SetValue( "barn", 11 );

// Displays the values of the Array.
Console.WriteLine( "The Array contains the following values:" );
PrintIndexAndValues( myArray );

// Searches for the last occurrence of the duplicated value.
string myString = "the";
int myIndex = Array.LastIndexOf( myArray, myString );
Console.WriteLine( "The last occurrence of \"{0}\" is at index {1}.",
myString, myIndex );

// Searches for the last occurrence of the duplicated value in the first
section of the Array.
myIndex = Array.LastIndexOf( myArray, myString, 8 );
Console.WriteLine( "The last occurrence of \"{0}\" between the start and
index 8 is at index {1}.", myString, myIndex );

// Searches for the last occurrence of the duplicated value in a section
of the Array.
// Note that the start index is greater than the end index because the
search is done backward.
myIndex = Array.LastIndexOf( myArray, myString, 10, 6 );
Console.WriteLine( "The last occurrence of \"{0}\" between index 5 and
index 10 is at index {1}.", myString, myIndex );

void PrintIndexAndValues( Array anArray )  {
   for ( int i = anArray.GetLowerBound(0); i <= anArray.GetUpperBound(0);
i++ )
      Console.WriteLine( "\t[{0}]:\t{1}", i, anArray.GetValue( i ) );
}

/*
This code produces the following output.

The Array contains the following values:
   [0]:    the
   [1]:    quick
   [2]:    brown
   [3]:    fox
   [4]:    jumps
   [5]:    over
   [6]:    the
   [7]:    lazy
   [8]:    dog
   [9]:    in
   [10]:    the
   [11]:    barn
The last occurrence of "the" is at index 10.
The last occurrence of "the" between the start and index 8 is at index 6.
```

```
The last occurrence of "the" between index 5 and index 10 is at index 10.
*/
```

Remarks

The one-dimensional Array is searched backward starting at the last element and ending at the first element.

The elements are compared to the specified value using the Object.Equals method. If the element type is a nonintrinsic (user-defined) type, the `Equals` implementation of that type is used.

Since most arrays will have a lower bound of zero, this method would generally return -1 when `value` is not found. In the rare case that the lower bound of the array is equal to Int32.MinValue and `value` is not found, this method returns Int32.MaxValue, which is `System.Int32.MinValue - 1`.

This method is an O(`n`) operation, where `n` is the Length of `array`.

In .NET Framework 2.0 and later versions, this method uses the Equals and CompareTo methods of the Array to determine whether the Object specified by the `value` parameter exists. In earlier versions of .NET Framework, this determination was made by using the Equals and CompareTo methods of the `value` Object itself.

CompareTo methods of the `item` parameter on the objects in the collection.

LastIndexOf(Array, Object, Int32)

Searches for the specified object and returns the index of the last occurrence within the range of elements in the one-dimensional Array that extends from the first element to the specified index.

C#

```
public static int LastIndexOf (Array array, object? value, int
startIndex);
```

Parameters

`array` Array

The one-dimensional Array to search.

`value` Object

The object to locate in `array`.

`startIndex` Int32

The starting index of the backward search.

Returns

Int32

The index of the last occurrence of `value` within the range of elements in `array` that extends from the first element to `startIndex`, if found; otherwise, the lower bound of the array minus 1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

RankException

`array` is multidimensional.

Examples

The following code example shows how to determine the index of the last occurrence of a specified element in an array.

C#

```
// Creates and initializes a new Array with three elements of the same
value.
Array myArray=Array.CreateInstance( typeof(string), 12 );
myArray.SetValue( "the", 0 );
myArray.SetValue( "quick", 1 );
myArray.SetValue( "brown", 2 );
myArray.SetValue( "fox", 3 );
myArray.SetValue( "jumps", 4 );
myArray.SetValue( "over", 5 );
myArray.SetValue( "the", 6 );
myArray.SetValue( "lazy", 7 );
myArray.SetValue( "dog", 8 );
myArray.SetValue( "in", 9 );
myArray.SetValue( "the", 10 );
myArray.SetValue( "barn", 11 );

// Displays the values of the Array.
Console.WriteLine( "The Array contains the following values:" );
PrintIndexAndValues( myArray );

// Searches for the last occurrence of the duplicated value.
string myString = "the";
int myIndex = Array.LastIndexOf( myArray, myString );
Console.WriteLine( "The last occurrence of \"{0}\" is at index {1}.",
myString, myIndex );

// Searches for the last occurrence of the duplicated value in the first
section of the Array.
myIndex = Array.LastIndexOf( myArray, myString, 8 );
Console.WriteLine( "The last occurrence of \"{0}\" between the start and
index 8 is at index {1}.", myString, myIndex );

// Searches for the last occurrence of the duplicated value in a section
of the Array.
// Note that the start index is greater than the end index because the
search is done backward.
myIndex = Array.LastIndexOf( myArray, myString, 10, 6 );
```

```
Console.WriteLine( "The last occurrence of \"{0}\" between index 5 and
index 10 is at index {1}.", myString, myIndex );

void PrintIndexAndValues( Array anArray )  {
   for ( int i = anArray.GetLowerBound(0); i <= anArray.GetUpperBound(0);
i++ )
      Console.WriteLine( "\t[{0}]:\t{1}", i, anArray.GetValue( i ) );
}

/*
This code produces the following output.

The Array contains the following values:
   [0]:    the
   [1]:    quick
   [2]:    brown
   [3]:    fox
   [4]:    jumps
   [5]:    over
   [6]:    the
   [7]:    lazy
   [8]:    dog
   [9]:    in
   [10]:    the
   [11]:    barn
The last occurrence of "the" is at index 10.
The last occurrence of "the" between the start and index 8 is at index 6.
The last occurrence of "the" between index 5 and index 10 is at index 10.
*/
```

Remarks

The one-dimensional Array is searched backward starting at `startIndex` and ending at the first element.

The elements are compared to the specified value using the Object.Equals method. If the element type is a nonintrinsic (user-defined) type, the `Equals` implementation of that type is used.

Since most arrays will have a lower bound of zero, this method would generally return -1 when `value` is not found. In the rare case that the lower bound of the array is equal to Int32.MinValue and `value` is not found, this method returns Int32.MaxValue, which is `System.Int32.MinValue - 1`.

This method is an O(`n`) operation, where `n` is the number of elements from the beginning of `array` to `startIndex`.

In .NET Framework 2.0 and later versions, this method uses the Equals and CompareTo methods of the Array to determine whether the Object specified by the `value` parameter exists. In earlier versions of .NET Framework, this determination was made by using the Equals and CompareTo methods of the `value` Object itself.

LastIndexOf(Array, Object, Int32, Int32)

Searches for the specified object and returns the index of the last occurrence within the range of elements in the one-dimensional Array that contains the specified number of elements and ends at the specified index.

C#

```
public static int LastIndexOf (Array array, object? value, int
startIndex, int count);
```

Parameters

`array` Array

The one-dimensional Array to search.

`value` Object

The object to locate in `array`.

`startIndex` Int32

The starting index of the backward search.

`count` Int32

The number of elements in the section to search.

Returns

Int32

The index of the last occurrence of `value` within the range of elements in `array` that contains the number of elements specified in `count` and ends at `startIndex`, if found; otherwise, the lower bound of the array minus 1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

-or-

`count` is less than zero.

-or-

`startIndex` and `count` do not specify a valid section in `array`.

RankException

`array` is multidimensional.

Examples

The following code example shows how to determine the index of the last occurrence of a specified element in an array. Note that the LastIndexOf method is a backward search; therefore, `count` must be less than or equal to (`startIndex` minus the lower bound of the array plus 1).

C#

```
// Creates and initializes a new Array with three elements of the same
value.
Array myArray=Array.CreateInstance( typeof(string), 12 );
myArray.SetValue( "the", 0 );
myArray.SetValue( "quick", 1 );
myArray.SetValue( "brown", 2 );
myArray.SetValue( "fox", 3 );
myArray.SetValue( "jumps", 4 );
myArray.SetValue( "over", 5 );
myArray.SetValue( "the", 6 );
myArray.SetValue( "lazy", 7 );
myArray.SetValue( "dog", 8 );
myArray.SetValue( "in", 9 );
myArray.SetValue( "the", 10 );
myArray.SetValue( "barn", 11 );

// Displays the values of the Array.
Console.WriteLine( "The Array contains the following values:" );
PrintIndexAndValues( myArray );

// Searches for the last occurrence of the duplicated value.
string myString = "the";
int myIndex = Array.LastIndexOf( myArray, myString );
Console.WriteLine( "The last occurrence of \"{0}\" is at index {1}.",
myString, myIndex );

// Searches for the last occurrence of the duplicated value in the first
section of the Array.
myIndex = Array.LastIndexOf( myArray, myString, 8 );
Console.WriteLine( "The last occurrence of \"{0}\" between the start and
index 8 is at index {1}.", myString, myIndex );

// Searches for the last occurrence of the duplicated value in a section
of the Array.
// Note that the start index is greater than the end index because the
search is done backward.
myIndex = Array.LastIndexOf( myArray, myString, 10, 6 );
Console.WriteLine( "The last occurrence of \"{0}\" between index 5 and
index 10 is at index {1}.", myString, myIndex );

void PrintIndexAndValues( Array anArray )  {
   for ( int i = anArray.GetLowerBound(0); i <= anArray.GetUpperBound(0);
i++ )
      Console.WriteLine( "\t[{0}]:\t{1}", i, anArray.GetValue( i ) );
}

/*
This code produces the following output.

The Array contains the following values:
   [0]:    the
   [1]:    quick
```

```
   [2]:    brown
   [3]:    fox
   [4]:    jumps
   [5]:    over
   [6]:    the
   [7]:    lazy
   [8]:    dog
   [9]:    in
   [10]:    the
   [11]:    barn
The last occurrence of "the" is at index 10.
The last occurrence of "the" between the start and index 8 is at index 6.
The last occurrence of "the" between index 5 and index 10 is at index 10.
*/
```

Remarks

The one-dimensional Array is searched backward starting at `startIndex` and ending at `startIndex` minus `count` plus 1, if `count` is greater than 0.

The elements are compared to the specified value using the Object.Equals method. If the element type is a nonintrinsic (user-defined) type, the `Equals` implementation of that type is used.

Since most arrays will have a lower bound of zero, this method would generally return -1 when `value` is not found. In the rare case that the lower bound of the array is equal to Int32.MinValue and `value` is not found, this method returns Int32.MaxValue, which is `System.Int32.MinValue - 1`.

This method is an O(`n`) operation, where `n` is `count`.

In .NET Framework 2.0 and later versions, this method uses the Equals and CompareTo methods of the Array to determine whether the Object specified by the `value` parameter exists. In earlier versions of .NET Framework, this determination was made by using the Equals and CompareTo methods of the `value` Object itself.

LastIndexOf<T>(T[], T)

Searches for the specified object and returns the index of the last occurrence within the entire Array.

```
C#

public static int LastIndexOf<T> (T[] array, T value);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`value` T

The object to locate in `array`.

Returns

Int32

The zero-based index of the last occurrence of `value` within the entire `array`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

Examples

The following code example demonstrates all three generic overloads of the LastIndexOf method. An array of strings is created, with one entry that appears twice, at index location 0 and index location 5. The LastIndexOf<T>(T[], T) method overload searches the entire array from the end, and finds the second occurrence of the string. The LastIndexOf<T>(T[], T, Int32) method overload is used to search the array backward beginning with index location 3 and continuing to the beginning of the array, and finds the first occurrence of the string. Finally, the LastIndexOf<T>(T[], T, Int32, Int32) method overload is used to search a range of four entries, beginning at index location 4 and extending backward (that is, it searches the items at locations 4, 3, 2, and 1); this search returns -1 because there are no instances of the search string in that range.

C#

```
string[] dinosaurs = { "Tyrannosaurus",
    "Amargasaurus",
    "Mamenchisaurus",
    "Brachiosaurus",
    "Deinonychus",
    "Tyrannosaurus",
    "Compsognathus" };

Console.WriteLine();
foreach(string dinosaur in dinosaurs)
{
    Console.WriteLine(dinosaur);
}

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\"): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus"));

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\", 3): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 3));

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\", 4, 4): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 4, 4));

/* This code example produces the following output:

Tyrannosaurus
```

```
Amargasaurus
Mamenchisaurus
Brachiosaurus
Deinonychus
Tyrannosaurus
Compsognathus

Array.LastIndexOf(dinosaurs, "Tyrannosaurus"): 5

Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 3): 0

Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 4, 4): -1
*/
```

Remarks

The Array is searched backward starting at the last element and ending at the first element.

The elements are compared to the specified value using the Object.Equals method. If the element type is a nonintrinsic (user-defined) type, the `Equals` implementation of that type is used.

This method is an O(`n`) operation, where `n` is the Length of `array`.

UWP	10.0

LastIndexOf<T>(T[], T, Int32)

Searches for the specified object and returns the index of the last occurrence within the range of elements in the Array that extends from the first element to the specified index.

```
C#
public static int LastIndexOf<T> (T[] array, T value, int startIndex);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to search.

`value` T

The object to locate in `array`.

`startIndex` Int32

The zero-based starting index of the backward search.

Returns

Int32

The zero-based index of the last occurrence of `value` within the range of elements in `array` that extends from the first element to `startIndex`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

Examples

The following code example demonstrates all three generic overloads of the LastIndexOf method. An array of strings is created, with one entry that appears twice, at index location 0 and index location 5. The LastIndexOf<T>(T[], T) method overload searches the entire array from the end, and finds the second occurrence of the string. The LastIndexOf<T>(T[], T, Int32) method overload is used to search the array backward beginning with index location 3 and continuing to the beginning of the array, and finds the first occurrence of the string. Finally, the LastIndexOf<T>(T[], T, Int32, Int32) method overload is used to search a range of four entries, beginning at index location 4 and extending backward (that is, it searches the items at locations 4, 3, 2, and 1); this search returns -1 because there are no instances of the search string in that range.

C#

```
string[] dinosaurs = { "Tyrannosaurus",
    "Amargasaurus",
    "Mamenchisaurus",
    "Brachiosaurus",
    "Deinonychus",
    "Tyrannosaurus",
    "Compsognathus" };

Console.WriteLine();
foreach(string dinosaur in dinosaurs)
{
    Console.WriteLine(dinosaur);
}

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\"): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus"));

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\", 3): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 3));

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\", 4, 4): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 4, 4));

/* This code example produces the following output:

Tyrannosaurus
Amargasaurus
Mamenchisaurus
Brachiosaurus
Deinonychus
Tyrannosaurus
```

```
Compsognathus

Array.LastIndexOf(dinosaurs, "Tyrannosaurus"): 5

Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 3): 0

Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 4, 4): -1
*/
```

Remarks

The Array is searched backward starting at `startIndex` and ending at the first element.

The elements are compared to the specified value using the Object.Equals method. If the element type is a nonintrinsic (user-defined) type, the `Equals` implementation of that type is used.

This method is an O(`n`) operation, where `n` is the number of elements from the beginning of `array` to `startIndex`.

UWP	10.0

LastIndexOf<T>(T[], T, Int32, Int32)

Searches for the specified object and returns the index of the last occurrence within the range of elements in the Array that contains the specified number of elements and ends at the specified index.

```
C#

public static int LastIndexOf<T> (T[] array, T value, int startIndex, int
count);
```

Type Parameters

T

The type of the elements of the array.

Parameters

array T[]

The one-dimensional, zero-based Array to search.

value T

The object to locate in `array`.

startIndex Int32

The zero-based starting index of the backward search.

count Int32

The number of elements in the section to search.

Returns

Int32

The zero-based index of the last occurrence of `value` within the range of elements in `array` that contains the number of elements specified in `count` and ends at `startIndex`, if found; otherwise, -1.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`startIndex` is outside the range of valid indexes for `array`.

-or-

`count` is less than zero.

-or-

`startIndex` and `count` do not specify a valid section in `array`.

Examples

The following code example demonstrates all three generic overloads of the LastIndexOf method. An array of strings is created, with one entry that appears twice, at index location 0 and index location 5. The LastIndexOf<T>(T[], T) method overload searches the entire array from the end, and finds the second occurrence of the string. The LastIndexOf<T>(T[], T, Int32) method overload is used to search the array backward beginning with index location 3 and continuing to the beginning of the array, and finds the first occurrence of the string. Finally, the LastIndexOf<T>(T[], T, Int32, Int32) method overload is used to search a range of four entries, beginning at index location 4 and extending backward (that is, it searches the items at locations 4, 3, 2, and 1); this search returns -1 because there are no instances of the search string in that range.

C#

```
string[] dinosaurs = { "Tyrannosaurus",
    "Amargasaurus",
    "Mamenchisaurus",
    "Brachiosaurus",
    "Deinonychus",
    "Tyrannosaurus",
    "Compsognathus" };

Console.WriteLine();
foreach(string dinosaur in dinosaurs)
{
    Console.WriteLine(dinosaur);
}

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\"): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus"));

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\", 3): {0}",
```

```
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 3));

Console.WriteLine(
    "\nArray.LastIndexOf(dinosaurs, \"Tyrannosaurus\", 4, 4): {0}",
    Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 4, 4));

/* This code example produces the following output:

Tyrannosaurus
Amargasaurus
Mamenchisaurus
Brachiosaurus
Deinonychus
Tyrannosaurus
Compsognathus

Array.LastIndexOf(dinosaurs, "Tyrannosaurus"): 5

Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 3): 0

Array.LastIndexOf(dinosaurs, "Tyrannosaurus", 4, 4): -1
*/
```

Remarks

The Array is searched backward starting at `startIndex` and ending at `startIndex` minus `count` plus 1, if `count` is greater than 0.

The elements are compared to the specified value using the Object.Equals method. If the element type is a nonintrinsic (user-defined) type, the `Equals` implementation of that type is used.

This method is an O(`n`) operation, where `n` is `count`.

Array.Resize<T>(T[], Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Changes the number of elements of a one-dimensional array to the specified new size.

C#

```
public static void Resize<T> (ref T[]? array, int newSize);
```

Type Parameters

T

The type of the elements of the array.

Parameters

array T[]

The one-dimensional, zero-based array to resize, or `null` to create a new array with the specified size.

newSize Int32

The size of the new array.

Exceptions

ArgumentOutOfRangeException

`newSize` is less than zero.

Examples

The following example shows how resizing affects the array.

C#

```
using System;

public class SamplesArray
{
    public static void Main()  {

        // Create and initialize a new string array.
        String[] myArr = {"The", "quick", "brown", "fox", "jumps",
            "over", "the", "lazy", "dog"};

        // Display the values of the array.
        Console.WriteLine(
            "The string array initially contains the following values:");
        PrintIndexAndValues(myArr);

        // Resize the array to a bigger size (five elements larger).
        Array.Resize(ref myArr, myArr.Length + 5);

        // Display the values of the array.
        Console.WriteLine("After resizing to a larger size, ");
        Console.WriteLine("the string array contains the following
values:");
        PrintIndexAndValues(myArr);

        // Resize the array to a smaller size (four elements).
        Array.Resize(ref myArr, 4);

        // Display the values of the array.
        Console.WriteLine("After resizing to a smaller size, ");
        Console.WriteLine("the string array contains the following
values:");
        PrintIndexAndValues(myArr);
    }

    public static void PrintIndexAndValues(String[] myArr)  {
        for(int i = 0; i < myArr.Length; i++)
        {
            Console.WriteLine("   [{0}] : {1}", i, myArr[i]);
        }
        Console.WriteLine();
    }
}

/*
This code produces the following output.

The string array initially contains the following values:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
```

```
   [7] : lazy
   [8] : dog

After resizing to a larger size,
the string array contains the following values:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog
   [9] :
   [10] :
   [11] :
   [12] :
   [13] :

After resizing to a smaller size,
the string array contains the following values:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox

*/
```

Remarks

This method allocates a new array with the specified size, copies elements from the old array to the new one, and then replaces the old array with the new one. `array` must be a one-dimensional array.

If `array` is `null`, this method creates a new array with the specified size.

If `newSize` is greater than the Length of the old array, a new array is allocated and all the elements are copied from the old array to the new one. If `newSize` is less than the Length of the old array, a new array is allocated and elements are copied from the old array to the new one until the new one is filled; the rest of the elements in the old array are ignored. If `newSize` is equal to the Length of the old array, this method does nothing.

This method is an O(`n`) operation, where `n` is `newSize`.

The Resize method resizes a one-dimensional array only. The Array class does not include a method for resizing multi-dimensional arrays. To do this, you must either

provide your own code or call a special-purpose method in a third-party library. The following code illustrates one possible implementation for a method that resizes an array of *n* dimensions.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int[,] arr = new int[10,2];
      for (int n1 = 0; n1 <= arr.GetUpperBound(0); n1++) {
         arr[n1, 0] = n1;
         arr[n1, 1] = n1 * 2;
      }

      // Make a 2-D array larger in the first dimension.
      arr = (int[,]) ResizeArray(arr, new int[] { 12, 2} );
      for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++)
         Console.WriteLine("{0}: {1}, {2}", ctr, arr[ctr, 0], arr[ctr, 1]);
      Console.WriteLine();

      // Make a 2-D array smaller in the first dimension.
      arr = (int[,]) ResizeArray(arr, new int[] { 2, 2} );
      for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++)
         Console.WriteLine("{0}: {1}, {2}", ctr, arr[ctr, 0], arr[ctr, 1]);
   }

   private static Array ResizeArray(Array arr, int[] newSizes)
   {
      if (newSizes.Length != arr.Rank)
         throw new ArgumentException("arr must have the same number of
dimensions " +
                                     "as there are elements in newSizes",
"newSizes");

      var temp = Array.CreateInstance(arr.GetType().GetElementType(),
newSizes);
      int length = arr.Length <= temp.Length ? arr.Length : temp.Length;
      Array.ConstrainedCopy(arr, 0, temp, 0, length);
      return temp;
   }
}
// The example displays the following output:
//       0: 0, 0
//       1: 1, 2
//       2: 2, 4
//       3: 3, 6
//       4: 4, 8
//       5: 5, 10
//       6: 6, 12
```

```
//        7: 7, 14
//        8: 8, 16
//        9: 9, 18
//        10: 0, 0
//        11: 0, 0
//
//        0: 0, 0
//        1: 1, 2
```

Array.Reverse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reverses the order of the elements in a one-dimensional Array or in a portion of the Array.

Overloads

Expand table

Reverse(Array)	Reverses the sequence of the elements in the entire one-dimensional Array.
Reverse(Array, Int32, Int32)	Reverses the sequence of a subset of the elements in the one-dimensional Array.
Reverse<T>(T[])	Reverses the sequence of the elements in the one-dimensional generic array.
Reverse<T>(T[], Int32, Int32)	Reverses the sequence of a subset of the elements in the one-dimensional generic array.

Reverse(Array)

Reverses the sequence of the elements in the entire one-dimensional Array.

C#

```
public static void Reverse (Array array);
```

Parameters

`array` Array

The one-dimensional Array to reverse.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

Examples

The following code example shows how to reverse the sort of the values in an Array.

C#

```
using System;
public class SamplesArray  {

   public static void Main()  {

      // Creates and initializes a new Array.
      Array myArray=Array.CreateInstance( typeof(string), 9 );
      myArray.SetValue( "The", 0 );
      myArray.SetValue( "quick", 1 );
      myArray.SetValue( "brown", 2 );
      myArray.SetValue( "fox", 3 );
      myArray.SetValue( "jumps", 4 );
      myArray.SetValue( "over", 5 );
      myArray.SetValue( "the", 6 );
      myArray.SetValue( "lazy", 7 );
      myArray.SetValue( "dog", 8 );

      // Displays the values of the Array.
      Console.WriteLine( "The Array initially contains the following
values:" );
      PrintIndexAndValues( myArray );

      // Reverses the sort of the values of the Array.
      Array.Reverse( myArray );

      // Displays the values of the Array.
      Console.WriteLine( "After reversing:" );
      PrintIndexAndValues( myArray );
   }

   public static void PrintIndexAndValues( Array myArray )  {
      for ( int i = myArray.GetLowerBound(0); i <=
myArray.GetUpperBound(0); i++ )
         Console.WriteLine( "\t[{0}]:\t{1}", i, myArray.GetValue( i ) );
   }
}
/*
```

```
This code produces the following output.

The Array initially contains the following values:
    [0]:    The
    [1]:    quick
    [2]:    brown
    [3]:    fox
    [4]:    jumps
    [5]:    over
    [6]:    the
    [7]:    lazy
    [8]:    dog
After reversing:
    [0]:    dog
    [1]:    lazy
    [2]:    the
    [3]:    over
    [4]:    jumps
    [5]:    fox
    [6]:    brown
    [7]:    quick
    [8]:    The
*/
```

Remarks

After a call to this method, the element at `myArray[i]`, where `i` is any index in the array, moves to `myArray[j]`, where `j` equals `(myArray.Length + myArray.GetLowerBound(0)) - (i - myArray.GetLowerBound(0)) - 1`.

This method is an O(`n`) operation, where `n` is the Length of `array`.

In F#, the Array.rev function can be used instead.

As the following example shows, the Reverse method can be used to reverse a jagged array. It initializes a jagged array with one element for each month of the current year in the current culture's calendar. Each element contains an array with as many elements as that month has days. The example displays the contents of the array, calls the Reverse method, and then displays the contents of the reversed array.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
```

```
      int nMonths =
DateTimeFormatInfo.CurrentInfo.Calendar.GetMonthsInYear(DateTime.Now.Year
);
      int[][] months = new int[nMonths][];

      // Populate elements with number of days in month.
      for (int ctr = 0; ctr <= months.GetUpperBound(0); ctr++) {
         int daysInMonth = DateTime.DaysInMonth(DateTime.Now.Year, ctr +
1);
         months[ctr] = new int[daysInMonth] ;
         for (int ctr2 = 1; ctr2 <= daysInMonth; ctr2++)
            months[ctr][ctr2 - 1] = ctr2;
      }

      foreach (var month in months) {
         foreach (var day in month)
            Console.Write("{0} ", day);

         Console.WriteLine();
      }
      Console.WriteLine();

      Console.WriteLine("About to reverse array.\n");
      Array.Reverse(months);

      foreach (var month in months) {
         foreach (var day in month)
            Console.Write("{0} ", day);

         Console.WriteLine();
      }
   }
}
// The example displays output similar to the following:
//    1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25
26 27 28 29 30 31

Reverse(Array, Int32, Int32)

Reverses the sequence of a subset of the elements in the one-dimensional Array.

```
C#

public static void Reverse (Array array, int index, int length);
```

Parameters

array Array

The one-dimensional Array to reverse.

index Int32

The starting index of the section to reverse.

length Int32

The number of elements in the section to reverse.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

Examples

The following code example shows how to reverse the sort of the values in a range of elements in an Array.

```
C#
```

```
using System;
public class SamplesArray1  {

   public static void Main()  {

      // Creates and initializes a new Array.
      Array myArray=Array.CreateInstance( typeof(string), 9 );
      myArray.SetValue( "The", 0 );
      myArray.SetValue( "QUICK", 1 );
      myArray.SetValue( "BROWN", 2 );
      myArray.SetValue( "FOX", 3 );
      myArray.SetValue( "jumps", 4 );
      myArray.SetValue( "over", 5 );
      myArray.SetValue( "the", 6 );
      myArray.SetValue( "lazy", 7 );
      myArray.SetValue( "dog", 8 );

      // Displays the values of the Array.
      Console.WriteLine( "The Array initially contains the following
values:" );
      PrintIndexAndValues( myArray );

      // Reverses the sort of the values of the Array.
      Array.Reverse( myArray, 1, 3 );

      // Displays the values of the Array.
      Console.WriteLine( "After reversing:" );
      PrintIndexAndValues( myArray );
   }

   public static void PrintIndexAndValues( Array myArray )  {
      for ( int i = myArray.GetLowerBound(0); i <=
myArray.GetUpperBound(0); i++ )
         Console.WriteLine( "\t[{0}]:\t{1}", i, myArray.GetValue( i ) );
   }
}
/*
This code produces the following output.

The Array initially contains the following values:
    [0]:    The
    [1]:    QUICK
    [2]:    BROWN
    [3]:    FOX
    [4]:    jumps
    [5]:    over
    [6]:    the
    [7]:    lazy
    [8]:    dog
After reversing:
    [0]:    The
    [1]:    FOX
    [2]:    BROWN
    [3]:    QUICK
```

```
    [4]:    jumps
    [5]:    over
    [6]:    the
    [7]:    lazy
    [8]:    dog
*/
```

Remarks

After a call to this method, the element at `myArray[i]`, where `i` is any index in the array, moves to `myArray[j]`, where `j` equals `(myArray.Length + myArray.GetLowerBound(0)) - (i - myArray.GetLowerBound(0)) - 1`.

The Reverse method can be used to reverse a jagged array.

This method is an O(`n`) operation, where `n` is `length`.

Reverse<T>(T[])

Reverses the sequence of the elements in the one-dimensional generic array.

C#

```
public static void Reverse<T> (T[] array);
```

Type Parameters

`T`

The type of the elements in `array`.

Parameters

`array` T[]

The one-dimensional array of elements to reverse.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

Array.SetValue Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sets the specified element in the current Array to the specified value.

Overloads

Expand table

SetValue(Object, Int32)	Sets a value to the element at the specified position in the one-dimensional Array. The index is specified as a 32-bit integer.
SetValue(Object, Int32[])	Sets a value to the element at the specified position in the multidimensional Array. The indexes are specified as an array of 32-bit integers.
SetValue(Object, Int64[])	Sets a value to the element at the specified position in the multidimensional Array. The indexes are specified as an array of 64-bit integers.
SetValue(Object, Int32, Int32)	Sets a value to the element at the specified position in the two-dimensional Array. The indexes are specified as 32-bit integers.
SetValue(Object, Int64, Int64)	Sets a value to the element at the specified position in the two-dimensional Array. The indexes are specified as 64-bit integers.
SetValue(Object, Int32, Int32, Int32)	Sets a value to the element at the specified position in the three-dimensional Array. The indexes are specified as 32-bit integers.
SetValue(Object, Int64, Int64, Int64)	Sets a value to the element at the specified position in the three-dimensional Array. The indexes are specified as 64-bit integers.
SetValue(Object, Int64)	Sets a value to the element at the specified position in the one-dimensional Array. The index is specified as a 64-bit integer.

Examples

The following code example demonstrates how to set and get a specific value in a one-dimensional or multidimensional array.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Creates and initializes a one-dimensional array.
      String[] myArr1 = new String[5];

      // Sets the element at index 3.
      myArr1.SetValue( "three", 3 );
      Console.WriteLine( "[3]:   {0}", myArr1.GetValue( 3 ) );

      // Creates and initializes a two-dimensional array.
      String[,] myArr2 = new String[5,5];

      // Sets the element at index 1,3.
      myArr2.SetValue( "one-three", 1, 3 );
      Console.WriteLine( "[1,3]:   {0}", myArr2.GetValue( 1, 3 ) );

      // Creates and initializes a three-dimensional array.
      String[,,] myArr3 = new String[5,5,5];

      // Sets the element at index 1,2,3.
      myArr3.SetValue( "one-two-three", 1, 2, 3 );
      Console.WriteLine( "[1,2,3]:   {0}", myArr3.GetValue( 1, 2, 3 ) );

      // Creates and initializes a seven-dimensional array.
      String[,,,,,,] myArr7 = new String[5,5,5,5,5,5,5];

      // Sets the element at index 1,2,3,0,1,2,3.
      int[] myIndices = new int[7] { 1, 2, 3, 0, 1, 2, 3 };
      myArr7.SetValue( "one-two-three-zero-one-two-three", myIndices );
      Console.WriteLine( "[1,2,3,0,1,2,3]:   {0}", myArr7.GetValue(
myIndices ) );
   }
}

/*
This code produces the following output.

[3]:   three
[1,3]:   one-three
[1,2,3]:   one-two-three
[1,2,3,0,1,2,3]:   one-two-three-zero-one-two-three

*/
```

SetValue(Object, Int32)

Sets a value to the element at the specified position in the one-dimensional Array. The index is specified as a 32-bit integer.

```
C#

public void SetValue (object? value, int index);
```

Parameters

`value` Object

The new value for the specified element.

`index` Int32

A 32-bit integer that represents the position of the Array element to set.

Exceptions

ArgumentException

The current Array does not have exactly one dimension.

InvalidCastException

`value` cannot be cast to the element type of the current Array.

IndexOutOfRangeException

`index` is outside the range of valid indexes for the current Array.

Remarks

The GetLowerBound and GetUpperBound methods can determine whether the value of `index` is out of bounds.

For more information about conversions, see Convert.

This method is an O(1) operation.

> ⓘ **Note**
>
> If **SetValue** is used to assign `null` to an element of an array of value types, all fields of the element are initialized to zero. The value of the element is not a null

reference, and cannot be found by searching for a null reference.

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

SetValue(Object, Int32[])

Sets a value to the element at the specified position in the multidimensional Array. The indexes are specified as an array of 32-bit integers.

C#

```
public void SetValue (object? value, params int[] indices);
```

Parameters

`value` Object

The new value for the specified element.

`indices` Int32[]

A one-dimensional array of 32-bit integers that represent the indexes specifying the position of the element to set.

Exceptions

ArgumentNullException

`indices` is `null`.

ArgumentException

The number of dimensions in the current Array is not equal to the number of elements in `indices`.

InvalidCastException

`value` cannot be cast to the element type of the current Array.

IndexOutOfRangeException

Any element in `indices` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

The number of elements in `indices` must equal the number of dimensions in the Array. All elements in the `indices` array must collectively specify the position of the desired element in the multidimensional Array.

The GetLowerBound and GetUpperBound methods can determine whether any of the values in the `indices` array is out of bounds.

For more information about conversions, see Convert.

This method is an O(1) operation.

> **Note**
>
> If **SetValue** is used to assign `null` to an element of an array of value types, all fields of the element are initialized to zero. The value of the element is not a null reference, and cannot be found by searching for a null reference.

SetValue(Object, Int64[])

Sets a value to the element at the specified position in the multidimensional Array. The indexes are specified as an array of 64-bit integers.

```
C#

public void SetValue (object? value, params long[] indices);
```

Parameters

`value` Object

The new value for the specified element.

`indices` Int64[]

A one-dimensional array of 64-bit integers that represent the indexes specifying the position of the element to set.

Exceptions

ArgumentNullException

`indices` is `null`.

ArgumentException

The number of dimensions in the current Array is not equal to the number of elements in `indices`.

InvalidCastException

`value` cannot be cast to the element type of the current Array.

ArgumentOutOfRangeException

SetValue(Object, Int32, Int32)

Sets a value to the element at the specified position in the two-dimensional Array. The indexes are specified as 32-bit integers.

```
C#
public void SetValue (object? value, int index1, int index2);
```

Parameters

`value` Object

The new value for the specified element.

`index1` Int32

A 32-bit integer that represents the first-dimension index of the Array element to set.

`index2` Int32

A 32-bit integer that represents the second-dimension index of the Array element to set.

Exceptions

ArgumentException

The current Array does not have exactly two dimensions.

.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

SetValue(Object, Int32, Int32, Int32)

Sets a value to the element at the specified position in the three-dimensional Array. The indexes are specified as 32-bit integers.

C#

```
public void SetValue (object? value, int index1, int index2, int index3);
```

Parameters

`value` Object

The new value for the specified element.

`index1` Int32

A 32-bit integer that represents the first-dimension index of the Array element to set.

`index2` Int32

A 32-bit integer that represents the second-dimension index of the Array element to set.

`index3` Int32

A 32-bit integer that represents the third-dimension index of the Array element to set.

Exceptions

ArgumentException

The current Array does not have exactly three dimensions.

InvalidCastException

`value` cannot be cast to the element type of the current Array.

IndexOutOfRangeException

`index1` or `index2` or `index3` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

The GetLowerBound and GetUpperBound methods can determine whether any of the indexes is out of bounds.

For more information about conversions, see Convert.

This method is an O(1) operation.

> ⓘ **Note**
>
> If **SetValue** is used to assign `null` to an element of an array of value types, all fields of the element are initialized to zero. The value of the element is not a null reference, and cannot be found by searching for a null reference.

SetValue(Object, Int64, Int64, Int64)

Sets a value to the element at the specified position in the three-dimensional Array. The indexes are specified as 64-bit integers.

```
C#

public void SetValue (object? value, long index1, long index2, long
index3);
```

Parameters

`value` Object

The new value for the specified element.

`index1` Int64

A 64-bit integer that represents the first-dimension index of the Array element to set.

`index2` Int64

A 64-bit integer that represents the second-dimension index of the Array element to set.

`index3` Int64

A 64-bit integer that represents the third-dimension index of the Array element to set.

Exceptions

ArgumentException

The current Array does not have exactly three dimensions.

InvalidCastException

`value` cannot be cast to the element type of the current Array.

ArgumentOutOfRangeException

`index1` or `index2` or `index3` is outside the range of valid indexes for the corresponding dimension of the current Array.

Remarks

Array.Sort Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sorts the elements in a one-dimensional array.

Overloads

Expand table

Sort(Array, Array, Int32, Int32, IComparer)	Sorts a range of elements in a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer.
Sort(Array, Int32, Int32, IComparer)	Sorts the elements in a range of elements in a one-dimensional Array using the specified IComparer.
Sort(Array, Array, Int32, Int32)	Sorts a range of elements in a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable implementation of each key.
Sort(Array, Int32, Int32)	Sorts the elements in a range of elements in a one-dimensional Array using the IComparable implementation of each element of the Array.
Sort(Array, Array, IComparer)	Sorts a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer.
Sort(Array, Array)	Sorts a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable implementation of each key.
Sort(Array)	Sorts the elements in an entire one-dimensional Array using the IComparable implementation of each element of the Array.
Sort(Array, IComparer)	Sorts the elements in a one-dimensional Array using the specified IComparer.

Sort<T>(T[])	Sorts the elements in an entire Array using the IComparable<T> generic interface implementation of each element of the Array.
Sort<T>(T[], IComparer<T>)	Sorts the elements in an Array using the specified IComparer<T> generic interface.
Sort<T>(T[], Comparison<T>)	Sorts the elements in an Array using the specified Comparison<T>.
Sort<T>(T[], Int32, Int32)	Sorts the elements in a range of elements in an Array using the IComparable<T> generic interface implementation of each element of the Array.
Sort<T>(T[], Int32, Int32, IComparer<T>)	Sorts the elements in a range of elements in an Array using the specified IComparer<T> generic interface.
Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>)	Sorts a range of elements in a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer<T> generic interface.
Sort<TKey,TValue>(TKey[], TValue[])	Sorts a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable<T> generic interface implementation of each key.
Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>)	Sorts a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer<T> generic interface.
Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32)	Sorts a range of elements in a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable<T> generic interface implementation of each key.

Sort(Array, Array, Int32, Int32, IComparer)

Sorts a range of elements in a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer.

C#

```
public static void Sort (Array keys, Array? items, int index, int length,
System.Collections.IComparer? comparer);
```

Parameters

`keys` Array

The one-dimensional Array that contains the keys to sort.

`items` Array

The one-dimensional Array that contains the items that correspond to each of the keys in the `keys` Array.

-or-

`null` to sort only the `keys` Array.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

`comparer` IComparer

The IComparer implementation to use when comparing elements.

-or-

`null` to use the IComparable implementation of each element.

Exceptions

ArgumentNullException

`keys` is `null`.

RankException

The `keys` Array is multidimensional.

-or-

The `items` Array is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `keys`.

-or-

`length` is less than zero.

ArgumentException

`items` is not `null`, and the lower bound of `keys` does not match the lower bound of `items`.

-or-

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

-or-

`index` and `length` do not specify a valid range in the `keys` Array.

-or-

`items` is not `null`, and `index` and `length` do not specify a valid range in the `items` Array.

-or-

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

InvalidOperationException

`comparer` is `null`, and one or more elements in the `keys` Array do not implement the IComparable interface.

Examples

The following code example shows how to sort two associated arrays where the first array contains the keys and the second array contains the values. Sorts are done using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

C#

```
using System;
using System.Collections;

public class SamplesArray  {

   public class myReverserClass : IComparer  {

      // Calls CaseInsensitiveComparer.Compare with the parameters
```

```
reversed.
      int IComparer.Compare( Object x, Object y )  {
          return( (new CaseInsensitiveComparer()).Compare( y, x ) );
      }
   }

   public static void Main()  {

      // Creates and initializes a new Array and a new custom comparer.
      String[] myKeys = { "red", "GREEN", "YELLOW", "BLUE", "purple",
"black", "orange" };
      String[] myValues = { "strawberries", "PEARS", "LIMES", "BERRIES",
"grapes", "olives", "cantaloupe" };
      IComparer myComparer = new myReverserClass();

      // Displays the values of the Array.
      Console.WriteLine( "The Array initially contains the following
values:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the default comparer.
      Array.Sort( myKeys, myValues, 1, 3 );
      Console.WriteLine( "After sorting a section of the Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, 1, 3, myComparer );
      Console.WriteLine( "After sorting a section of the Array using the
reverse case-insensitive comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the default comparer.
      Array.Sort( myKeys, myValues );
      Console.WriteLine( "After sorting the entire Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, myComparer );
      Console.WriteLine( "After sorting the entire Array using the
reverse case-insensitive comparer:" );
      PrintKeysAndValues( myKeys, myValues );
   }

   public static void PrintKeysAndValues( String[] myKeys, String[]
myValues )  {
      for ( int i = 0; i < myKeys.Length; i++ )  {
         Console.WriteLine( "   {0,-10}: {1}", myKeys[i], myValues[i] );
      }
      Console.WriteLine();
   }
}
```

```
/*
This code produces the following output.

The Array initially contains the following values:
   red       : strawberries
   GREEN     : PEARS
   YELLOW    : LIMES
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the default comparer:
   red       : strawberries
   BLUE      : BERRIES
   GREEN     : PEARS
   YELLOW    : LIMES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the reverse case-insensitive
comparer:
   red       : strawberries
   YELLOW    : LIMES
   GREEN     : PEARS
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting the entire Array using the default comparer:
   black     : olives
   BLUE      : BERRIES
   GREEN     : PEARS
   orange    : cantaloupe
   purple    : grapes
   red       : strawberries
   YELLOW    : LIMES

After sorting the entire Array using the reverse case-insensitive
comparer:
   YELLOW    : LIMES
   red       : strawberries
   purple    : grapes
   orange    : cantaloupe
   GREEN     : PEARS
   BLUE      : BERRIES
   black     : olives

*/
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

If `comparer` is `null`, each key within the specified range of elements in the `keys` Array must implement the IComparable interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

.NET includes predefined IComparer implementations listed in the following table.

Expand table

Implementation	Description
System.Collections.CaseInsensitiveComparer	Compares any two objects, but performs a case-insensitive comparison of strings.
Comparer.Default	Compares any two objects by using the sorting conventions of the current culture.
Comparer.DefaultInvariant	Compares any two objects by using the sorting conventions of the invariant culture.
Comparer<T>.Default	Compares two objects of type `T` by using the type's default sort order.

You can also support custom comparisons by providing an instance of your own IComparer implementation to the `comparer` parameter. The example does this by defining a custom IComparer implementation that reverses the default sort order and performs case-insensitive string comparison.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.

- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

UWP	10.0

Sort(Array, Int32, Int32, IComparer)

Sorts the elements in a range of elements in a one-dimensional Array using the specified IComparer.

```
C#

public static void Sort (Array array, int index, int length,
System.Collections.IComparer? comparer);
```

Parameters

`array` Array

The one-dimensional Array to sort.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

`comparer` IComparer

The IComparer implementation to use when comparing elements.

-or-

`null` to use the IComparable implementation of each element.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

-or-

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

InvalidOperationException

`comparer` is `null`, and one or more elements in `array` do not implement the IComparable interface.

Examples

The following code example shows how to sort the values in an Array using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

C#

```
using System;
using System.Collections;

public class ReverseComparer : IComparer
{
   // Call CaseInsensitiveComparer.Compare with the parameters reversed.
   public int Compare(Object x, Object y)
   {
       return (new CaseInsensitiveComparer()).Compare(y, x );
   }
}

public class Example
{
   public static void Main()
   {
      // Create and initialize a new array.
      String[] words = { "The", "QUICK", "BROWN", "FOX", "jumps",
                         "over", "the", "lazy", "dog" };
      // Instantiate the reverse comparer.
      IComparer revComparer = new ReverseComparer();

      // Display the values of the array.
      Console.WriteLine( "The original order of elements in the array:"
);
      DisplayValues(words);

      // Sort a section of the array using the default comparer.
      Array.Sort(words, 1, 3);
```

```
      Console.WriteLine( "After sorting elements 1-3 by using the default
comparer:");
      DisplayValues(words);

      // Sort a section of the array using the reverse case-insensitive
comparer.
      Array.Sort(words, 1, 3, revComparer);
      Console.WriteLine( "After sorting elements 1-3 by using the reverse
case-insensitive comparer:");
      DisplayValues(words);

      // Sort the entire array using the default comparer.
      Array.Sort(words);
      Console.WriteLine( "After sorting the entire array by using the
default comparer:");
      DisplayValues(words);

      // Sort the entire array by using the reverse case-insensitive
comparer.
      Array.Sort(words, revComparer);
      Console.WriteLine( "After sorting the entire array using the
reverse case-insensitive comparer:");
      DisplayValues(words);
   }

   public static void DisplayValues(String[] arr)
   {
      for ( int i = arr.GetLowerBound(0); i <= arr.GetUpperBound(0);
            i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, arr[i] );
      }
      Console.WriteLine();
   }
}
// The example displays the following output:
//    The original order of elements in the array:
//       [0] : The
//       [1] : QUICK
//       [2] : BROWN
//       [3] : FOX
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting elements 1-3 by using the default comparer:
//       [0] : The
//       [1] : BROWN
//       [2] : FOX
//       [3] : QUICK
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
```

```
//       [8] : dog
//
//    After sorting elements 1-3 by using the reverse case-insensitive
comparer:
//       [0] : The
//       [1] : QUICK
//       [2] : FOX
//       [3] : BROWN
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting the entire array by using the default comparer:
//       [0] : BROWN
//       [1] : dog
//       [2] : FOX
//       [3] : jumps
//       [4] : lazy
//       [5] : over
//       [6] : QUICK
//       [7] : the
//       [8] : The
//
//    After sorting the entire array using the reverse case-insensitive
comparer:
//       [0] : the
//       [1] : The
//       [2] : QUICK
//       [3] : over
//       [4] : lazy
//       [5] : jumps
//       [6] : FOX
//       [7] : dog
//       [8] : BROWN
```

Remarks

If `comparer` is `null`, each element within the specified range of elements in `array` must implement the IComparable interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

.NET includes predefined IComparer implementations listed in the following table.

Expand table

Implementation	Description
System.Collections.CaseInsensitiveComparer	Compares any two objects, but performs a case-insensitive comparison of strings.
Comparer.Default	Compares any two objects by using the sorting conventions of the current culture.
Comparer.DefaultInvariant	Compares any two objects by using the sorting conventions of the invariant culture.
Comparer<T>.Default	Compares two objects of type `T` by using the type's default sort order.

You can also support custom comparisons by providing an instance of your own IComparer implementation to the `comparer` parameter. The example does this by defining a `ReverseComparer` class that reverses the default sort order for instances of a type and performs case-insensitive string comparison.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort(Array, Array, Int32, Int32)

Sorts a range of elements in a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable implementation of each key.

C#

```
public static void Sort (Array keys, Array? items, int index, int
length);
```

Parameters

keys Array

The one-dimensional Array that contains the keys to sort.

items Array

The one-dimensional Array that contains the items that correspond to each of the keys in the `keys` Array.

-or-

`null` to sort only the `keys` Array.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

Exceptions

ArgumentNullException

`keys` is `null`.

RankException

The `keys` Array is multidimensional.

-or-

The `items` Array is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `keys`.

-or-

`length` is less than zero.

ArgumentException

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

-or-

`index` and `length` do not specify a valid range in the `keys` Array.

-or-

`items` is not `null`, and `index` and `length` do not specify a valid range in the `items` Array.

InvalidOperationException

One or more elements in the `keys` Array do not implement the IComparable interface.

Examples

The following code example shows how to sort two associated arrays where the first array contains the keys and the second array contains the values. Sorts are done using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

C#

```
using System;
using System.Collections;

public class SamplesArray  {

   public class myReverserClass : IComparer  {

      // Calls CaseInsensitiveComparer.Compare with the parameters
reversed.
      int IComparer.Compare( Object x, Object y )  {
          return( (new CaseInsensitiveComparer()).Compare( y, x ) );
      }
   }

   public static void Main()  {

      // Creates and initializes a new Array and a new custom comparer.
      String[] myKeys = { "red", "GREEN", "YELLOW", "BLUE", "purple",
"black", "orange" };
      String[] myValues = { "strawberries", "PEARS", "LIMES", "BERRIES",
"grapes", "olives", "cantaloupe" };
      IComparer myComparer = new myReverserClass();

      // Displays the values of the Array.
      Console.WriteLine( "The Array initially contains the following
values:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the default comparer.
      Array.Sort( myKeys, myValues, 1, 3 );
      Console.WriteLine( "After sorting a section of the Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, 1, 3, myComparer );
      Console.WriteLine( "After sorting a section of the Array using the
reverse case-insensitive comparer:" );
```

```
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the default comparer.
      Array.Sort( myKeys, myValues );
      Console.WriteLine( "After sorting the entire Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, myComparer );
      Console.WriteLine( "After sorting the entire Array using the
reverse case-insensitive comparer:" );
      PrintKeysAndValues( myKeys, myValues );
   }

   public static void PrintKeysAndValues( String[] myKeys, String[]
myValues )  {
      for ( int i = 0; i < myKeys.Length; i++ )  {
         Console.WriteLine( "   {0,-10}: {1}", myKeys[i], myValues[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.

The Array initially contains the following values:
   red       : strawberries
   GREEN     : PEARS
   YELLOW    : LIMES
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the default comparer:
   red       : strawberries
   BLUE      : BERRIES
   GREEN     : PEARS
   YELLOW    : LIMES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the reverse case-insensitive
comparer:
   red       : strawberries
   YELLOW    : LIMES
   GREEN     : PEARS
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
```

```
   orange    : cantaloupe

After sorting the entire Array using the default comparer:
   black     : olives
   BLUE      : BERRIES
   GREEN     : PEARS
   orange    : cantaloupe
   purple    : grapes
   red       : strawberries
   YELLOW    : LIMES

After sorting the entire Array using the reverse case-insensitive
comparer:
   YELLOW    : LIMES
   red       : strawberries
   purple    : grapes
   orange    : cantaloupe
   GREEN     : PEARS
   BLUE      : BERRIES
   black     : olives

*/
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

Each key within the specified range of elements in the `keys` Array must implement the IComparable interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^{N}, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Sort(Array, Int32, Int32)

Sorts the elements in a range of elements in a one-dimensional Array using the IComparable implementation of each element of the Array.

C#

```
public static void Sort (Array array, int index, int length);
```

Parameters

`array` Array

The one-dimensional Array to sort.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

InvalidOperationException

One or more elements in `array` do not implement the IComparable interface.

Examples

The following code example shows how to sort the values in an Array using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

```C#
using System;
using System.Collections;

public class ReverseComparer : IComparer
{
   // Call CaseInsensitiveComparer.Compare with the parameters reversed.
   public int Compare(Object x, Object y)
   {
```

```
        return (new CaseInsensitiveComparer()).Compare(y, x );
    }
}

public class Example
{
   public static void Main()
   {
      // Create and initialize a new array.
      String[] words = { "The", "QUICK", "BROWN", "FOX", "jumps",
                         "over", "the", "lazy", "dog" };
      // Instantiate the reverse comparer.
      IComparer revComparer = new ReverseComparer();

      // Display the values of the array.
      Console.WriteLine( "The original order of elements in the array:"
);
      DisplayValues(words);

      // Sort a section of the array using the default comparer.
      Array.Sort(words, 1, 3);
      Console.WriteLine( "After sorting elements 1-3 by using the default
comparer:");
      DisplayValues(words);

      // Sort a section of the array using the reverse case-insensitive
comparer.
      Array.Sort(words, 1, 3, revComparer);
      Console.WriteLine( "After sorting elements 1-3 by using the reverse
case-insensitive comparer:");
      DisplayValues(words);

      // Sort the entire array using the default comparer.
      Array.Sort(words);
      Console.WriteLine( "After sorting the entire array by using the
default comparer:");
      DisplayValues(words);

      // Sort the entire array by using the reverse case-insensitive
comparer.
      Array.Sort(words, revComparer);
      Console.WriteLine( "After sorting the entire array using the
reverse case-insensitive comparer:");
      DisplayValues(words);
   }

   public static void DisplayValues(String[] arr)
   {
      for ( int i = arr.GetLowerBound(0); i <= arr.GetUpperBound(0);
            i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, arr[i] );
      }
      Console.WriteLine();
   }
}
```

```
// The example displays the following output:
//    The original order of elements in the array:
//       [0] : The
//       [1] : QUICK
//       [2] : BROWN
//       [3] : FOX
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting elements 1-3 by using the default comparer:
//       [0] : The
//       [1] : BROWN
//       [2] : FOX
//       [3] : QUICK
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting elements 1-3 by using the reverse case-insensitive
comparer:
//       [0] : The
//       [1] : QUICK
//       [2] : FOX
//       [3] : BROWN
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting the entire array by using the default comparer:
//       [0] : BROWN
//       [1] : dog
//       [2] : FOX
//       [3] : jumps
//       [4] : lazy
//       [5] : over
//       [6] : QUICK
//       [7] : the
//       [8] : The
//
//    After sorting the entire array using the reverse case-insensitive
comparer:
//       [0] : the
//       [1] : The
//       [2] : QUICK
//       [3] : over
//       [4] : lazy
//       [5] : jumps
//       [6] : FOX
```

```
//        [7] : dog
//        [8] : BROWN
```

Remarks

Each element within the specified range of elements in `array` must implement the IComparable interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Sort(Array, Array, IComparer)

Sorts a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer.

```
C#

public static void Sort (Array keys, Array? items,
System.Collections.IComparer? comparer);
```

Parameters

`keys` Array

The one-dimensional Array that contains the keys to sort.

`items` Array

The one-dimensional Array that contains the items that correspond to each of the keys in the `keys` Array.

-or-

`null` to sort only the `keys` Array.

`comparer` IComparer

The IComparer implementation to use when comparing elements.

-or-

`null` to use the IComparable implementation of each element.

Exceptions

ArgumentNullException

`keys` is `null`.

RankException

The `keys` Array is multidimensional.

-or-

The `items` Array is multidimensional.

ArgumentException

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

-or-

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

InvalidOperationException

`comparer` is `null`, and one or more elements in the `keys` Array do not implement the IComparable interface.

Examples

The following example shows how to sort two associated arrays where the first array contains the keys and the second array contains the values. Sorts are done using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

C#

```
using System;
using System.Collections;

public class SamplesArray  {

   public class myReverserClass : IComparer  {

      // Calls CaseInsensitiveComparer.Compare with the parameters
reversed.
      int IComparer.Compare( Object x, Object y )  {
          return( (new CaseInsensitiveComparer()).Compare( y, x ) );
      }
   }

   public static void Main()  {

      // Creates and initializes a new Array and a new custom comparer.
      String[] myKeys = { "red", "GREEN", "YELLOW", "BLUE", "purple",
"black", "orange" };
```

```
      String[] myValues = { "strawberries", "PEARS", "LIMES", "BERRIES",
"grapes", "olives", "cantaloupe" };
      IComparer myComparer = new myReverserClass();

      // Displays the values of the Array.
      Console.WriteLine( "The Array initially contains the following
values:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the default comparer.
      Array.Sort( myKeys, myValues, 1, 3 );
      Console.WriteLine( "After sorting a section of the Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, 1, 3, myComparer );
      Console.WriteLine( "After sorting a section of the Array using the
reverse case-insensitive comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the default comparer.
      Array.Sort( myKeys, myValues );
      Console.WriteLine( "After sorting the entire Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, myComparer );
      Console.WriteLine( "After sorting the entire Array using the
reverse case-insensitive comparer:" );
      PrintKeysAndValues( myKeys, myValues );
   }

   public static void PrintKeysAndValues( String[] myKeys, String[]
myValues )  {
      for ( int i = 0; i < myKeys.Length; i++ )  {
         Console.WriteLine( "   {0,-10}: {1}", myKeys[i], myValues[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.

The Array initially contains the following values:
   red       : strawberries
   GREEN     : PEARS
   YELLOW    : LIMES
   BLUE      : BERRIES
   purple    : grapes
```

```
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the default comparer:
   red       : strawberries
   BLUE      : BERRIES
   GREEN     : PEARS
   YELLOW    : LIMES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the reverse case-insensitive
comparer:
   red       : strawberries
   YELLOW    : LIMES
   GREEN     : PEARS
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting the entire Array using the default comparer:
   black     : olives
   BLUE      : BERRIES
   GREEN     : PEARS
   orange    : cantaloupe
   purple    : grapes
   red       : strawberries
   YELLOW    : LIMES

After sorting the entire Array using the reverse case-insensitive
comparer:
   YELLOW    : LIMES
   red       : strawberries
   purple    : grapes
   orange    : cantaloupe
   GREEN     : PEARS
   BLUE      : BERRIES
   black     : olives

*/
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

If `comparer` is `null`, each key in the `keys` Array must implement the IComparable interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

.NET includes predefined IComparer implementations listed in the following table.

Expand table

Implementation	Description
System.Collections.CaseInsensitiveComparer	Compares any two objects, but performs a case-insensitive comparison of strings.
Comparer.Default	Compares any two objects by using the sorting conventions of the current culture.
Comparer.DefaultInvariant	Compares any two objects by using the sorting conventions of the invariant culture.
Comparer<T>.Default	Compares two objects of type `T` by using the type's default sort order.

You can also support custom comparisons by providing an instance of your own IComparer implementation to the `comparer` parameter. The example does this by defining an IComparer implementation that reverses the default sort order and performs case-insensitive string comparison.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `keys`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort(Array, Array)

Sorts a pair of one-dimensional Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable implementation of each key.

```
C#
```

```
public static void Sort (Array keys, Array? items);
```

Parameters

`keys` Array

The one-dimensional Array that contains the keys to sort.

`items` Array

The one-dimensional Array that contains the items that correspond to each of the keys in the `keys` Array.

-or-

`null` to sort only the `keys` Array.

Exceptions

ArgumentNullException

`keys` is `null`.

RankException

The `keys` Array is multidimensional.

-or-

The `items` Array is multidimensional.

ArgumentException

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

InvalidOperationException

One or more elements in the `keys` Array do not implement the IComparable interface.

Examples

The following example shows how to sort two associated arrays where the first array contains the keys and the second array contains the values. Sorts are done using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

C#

```
using System;
using System.Collections;

public class SamplesArray  {

   public class myReverserClass : IComparer  {

      // Calls CaseInsensitiveComparer.Compare with the parameters
reversed.
      int IComparer.Compare( Object x, Object y )  {
          return( (new CaseInsensitiveComparer()).Compare( y, x ) );
      }
   }

   public static void Main()  {

      // Creates and initializes a new Array and a new custom comparer.
      String[] myKeys = { "red", "GREEN", "YELLOW", "BLUE", "purple",
"black", "orange" };
      String[] myValues = { "strawberries", "PEARS", "LIMES", "BERRIES",
"grapes", "olives", "cantaloupe" };
      IComparer myComparer = new myReverserClass();

      // Displays the values of the Array.
      Console.WriteLine( "The Array initially contains the following
values:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the default comparer.
      Array.Sort( myKeys, myValues, 1, 3 );
      Console.WriteLine( "After sorting a section of the Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts a section of the Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, 1, 3, myComparer );
      Console.WriteLine( "After sorting a section of the Array using the
reverse case-insensitive comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the default comparer.
      Array.Sort( myKeys, myValues );
      Console.WriteLine( "After sorting the entire Array using the
default comparer:" );
      PrintKeysAndValues( myKeys, myValues );

      // Sorts the entire Array using the reverse case-insensitive
comparer.
      Array.Sort( myKeys, myValues, myComparer );
      Console.WriteLine( "After sorting the entire Array using the
reverse case-insensitive comparer:" );
```

```
      PrintKeysAndValues( myKeys, myValues );
   }

   public static void PrintKeysAndValues( String[] myKeys, String[]
myValues )  {
      for ( int i = 0; i < myKeys.Length; i++ )  {
         Console.WriteLine( "   {0,-10}: {1}", myKeys[i], myValues[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.

The Array initially contains the following values:
   red       : strawberries
   GREEN     : PEARS
   YELLOW    : LIMES
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the default comparer:
   red       : strawberries
   BLUE      : BERRIES
   GREEN     : PEARS
   YELLOW    : LIMES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting a section of the Array using the reverse case-insensitive
comparer:
   red       : strawberries
   YELLOW    : LIMES
   GREEN     : PEARS
   BLUE      : BERRIES
   purple    : grapes
   black     : olives
   orange    : cantaloupe

After sorting the entire Array using the default comparer:
   black     : olives
   BLUE      : BERRIES
   GREEN     : PEARS
   orange    : cantaloupe
   purple    : grapes
   red       : strawberries
   YELLOW    : LIMES

After sorting the entire Array using the reverse case-insensitive
comparer:
```

```
    YELLOW     : LIMES
    red        : strawberries
    purple     : grapes
    orange     : cantaloupe
    GREEN      : PEARS
    BLUE       : BERRIES
    black      : olives

*/
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

Each key in the `keys` Array must implement the IComparable interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `keys`.

Sort(Array)

Sorts the elements in an entire one-dimensional Array using the IComparable implementation of each element of the Array.

C#

```
public static void Sort (Array array);
```

Parameters

`array` Array

The one-dimensional Array to sort.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

InvalidOperationException

One or more elements in `array` do not implement the IComparable interface.

Examples

The following code example shows how to sort the values in an Array using the default comparer and a custom comparer that reverses the sort order. Note that the result might vary depending on the current CultureInfo.

C#

```
using System;
using System.Collections;

public class ReverseComparer : IComparer
{
   // Call CaseInsensitiveComparer.Compare with the parameters reversed.
   public int Compare(Object x, Object y)
   {
       return (new CaseInsensitiveComparer()).Compare(y, x );
   }
}

public class Example
{
   public static void Main()
   {
      // Create and initialize a new array.
      String[] words = { "The", "QUICK", "BROWN", "FOX", "jumps",
                         "over", "the", "lazy", "dog" };
      // Instantiate the reverse comparer.
      IComparer revComparer = new ReverseComparer();

      // Display the values of the array.
      Console.WriteLine( "The original order of elements in the array:"
);
      DisplayValues(words);

      // Sort a section of the array using the default comparer.
      Array.Sort(words, 1, 3);
      Console.WriteLine( "After sorting elements 1-3 by using the default
comparer:");
      DisplayValues(words);

      // Sort a section of the array using the reverse case-insensitive
comparer.
      Array.Sort(words, 1, 3, revComparer);
      Console.WriteLine( "After sorting elements 1-3 by using the reverse
case-insensitive comparer:");
      DisplayValues(words);
```

```
      // Sort the entire array using the default comparer.
      Array.Sort(words);
      Console.WriteLine( "After sorting the entire array by using the
default comparer:");
      DisplayValues(words);

      // Sort the entire array by using the reverse case-insensitive
comparer.
      Array.Sort(words, revComparer);
      Console.WriteLine( "After sorting the entire array using the
reverse case-insensitive comparer:");
      DisplayValues(words);
   }

   public static void DisplayValues(String[] arr)
   {
      for ( int i = arr.GetLowerBound(0); i <= arr.GetUpperBound(0);
            i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, arr[i] );
      }
      Console.WriteLine();
   }
}
// The example displays the following output:
//    The original order of elements in the array:
//       [0] : The
//       [1] : QUICK
//       [2] : BROWN
//       [3] : FOX
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting elements 1-3 by using the default comparer:
//       [0] : The
//       [1] : BROWN
//       [2] : FOX
//       [3] : QUICK
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting elements 1-3 by using the reverse case-insensitive
comparer:
//       [0] : The
//       [1] : QUICK
//       [2] : FOX
//       [3] : BROWN
//       [4] : jumps
//       [5] : over
//       [6] : the
```

```
//       [7] : lazy
//       [8] : dog
//
//    After sorting the entire array by using the default comparer:
//       [0] : BROWN
//       [1] : dog
//       [2] : FOX
//       [3] : jumps
//       [4] : lazy
//       [5] : over
//       [6] : QUICK
//       [7] : the
//       [8] : The
//
//    After sorting the entire array using the reverse case-insensitive
comparer:
//       [0] : the
//       [1] : The
//       [2] : QUICK
//       [3] : over
//       [4] : lazy
//       [5] : jumps
//       [6] : FOX
//       [7] : dog
//       [8] : BROWN
```

Remarks

Each element of `array` must implement the IComparable interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `array`.

Sort(Array, IComparer)

Sorts the elements in a one-dimensional Array using the specified IComparer.

C#

```
public static void Sort (Array array, System.Collections.IComparer?
comparer);
```

Parameters

`array` Array

The one-dimensional array to sort.

`comparer` IComparer

The implementation to use when comparing elements.

-or-

`null` to use the IComparable implementation of each element.

Exceptions

ArgumentNullException

`array` is `null`.

RankException

`array` is multidimensional.

InvalidOperationException

`comparer` is `null`, and one or more elements in `array` do not implement the IComparable interface.

ArgumentException

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

Examples

The following example sorts the values in a string array by using the default comparer. It also defines a custom IComparer implementation named `ReverseComparer` that reverses an object's default sort order while performing a case-insensitive string comparison. Note that the output might vary depending on the current culture.

C#

```
using System;
using System.Collections;

public class ReverseComparer : IComparer
{
   // Call CaseInsensitiveComparer.Compare with the parameters reversed.
   public int Compare(Object x, Object y)
   {
       return (new CaseInsensitiveComparer()).Compare(y, x );
   }
}

public class Example
{
   public static void Main()
   {
      // Create and initialize a new array.
      String[] words = { "The", "QUICK", "BROWN", "FOX", "jumps",
                         "over", "the", "lazy", "dog" };
      // Instantiate the reverse comparer.
```

```
      IComparer revComparer = new ReverseComparer();

      // Display the values of the array.
      Console.WriteLine( "The original order of elements in the array:"
);
      DisplayValues(words);

      // Sort a section of the array using the default comparer.
      Array.Sort(words, 1, 3);
      Console.WriteLine( "After sorting elements 1-3 by using the default
comparer:");
      DisplayValues(words);

      // Sort a section of the array using the reverse case-insensitive
comparer.
      Array.Sort(words, 1, 3, revComparer);
      Console.WriteLine( "After sorting elements 1-3 by using the reverse
case-insensitive comparer:");
      DisplayValues(words);

      // Sort the entire array using the default comparer.
      Array.Sort(words);
      Console.WriteLine( "After sorting the entire array by using the
default comparer:");
      DisplayValues(words);

      // Sort the entire array by using the reverse case-insensitive
comparer.
      Array.Sort(words, revComparer);
      Console.WriteLine( "After sorting the entire array using the
reverse case-insensitive comparer:");
      DisplayValues(words);
   }

   public static void DisplayValues(String[] arr)
   {
      for ( int i = arr.GetLowerBound(0); i <= arr.GetUpperBound(0);
            i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, arr[i] );
      }
      Console.WriteLine();
   }
}
// The example displays the following output:
//    The original order of elements in the array:
//       [0] : The
//       [1] : QUICK
//       [2] : BROWN
//       [3] : FOX
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
```

```
//    After sorting elements 1-3 by using the default comparer:
//       [0] : The
//       [1] : BROWN
//       [2] : FOX
//       [3] : QUICK
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting elements 1-3 by using the reverse case-insensitive
comparer:
//       [0] : The
//       [1] : QUICK
//       [2] : FOX
//       [3] : BROWN
//       [4] : jumps
//       [5] : over
//       [6] : the
//       [7] : lazy
//       [8] : dog
//
//    After sorting the entire array by using the default comparer:
//       [0] : BROWN
//       [1] : dog
//       [2] : FOX
//       [3] : jumps
//       [4] : lazy
//       [5] : over
//       [6] : QUICK
//       [7] : the
//       [8] : The
//
//    After sorting the entire array using the reverse case-insensitive
comparer:
//       [0] : the
//       [1] : The
//       [2] : QUICK
//       [3] : over
//       [4] : lazy
//       [5] : jumps
//       [6] : FOX
//       [7] : dog
//       [8] : BROWN
```

Remarks

If `comparer` is `null`, each element of `array` must implement the IComparable interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `array`.

.NET includes predefined IComparer implementations listed in the following table.

Expand table

Implementation	Description
System.Collections.CaseInsensitiveComparer	Compares any two objects, but performs a case-insensitive comparison of strings.
Comparer.Default	Compares any two objects by using the sorting conventions of the current culture.
Comparer.DefaultInvariant	Compares any two objects by using the sorting conventions of the invariant culture.
Comparer<T>.Default	Compares two objects of type `T` by using the type's default sort order.

You can also support custom comparisons by providing an instance of your own IComparer implementation to the `comparer` parameter. The example does this by defining a `ReverseComparer` class that reverses the default sort order for instances of a type and performs case-insensitive string comparison.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception,

because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort<T>(T[])

Sorts the elements in an entire Array using the IComparable<T> generic interface implementation of each element of the Array.

C#

```
public static void Sort<T> (T[] array);
```

Type Parameters

T

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to sort.

Exceptions

ArgumentNullException

`array` is `null`.

InvalidOperationException

One or more elements in `array` do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<T>(T[]) generic method overload and the BinarySearch<T>(T[], T) generic method overload. An array of strings is created, in no particular order.

The array is displayed, sorted, and displayed again.

> **Note**
>
> The calls to the **Sort** and **BinarySearch** generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, C#, and C++ infer the type of the generic type parameter from the type of the first argument. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

The BinarySearch<T>(T[], T) generic method overload is then used to search for two strings, one that is not in the array and one that is. The array and the return value of the BinarySearch method are passed to the `ShowWhere` generic method, which displays the index value if the string is found, and otherwise the elements the search string would fall between if it were in the array. The index is negative if the string is not n the array, so the `ShowWhere` method takes the bitwise complement (the ~ operator in C# and Visual C++, `Xor` -1 in Visual Basic) to obtain the index of the first element in the list that is larger than the search string.

```
C#
```

```
using System;
using System.Collections.Generic;

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {"Pachycephalosaurus",
                              "Amargasaurus",
                              "Tyrannosaurus",
                              "Mamenchisaurus",
                              "Deinonychus",
                              "Edmontosaurus"};

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nSort");
        Array.Sort(dinosaurs);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nBinarySearch for 'Coelophysis':");
        int index = Array.BinarySearch(dinosaurs, "Coelophysis");
        ShowWhere(dinosaurs, index);

        Console.WriteLine("\nBinarySearch for 'Tyrannosaurus':");
        index = Array.BinarySearch(dinosaurs, "Tyrannosaurus");
        ShowWhere(dinosaurs, index);
    }

    private static void ShowWhere<T>(T[] array, int index)
    {
        if (index<0)
        {
            // If the index is negative, it represents the bitwise
            // complement of the next larger element in the array.
            //
            index = ~index;

            Console.Write("Not found. Sorts between: ");

            if (index == 0)
                Console.Write("beginning of array and ");
            else
                Console.Write("{0} and ", array[index-1]);
```

```
            if (index == array.Length)
                Console.WriteLine("end of array.");
            else
                Console.WriteLine("{0}.", array[index]);
        }
        else
        {
            Console.WriteLine("Found at index {0}.", index);
        }
    }
}

/* This code example produces the following output:

Pachycephalosaurus
Amargasaurus
Tyrannosaurus
Mamenchisaurus
Deinonychus
Edmontosaurus

Sort

Amargasaurus
Deinonychus
Edmontosaurus
Mamenchisaurus
Pachycephalosaurus
Tyrannosaurus

BinarySearch for 'Coelophysis':
Not found. Sorts between: Amargasaurus and Deinonychus.

BinarySearch for 'Tyrannosaurus':
Found at index 5.
 */
```

Remarks

Each element of `array` must implement the IComparable<T> generic interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.

- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `array`.

UWP	10.0

Sort<T>(T[], IComparer<T>)

Sorts the elements in an Array using the specified IComparer<T> generic interface.

C#

```
public static void Sort<T> (T[] array,
System.Collections.Generic.IComparer<T>? comparer);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-base Array to sort.

`comparer` IComparer<T>

The IComparer<T> generic interface implementation to use when comparing elements, or `null` to use the IComparable<T> generic interface implementation of each element.

Exceptions

ArgumentNullException

`array` is `null`.

InvalidOperationException

`comparer` is `null`, and one or more elements in `array` do not implement the IComparable<T> generic interface.

ArgumentException

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

Examples

The following code example demonstrates the Sort<T>(T[], IComparer<T>) generic method overload and the BinarySearch<T>(T[], T, IComparer<T>) generic method overload.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The array is displayed, sorted, and displayed again. Arrays must be sorted in order to use the BinarySearch method.

> **Note**
>
> The calls to the **Sort<T>(T[], IComparer<T>)** and **BinarySearch<T>(T[], T, IComparer<T>)** generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, C#, and C++ infer the type of the generic type parameter from the type of the first argument. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

The BinarySearch<T>(T[], T, IComparer<T>) generic method overload is then used to search for two strings, one that is not in the array and one that is. The array and the return value of the BinarySearch<T>(T[], T, IComparer<T>) method are passed to the `ShowWhere` generic method, which displays the index value if the string is found, and otherwise the elements the search string would fall between if it were in the array. The index is negative if the string is not n the array, so the `ShowWhere` method takes the bitwise complement (the ~ operator in C# and Visual C++, `Xor` -1 in Visual Basic) to obtain the index of the first element in the list that is larger than the search string.

C#

```
using System;
using System.Collections.Generic;

public class ReverseComparer: IComparer<string>
{
    public int Compare(string x, string y)
    {
        // Compare y and x in reverse order.
        return y.CompareTo(x);
    }
}

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {"Pachycephalosaurus",
                              "Amargasaurus",
                              "Tyrannosaurus",
                              "Mamenchisaurus",
                              "Deinonychus",
                              "Edmontosaurus"};

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
```

```
            Console.WriteLine(dinosaur);
        }

        ReverseComparer rc = new ReverseComparer();

        Console.WriteLine("\nSort");
        Array.Sort(dinosaurs, rc);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nBinarySearch for 'Coelophysis':");
        int index = Array.BinarySearch(dinosaurs, "Coelophysis", rc);
        ShowWhere(dinosaurs, index);

        Console.WriteLine("\nBinarySearch for 'Tyrannosaurus':");
        index = Array.BinarySearch(dinosaurs, "Tyrannosaurus", rc);
        ShowWhere(dinosaurs, index);
    }

    private static void ShowWhere<T>(T[] array, int index)
    {
        if (index<0)
        {
            // If the index is negative, it represents the bitwise
            // complement of the next larger element in the array.
            //
            index = ~index;

            Console.Write("Not found. Sorts between: ");

            if (index == 0)
                Console.Write("beginning of array and ");
            else
                Console.Write("{0} and ", array[index-1]);

            if (index == array.Length)
                Console.WriteLine("end of array.");
            else
                Console.WriteLine("{0}.", array[index]);
        }
        else
        {
            Console.WriteLine("Found at index {0}.", index);
        }
    }
}

/* This code example produces the following output:

Pachycephalosaurus
Amargasaurus
```

```
Tyrannosaurus
Mamenchisaurus
Deinonychus
Edmontosaurus

Sort

Tyrannosaurus
Pachycephalosaurus
Mamenchisaurus
Edmontosaurus
Deinonychus
Amargasaurus

BinarySearch for 'Coelophysis':
Not found. Sorts between: Deinonychus and Amargasaurus.

BinarySearch for 'Tyrannosaurus':
Found at index 0.
 */
```

Remarks

If `comparer` is `null`, each element of `array` must implement the IComparable<T> generic interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^{N}, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `array`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort<T>(T[], Comparison<T>)

Sorts the elements in an Array using the specified Comparison<T>.

C#

```
public static void Sort<T> (T[] array, Comparison<T> comparison);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to sort.

`comparison` Comparison<T>

The Comparison<T> to use when comparing elements.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`comparison` is `null`.

ArgumentException

The implementation of `comparison` caused an error during the sort. For example, `comparison` might not return 0 when comparing an item with itself.

Examples

The following code example demonstrates the Sort(Comparison<T>) method overload.

The code example defines an alternative comparison method for strings, named `CompareDinosByLength`. This method works as follows: First, the comparands are tested for `null`, and a null reference is treated as less than a non-null. Second, the string lengths are compared, and the longer string is deemed to be greater. Third, if the lengths are equal, ordinary string comparison is used.

A array of strings is created and populated with four strings, in no particular order. The list also includes an empty string and a null reference. The list is displayed, sorted using a Comparison<T> generic delegate representing the `CompareDinosByLength` method, and displayed again.

```
C#
```

```
using System;
using System.Collections.Generic;

public class Example
{
    private static int CompareDinosByLength(string x, string y)
    {
        if (x == null)
        {
            if (y == null)
            {
                // If x is null and y is null, they're
                // equal.
                return 0;
            }
            else
            {
                // If x is null and y is not null, y
                // is greater.
                return -1;
            }
        }
        else
        {
            // If x is not null...
            //
            if (y == null)
                // ...and y is null, x is greater.
            {
                return 1;
            }
            else
            {
                // ...and y is not null, compare the
                // lengths of the two strings.
                //
                int retval = x.Length.CompareTo(y.Length);

                if (retval != 0)
                {
                    // If the strings are not of equal length,
                    // the longer string is greater.
                    //
                    return retval;
                }
                else
                {
                    // If the strings are of equal length,
                    // sort them with ordinary string comparison.
                    //
                    return x.CompareTo(y);
                }
            }
        }
```

```
    }

    public static void Main()
    {
        string[] dinosaurs = {
            "Pachycephalosaurus",
            "Amargasaurus",
            "",
            null,
            "Mamenchisaurus",
            "Deinonychus" };
        Display(dinosaurs);

        Console.WriteLine("\nSort with generic Comparison<string>
delegate:");
        Array.Sort(dinosaurs, CompareDinosByLength);
        Display(dinosaurs);
    }

    private static void Display(string[] arr)
    {
        Console.WriteLine();
        foreach( string s in arr )
        {
            if (s == null)
                Console.WriteLine("(null)");
            else
                Console.WriteLine("\"{0}\"", s);
        }
    }
}

/* This code example produces the following output:

"Pachycephalosaurus"
"Amargasaurus"
""
(null)
"Mamenchisaurus"
"Deinonychus"

Sort with generic Comparison<string> delegate:

(null)
""
"Deinonychus"
"Amargasaurus"
"Mamenchisaurus"
"Pachycephalosaurus"
 */
```

Remarks

If the sort is not successfully completed, the results are undefined.

This method uses introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `array`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 6 elements.

Sort<T>(T[], Int32, Int32)

Sorts the elements in a range of elements in an Array using the IComparable<T> generic interface implementation of each element of the Array.

```
C#

public static void Sort<T> (T[] array, int index, int length);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to sort.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

InvalidOperationException

One or more elements in `array` do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<T>(T[], Int32, Int32) generic method overload and the Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overload for sorting a range in an array.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The code example creates and displays an array of dinosaur names, consisting of three herbivores followed by three carnivores (tyrannosaurids, to be precise). The Sort<T>(T[], Int32, Int32) generic method overload is used to sort the last three elements of the array, which is then displayed. The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overload is used with `ReverseCompare` to sort the last three elements in reverse order. The thoroughly confused dinosaurs are displayed again.

> **Note**
>
> The calls to the **Sort<T>(T[], IComparer<T>)** and **BinarySearch<T>(T[], T, IComparer<T>)** generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, C#, and C++ infer the type of the generic type parameter from the type of the first argument. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

```
C#
```

```
using System;
using System.Collections.Generic;

public class ReverseComparer: IComparer<string>
{
    public int Compare(string x, string y)
    {
        // Compare y and x in reverse order.
        return y.CompareTo(x);
    }
}

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {"Pachycephalosaurus",
                              "Amargasaurus",
                              "Mamenchisaurus",
                              "Tarbosaurus",
                              "Tyrannosaurus",
                              "Albertasaurus"};

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nSort(dinosaurs, 3, 3)");
        Array.Sort(dinosaurs, 3, 3);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        ReverseComparer rc = new ReverseComparer();

        Console.WriteLine("\nSort(dinosaurs, 3, 3, rc)");
        Array.Sort(dinosaurs, 3, 3, rc);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }
    }
}

Sort<T>(T[], Int32, Int32, IComparer<T>)

Sorts the elements in a range of elements in an Array using the specified IComparer<T> generic interface.

C#

```
public static void Sort<T> (T[] array, int index, int length,
System.Collections.Generic.IComparer<T>? comparer);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to sort.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

`comparer` IComparer<T>

The IComparer<T> generic interface implementation to use when comparing elements, or `null` to use the IComparable<T> generic interface implementation of each element.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `array`.

-or-

`length` is less than zero.

ArgumentException

`index` and `length` do not specify a valid range in `array`.

-or-

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

InvalidOperationException

`comparer` is `null`, and one or more elements in `array` do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<T>(T[], Int32, Int32) generic method overload and the Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overload for sorting a range in an array.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in

Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The code example creates and displays an array of dinosaur names, consisting of three herbivores followed by three carnivores (tyrannosaurids, to be precise). The Sort<T>(T[], Int32, Int32) generic method overload is used to sort the last three elements of the array, which is then displayed. The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overload is used with `ReverseCompare` to sort the last three elements in reverse order. The thoroughly confused dinosaurs are displayed again.

    {
        // Compare y and x in reverse order.
        return y.CompareTo(x);
    }
}

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {"Pachycephalosaurus",
                              "Amargasaurus",
                              "Mamenchisaurus",
                              "Tarbosaurus",
                              "Tyrannosaurus",
                              "Albertasaurus"};

        Console.WriteLine();
```

```
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        Console.WriteLine("\nSort(dinosaurs, 3, 3)");
        Array.Sort(dinosaurs, 3, 3);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }

        ReverseComparer rc = new ReverseComparer();

        Console.WriteLine("\nSort(dinosaurs, 3, 3, rc)");
        Array.Sort(dinosaurs, 3, 3, rc);

        Console.WriteLine();
        foreach( string dinosaur in dinosaurs )
        {
            Console.WriteLine(dinosaur);
        }
    }
}

Tarbosaurus
Tyrannosaurus

Sort(dinosaurs, 3, 3, rc)

Pachycephalosaurus
Amargasaurus
Mamenchisaurus
Tyrannosaurus
Tarbosaurus
Albertasaurus
 */
```

Remarks

If `comparer` is `null`, each element within the specified range of elements in `array` must implement the IComparable<T> generic interface to be capable of comparisons with every other element in `array`.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^{N}, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>)

Sorts a range of elements in a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer<T> generic interface.

C#

```
public static void Sort<TKey,TValue> (TKey[] keys, TValue[]? items, int
index, int length, System.Collections.Generic.IComparer<TKey>? comparer);
```

Type Parameters

`TKey`

The type of the elements of the key array.

`TValue`

The type of the elements of the items array.

Parameters

`keys` TKey[]

The one-dimensional, zero-based Array that contains the keys to sort.

`items` TValue[]

The one-dimensional, zero-based Array that contains the items that correspond to the keys in `keys`, or `null` to sort only `keys`.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

`comparer` IComparer<TKey>

The IComparer<T> generic interface implementation to use when comparing elements, or `null` to use the IComparable<T> generic interface implementation of each element.

Exceptions

ArgumentNullException

`keys` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `keys`.

-or-

`length` is less than zero.

ArgumentException

`items` is not `null`, and the lower bound of `keys` does not match the lower bound of `items`.

-or-

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

-or-

`index` and `length` do not specify a valid range in the `keys` Array.

-or-

`items` is not `null`, and `index` and `length` do not specify a valid range in the `items` Array.

-or-

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

InvalidOperationException
`comparer` is `null`, and one or more elements in the `keys` Array do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<TKey,TValue>(TKey[], TValue[]), Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>), Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32), and Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overloads, for sorting pairs of arrays that represent keys and values.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The code example creates and displays an array of dinosaur names (the keys) and an array of integers representing the maximum length of each dinosaur in meters (the values). The arrays are then sorted and displayed several times:

- The Sort<TKey,TValue>(TKey[], TValue[]) overload is used to sort both arrays in order of the dinosaur names in the first array.
- The Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>) overload and an instance of `ReverseCompare` are used to reverse the sort order of the paired arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32) overload is used to sort the last three elements of both arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) overload is used to sort the last three elements of both arrays in reverse order.

Note

The calls to the generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, C#, and C++ infer the type of the generic type parameter from the type of the first two arguments. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

C#

```
using System;
using System.Collections.Generic;

public class ReverseComparer: IComparer<string>
{
    public int Compare(string x, string y)
    {
        // Compare y and x in reverse order.
        return y.CompareTo(x);
    }
}

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {
            "Seismosaurus",
            "Chasmosaurus",
            "Coelophysis",
            "Mamenchisaurus",
            "Caudipteryx",
            "Cetiosaurus"  };

        int[] dinosaurSizes = { 40, 5, 3, 22, 1, 18 };

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }

        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes)");
        Array.Sort(dinosaurs, dinosaurSizes);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }

        ReverseComparer rc = new ReverseComparer();
```

```
        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes, rc)");
        Array.Sort(dinosaurs, dinosaurSizes, rc);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }

        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes, 3, 3)");
        Array.Sort(dinosaurs, dinosaurSizes, 3, 3);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }

        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes, 3, 3, rc)");
        Array.Sort(dinosaurs, dinosaurSizes, 3, 3, rc);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }
    }
}

/* This code example produces the following output:

Seismosaurus: up to 40 meters long.
Chasmosaurus: up to 5 meters long.

Caudipteryx: up to 1 meters long.
Cetiosaurus: up to 18 meters long.
Chasmosaurus: up to 5 meters long.

Sort(dinosaurs, dinosaurSizes, 3, 3, rc)

Seismosaurus: up to 40 meters long.
Mamenchisaurus: up to 22 meters long.
Coelophysis: up to 3 meters long.
Chasmosaurus: up to 5 meters long.
Cetiosaurus: up to 18 meters long.
Caudipteryx: up to 1 meters long.
 */
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

If `comparer` is `null`, each key within the specified range of elements in the `keys` Array must implement the IComparable<T> generic interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.

- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort<TKey,TValue>(TKey[], TValue[])

Sorts a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable<T> generic interface implementation of each key.

```
C#
public static void Sort<TKey,TValue> (TKey[] keys, TValue[]? items);
```

Type Parameters

`TKey`

The type of the elements of the key array.

`TValue`

The type of the elements of the items array.

Parameters

`keys` TKey[]

The one-dimensional, zero-based Array that contains the keys to sort.

`items` TValue[]

The one-dimensional, zero-based Array that contains the items that correspond to the keys in `keys`, or `null` to sort only `keys`.

Exceptions

ArgumentNullException

`keys` is `null`.

ArgumentException

`items` is not `null`, and the lower bound of `keys` does not match the lower bound of `items`.

-or-

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

InvalidOperationException

One or more elements in the `keys` Array do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<TKey,TValue>(TKey[], TValue[]), Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>), Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32), and Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overloads, for sorting pairs of arrays that represent keys and values.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The code example creates and displays an array of dinosaur names (the keys) and an array of integers representing the maximum length of each dinosaur in meters (the values). The arrays are then sorted and displayed several times:

- The Sort<TKey,TValue>(TKey[], TValue[]) overload is used to sort both arrays in order of the dinosaur names in the first array.
- The Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>) overload and an instance of `ReverseCompare` are used to reverse the sort order of the paired arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32) overload is used to sort the last three elements of both arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) overload is used to sort the last three elements of both arrays in reverse order.

Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>)

Sorts a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the specified IComparer<T> generic interface.

C#

```
public static void Sort<TKey,TValue> (TKey[] keys, TValue[]? items,
System.Collections.Generic.IComparer<TKey>? comparer);
```

Type Parameters

TKey

The type of the elements of the key array.

`TValue`

The type of the elements of the items array.

Parameters

`keys` TKey[]

The one-dimensional, zero-based Array that contains the keys to sort.

`items` TValue[]

The one-dimensional, zero-based Array that contains the items that correspond to the keys in `keys`, or `null` to sort only `keys`.

`comparer` IComparer<TKey>

The IComparer<T> generic interface implementation to use when comparing elements, or `null` to use the IComparable<T> generic interface implementation of each element.

Exceptions

ArgumentNullException

`keys` is `null`.

ArgumentException

`items` is not `null`, and the lower bound of `keys` does not match the lower bound of `items`.

-or-

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

-or-

The implementation of `comparer` caused an error during the sort. For example, `comparer` might not return 0 when comparing an item with itself.

InvalidOperationException

`comparer` is `null`, and one or more elements in the `keys` Array do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<TKey,TValue>(TKey[], TValue[]), [], Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>), Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32), and Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overloads, for sorting pairs of arrays that represent keys and values.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The code example creates and displays an array of dinosaur names (the keys) and an array of integers representing the maximum length of each dinosaur in meters (the values). The arrays are then sorted and displayed several times:

- The Sort<TKey,TValue>(TKey[], TValue[]) overload is used to sort both arrays in order of the dinosaur names in the first array.
- The Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>) overload and an instance of `ReverseCompare` are used to reverse the sort order of the paired arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32) overload is used to sort the last three elements of both arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) overload is used to sort the last three elements of both arrays in reverse order.

> **Note**

 Chasmosaurus: up to 5 meters long.
 Cetiosaurus: up to 18 meters long.
 Caudipteryx: up to 1 meters long.
  */
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

If `comparer` is `null`, each key in the `keys` Array must implement the IComparable<T> generic interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is the Length of `array`.

Notes to Callers

.NET Framework 4 and earlier versions used only the Quicksort algorithm. Quicksort identifies invalid comparers in some situations in which the sorting operation throws an IndexOutOfRangeException exception, and throws an ArgumentException exception to the caller. Starting with .NET Framework 4.5, it is possible that sorting operations that previously threw ArgumentException will not throw an exception, because the insertion sort and heapsort algorithms do not detect an invalid comparer. For the most part, this applies to arrays with less than or equal to 16 elements.

Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32)

Sorts a range of elements in a pair of Array objects (one contains the keys and the other contains the corresponding items) based on the keys in the first Array using the IComparable<T> generic interface implementation of each key.

```
C#
```

```
public static void Sort<TKey,TValue> (TKey[] keys, TValue[]? items, int
index, int length);
```

Type Parameters

`TKey`

The type of the elements of the key array.

`TValue`

The type of the elements of the items array.

Parameters

`keys` TKey[]

The one-dimensional, zero-based Array that contains the keys to sort.

`items` TValue[]

The one-dimensional, zero-based Array that contains the items that correspond to the keys in `keys`, or `null` to sort only `keys`.

`index` Int32

The starting index of the range to sort.

`length` Int32

The number of elements in the range to sort.

Exceptions

ArgumentNullException

`keys` is `null`.

ArgumentOutOfRangeException

`index` is less than the lower bound of `keys`.

-or-

`length` is less than zero.

ArgumentException

`items` is not `null`, and the lower bound of `keys` does not match the lower bound of `items`.

-or-

`items` is not `null`, and the length of `keys` is greater than the length of `items`.

-or-

`index` and `length` do not specify a valid range in the `keys` Array.

-or-

`items` is not `null`, and `index` and `length` do not specify a valid range in the `items` Array.

InvalidOperationException
One or more elements in the `keys` Array do not implement the IComparable<T> generic interface.

Examples

The following code example demonstrates the Sort<TKey,TValue>(TKey[], TValue[]), Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>), Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32), and Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) generic method overloads, for sorting pairs of arrays that represent keys and values.

The code example defines an alternative comparer for strings, named `ReverseCompare`, which implements the `IComparer<string>` (`IComparer(Of String)` in Visual Basic, `IComparer<String^>` in Visual C++) generic interface. The comparer calls the CompareTo(String) method, reversing the order of the comparands so that the strings sort high-to-low instead of low-to-high.

The code example creates and displays an array of dinosaur names (the keys) and an array of integers representing the maximum length of each dinosaur in meters (the values). The arrays are then sorted and displayed several times:

- The Sort<TKey,TValue>(TKey[], TValue[]) overload is used to sort both arrays in order of the dinosaur names in the first array.
- The Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>) overload and an instance of `ReverseCompare` are used to reverse the sort order of the paired

arrays.

- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32) overload is used to sort the last three elements of both arrays.
- The Sort<TKey,TValue>(TKey[], TValue[], Int32, Int32, IComparer<TKey>) overload is used to sort the last three elements of both arrays in reverse order.

> **Note**
>
> The calls to the generic methods do not look any different from calls to their nongeneric counterparts, because Visual Basic, C#, and C++ infer the type of the generic type parameter from the type of the first two arguments. If you use the **Ildasm.exe (IL Disassembler)** to examine the Microsoft intermediate language (MSIL), you can see that the generic methods are being called.

C#

```
using System;
using System.Collections.Generic;

public class ReverseComparer: IComparer<string>
{
    public int Compare(string x, string y)
    {
        // Compare y and x in reverse order.
        return y.CompareTo(x);
    }
}

public class Example
{
    public static void Main()
    {
        string[] dinosaurs = {
            "Seismosaurus",
            "Chasmosaurus",
            "Coelophysis",
            "Mamenchisaurus",
            "Caudipteryx",
            "Cetiosaurus"  };

        int[] dinosaurSizes = { 40, 5, 3, 22, 1, 18 };

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
```

```
        }

        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes)");
        Array.Sort(dinosaurs, dinosaurSizes);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }

        ReverseComparer rc = new ReverseComparer();

        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes, rc)");
        Array.Sort(dinosaurs, dinosaurSizes, rc);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {
            Console.WriteLine("{0}: up to {1} meters long.",
                dinosaurs[i], dinosaurSizes[i]);
        }

        Console.WriteLine("\nSort(dinosaurs, dinosaurSizes, 3, 3)");
        Array.Sort(dinosaurs, dinosaurSizes, 3, 3);

        Console.WriteLine();
        for (int i = 0; i < dinosaurs.Length; i++)
        {

Caudipteryx: up to 1 meters long.
Cetiosaurus: up to 18 meters long.
Chasmosaurus: up to 5 meters long.

Sort(dinosaurs, dinosaurSizes, 3, 3, rc)

Seismosaurus: up to 40 meters long.
Mamenchisaurus: up to 22 meters long.
Coelophysis: up to 3 meters long.
Chasmosaurus: up to 5 meters long.
Cetiosaurus: up to 18 meters long.
Caudipteryx: up to 1 meters long.
 */
```

Remarks

Each key in the `keys` Array has a corresponding item in the `items` Array. When a key is repositioned during the sorting, the corresponding item in the `items` Array is similarly repositioned. Therefore, the `items` Array is sorted according to the arrangement of the corresponding keys in the `keys` Array.

Each key within the specified range of elements in the `keys` Array must implement the IComparable<T> generic interface to be capable of comparisons with every other key.

You can sort if there are more items than keys, but the items that have no corresponding keys will not be sorted. You cannot sort if there are more keys than items; doing this throws an ArgumentException.

If the sort is not successfully completed, the results are undefined.

This method uses the introspective sort (introsort) algorithm as follows:

- If the partition size is less than or equal to 16 elements, it uses an insertion sort algorithm.
- If the number of partitions exceeds 2 * Log^N, where *N* is the range of the input array, it uses a Heapsort algorithm.
- Otherwise, it uses a Quicksort algorithm.

This implementation performs an unstable sort; that is, if two elements are equal, their order might not be preserved. In contrast, a stable sort preserves the order of elements that are equal.

This method is an O(`n` log `n`) operation, where `n` is `length`.

Array.TrueForAll<T>(T[], Predicate<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether every element in the array matches the conditions defined by the specified predicate.

```
C#

public static bool TrueForAll<T> (T[] array, Predicate<T> match);
```

Type Parameters

`T`

The type of the elements of the array.

Parameters

`array` T[]

The one-dimensional, zero-based Array to check against the conditions.

`match` Predicate<T>

The predicate that defines the conditions to check against the elements.

Returns

Boolean

`true` if every element in `array` matches the conditions defined by the specified predicate; otherwise, `false`. If there are no elements in the array, the return value is `true`.

Exceptions

ArgumentNullException

`array` is `null`.

-or-

`match` is `null`.

Examples

The following example determines whether the last character of each element in a string array is a number. It creates two string arrays. The first array includes both strings that end with alphabetic characters and strings that end with numeric characters. The second array consists only of strings that end with numeric characters. The example also defines an `EndWithANumber` method whose signature matches the Predicate<T> delegate. The example passes each array to the TrueForAll method along with a delegate that represents the `EndsWithANumber` method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] values1 = { "Y2K", "A2000", "DC2A6", "MMXIV", "0C3" };
      String[] values2 = { "Y2", "A2000", "DC2A6", "MMXIV_0", "0C3" };

      if (Array.TrueForAll(values1, EndsWithANumber))
         Console.WriteLine("All elements end with an integer.");
      else
         Console.WriteLine("Not all elements end with an integer.");

      if (Array.TrueForAll(values2, EndsWithANumber))
         Console.WriteLine("All elements end with an integer.");
      else
         Console.WriteLine("Not all elements end with an integer.");
   }

   private static bool EndsWithANumber(string value)
   {
      int s;
      return int.TryParse(value.Substring(value.Length - 1), out s);
   }
}
// The example displays the following output:
//       Not all elements end with an integer.
//       All elements end with an integer.
```

The following example is similar to the first, except that it passes the string array to the TrueForAll method along with a lambda expression that determines whether a particular array element ends with the string representation of a number.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] values = { "Y2K", "A2000", "DC2A6", "MMXIV", "0C3" };
      if (Array.TrueForAll(values, value => {
                                      int s;
                                      return
int.TryParse(value.Substring(value.Length - 1), out s); }
                                    ))
         Console.WriteLine("All elements end with an integer.");
      else
         Console.WriteLine("Not all elements end with an integer.");
   }
}
// The example displays the following output:
//        Not all elements end with an integer.
```

In both cases, the TrueForAll method returns `false` as soon as it encounters the first array element that does not end in a number. Otherwise, it returns `true` after iterating all the elements in the array.

> **Note**
>
> As both examples show, in C# and Visual Basic, it is not necessary to create the `Predicate<string>` delegate (`Predicate(Of String)` in Visual Basic) explicitly. These languages infer the correct delegate from context and create it automatically.

Remarks

The Predicate<T> is a delegate to a method that returns `true` if the object passed to it matches the conditions defined in the delegate. The elements of `array` are individually passed to the Predicate<T>, and processing is stopped when the delegate returns `false` for any element.

This method is an O(`n`) operation, where `n` is the Length of `array`.

Array.ICollection.Count Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements contained in the Array.

C#

```
int System.Collections.ICollection.Count { get; }
```

Property Value

Int32

The number of elements contained in the collection.

Implements

Count

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an ICollection interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Array.IList.Add(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calling this method always throws a NotSupportedException exception.

```
C#
int IList.Add (object value);
```

Parameters

`value` Object

The object to be added to the IList.

Returns

Int32

Adding a value to an array is not supported. No value is returned.

Implements

Add(Object)

Exceptions

NotSupportedException

The IList has a fixed size.

Remarks

Ordinarily, an IList.Add implementation adds a member to a collection. However, because arrays have a fixed size (the IsFixedSize property always returns `true`), this method always throws a NotSupportedException exception.

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Array.IList.Contains(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether an element is in the IList.

```
C#
bool IList.Contains (object value);
```

Parameters

`value` Object

The object to locate in the current list. The element to locate can be `null` for reference types.

Returns

Boolean

`true` if `value` is found in the IList; otherwise, `false`.

Implements

Contains(Object)

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Array.IList.IndexOf(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines the index of a specific item in the IList.

```
C#
int IList.IndexOf (object value);
```

Parameters

`value` Object

The object to locate in the current list.

Returns

Int32

The index of value if found in the list; otherwise, -1.

Implements

IndexOf(Object)

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Array.IList.Insert(Int32, Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Inserts an item to the IList at the specified index.

```
C#
void IList.Insert (int index, object value);
```

Parameters

index Int32

The index at which `value` should be inserted.

value Object

The object to insert.

Implements

Insert(Int32, Object)

Exceptions

ArgumentOutOfRangeException

`index` is not a valid index in the IList.

NotSupportedException

The IList is read-only.

-or-

The IList has a fixed size.

NullReferenceException

`value` is null reference in the IList.

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.IList.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the element at the specified index.

```
C#
object? System.Collections.IList.Item[int index] { get; set; }
```

Parameters

`index` Int32

The index of the element to get or set.

Property Value

Object

The element at the specified index.

Implements

Item[Int32]

Exceptions

ArgumentOutOfRangeException

`index` is less than zero.

-or-

`index` is equal to or greater than Count.

ArgumentException

The current Array does not have exactly one dimension.

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.IList.Remove(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Removes the first occurrence of a specific object from the IList.

C#

```
void IList.Remove (object value);
```

Parameters

`value` Object

The object to remove from the IList.

Implements

Remove(Object)

Exceptions

NotSupportedException

The IList is read-only.

-or-

The IList has a fixed size.

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.IList.RemoveAt(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Removes the IList item at the specified index.

```
C#

void IList.RemoveAt (int index);
```

Parameters

`index` Int32

The index of the element to remove.

Implements

RemoveAt(Int32)

Exceptions

ArgumentOutOfRangeException

index is not a valid index in the IList.

NotSupportedException

The IList is read-only.

-or-

The IList has a fixed size.

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IList interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.IStructuralComparable.CompareTo(Object, IComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the current collection object precedes, occurs in the same position as, or follows another object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

The object to compare with the current instance.

`comparer` IComparer

An object that compares the current object and `other`.

Returns

Int32

An integer that indicates the relationship of the current collection object to other, as shown in the following table.

Expand table

Return value	Description
-1	The current instance precedes `other`.
0	The current instance and `other` are equal.
1	The current instance follows `other`.

Implements

CompareTo(Object, IComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IStructuralComparable interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.IStructuralEquatable.Equals(Object, IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether an object is equal to the current instance.

```
C#

bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

`other` Object

The object to compare with the current instance.

`comparer` IEqualityComparer

An object that determines whether the current instance and `other` are equal.

Returns

Boolean

`true` if the two objects are equal; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IStructuralEquatable interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Array.IStructuralEquatable.GetHashCode(IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a hash code for the current instance.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object that computes the hash code of the current object.

Returns

Int32

The hash code for the current instance.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Array instance is cast to an IStructuralEquatable interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArraySegment<T>.Enumerator Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides an enumerator for the elements of an ArraySegment<T>.

C#

```
public struct ArraySegment<T>.Enumerator :
System.Collections.Generic.IEnumerator<T>
```

Type Parameters

T

Inheritance Object → ValueType → ArraySegment<T>.Enumerator

Implements IEnumerator<T> , IEnumerator , IDisposable

Remarks

The C# foreach of the C# language and the For Each...Next construct in Visual Basic hides the complexity of enumerators. Instead of directly manipulating the enumerator, using `foreach` or `For Each...Next` is recommended.

Initially, the enumerator is positioned before the first element in the ArraySegment<T>. At this position, Current is undefined. You must call MoveNext to advance the enumerator to the first item in the ArraySegment<T> before reading the value of Current.

Current returns the same value until MoveNext is called. MoveNext sets Current to the next item in the ArraySegment<T>.

If MoveNext passes the end of the ArraySegment<T>, MoveNext returns `false`. When the enumerator is at this state, subsequent calls to MoveNext also return `false` and

Current is undefined. You cannot set Current to the first item in the ArraySegment<T> again; you must create a new enumerator instance instead.

Properties

Expand table

Current	Gets a reference to the item at the current position of the enumerator.

Methods

Expand table

Dispose()	Releases all resources used by this enumerator instance.
MoveNext()	Advances the enumerator to the next element of the ArraySegment<T>.

Explicit Interface Implementations

Expand table

IEnumerator.Current	Gets the element at the current position of the enumerator.
IEnumerator.Reset()	Sets the enumerator to its initial position, which is before the first element in the array segment.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T>.Enumerator.Current Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a reference to the item at the current position of the enumerator.

```
C#
public T Current { get; }
```

Property Value

T

The element of the ArraySegment<T> at the current position of the enumerator.

Implements

Current

Remarks

`Current` is undefined under either of the following conditions:

- Immediately after the enumerator is created, the enumerator is positioned before the first element in the array segment. MoveNext must be called to advance the enumerator to the first element of the array segment before reading the value of `Current`.
- The last call to MoveNext returned `false`, which indicates the end of the array segment.

`Current` returns the same value until MoveNext is called. MoveNext sets `Current` to the next item in the array segment.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T>.Enumerator.Dispose Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Releases all resources used by this enumerator instance.

C#

```
public void Dispose ();
```

Implements

Dispose()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Provide product feedback

ArraySegment<T>.Enumerator.MoveNext Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Advances the enumerator to the next element of the ArraySegment<T>.

```
C#
public bool MoveNext ();
```

Returns

Boolean

`true` if the enumerator was successfully advanced to the next element; `false` if the enumerator has passed the end of the array segment.

Implements

MoveNext()

Remarks

After an enumerator is created, it is positioned before the first element in the array segment, and the first call to `MoveNext` advances the enumerator to the first item in the array segment.

If `MoveNext` passes the end of the array segment, `MoveNext` returns `false`. When the enumerator is at this state, subsequent calls to `MoveNext` also return `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ArraySegment<T>.Enumerator.IEnumerator.Current Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the element at the current position of the enumerator.

```
C#
object? System.Collections.IEnumerator.Current { get; }
```

Property Value

Object

The element in the array segment at the current position of the enumerator.

Implements

Current

Exceptions

InvalidOperationException

The enumerator is positioned before the first element of the array segment or after the last element.

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T>.Enumerator instance is cast to an IEnumerator interface.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T>.Enumerator.IEnumerator.Reset Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sets the enumerator to its initial position, which is before the first element in the array segment.

C#

```
void IEnumerator.Reset ();
```

Implements

Reset()

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T>.Enumerator instance is cast to an IEnumerator interface.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Delimits a section of a one-dimensional array.

C#

```
public readonly struct ArraySegment<T> :
System.Collections.Generic.ICollection<T>,
System.Collections.Generic.IEnumerable<T>,
System.Collections.Generic.IList<T>,
System.Collections.Generic.IReadOnlyCollection<T>,
System.Collections.Generic.IReadOnlyList<T>
```

Type Parameters

T

The type of the elements in the array segment.

Inheritance Object → ValueType → ArraySegment<T>

Implements ICollection<T> , IEnumerable<T> , IList<T> , IReadOnlyCollection<T> , IReadOnlyList<T> , IEnumerable

Examples

The following code example passes an ArraySegment<T> structure to a method.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new string array.
```

```
      String[] myArr = { "The", "quick", "brown", "fox", "jumps", "over",
"the", "lazy", "dog" };

      // Display the initial contents of the array.
      Console.WriteLine( "The original array initially contains:" );
      PrintIndexAndValues( myArr );

      // Define an array segment that contains the entire array.
      ArraySegment<string> myArrSegAll = new ArraySegment<string>( myArr );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The first array segment (with all the array's
elements) contains:" );
      PrintIndexAndValues( myArrSegAll );

      // Define an array segment that contains the middle five values of the
array.
      ArraySegment<string> myArrSegMid = new ArraySegment<string>( myArr, 2,
5 );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The second array segment (with the middle five
elements) contains:" );
      PrintIndexAndValues( myArrSegMid );

      // Modify the fourth element of the first array segment myArrSegAll.
      myArrSegAll.Array[3] = "LION";

      // Display the contents of the second array segment myArrSegMid.
      // Note that the value of its second element also changed.
      Console.WriteLine( "After the first array segment is modified, the
second array segment now contains:" );
      PrintIndexAndValues( myArrSegMid );
   }

   public static void PrintIndexAndValues( ArraySegment<string> arrSeg )  {
      for ( int i = arrSeg.Offset; i < (arrSeg.Offset + arrSeg.Count); i++ )
{
         Console.WriteLine( "   [{0}] : {1}", i, arrSeg.Array[i] );
      }
      Console.WriteLine();
   }

   public static void PrintIndexAndValues( String[] myArr )  {
      for ( int i = 0; i < myArr.Length; i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, myArr[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.
```

```
The original array initially contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog

The first array segment (with all the array's elements) contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog

The second array segment (with the middle five elements) contains:
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the

After the first array segment is modified, the second array segment now
contains:
   [2] : brown
   [3] : LION
   [4] : jumps
   [5] : over
   [6] : the

*/
```

Remarks

ArraySegment<T> is a wrapper around an array that delimits a range of elements in that array. Multiple ArraySegment<T> instances can refer to the same original array and can overlap. The original array must be one-dimensional and must have zero-based indexing.

> ⓘ **Note**

ArraySegment<T> implements the **IReadOnlyCollection<T>** interface starting with the .NET Framework 4.6; in previous versions of the .NET Framework, the **ArraySegment<T>** structure did not implement this interface.

The ArraySegment<T> structure is useful whenever the elements of an array will be manipulated in distinct segments. For example:

- You can pass an ArraySegment<T> object that represents only a portion of an array as an argument to a method, rather than call a relatively expensive method like Copy to pass a copy of a portion of an array.
- In a multithreaded app, you can use the ArraySegment<T> structure to have each thread operate on only a portion of the array.
- For task-based asynchronous operations, you can use an ArraySegment<T> object to ensure that each task operates on a distinct segment of the array. The following example divides an array into individual segments with up to ten elements. Each element in the segment is multiplied by its segment number. The result shows that using the ArraySegment<T> class to manipulate elements in this way changes the values of its underlying array.

C#

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;

public class Example
{
   private const int segmentSize = 10;

   public static async Task Main()
   {
      List<Task> tasks = new List<Task>();

      // Create array.
      int[] arr = new int[50];
      for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++)
         arr[ctr] = ctr + 1;

      // Handle array in segments of 10.
      for (int ctr = 1; ctr <=
Math.Ceiling(((double)arr.Length)/segmentSize); ctr++) {
         int multiplier = ctr;
         int elements = (multiplier - 1) * 10 + segmentSize >
arr.Length ?
                           arr.Length - (multiplier - 1) * 10 :
segmentSize;
```

```
         ArraySegment<int> segment = new ArraySegment<int>(arr, (ctr -
1) * 10, elements);
         tasks.Add(Task.Run( () => { IList<int> list = (IList<int>)
segment;
                                     for (int index = 0; index <
list.Count; index++)
                                        list[index] = list[index] *
multiplier;
                                  } ));
      }
      try {
         await Task.WhenAll(tasks.ToArray());
         int elementsShown = 0;
         foreach (var value in arr) {
            Console.Write("{0,3} ", value);
            elementsShown++;
            if (elementsShown % 18 == 0)
               Console.WriteLine();
         }
      }
      catch (AggregateException e) {
         Console.WriteLine("Errors occurred when working with the
array:");
         foreach (var inner in e.InnerExceptions)
            Console.WriteLine("{0}: {1}", inner.GetType().Name,
inner.Message);
      }
   }
}
// The example displays the following output:
//      1   2   3   4   5   6   7   8   9  10  22  24  26  28  30  32
34  36
//     38  40  63  66  69  72  75  78  81  84  87  90 124 128 132 136
140 144
//    148 152 156 160 205 210 215 220 225 230 235 240 245 250
```

Note, however, that although the ArraySegment<T> structure can be used to divide an array into distinct segments, the segments are not completely independent of one another. The Array property returns the entire original array, not a copy of the array; therefore, changes made to the array returned by the Array property are made to the original array. If this is undesirable, you should perform operations on a copy of the array, rather than an ArraySegment<T> object that represents a portion of the array.

The Equals method and the equality and inequality operators test for reference equality when they compare two ArraySegment<T> objects. For two ArraySegment<T> objects to be considered equal, they must meet all of the following conditions:

- Reference the same array.
- Begin at the same index in the array.

- Have the same number of elements.

If you want to retrieve an element by its index in the ArraySegment<T> object, you must cast it to an IList<T> object and retrieve it or modify it by using the IList<T>.Item[] property. Note that this is not necessary in F#. The following example retrieves the element in an ArraySegment<T> object that delimits a section of a string array.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      String[] names = { "Adam", "Bruce", "Charles", "Daniel",
                         "Ebenezer", "Francis", "Gilbert",
                         "Henry", "Irving", "John", "Karl",
                         "Lucian", "Michael" };
      var partNames = new ArraySegment<string>(names, 2, 5);

      // Cast the ArraySegment object to an IList<string> and enumerate it.
      var list = (IList<string>) partNames;
      for (int ctr = 0; ctr <= list.Count - 1; ctr++)
         Console.WriteLine(list[ctr]);
   }
}
// The example displays the following output:
//    Charles
//    Daniel
//    Ebenezer
//    Francis
//    Gilbert
```

Constructors

Expand table

ArraySegment<T>(T[])	Initializes a new instance of the ArraySegment<T> structure that delimits all the elements in the specified array.
ArraySegment<T>(T[], Int32, Int32)	Initializes a new instance of the ArraySegment<T> structure that delimits the specified range of the elements in the specified array.

Properties

Expand table

Array	Gets the original array containing the range of elements that the array segment delimits.
Count	Gets the number of elements in the range delimited by the array segment.
Empty	Represents the empty array segment. This field is read-only.
Item[Int32]	Gets or sets the element at the specified index.
Offset	Gets the position of the first element in the range delimited by the array segment, relative to the start of the original array.

Methods

Expand table

CopyTo(ArraySegment<T>)	Copies the contents of this instance into the specified destination array segment of the same type `T`.
CopyTo(T[])	Copies the contents of this instance into the specified destination array of the same type `T`.
CopyTo(T[], Int32)	Copies the contents of this instance into the specified destination array of the same type `T`, starting at the specified destination index.
Equals(ArraySegment<T>)	Determines whether the specified ArraySegment<T> structure is equal to the current instance.
Equals(Object)	Determines whether the specified object is equal to the current instance.
GetEnumerator()	Returns an enumerator that can be used to iterate through the array segment.
GetHashCode()	Returns the hash code for the current instance.
Slice(Int32)	Forms a slice out of the current array segment starting at the specified index.
Slice(Int32, Int32)	Forms a slice of the specified length out of the current array segment starting at the specified index.
ToArray()	Copies the contents of this array segment into a new array.

Operators

Expand table

Equality(ArraySegment<T>, ArraySegment<T>)	Indicates whether two ArraySegment<T> structures are equal.
Implicit(T[] to ArraySegment<T>)	Defines an implicit conversion of an array of type `T` to an array segment of type `T`.
Inequality(ArraySegment<T>, ArraySegment<T>)	Indicates whether two ArraySegment<T> structures are unequal.

Explicit Interface Implementations

Expand table

ICollection<T>.Add(T)	Throws a NotSupportedException exception in all cases.
ICollection<T>.Clear()	Throws a NotSupportedException exception in all cases.
ICollection<T>.Contains(T)	Determines whether the array segment contains a specific value.
ICollection<T>.IsReadOnly	Gets a value that indicates whether the array segment is read-only.
ICollection<T>.Remove(T)	Throws a NotSupportedException exception in all cases.
IEnumerable.GetEnumerator()	Returns an enumerator that iterates through an array segment.
IEnumerable<T>.GetEnumerator()	Returns an enumerator that iterates through the array segment.
IList<T>.IndexOf(T)	Determines the index of a specific item in the array segment.
IList<T>.Insert(Int32, T)	Throws a NotSupportedException exception in all cases.
IList<T>.Item[Int32]	Gets or sets the element at the specified index.
IList<T>.RemoveAt(Int32)	Throws a NotSupportedException exception in all cases.
IReadOnlyList<T>.Item[Int32]	Gets the element at the specified index of the array segment.

Extension Methods

Expand table

ToFrozenDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Creates a FrozenDictionary<TKey,TValue> from an IEnumerable<T> according to specified key selector function.
ToFrozenDictionary<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEqualityComparer<TKey>)	Creates a FrozenDictionary<TKey,TValue> from an IEnumerable<T> according to specified key selector and element selector functions.
ToFrozenSet<T>(IEnumerable<T>, IEqualityComparer<T>)	Creates a FrozenSet<T> with the specified values.
AsReadOnly<T>(IList<T>)	Returns a read-only ReadOnlyCollection<T> wrapper for the specified list.
ToImmutableArray<TSource>(IEnumerable<TSource>)	Creates an immutable array from the specified collection.
ToImmutableDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Constructs an immutable dictionary from an existing collection of elements, applying a transformation function to the source keys.
ToImmutableDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Constructs an immutable dictionary based on some transformation of a sequence.
ToImmutableDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>)	Enumerates and transforms a sequence, and produces an immutable dictionary of its contents.
ToImmutableDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IEqualityComparer<TKey>)	Enumerates and transforms a sequence, and produces an immutable dictionary of its contents by using the specified key comparer.
ToImmutableDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IEqualityComparer<TKey>, IEqualityComparer<TValue>)	Enumerates and transforms a sequence, and produces an immutable dictionary of its contents by using the specified key and value comparers.

ToImmutableHashSet<TSource>(IEnumerable<TSource>)	Enumerates a sequence and produces an immutable hash set of its contents.
ToImmutableHashSet<TSource>(IEnumerable<TSource>, IEqualityComparer<TSource>)	Enumerates a sequence, produces an immutable hash set of its contents, and uses the specified equality comparer for the set type.
ToImmutableList<TSource>(IEnumerable<TSource>)	Enumerates a sequence and produces an immutable list of its contents.
ToImmutableSortedDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>)	Enumerates and transforms a sequence, and produces an immutable sorted dictionary of its contents.
ToImmutableSortedDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IComparer<TKey>)	Enumerates and transforms a sequence, and produces an immutable sorted dictionary of its contents by using the specified key comparer.
ToImmutableSortedDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IComparer<TKey>, IEqualityComparer<TValue>)	Enumerates and transforms a sequence, and produces an immutable sorted dictionary of its contents by using the specified key and value comparers.
ToImmutableSortedSet<TSource>(IEnumerable<TSource>)	Enumerates a sequence and produces an immutable sorted set of its contents.
ToImmutableSortedSet<TSource>(IEnumerable<TSource>, IComparer<TSource>)	Enumerates a sequence, produces an immutable sorted set of its contents, and uses the specified comparer.
CopyToDataTable<T>(IEnumerable<T>)	Returns a DataTable that contains copies of the DataRow objects, given an input IEnumerable<T> object where the generic parameter `T` is DataRow.
CopyToDataTable<T>(IEnumerable<T>, DataTable, LoadOption)	Copies DataRow objects to the specified DataTable, given an input IEnumerable<T>

	object where the generic parameter `T` is DataRow.
CopyToDataTable<T>(IEnumerable<T>, DataTable, LoadOption, FillErrorEventHandler)	Copies DataRow objects to the specified DataTable, given an input IEnumerable<T> object where the generic parameter `T` is DataRow.
Aggregate<TSource>(IEnumerable<TSource>, Func<TSource,TSource,TSource>)	Applies an accumulator function over a sequence.
Aggregate<TSource,TAccumulate>(IEnumerable<TSource>, TAccumulate, Func<TAccumulate,TSource,TAccumulate>)	Applies an accumulator function over a sequence. The specified seed value is used as the initial accumulator value.
Aggregate<TSource,TAccumulate,TResult>(IEnumerable<TSource>, TAccumulate, Func<TAccumulate,TSource,TAccumulate>, Func<TAccumulate,TResult>)	Applies an accumulator function over a sequence. The specified seed value is used as the initial accumulator value, and the specified function is used to select the result value.
All<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Determines whether all elements of a sequence satisfy a condition.
Any<TSource>(IEnumerable<TSource>)	Determines whether a sequence contains any elements.
Any<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Determines whether any element of a sequence satisfies a condition.
Append<TSource>(IEnumerable<TSource>, TSource)	Appends a value to the end of the sequence.
AsEnumerable<TSource>(IEnumerable<TSource>)	Returns the input typed as IEnumerable<T>.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Computes the average of a sequence of Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Computes the average of a sequence of Double values

	that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Computes the average of a sequence of Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Computes the average of a sequence of Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Computes the average of a sequence of nullable Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Computes the average of a sequence of nullable Double values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Computes the average of a sequence of nullable Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Computes the average of a sequence of nullable Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Computes the average of a sequence of nullable Single values that are obtained by invoking a transform function

	on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Computes the average of a sequence of Single values that are obtained by invoking a transform function on each element of the input sequence.
Cast<TResult>(IEnumerable)	Casts the elements of an IEnumerable to the specified type.
Chunk<TSource>(IEnumerable<TSource>, Int32)	Splits the elements of a sequence into chunks of size at most `size`.
Concat<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Concatenates two sequences.
Contains<TSource>(IEnumerable<TSource>, TSource)	Determines whether a sequence contains a specified element by using the default equality comparer.
Contains<TSource>(IEnumerable<TSource>, TSource, IEqualityComparer<TSource>)	Determines whether a sequence contains a specified element by using a specified IEqualityComparer<T>.
Count<TSource>(IEnumerable<TSource>)	Returns the number of elements in a sequence.
Count<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns a number that represents how many elements in the specified sequence satisfy a condition.
DefaultIfEmpty<TSource>(IEnumerable<TSource>)	Returns the elements of the specified sequence or the type parameter's default value in a singleton collection if the sequence is empty.
DefaultIfEmpty<TSource>(IEnumerable<TSource>, TSource)	Returns the elements of the specified sequence or the specified value in a singleton collection if the sequence is empty.

Distinct<TSource>(IEnumerable<TSource>)	Returns distinct elements from a sequence by using the default equality comparer to compare values.
Distinct<TSource>(IEnumerable<TSource>, IEqualityComparer<TSource>)	Returns distinct elements from a sequence by using a specified IEqualityComparer<T> to compare values.
DistinctBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Returns distinct elements from a sequence according to a specified key selector function.
DistinctBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Returns distinct elements from a sequence according to a specified key selector function and using a specified comparer to compare keys.
ElementAt<TSource>(IEnumerable<TSource>, Index)	Returns the element at a specified index in a sequence.
ElementAt<TSource>(IEnumerable<TSource>, Int32)	Returns the element at a specified index in a sequence.
ElementAtOrDefault<TSource>(IEnumerable<TSource>, Index)	Returns the element at a specified index in a sequence or a default value if the index is out of range.
ElementAtOrDefault<TSource>(IEnumerable<TSource>, Int32)	Returns the element at a specified index in a sequence or a default value if the index is out of range.
Except<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Produces the set difference of two sequences by using the default equality comparer to compare values.
Except<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Produces the set difference of two sequences by using the specified IEqualityComparer<T> to compare values.
ExceptBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>)	Produces the set difference of two sequences according to a

	specified key selector function.
ExceptBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Produces the set difference of two sequences according to a specified key selector function.
First<TSource>(IEnumerable<TSource>)	Returns the first element of a sequence.
First<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the first element in a sequence that satisfies a specified condition.
FirstOrDefault<TSource>(IEnumerable<TSource>)	Returns the first element of a sequence, or a default value if the sequence contains no elements.
FirstOrDefault<TSource>(IEnumerable<TSource>, TSource)	Returns the first element of a sequence, or a specified default value if the sequence contains no elements.
FirstOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the first element of the sequence that satisfies a condition or a default value if no such element is found.
FirstOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>, TSource)	Returns the first element of the sequence that satisfies a condition, or a specified default value if no such element is found.
GroupBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Groups the elements of a sequence according to a specified key selector function.
GroupBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Groups the elements of a sequence according to a specified key selector function and compares the keys by using a specified comparer.
GroupBy<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>)	Groups the elements of a sequence according to a specified key selector function and projects the elements for

	each group by using a specified function.
GroupBy<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEqualityComparer<TKey>)	Groups the elements of a sequence according to a key selector function. The keys are compared by using a comparer and each group's elements are projected by using a specified function.
GroupBy<TSource,TKey,TResult>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TKey,IEnumerable<TSource>,TResult>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key.
GroupBy<TSource,TKey,TResult>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TKey,IEnumerable<TSource>,TResult>, IEqualityComparer<TKey>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key. The keys are compared by using a specified comparer.
GroupBy<TSource,TKey,TElement,TResult> (IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, Func<TKey,IEnumerable<TElement>,TResult>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key. The elements of each group are projected by using a specified function.
GroupBy<TSource,TKey,TElement,TResult> (IEnumerable<TSource>, Func<TSource, TKey>, Func<TSource,TElement>, Func<TKey,IEnumerable<TElement>, TResult>, IEqualityComparer<TKey>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key. Key values are compared by using a specified comparer, and the elements of each group are projected by using a specified function.
GroupJoin<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,IEnumerable<TInner>, TResult>)	Correlates the elements of two sequences based on equality of keys and groups the results. The default

	equality comparer is used to compare keys.
GroupJoin<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,IEnumerable<TInner>, TResult>, IEqualityComparer<TKey>)	Correlates the elements of two sequences based on key equality and groups the results. A specified IEqualityComparer<T> is used to compare keys.
Intersect<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Produces the set intersection of two sequences by using the default equality comparer to compare values.
Intersect<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Produces the set intersection of two sequences by using the specified IEqualityComparer<T> to compare values.
IntersectBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>)	Produces the set intersection of two sequences according to a specified key selector function.
IntersectBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Produces the set intersection of two sequences according to a specified key selector function.
Join<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,TInner,TResult>)	Correlates the elements of two sequences based on matching keys. The default equality comparer is used to compare keys.
Join<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,TInner,TResult>, IEqualityComparer<TKey>)	Correlates the elements of two sequences based on matching keys. A specified IEqualityComparer<T> is used to compare keys.
Last<TSource>(IEnumerable<TSource>)	Returns the last element of a sequence.
Last<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the last element of a sequence that satisfies a specified condition.

LastOrDefault<TSource>(IEnumerable<TSource>)	Returns the last element of a sequence, or a default value if the sequence contains no elements.
LastOrDefault<TSource>(IEnumerable<TSource>, TSource)	Returns the last element of a sequence, or a specified default value if the sequence contains no elements.
LastOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the last element of a sequence that satisfies a condition or a default value if no such element is found.
LastOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>, TSource)	Returns the last element of a sequence that satisfies a condition, or a specified default value if no such element is found.
LongCount<TSource>(IEnumerable<TSource>)	Returns an Int64 that represents the total number of elements in a sequence.
LongCount<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns an Int64 that represents how many elements in a sequence satisfy a condition.
Max<TSource>(IEnumerable<TSource>)	Returns the maximum value in a generic sequence.
Max<TSource>(IEnumerable<TSource>, IComparer<TSource>)	Returns the maximum value in a generic sequence.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Invokes a transform function on each element of a sequence and returns the maximum Decimal value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Invokes a transform function on each element of a sequence and returns the maximum Double value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Invokes a transform function on each element of a sequence and returns the maximum Int32 value.

Max<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Invokes a transform function on each element of a sequence and returns the maximum Int64 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Decimal value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Double value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Int32 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Int64 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Single value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Invokes a transform function on each element of a sequence and returns the maximum Single value.
Max<TSource,TResult>(IEnumerable<TSource>, Func<TSource,TResult>)	Invokes a transform function on each element of a generic sequence and returns the maximum resulting value.
MaxBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Returns the maximum value in a generic sequence according to a specified key selector function.

MaxBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Returns the maximum value in a generic sequence according to a specified key selector function and key comparer.
Min<TSource>(IEnumerable<TSource>)	Returns the minimum value in a generic sequence.
Min<TSource>(IEnumerable<TSource>, IComparer<TSource>)	Returns the minimum value in a generic sequence.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Invokes a transform function on each element of a sequence and returns the minimum Decimal value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Invokes a transform function on each element of a sequence and returns the minimum Double value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Invokes a transform function on each element of a sequence and returns the minimum Int32 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Invokes a transform function on each element of a sequence and returns the minimum Int64 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Decimal value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Double value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Int32 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Invokes a transform function on each element of a

	sequence and returns the minimum nullable Int64 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Single value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Invokes a transform function on each element of a sequence and returns the minimum Single value.
Min<TSource,TResult>(IEnumerable<TSource>, Func<TSource,TResult>)	Invokes a transform function on each element of a generic sequence and returns the minimum resulting value.
MinBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Returns the minimum value in a generic sequence according to a specified key selector function.
MinBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Returns the minimum value in a generic sequence according to a specified key selector function and key comparer.
OfType<TResult>(IEnumerable)	Filters the elements of an IEnumerable based on a specified type.
Order<T>(IEnumerable<T>)	Sorts the elements of a sequence in ascending order.
Order<T>(IEnumerable<T>, IComparer<T>)	Sorts the elements of a sequence in ascending order.
OrderBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Sorts the elements of a sequence in ascending order according to a key.
OrderBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Sorts the elements of a sequence in ascending order by using a specified comparer.
OrderByDescending<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Sorts the elements of a sequence in descending order according to a key.

OrderByDescending<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Sorts the elements of a sequence in descending order by using a specified comparer.
OrderDescending<T>(IEnumerable<T>)	Sorts the elements of a sequence in descending order.
OrderDescending<T>(IEnumerable<T>, IComparer<T>)	Sorts the elements of a sequence in descending order.
Prepend<TSource>(IEnumerable<TSource>, TSource)	Adds a value to the beginning of the sequence.
Reverse<TSource>(IEnumerable<TSource>)	Inverts the order of the elements in a sequence.
Select<TSource,TResult>(IEnumerable<TSource>, Func<TSource,TResult>)	Projects each element of a sequence into a new form.
Select<TSource,TResult>(IEnumerable<TSource>, Func<TSource,Int32,TResult>)	Projects each element of a sequence into a new form by incorporating the element's index.
SelectMany<TSource,TResult>(IEnumerable<TSource>, Func<TSource,IEnumerable<TResult>>)	Projects each element of a sequence to an IEnumerable<T> and flattens the resulting sequences into one sequence.
SelectMany<TSource,TResult>(IEnumerable<TSource>, Func<TSource,Int32,IEnumerable<TResult>>)	Projects each element of a sequence to an IEnumerable<T>, and flattens the resulting sequences into one sequence. The index of each source element is used in the projected form of that element.
SelectMany<TSource,TCollection,TResult>(IEnumerable<TSource>, Func<TSource,IEnumerable<TCollection>>, Func<TSource,TCollection,TResult>)	Projects each element of a sequence to an IEnumerable<T>, flattens the resulting sequences into one sequence, and invokes a result selector function on each element therein.

SelectMany<TSource,TCollection,TResult>(IEnumerable<TSource>, Func<TSource,Int32,IEnumerable<TCollection>>, Func<TSource,TCollection,TResult>)	Projects each element of a sequence to an IEnumerable<T>, flattens the resulting sequences into one sequence, and invokes a result selector function on each element therein. The index of each source element is used in the intermediate projected form of that element.
SequenceEqual<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Determines whether two sequences are equal by comparing the elements by using the default equality comparer for their type.
SequenceEqual<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Determines whether two sequences are equal by comparing their elements by using a specified IEqualityComparer<T>.
Single<TSource>(IEnumerable<TSource>)	Returns the only element of a sequence, and throws an exception if there is not exactly one element in the sequence.
Single<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the only element of a sequence that satisfies a specified condition, and throws an exception if more than one such element exists.
SingleOrDefault<TSource>(IEnumerable<TSource>)	Returns the only element of a sequence, or a default value if the sequence is empty; this method throws an exception if there is more than one element in the sequence.
SingleOrDefault<TSource>(IEnumerable<TSource>, TSource)	Returns the only element of a sequence, or a specified default value if the sequence is empty; this method throws an exception if there is more than one element in the sequence.

SingleOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the only element of a sequence that satisfies a specified condition or a default value if no such element exists; this method throws an exception if more than one element satisfies the condition.
SingleOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>, TSource)	Returns the only element of a sequence that satisfies a specified condition, or a specified default value if no such element exists; this method throws an exception if more than one element satisfies the condition.
Skip<TSource>(IEnumerable<TSource>, Int32)	Bypasses a specified number of elements in a sequence and then returns the remaining elements.
SkipLast<TSource>(IEnumerable<TSource>, Int32)	Returns a new enumerable collection that contains the elements from `source` with the last `count` elements of the source collection omitted.
SkipWhile<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Bypasses elements in a sequence as long as a specified condition is true and then returns the remaining elements.
SkipWhile<TSource>(IEnumerable<TSource>, Func<TSource,Int32,Boolean>)	Bypasses elements in a sequence as long as a specified condition is true and then returns the remaining elements. The element's index is used in the logic of the predicate function.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Computes the sum of the sequence of Decimal values that are obtained by invoking a transform function on each element of the input sequence.

Sum<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Computes the sum of the sequence of Double values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Computes the sum of the sequence of Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Computes the sum of the sequence of Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Computes the sum of the sequence of nullable Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Computes the sum of the sequence of nullable Double values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Computes the sum of the sequence of nullable Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Computes the sum of the sequence of nullable Int64 values that are obtained by invoking a transform function on each element of the input sequence.

Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Computes the sum of the sequence of nullable Single values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Computes the sum of the sequence of Single values that are obtained by invoking a transform function on each element of the input sequence.
Take<TSource>(IEnumerable<TSource>, Int32)	Returns a specified number of contiguous elements from the start of a sequence.
Take<TSource>(IEnumerable<TSource>, Range)	Returns a specified range of contiguous elements from a sequence.
TakeLast<TSource>(IEnumerable<TSource>, Int32)	Returns a new enumerable collection that contains the last `count` elements from `source`.
TakeWhile<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns elements from a sequence as long as a specified condition is true.
TakeWhile<TSource>(IEnumerable<TSource>, Func<TSource,Int32,Boolean>)	Returns elements from a sequence as long as a specified condition is true. The element's index is used in the logic of the predicate function.
ToArray<TSource>(IEnumerable<TSource>)	Creates an array from a IEnumerable<T>.
ToDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to a specified key selector function.
ToDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to a specified key

	selector function and key comparer.
ToDictionary<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to specified key selector and element selector functions.
ToDictionary<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEqualityComparer<TKey>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to a specified key selector function, a comparer, and an element selector function.
ToHashSet<TSource>(IEnumerable<TSource>)	Creates a HashSet<T> from an IEnumerable<T>.
ToHashSet<TSource>(IEnumerable<TSource>, IEqualityComparer<TSource>)	Creates a HashSet<T> from an IEnumerable<T> using the `comparer` to compare keys.
ToList<TSource>(IEnumerable<TSource>)	Creates a List<T> from an IEnumerable<T>.
ToLookup<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to a specified key selector function.
ToLookup<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to a specified key selector function and key comparer.
ToLookup<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to specified key selector and element selector functions.
ToLookup<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEqualityComparer<TKey>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T>

	according to a specified key selector function, a comparer and an element selector function.
TryGetNonEnumeratedCount<TSource>(IEnumerable<TSource>, Int32)	Attempts to determine the number of elements in a sequence without forcing an enumeration.
Union<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Produces the set union of two sequences by using the default equality comparer.
Union<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Produces the set union of two sequences by using a specified IEqualityComparer<T>.
UnionBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TSource>, Func<TSource,TKey>)	Produces the set union of two sequences according to a specified key selector function.
UnionBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TSource>, Func<TSource,TKey>, IEquality Comparer<TKey>)	Produces the set union of two sequences according to a specified key selector function.
Where<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Filters a sequence of values based on a predicate.
Where<TSource>(IEnumerable<TSource>, Func<TSource,Int32,Boolean>)	Filters a sequence of values based on a predicate. Each element's index is used in the logic of the predicate function.
Zip<TFirst,TSecond>(IEnumerable<TFirst>, IEnumerable<TSecond>)	Produces a sequence of tuples with elements from the two specified sequences.
Zip<TFirst,TSecond,TThird>(IEnumerable<TFirst>, IEnumerable<TSecond>, IEnumerable<TThird>)	Produces a sequence of tuples with elements from the three specified sequences.
Zip<TFirst,TSecond,TResult>(IEnumerable<TFirst>, IEnumerable<TSecond>, Func<TFirst,TSecond,TResult>)	Applies a specified function to the corresponding elements of two sequences, producing a sequence of the results.

AsParallel(IEnumerable)	Enables parallelization of a query.
AsParallel<TSource>(IEnumerable<TSource>)	Enables parallelization of a query.
AsQueryable(IEnumerable)	Converts an IEnumerable to an IQueryable.
AsQueryable<TElement>(IEnumerable<TElement>)	Converts a generic IEnumerable<T> to a generic IQueryable<T>.
AsMemory<T>(ArraySegment<T>)	Creates a new memory region over the portion of the target array segment.
AsMemory<T>(ArraySegment<T>, Int32)	Creates a new memory region over the portion of the target array segment starting at a specified position to the end of the segment.
AsMemory<T>(ArraySegment<T>, Int32, Int32)	Creates a new memory region over the portion of the target array segment beginning at a specified position with a specified length.
AsSpan<T>(ArraySegment<T>)	Creates a new span over a target array segment.
AsSpan<T>(ArraySegment<T>, Index)	Creates a new span over a portion of the target array segment beginning at a specified index and ending at the end of the segment.
AsSpan<T>(ArraySegment<T>, Int32)	Creates a new span over a portion of a target array segment from a specified position to the end of the segment.
AsSpan<T>(ArraySegment<T>, Int32, Int32)	Creates a new span over a portion of a target array segment from a specified position for a specified length.

AsSpan<T>(ArraySegment<T>, Range)	Creates a new span over a portion of a target array segment using the range start and end indexes.
Ancestors<T>(IEnumerable<T>)	Returns a collection of elements that contains the ancestors of every node in the source collection.
Ancestors<T>(IEnumerable<T>, XName)	Returns a filtered collection of elements that contains the ancestors of every node in the source collection. Only elements that have a matching XName are included in the collection.
DescendantNodes<T>(IEnumerable<T>)	Returns a collection of the descendant nodes of every document and element in the source collection.
Descendants<T>(IEnumerable<T>)	Returns a collection of elements that contains the descendant elements of every element and document in the source collection.
Descendants<T>(IEnumerable<T>, XName)	Returns a filtered collection of elements that contains the descendant elements of every element and document in the source collection. Only elements that have a matching XName are included in the collection.
Elements<T>(IEnumerable<T>)	Returns a collection of the child elements of every element and document in the source collection.
Elements<T>(IEnumerable<T>, XName)	Returns a filtered collection of the child elements of every element and document in the source collection. Only elements that have a matching XName are included in the collection.

InDocumentOrder<T>(IEnumerable<T>)	Returns a collection of nodes that contains all nodes in the source collection, sorted in document order.
Nodes<T>(IEnumerable<T>)	Returns a collection of the child nodes of every document and element in the source collection.
Remove<T>(IEnumerable<T>)	Removes every node in the source collection from its parent node.

ArraySegment<T> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArraySegment<T> structure.

Overloads

Expand table

ArraySegment<T>(T[])	Initializes a new instance of the ArraySegment<T> structure that delimits all the elements in the specified array.
ArraySegment<T>(T[], Int32, Int32)	Initializes a new instance of the ArraySegment<T> structure that delimits the specified range of the elements in the specified array.

Examples

The following code example passes an ArraySegment<T> structure to a method.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new string array.
      String[] myArr = { "The", "quick", "brown", "fox", "jumps", "over",
"the", "lazy", "dog" };

      // Display the initial contents of the array.
      Console.WriteLine( "The original array initially contains:" );
      PrintIndexAndValues( myArr );

      // Define an array segment that contains the entire array.
      ArraySegment<string> myArrSegAll = new ArraySegment<string>( myArr );

      // Display the contents of the ArraySegment.
```

```
      Console.WriteLine( "The first array segment (with all the array's
elements) contains:" );
      PrintIndexAndValues( myArrSegAll );

      // Define an array segment that contains the middle five values of the
array.
      ArraySegment<string> myArrSegMid = new ArraySegment<string>( myArr, 2,
5 );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The second array segment (with the middle five
elements) contains:" );
      PrintIndexAndValues( myArrSegMid );

      // Modify the fourth element of the first array segment myArrSegAll.
      myArrSegAll.Array[3] = "LION";

      // Display the contents of the second array segment myArrSegMid.
      // Note that the value of its second element also changed.
      Console.WriteLine( "After the first array segment is modified, the
second array segment now contains:" );
      PrintIndexAndValues( myArrSegMid );
   }

   public static void PrintIndexAndValues( ArraySegment<string> arrSeg )  {
      for ( int i = arrSeg.Offset; i < (arrSeg.Offset + arrSeg.Count); i++ )
{
         Console.WriteLine( "   [{0}] : {1}", i, arrSeg.Array[i] );
      }
      Console.WriteLine();
   }

   public static void PrintIndexAndValues( String[] myArr )  {
      for ( int i = 0; i < myArr.Length; i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, myArr[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.

The original array initially contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog
```

```
The first array segment (with all the array's elements) contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog

The second array segment (with the middle five elements) contains:
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the

After the first array segment is modified, the second array segment now
contains:
   [2] : brown
   [3] : LION
   [4] : jumps
   [5] : over
   [6] : the

*/
```

ArraySegment<T>(T[])

Initializes a new instance of the ArraySegment<T> structure that delimits all the elements in the specified array.

```
C#

public ArraySegment (T[] array);
```

Parameters

array T[]

The array to wrap.

Exceptions

ArgumentNullException

`array` is `null`.

Remarks

This constructor creates an ArraySegment<T> that delimits all the elements of `array`. That is, the Offset property of the ArraySegment<T> is 0 and its Count property is the length of `array`. To create an ArraySegment<T> that delimits only part of an array, use the ArraySegment<T>(T[], Int32, Int32) constructor.

The original array must be one-dimensional and must have zero-based indexing.

Multiple ArraySegment<T> instances can refer to the same original array and can overlap.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArraySegment<T>(T[], Int32, Int32)

Initializes a new instance of the ArraySegment<T> structure that delimits the specified range of the elements in the specified array.

C#

```
public ArraySegment (T[] array, int offset, int count);
```

Parameters

`array` T[]

The array containing the range of elements to delimit.

`offset` Int32

The zero-based index of the first element in the range.

`count` Int32

The number of elements in the range.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`offset` or `count` is less than 0.

ArgumentException

`offset` and `count` do not specify a valid range in `array`.

Remarks

The original array must be one-dimensional and must have zero-based indexing.

Multiple ArraySegment<T> instances can refer to the same original array and can overlap.

ArraySegment<T>.Array Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the original array containing the range of elements that the array segment delimits.

C#

```
public T[]? Array { get; }
```

Property Value

T[]

The original array that was passed to the constructor, and that contains the range delimited by the ArraySegment<T>.

Examples

The following code example passes an ArraySegment<T> to a method.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new string array.
      String[] myArr = { "The", "quick", "brown", "fox", "jumps", "over",
"the", "lazy", "dog" };

      // Display the initial contents of the array.
      Console.WriteLine( "The original array initially contains:" );
      PrintIndexAndValues( myArr );

      // Define an array segment that contains the entire array.
      ArraySegment<string> myArrSegAll = new ArraySegment<string>( myArr );
```

```
      // Display the contents of the ArraySegment.
      Console.WriteLine( "The first array segment (with all the array's
elements) contains:" );
      PrintIndexAndValues( myArrSegAll );

      // Define an array segment that contains the middle five values of the
array.
      ArraySegment<string> myArrSegMid = new ArraySegment<string>( myArr, 2,
5 );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The second array segment (with the middle five
elements) contains:" );
      PrintIndexAndValues( myArrSegMid );

      // Modify the fourth element of the first array segment myArrSegAll.
      myArrSegAll.Array[3] = "LION";

      // Display the contents of the second array segment myArrSegMid.
      // Note that the value of its second element also changed.
      Console.WriteLine( "After the first array segment is modified, the
second array segment now contains:" );
      PrintIndexAndValues( myArrSegMid );
   }

   public static void PrintIndexAndValues( ArraySegment<string> arrSeg )  {
      for ( int i = arrSeg.Offset; i < (arrSeg.Offset + arrSeg.Count); i++ )
{
         Console.WriteLine( "   [{0}] : {1}", i, arrSeg.Array[i] );
      }
      Console.WriteLine();
   }

   public static void PrintIndexAndValues( String[] myArr )  {
      for ( int i = 0; i < myArr.Length; i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, myArr[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.

The original array initially contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog
```

```
The first array segment (with all the array's elements) contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the
   [7] : lazy
   [8] : dog

The second array segment (with the middle five elements) contains:
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the

After the first array segment is modified, the second array segment now
contains:
   [2] : brown
   [3] : LION
   [4] : jumps
   [5] : over
   [6] : the

*/
```

Remarks

The Array property returns the original array, not a copy of the array; therefore, changes made through the property are made directly to the original array.

ArraySegment<T>.Count Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the range delimited by the array segment.

C#

```
public int Count { get; }
```

Property Value

Int32

The number of elements in the range delimited by the ArraySegment<T>.

Implements

Count , Count

Examples

The following code example passes an ArraySegment<T> structure to a method.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new string array.
      String[] myArr = { "The", "quick", "brown", "fox", "jumps", "over",
"the", "lazy", "dog" };

      // Display the initial contents of the array.
      Console.WriteLine( "The original array initially contains:" );
      PrintIndexAndValues( myArr );
```

```
      // Define an array segment that contains the entire array.
      ArraySegment<string> myArrSegAll = new ArraySegment<string>( myArr );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The first array segment (with all the array's
elements) contains:" );
      PrintIndexAndValues( myArrSegAll );

      // Define an array segment that contains the middle five values of the
array.
      ArraySegment<string> myArrSegMid = new ArraySegment<string>( myArr, 2,
5 );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The second array segment (with the middle five
elements) contains:" );
      PrintIndexAndValues( myArrSegMid );

      // Modify the fourth element of the first array segment myArrSegAll.
      myArrSegAll.Array[3] = "LION";

      // Display the contents of the second array segment myArrSegMid.
      // Note that the value of its second element also changed.
      Console.WriteLine( "After the first array segment is modified, the
second array segment now contains:" );
      PrintIndexAndValues( myArrSegMid );
   }

   public static void PrintIndexAndValues( ArraySegment<string> arrSeg )  {
      for ( int i = arrSeg.Offset; i < (arrSeg.Offset + arrSeg.Count); i++ )
{
         Console.WriteLine( "   [{0}] : {1}", i, arrSeg.Array[i] );
      }
      Console.WriteLine();
   }

   public static void PrintIndexAndValues( String[] myArr )  {
      for ( int i = 0; i < myArr.Length; i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, myArr[i] );
      }
      Console.WriteLine();
   }
}

/*
This code produces the following output.

The original array initially contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
```

```
   [6] : the
   [7] : lazy
   [8] : dog

The first array segment (with all the array's elements) contains:
   [0] : The
   [1] : quick
   [2] : brown
   [3] : fox
   [4] : jumps
   [5] : over
   [6] : the

ArraySegment<T>.Empty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the empty array segment. This field is read-only.

C#

```
public static ArraySegment<T> Empty { get; }
```

Property Value

ArraySegment<T>

An array segment of type `T` containing zero elements.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T>.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the element at the specified index.

```
C#
public T this[int index] { get; set; }
```

Parameters

`index` Int32

The zero-based index of the element to get or set.

Property Value

T

The element at the specified index.

Implements

Item[Int32]

Exceptions

ArgumentOutOfRangeException

`index` is not a valid index in the ArraySegment<T>.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

ArraySegment<T>.Offset Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the position of the first element in the range delimited by the array segment, relative to the start of the original array.

C#

```
public int Offset { get; }
```

Property Value

Int32

The position of the first element in the range delimited by the ArraySegment<T>, relative to the start of the original array.

Examples

The following code example passes an ArraySegment<T> structure to a method.

C#

```
using System;

public class SamplesArray  {

   public static void Main()  {

      // Create and initialize a new string array.
      String[] myArr = { "The", "quick", "brown", "fox", "jumps", "over",
"the", "lazy", "dog" };

      // Display the initial contents of the array.
      Console.WriteLine( "The original array initially contains:" );
      PrintIndexAndValues( myArr );

      // Define an array segment that contains the entire array.
      ArraySegment<string> myArrSegAll = new ArraySegment<string>( myArr );
```

```
      // Display the contents of the ArraySegment.
      Console.WriteLine( "The first array segment (with all the array's
elements) contains:" );
      PrintIndexAndValues( myArrSegAll );

      // Define an array segment that contains the middle five values of the
array.
      ArraySegment<string> myArrSegMid = new ArraySegment<string>( myArr, 2,
5 );

      // Display the contents of the ArraySegment.
      Console.WriteLine( "The second array segment (with the middle five
elements) contains:" );
      PrintIndexAndValues( myArrSegMid );

      // Modify the fourth element of the first array segment myArrSegAll.
      myArrSegAll.Array[3] = "LION";

      // Display the contents of the second array segment myArrSegMid.
      // Note that the value of its second element also changed.
      Console.WriteLine( "After the first array segment is modified, the
second array segment now contains:" );
      PrintIndexAndValues( myArrSegMid );
   }

   public static void PrintIndexAndValues( ArraySegment<string> arrSeg )  {
      for ( int i = arrSeg.Offset; i < (arrSeg.Offset + arrSeg.Count); i++ )
{
         Console.WriteLine( "   [{0}] : {1}", i, arrSeg.Array[i] );
      }
      Console.WriteLine();
   }

   public static void PrintIndexAndValues( String[] myArr )  {
      for ( int i = 0; i < myArr.Length; i++ )  {
         Console.WriteLine( "   [{0}] : {1}", i, myArr[i] );
      }
      Console.WriteLine();
   }
}

/*

ArraySegment<T>.CopyTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CopyTo(ArraySegment<T>)	Copies the contents of this instance into the specified destination array segment of the same type `T`.
CopyTo(T[])	Copies the contents of this instance into the specified destination array of the same type `T`.
CopyTo(T[], Int32)	Copies the contents of this instance into the specified destination array of the same type `T`, starting at the specified destination index.

CopyTo(ArraySegment<T>)

Copies the contents of this instance into the specified destination array segment of the same type `T`.

C#

```
public void CopyTo (ArraySegment<T> destination);
```

Parameters

`destination` ArraySegment<T>

The array segment into which the contents of this instance will be copied.

Exceptions

InvalidOperationException

The underlying array of this instance is `null`.

-or-

The underlying array of `destination` is `null`.

ArgumentException

The length of the underlying array of this instance is larger than the length of the underlying array of `destination`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

CopyTo(T[])

Copies the contents of this instance into the specified destination array of the same type `T`.

C#

```
public void CopyTo (T[] destination);
```

Parameters

`destination` T[]

The array of type `T` into which the contents of this instance will be copied.

Exceptions

InvalidOperationException

The underlying array of this instance is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

CopyTo(T[], Int32)

Copies the contents of this instance into the specified destination array of the same type `T`, starting at the specified destination index.

C#

```
public void CopyTo (T[] destination, int destinationIndex);
```

Parameters

`destination` T[]

The array of type `T` into which the contents of this instance will be copied.

`destinationIndex` Int32

The index in `destination` at which storing begins.

Implements

CopyTo(T[], Int32)

Exceptions

InvalidOperationException

The underlying array of this instance is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two objects are equal.

Overloads

Expand table

Equals(ArraySegment<T>)	Determines whether the specified ArraySegment<T> structure is equal to the current instance.
Equals(Object)	Determines whether the specified object is equal to the current instance.

Equals(ArraySegment<T>)

Determines whether the specified ArraySegment<T> structure is equal to the current instance.

C#

```
public bool Equals (ArraySegment<T> obj);
```

Parameters

`obj` ArraySegment<T>

The structure to compare with the current instance.

Returns

Boolean

`true` if the specified ArraySegment<T> structure is equal to the current instance; otherwise, `false`.

Remarks

Two ArraySegment<T> objects are considered to be equal if all the following conditions are met:

- They reference the same array.
- They begin at the same index in the array.
- They have the same number of elements.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Determines whether the specified object is equal to the current instance.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to be compared with the current instance.

Returns

Boolean

`true` if the specified object is a ArraySegment<T> structure and is equal to the current instance; otherwise, `false`.

Remarks

Two ArraySegment<T> objects are considered to be equal if all the following conditions are met:

- They reference the same array.
- They begin at the same index in the array.
- They have the same number of elements.

Applies to

▼ .NET 9 and other versions

Product	Versions

ArraySegment<T>.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumerator that can be used to iterate through the array segment.

C#

```
public ArraySegment<T>.Enumerator GetEnumerator ();
```

Returns

ArraySegment<T>.Enumerator

An enumerator that can be used to iterate through the array segment.

Exceptions

InvalidOperationException

The underlying array is `null`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArraySegment<T>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArraySegment<T>.Slice Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Slice(Int32)	Forms a slice out of the current array segment starting at the specified index.
Slice(Int32, Int32)	Forms a slice of the specified length out of the current array segment starting at the specified index.

Slice(Int32)

Forms a slice out of the current array segment starting at the specified index.

C#

```
public ArraySegment<T> Slice (int index);
```

Parameters

`index` Int32

The index at which to begin the slice.

Returns

ArraySegment<T>

An array segment that consists of all elements of the current array segment from `index` to the end of the array segment.

Exceptions

InvalidOperationException

The underlying array of this instance is `null`.

ArgumentOutOfRangeException

`index` is greater than the length of the underlying array of this instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Slice(Int32, Int32)

Forms a slice of the specified length out of the current array segment starting at the specified index.

C#

```
public ArraySegment<T> Slice (int index, int count);
```

Parameters

`index` Int32

The index at which to begin the slice.

`count` Int32

The desired length of the slice.

Returns

ArraySegment<T>

An array segment of `count` elements starting at `index`.

Exceptions

InvalidOperationException

The underlying array of this instance is `null`.

ArgumentOutOfRangeException

`index` is greater than the length of the underlying array of this instance.

-or-

`count` is greater than the length of the underlying array of this instance - `index`.

Applies to

▼ .NET 9 and other versions

ArraySegment<T>.ToArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of this array segment into a new array.

C#

```
public T[] ToArray ();
```

Returns

T[]

An array containing the data in the current array segment.

Exceptions

InvalidOperationException

`default(ArraySegment<T>)` cannot be converted to an array.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArraySegment<T>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two ArraySegment<T> structures are equal.

```
C#
public static bool operator == (ArraySegment<T> a, ArraySegment<T> b);
```

Parameters

a ArraySegment<T>

The structure on the left side of the equality operator.

b ArraySegment<T>

The structure on the right side of the equality operator.

Returns

Boolean

`true` if `a` is equal to `b`; otherwise, `false`.

Remarks

Two ArraySegment<T> objects are considered to be equal if all the following conditions are met:

- They reference the same array.
- They begin at the same index.
- They have the same number of elements.

The equivalent method for this operator is ArraySegment<T>.Equals(ArraySegment<T>)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArraySegment<T>.Implicit(T[] to ArraySegment<T>) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines an implicit conversion of an array of type `T` to an array segment of type `T`.

```
C#
public static implicit operator ArraySegment<T> (T[] array);
```

Parameters

`array` T[]

The array to convert.

Returns

ArraySegment<T>

An array segment representation of the array.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ArraySegment<T>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two ArraySegment<T> structures are unequal.

```
C#
public static bool operator != (ArraySegment<T> a, ArraySegment<T> b);
```

Parameters

a ArraySegment<T>

The structure on the left side of the inequality operator.

b ArraySegment<T>

The structure on the right side of the inequality operator.

Returns

Boolean

`true` if `a` is not equal to `b`; otherwise, `false`.

Remarks

Two ArraySegment<T> objects are considered to be unequal if they are of the same closed generic type but any of the following conditions is true:

- They do not reference the same array.
- They have different starting indexes.
- They have a different number of elements.

The equivalent method for this operator is ArraySegment<T>.Equals(ArraySegment<T>)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Array Segment<T>.ICollection<T>.Add(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws a NotSupportedException exception in all cases.

```
C#
void ICollection<T>.Add (T item);
```

Parameters

`item` T

The object to add to the array segment.

Implements

Add(T)

Exceptions

NotSupportedException

In all cases.

Remarks

This method always throws a NotSupportedException because an array segment cannot be expanded.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Namespace: System

Assembly: System.Runtime.dll

Throws a NotSupportedException exception in all cases.

```
C#
void ICollection<T>.Clear ();
```

Implements

Clear()

Exceptions

NotSupportedException

In all cases.

Remarks

This method always throws a NotSupportedException because an array segment cannot be contracted.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Array Segment<T>.ICollection<T>.Contains(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the array segment contains a specific value.

```
C#
bool ICollection<T>.Contains (T item);
```

Parameters

`item` T

The object to locate in the array segment.

Returns

Boolean

`true` if `item` is found in the array segment; otherwise, `false`.

Implements

Contains(T)

Exceptions

InvalidOperationException

The underlying array is `null`.

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T> instance is cast to an ICollection<T> interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArraySegment<T>.ICollection<T>.IsReadOnly Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the array segment is read-only.

C#

```
bool System.Collections.Generic.ICollection<T>.IsReadOnly { get; }
```

Property Value

Boolean

`true` if the array segment is read-only; otherwise, `false`.

Implements

IsReadOnly

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T> instance is cast to an ICollection<T> interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Array Segment<T>.ICollection<T>.Remove(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws a NotSupportedException exception in all cases.

```
C#
bool ICollection<T>.Remove (T item);
```

Parameters

`item` T

The object to remove from the array segment.

Returns

Boolean

Always throws an exception.

Implements

Remove(T)

Exceptions

NotSupportedException

In all cases.

Remarks

This method always throws a NotSupportedException because an array segment cannot be contracted.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

ArraySegment<T>.IEnumerable<T>.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumerator that iterates through the array segment.

```
C#
System.Collections.Generic.IEnumerator<T> IEnumerable<T>.GetEnumerator ();
```

Returns

IEnumerator<T>

An enumerator that can be used to iterate through the array segment.

Implements

GetEnumerator()

Exceptions

InvalidOperationException

The underlying array is `null`.

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T> instance is cast to an IEnumerable<T> interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArraySegment<T>.IList<T>.IndexOf(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines the index of a specific item in the array segment.

```
C#
int IList<T>.IndexOf (T item);
```

Parameters

`item` T

The object to locate in the array segment.

Returns

Int32

The index of `item` if found in the list; otherwise, -1.

Implements

IndexOf(T)

Exceptions

InvalidOperationException

The underlying array is `null`.

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T> instance is cast to an IList<T> interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArraySegment<T>.IList<T>.Insert(Int32, T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws a NotSupportedException exception in all cases.

```
C#
void IList<T>.Insert (int index, T item);
```

Parameters

index Int32

The zero-based index at which `item` should be inserted.

item T

The object to insert into the array segment.

Implements

Insert(Int32, T)

Exceptions

NotSupportedException

In all cases.

Remarks

This method always throws a NotSupportedException because an array segment cannot be expanded.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArraySegment<T>.IList<T>.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the element at the specified index.

```
C#

T System.Collections.Generic.IList<T>.Item[int index] { get; set; }
```

Parameters

`index` Int32

The zero-based index of the element to get or set.

Property Value

T

The element at the specified index.

Implements

Item[Int32]

Exceptions

ArgumentOutOfRangeException

`index` is not a valid index in the ArraySegment<T>.

NotSupportedException

The property is set and the array segment is read-only.

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T> instance is cast to an IList<T> interface, as the following example shows.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      String[] names = { "Adam", "Bruce", "Charles", "Daniel",
                         "Ebenezer", "Francis", "Gilbert",
                         "Henry", "Irving", "John", "Karl",
                         "Lucian", "Michael" };
      var partNames = new ArraySegment<string>(names, 2, 5);

      // Cast the ArraySegment object to an IList<string> and enumerate it.
      var list = (IList<string>) partNames;
      for (int ctr = 0; ctr <= list.Count - 1; ctr++)
         Console.WriteLine(list[ctr]);
   }
}
// The example displays the following output:
//    Charles
//    Daniel
//    Ebenezer
//    Francis
//    Gilbert
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArraySegment<T>.IList<T>.RemoveAt(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Throws a NotSupportedException exception in all cases.

```
C#
void IList<T>.RemoveAt (int index);
```

Parameters

`index` Int32

The zero-based index of the item to remove.

Implements

RemoveAt(Int32)

Exceptions

NotSupportedException

In all cases.

Remarks

This method always throws a NotSupportedException because an array segment cannot be contracted.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ArraySegment<T>.IReadOnlyList<T>.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the element at the specified index of the array segment.

```
C#

T System.Collections.Generic.IReadOnlyList<T>.Item[int index] { get; }
```

Parameters

index Int32

The zero-based index of the element to get.

Property Value

T

The element at the specified index.

Implements

Item[Int32]

Exceptions

ArgumentOutOfRangeException

`index` is not a valid index in the ArraySegment<T>.

InvalidOperationException

The underlying array is `null`.

NotSupportedException

The property is set.

Remarks

This member is an explicit interface member implementation. It can be used only when the ArraySegment<T> instance is cast to an IReadOnlyList<T> interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ArrayTypeMismatchException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt is made to store an element of the wrong type within an array.

C#

```
public class ArrayTypeMismatchException : SystemException
```

Inheritance Object → Exception → SystemException → ArrayTypeMismatchException

Examples

The following code example demonstrates scenarios where ArrayTypeMismatchException is thrown.

C#

```
using System;

namespace ArrayTypeMismatch
{
    class Class1
    {
        static void Main(string[] args)
        {
            string[] names = {"Dog", "Cat", "Fish"};
            Object[] objs  = (Object[]) names;

            try
            {
                objs[2] = "Mouse";

                foreach (object animalName in objs)
                {
                    System.Console.WriteLine(animalName);
                }
            }
            catch (System.ArrayTypeMismatchException)
```

```
            {
                // Not reached; "Mouse" is of the correct type.
                System.Console.WriteLine("Exception Thrown.");
            }

            try
            {
                Object obj = (Object) 13;
                objs[2] = obj;
            }
            catch (System.ArrayTypeMismatchException)
            {
                // Always reached, 13 is not a string.
                System.Console.WriteLine(
                    "New element is not of the correct type.");
            }

            // Set objs to an array of objects instead of
            // an array of strings.
            objs  = new Object[3];
            try
            {
                objs[0] = (Object) "Turtle";
                objs[1] = (Object) 12;
                objs[2] = (Object) 2.341;

                foreach (object element in objs)
                {
                    System.Console.WriteLine(element);
                }
            }
            catch (System.ArrayTypeMismatchException)
            {
                // ArrayTypeMismatchException is not thrown this time.
                System.Console.WriteLine("Exception Thrown.");
            }
        }
    }
}
```

Remarks

ArrayTypeMismatchException is thrown when the system cannot convert the element to the type declared for the array. For example, an element of type String cannot be stored in an Int32 array because conversion between these types is not supported. It is generally unnecessary for applications to throw this exception.

The following Microsoft intermediate language (MSIL) instructions throw ArrayTypeMismatchException:

- `ldelem.<type>`
- `ldelema`
- `stelem.<type>`

ArrayTypeMismatchException uses the HRESULT COR_E_ARRAYTYPEMISMATCH, which has the value 0x80131503.

For a list of initial property values for an instance of ArrayTypeMismatchException, see the ArrayTypeMismatchException constructors.

Constructors

Expand table

ArrayTypeMismatchException()	Initializes a new instance of the ArrayTypeMismatchException class.
ArrayTypeMismatchException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArrayTypeMismatchException class with serialized data.
ArrayTypeMismatchException(String)	Initializes a new instance of the ArrayTypeMismatchException class with a specified error message.
ArrayTypeMismatchException(String, Exception)	Initializes a new instance of the ArrayTypeMismatchException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

	(Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArrayTypeMismatchException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ArrayTypeMismatchException class.

Overloads

Expand table

ArrayTypeMismatchException()	Initializes a new instance of the ArrayTypeMismatchException class.
ArrayTypeMismatchException(String)	Initializes a new instance of the ArrayTypeMismatchException class with a specified error message.
ArrayTypeMismatchException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ArrayTypeMismatchException class with serialized data.
ArrayTypeMismatchException(String, Exception)	Initializes a new instance of the ArrayTypeMismatchException class with a specified error message and a reference to the inner exception that is the cause of this exception.

ArrayTypeMismatchException()

Initializes a new instance of the ArrayTypeMismatchException class.

C#

```
public ArrayTypeMismatchException ();
```

Examples

The following example demonstrates the ArrayTypeMismatchException() constructor of the ArrayTypeMismatchException class. It contains a function which takes two arrays as arguments and checks whether the two arrays are of the same type. If the arrays are of different types, a new ArrayTypeMismatchException is thrown and then caught in the calling method.

C#

```
using System;

public class ArrayTypeMisMatchConst
{
   public void CopyArray(Array myArray,Array myArray1)
   {
      string typeArray1 = myArray.GetType().ToString();
      string typeArray2 = myArray1.GetType().ToString();
      // Check whether the two arrays are of same type or not.
      if(typeArray1==typeArray2)
      {
         // Copy the values from one array to another.
         myArray.SetValue("Name: "+myArray1.GetValue(0),0);
         myArray.SetValue("Name: "+myArray1.GetValue(1),1);
      }
      else
      {
         // Throw an exception of type 'ArrayTypeMismatchException'.
         throw new ArrayTypeMismatchException();
      }
   }
   static void Main()
   {
      try
      {
         string[] myStringArray = new string[2];
         myStringArray.SetValue("Jones",0);
         myStringArray.SetValue("John",1);

         int[] myIntArray = new int[2];
         ArrayTypeMisMatchConst myArrayType = new
ArrayTypeMisMatchConst();
         myArrayType.CopyArray(myStringArray,myIntArray);
      }
      catch(ArrayTypeMismatchException e)
      {
         Console.WriteLine("The Exception is :"+e);
      }
   }
}
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Source array type cannot be assigned to destination array type." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ArrayTypeMismatchException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ArrayTypeMismatchException(String)

Initializes a new instance of the ArrayTypeMismatchException class with a specified error message.

C#

```
public ArrayTypeMismatchException (string? message);
```

Parameters

`message` String

A String that describes the error.

Examples

The following example demonstrates the ArrayTypeMismatchException(String) constructor of the ArrayTypeMismatchException class. It contains a function which takes two arrays as arguments and checks whether the two arrays are of the same type. If the arrays are of different types, a new ArrayTypeMismatchException is thrown and then caught in the calling method.

C#

```
using System;

public class ArrayTypeMisMatchConst
{
   public void CopyArray(Array myArray,Array myArray1)
   {
      string typeArray1 = myArray.GetType().ToString();
      string typeArray2 = myArray1.GetType().ToString();
      // Check whether the two arrays are of same type or not.
      if(typeArray1==typeArray2)
      {
         // Copies the values from one array to another.
         myArray.SetValue("Name: "+myArray1.GetValue(0),0);
         myArray.SetValue("Name: "+myArray1.GetValue(1),1);
      }
      else
      {
          // Throw an exception of type 'ArrayTypeMismatchException' with
a message string as parameter.
         throw new ArrayTypeMismatchException("The Source and destination
arrays are not of same type.");
      }
   }

   static void Main()
   {
      try
      {
         string[] myStringArray = new string[2];
         myStringArray.SetValue("Jones",0);
         myStringArray.SetValue("John",1);
         int[] myIntArray = new int[2];
         ArrayTypeMisMatchConst myArrayType = new
ArrayTypeMisMatchConst();
         myArrayType.CopyArray(myStringArray,myIntArray);
```

```
        }
        catch(ArrayTypeMismatchException e)
        {
           Console.WriteLine("The Exception Message is : " + e.Message);
        }
    }
}
```

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of ArrayTypeMismatchException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

ArrayTypeMismatchException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ArrayTypeMismatchException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ArrayTypeMismatchException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ArrayTypeMismatchException(String, Exception)

Initializes a new instance of the ArrayTypeMismatchException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public ArrayTypeMismatchException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Examples

The following code example demonstrates the ArrayTypeMismatchException constructor of the ArrayTypeMismatchException class. It contains a function that takes two arrays as arguments and checks whether the two arrays are of the same type. If the arrays are of different types, a new ArrayTypeMismatchException is thrown and then caught in the calling method.

C#

```
using System;

public class ArrayTypeMisMatchConst
{
   public void CopyArray(Array myArray,Array myArray1)
   {
      try
      {
         // Copies the value of one array into another array.
         myArray.SetValue(myArray1.GetValue(0),0);
         myArray.SetValue(myArray1.GetValue(1),1);
      }
      catch(Exception e)
      {
         // Throw an exception of with a message and innerexception.
         throw new ArrayTypeMismatchException("The Source and destination
arrays are of not same type.", e);
      }
   }
   static void Main()
   {
         try
         {
            string[] myStringArray = new string[2];
            myStringArray.SetValue("Jones",0);
            myStringArray.SetValue("John",1);
            int[] myIntArray = new int[2];
            ArrayTypeMisMatchConst myArrayType = new
ArrayTypeMisMatchConst();
            myArrayType.CopyArray(myStringArray,myIntArray);
         }
         catch(ArrayTypeMismatchException e)
         {
            Console.WriteLine("The Exception Message is : "+e.Message);
            Console.WriteLine("The Inner exception is
:"+e.InnerException);
         }
      }
}
```

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of ArrayTypeMismatchException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

AssemblyLoadEventArgs Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides data for the AssemblyLoad event.

C#

```
public class AssemblyLoadEventArgs : EventArgs
```

Inheritance Object → EventArgs → AssemblyLoadEventArgs

Constructors

Expand table

AssemblyLoadEventArgs(Assembly)	Initializes a new instance of the AssemblyLoadEventArgs class using the specified Assembly.

Properties

Expand table

LoadedAssembly	Gets an Assembly that represents the currently loaded assembly.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)

GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AssemblyLoadEventArgs(Assembly) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the AssemblyLoadEventArgs class using the specified Assembly.

C#

```
public AssemblyLoadEventArgs (System.Reflection.Assembly loadedAssembly);
```

Parameters

`loadedAssembly` Assembly

An instance that represents the currently loaded assembly.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AssemblyLoadEventArgs.LoadedAssembly Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an Assembly that represents the currently loaded assembly.

C#

```
public System.Reflection.Assembly LoadedAssembly { get; }
```

Property Value

Assembly

An instance of Assembly that represents the currently loaded assembly.

Remarks

The value of this property is set by the common language runtime when the AppDomain.AssemblyLoad event occurs.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AssemblyLoadEventHandler Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the method that handles the AssemblyLoad event of an AppDomain.

C#

```
public delegate void AssemblyLoadEventHandler(object? sender,
AssemblyLoadEventArgs args);
```

Parameters

sender Object

The source of the event.

args AssemblyLoadEventArgs

An AssemblyLoadEventArgs that contains the event data.

Remarks

An AssemblyLoadEventHandler is used to specify the methods that are invoked in response to an AssemblyLoad event. To associate an instance of AssemblyLoadEventHandler with an event, add the instance to the event. The methods referenced by the AssemblyLoadEventHandler are invoked whenever an assembly is loaded, until the AssemblyLoadEventHandler is removed from the event.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

AsyncCallback Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

References a method to be called when a corresponding asynchronous operation completes.

C#

```
public delegate void AsyncCallback(IAsyncResult ar);
```

Parameters

ar IAsyncResult

The result of the asynchronous operation.

Examples

The following code example demonstrates using asynchronous methods in the Dns class to retrieve Domain Name System (DNS) information for user-specified computers. This example creates an AsyncCallback delegate that references the `ProcessDnsInformation` method. This method is called once for each asynchronous request for DNS information.

C#

```
/*
The following example demonstrates using asynchronous methods to
get Domain Name System information for the specified host computers.
This example uses a delegate to obtain the results of each asynchronous
operation.
*/

using System;
using System.Net;
using System.Net.Sockets;
using System.Threading;
using System.Collections.Specialized;
using System.Collections;
```

```
namespace Examples.AdvancedProgramming.AsynchronousOperations
{
    public class UseDelegateForAsyncCallback
    {
        static int requestCounter;
        static ArrayList hostData = new ArrayList();
        static StringCollection hostNames = new StringCollection();
        static void UpdateUserInterface()
        {
            // Print a message to indicate that the application
            // is still working on the remaining requests.
            Console.WriteLine("{0} requests remaining.", requestCounter);
        }
        public static void Main()
        {
            // Create the delegate that will process the results of the
            // asynchronous request.
            AsyncCallback callBack = new
AsyncCallback(ProcessDnsInformation);
            string host;
            do
            {
                Console.Write(" Enter the name of a host computer or <enter>
to finish: ");
                host = Console.ReadLine();
                if (host.Length > 0)
                {
                    // Increment the request counter in a thread safe
manner.
                    Interlocked.Increment(ref requestCounter);
                    // Start the asynchronous request for DNS information.
                    Dns.BeginGetHostEntry(host, callBack, host);
                 }
            } while (host.Length > 0);
            // The user has entered all of the host names for lookup.
            // Now wait until the threads complete.
            while (requestCounter > 0)
            {
                UpdateUserInterface();
            }
            // Display the results.
            for (int i = 0; i< hostNames.Count; i++)
            {
                object data = hostData [i];
                string message = data as string;
                // A SocketException was thrown.
                if (message != null)
                {
                    Console.WriteLine("Request for {0} returned message:
{1}",
                        hostNames[i], message);
                    continue;
                }
                // Get the results.
                IPHostEntry h = (IPHostEntry) data;
```

```
                string[] aliases = h.Aliases;
                IPAddress[] addresses = h.AddressList;
                if (aliases.Length > 0)
                {
                    Console.WriteLine("Aliases for {0}", hostNames[i]);
                    for (int j = 0; j < aliases.Length; j++)
                    {
                        Console.WriteLine("{0}", aliases[j]);
                    }
                }
                if (addresses.Length > 0)
                {
                    Console.WriteLine("Addresses for {0}", hostNames[i]);
                    for (int k = 0; k < addresses.Length; k++)
                    {
                        Console.WriteLine("{0}",addresses[k].ToString());
                    }
                }
            }
        }

        // The following method is called when each asynchronous operation
completes.
        static void ProcessDnsInformation(IAsyncResult result)
        {
            string hostName = (string) result.AsyncState;
            hostNames.Add(hostName);
            try
            {
                // Get the results.
                IPHostEntry host = Dns.EndGetHostEntry(result);
                hostData.Add(host);
            }
            // Store the exception message.
            catch (SocketException e)
            {
                hostData.Add(e.Message);
            }
            finally
            {
                // Decrement the request counter in a thread-safe manner.
                Interlocked.Decrement(ref requestCounter);
            }
        }
    }
}
```

Remarks

Use an AsyncCallback delegate to process the results of an asynchronous operation in a separate thread. The AsyncCallback delegate represents a callback method that is called

when the asynchronous operation completes. The callback method takes an IAsyncResult parameter, which is subsequently used to obtain the results of the asynchronous operation.

For more information about asynchronous programming, see Using an AsyncCallback Delegate to End an Asynchronous Operation and Using an AsyncCallback Delegate and State Object in Event-based Asynchronous Pattern (EAP).

Attribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the base class for custom attributes.

C#

```
[System.AttributeUsage(System.AttributeTargets.All, AllowMultiple=false,
Inherited=true)]
public abstract class Attribute
```

Inheritance Object → Attribute

Derived Microsoft.Extensions.Compliance.Classification.DataClassificationAttribute
Microsoft.Extensions.Configuration.ConfigurationKeyNameAttribute
Microsoft.Extensions.Configuration.UserSecrets.UserSecretsIdAttribute
Microsoft.Extensions.DependencyInjection.ActivatorUtilitiesConstructorAttribute
Microsoft.Extensions.DependencyInjection.FromKeyedServicesAttribute
More...

Attributes AttributeUsageAttribute

Examples

The following code example demonstrates the usage of Attribute.

C#

```
using System;
using System.Reflection;

// An enumeration of animals. Start at 1 (0 = uninitialized).
public enum Animal {
    // Pets.
    Dog = 1,
    Cat,
```

```
    Bird,
}

// A custom attribute to allow a target to have a pet.
public class AnimalTypeAttribute : Attribute {
    // The constructor is called when the attribute is set.
    public AnimalTypeAttribute(Animal pet) {
        thePet = pet;
    }

    // Keep a variable internally ...
    protected Animal thePet;

    // .. and show a copy to the outside world.
    public Animal Pet {
        get { return thePet; }
        set { thePet = value; }
    }
}

// A test class where each method has its own pet.
class AnimalTypeTestClass {
    [AnimalType(Animal.Dog)]
    public void DogMethod() {}

    [AnimalType(Animal.Cat)]
    public void CatMethod() {}

    [AnimalType(Animal.Bird)]
    public void BirdMethod() {}
}

class DemoClass {
    static void Main(string[] args) {
        AnimalTypeTestClass testClass = new AnimalTypeTestClass();
        Type type = testClass.GetType();
        // Iterate through all the methods of the class.
        foreach(MethodInfo mInfo in type.GetMethods()) {
            // Iterate through all the Attributes for each method.
            foreach (Attribute attr in
                Attribute.GetCustomAttributes(mInfo)) {
                // Check for the AnimalType attribute.
                if (attr.GetType() == typeof(AnimalTypeAttribute))
                    Console.WriteLine(
                        "Method {0} has a pet {1} attribute.",
                        mInfo.Name, ((AnimalTypeAttribute)attr).Pet);
            }
        }
    }
}
/*
 * Output:
 * Method DogMethod has a pet Dog attribute.
 * Method CatMethod has a pet Cat attribute.
```

```
 * Method BirdMethod has a pet Bird attribute.
 */
```

Remarks

The Attribute class associates predefined system information or user-defined custom information with a target element. A target element can be an assembly, class, constructor, delegate, enum, event, field, interface, method, portable executable file module, parameter, property, return value, struct, or another attribute.

Information provided by an attribute is also known as metadata. Metadata can be examined at run time by your application to control how your program processes data, or before run time by external tools to control how your application itself is processed or maintained. For example, .NET predefines and uses attribute types to control run-time behavior, and some programming languages use attribute types to represent language features not directly supported by the .NET common type system.

All attribute types derive directly or indirectly from the Attribute class. Attributes can be applied to any target element; multiple attributes can be applied to the same target element; and attributes can be inherited by an element derived from a target element. Use the AttributeTargets class to specify the target element to which the attribute is applied.

The Attribute class provides convenient methods to retrieve and test custom attributes. For more information about using attributes, see Applying Attributes and Attributes.

Constructors

Expand table

Attribute()	Initializes a new instance of the Attribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object.
GetCustomAttribute(Assembly, Type)	Retrieves a custom attribute applied to a specified assembly. Parameters specify the assembly and the type of the custom attribute to search for.
GetCustomAttribute(Assembly, Type, Boolean)	Retrieves a custom attribute applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.
GetCustomAttribute(MemberInfo, Type)	Retrieves a custom attribute applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.
GetCustomAttribute(MemberInfo, Type, Boolean)	Retrieves a custom attribute applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
GetCustomAttribute(Module, Type)	Retrieves a custom attribute applied to a module. Parameters specify the module, and the type of the custom attribute to search for.
GetCustomAttribute(Module, Type, Boolean)	Retrieves a custom attribute applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.
GetCustomAttribute(ParameterInfo, Type)	Retrieves a custom attribute applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.
GetCustomAttribute(ParameterInfo, Type, Boolean)	Retrieves a custom attribute applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.
GetCustomAttributes(Assembly)	Retrieves an array of the custom attributes applied to an assembly. A parameter specifies the assembly.
GetCustomAttributes(Assembly, Boolean)	Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, and an ignored search option.
GetCustomAttributes(Assembly, Type)	Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, and the type of the custom attribute to search for.
GetCustomAttributes(Assembly, Type,	Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, the type of the

Boolean)	custom attribute to search for, and an ignored search option.
GetCustomAttributes(MemberInfo)	Retrieves an array of the custom attributes applied to a member of a type. A parameter specifies the member.
GetCustomAttributes(MemberInfo, Boolean)	Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
GetCustomAttributes(MemberInfo, Type)	Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.
GetCustomAttributes(MemberInfo, Type, Boolean)	Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
GetCustomAttributes(Module)	Retrieves an array of the custom attributes applied to a module. A parameter specifies the module.
GetCustomAttributes(Module, Boolean)	Retrieves an array of the custom attributes applied to a module. Parameters specify the module, and an ignored search option.
GetCustomAttributes(Module, Type)	Retrieves an array of the custom attributes applied to a module. Parameters specify the module, and the type of the custom attribute to search for.
GetCustomAttributes(Module, Type, Boolean)	Retrieves an array of the custom attributes applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.
GetCustomAttributes(ParameterInfo)	Retrieves an array of the custom attributes applied to a method parameter. A parameter specifies the method parameter.
GetCustomAttributes(ParameterInfo, Boolean)	Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, and whether to search ancestors of the method parameter.
GetCustomAttributes(ParameterInfo, Type)	Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.
GetCustomAttributes(ParameterInfo, Type, Boolean)	Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.
GetHashCode()	Returns the hash code for this instance.
GetType()	Gets the Type of the current instance.

	(Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class.
IsDefined(Assembly, Type)	Determines whether any custom attributes are applied to an assembly. Parameters specify the assembly, and the type of the custom attribute to search for.
IsDefined(Assembly, Type, Boolean)	Determines whether any custom attributes are applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.
IsDefined(MemberInfo, Type)	Determines whether any custom attributes are applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.
IsDefined(MemberInfo, Type, Boolean)	Determines whether any custom attributes are applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
IsDefined(Module, Type)	Determines whether any custom attributes of a specified type are applied to a module. Parameters specify the module, and the type of the custom attribute to search for.
IsDefined(Module, Type, Boolean)	Determines whether any custom attributes are applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.
IsDefined(ParameterInfo, Type)	Determines whether any custom attributes are applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.
IsDefined(ParameterInfo, Type, Boolean)	Determines whether any custom attributes are applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Attribute Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Attribute class.

C#

```
protected Attribute ();
```

Examples

The following code example shows the definition of a custom parameter Attribute class with its constructor.

C#

```
// Define a custom parameter attribute that takes a single message argument.
[AttributeUsage( AttributeTargets.Parameter )]
public class ArgumentUsageAttribute : Attribute
{
    // This is the attribute constructor.
    public ArgumentUsageAttribute( string UsageMsg )
    {
        this.usageMsg = UsageMsg;
    }

    // usageMsg is storage for the attribute message.
    protected string usageMsg;

    // This is the Message property for the attribute.
    public string Message
    {
        get { return usageMsg; }
        set { usageMsg = value; }
    }
}
```

F#

```
// Define a custom parameter attribute that takes a single message argument.
[<AttributeUsage(AttributeTargets.Parameter); AllowNullLiteral>]
type ArgumentUsageAttribute(usageMsg) =
    inherit Attribute()

    // This is the Message property for the attribute.
    member val Message = usageMsg with get, set
```

VB

```
' Define a custom parameter attribute that takes a single message argument.
<AttributeUsage(AttributeTargets.Parameter)>  _
Public Class ArgumentUsageAttribute
    Inherits Attribute

    ' This is the attribute constructor.
    Public Sub New(UsageMsg As String)
        Me.usageMsg = UsageMsg
    End Sub

    ' usageMsg is storage for the attribute message.
    Protected usageMsg As String

    ' This is the Message property for the attribute.
    Public Property Message() As String
        Get
            Return usageMsg
        End Get
        Set
            usageMsg = value
        End Set
    End Property
End Class
```

Remarks

This constructor is only called by classes that derive from Attribute.

Attribute.TypeId Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When implemented in a derived class, gets a unique identifier for this Attribute.

C#

```
public virtual object TypeId { get; }
```

Property Value

Object

An Object that is a unique identifier for the attribute.

Examples

The following code example implements the TypeId property in a custom parameter Attribute class and shows its use.

C#

```
// Example for the Attribute.TypeId property.
using System;
using System.Reflection;

namespace NDP_UE_CS
{
    // Define a custom parameter attribute that takes a single message
argument.
    [AttributeUsage( AttributeTargets.Parameter )]
    public class ArgumentUsageAttribute : Attribute
    {
        // The constructor saves the message and creates a unique
identifier.
        public ArgumentUsageAttribute( string UsageMsg )
        {
            this.usageMsg = UsageMsg;
            this.instanceGUID = Guid.NewGuid( );
```

```
        }

        // This is storage for the attribute message and unique ID.
        protected string usageMsg;
        protected Guid instanceGUID;

        // This is the Message property for the attribute.
        public string Message
        {
            get { return usageMsg; }
            set { usageMsg = value; }
        }

        // Override TypeId to provide a unique identifier for the instance.
        public override object TypeId
        {
            get { return (object)instanceGUID; }
        }

        // Override ToString() to append the message to what the base
generates.
        public override string ToString( )
        {
            return base.ToString( ) + ":" + usageMsg;
        }
    }

    public class TestClass
    {
        // Assign an ArgumentUsage attribute to each parameter.
        // Assign a ParamArray attribute to strList using the params
keyword.
        public void TestMethod(
            [ArgumentUsage("Must pass an array here.")]
            String[] strArray,
            [ArgumentUsage("Can pass a param list or array here.")]
            params String[] strList)
        { }
    }

    class AttributeTypeIdDemo
    {
        static void ShowAttributeTypeIds( )
        {
            // Get the class type, and then get the MethodInfo object
            // for TestMethod to access its metadata.
            Type clsType = typeof( TestClass );
            MethodInfo mInfo = clsType.GetMethod("TestMethod");

            // There will be two elements in pInfoArray, one for each
parameter.
            ParameterInfo[] pInfoArray = mInfo.GetParameters();
            if (pInfoArray != null)
            {
                // Create an instance of the param array attribute on
```

```
strList.
                ParamArrayAttribute listArrayAttr = (ParamArrayAttribute)
                    Attribute.GetCustomAttribute( pInfoArray[1],
                        typeof(ParamArrayAttribute) );

                // Create an instance of the argument usage attribute on
strArray.
                ArgumentUsageAttribute arrayUsageAttr1 =
(ArgumentUsageAttribute)
                    Attribute.GetCustomAttribute( pInfoArray[0],
                        typeof(ArgumentUsageAttribute) );

                // Create another instance of the argument usage attribute
                // on strArray.
                ArgumentUsageAttribute arrayUsageAttr2 =
(ArgumentUsageAttribute)
                    Attribute.GetCustomAttribute( pInfoArray[0],
                        typeof(ArgumentUsageAttribute) );

                // Create an instance of the argument usage attribute on
strList.
                ArgumentUsageAttribute listUsageAttr =
(ArgumentUsageAttribute)
                    Attribute.GetCustomAttribute( pInfoArray[1],
                        typeof(ArgumentUsageAttribute) );

                // Display the attributes and corresponding TypeId values.
                Console.WriteLine( "\n\"{0}\" \nTypeId: {1}",
                    listArrayAttr.ToString(), listArrayAttr.TypeId );
                Console.WriteLine( "\n\"{0}\" \nTypeId: {1}",
                    arrayUsageAttr1.ToString(), arrayUsageAttr1.TypeId );
                Console.WriteLine( "\n\"{0}\" \nTypeId: {1}",
                    arrayUsageAttr2.ToString(), arrayUsageAttr2.TypeId );
                Console.WriteLine( "\n\"{0}\" \nTypeId: {1}",
                    listUsageAttr.ToString(), listUsageAttr.TypeId );
            }
            else
                Console.WriteLine( "The parameters information could " +
                    "not be retrieved for method {0}.", mInfo.Name );
        }

        static void Main( )
        {
            Console.WriteLine(
                "This example of the Attribute.TypeId property\n" +
                "generates the following output." );
            Console.WriteLine(
                "\nCreate instances from a derived Attribute " +
                "class that implements TypeId, \nand then " +
                "display the attributes and corresponding TypeId values:" );

            ShowAttributeTypeIds( );
        }
    }
}
```

```
/*
This example of the Attribute.TypeId property
generates output similar to the following:

Create instances from a derived Attribute class that implements TypeId,
and then display the attributes and corresponding TypeId values:

"System.ParamArrayAttribute"
TypeId: System.ParamArrayAttribute

"NDP_UE_CS.ArgumentUsageAttribute:Must pass an array here."
TypeId: d03a23f4-2536-4478-920f-8b0426dec7f1

"NDP_UE_CS.ArgumentUsageAttribute:Must pass an array here."
TypeId: a1b412e8-3047-49fa-8d03-7660d37ef718

"NDP_UE_CS.ArgumentUsageAttribute:Can pass a param list or array here."
TypeId: 7ac2bf61-0327-48d6-a07e-eb9aaf3dd45e
*/
```

Remarks

As implemented, this identifier is merely the Type of the attribute. However, it is intended that the unique identifier be used to identify two attributes of the same type.

Attribute.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An Object to compare with this instance or `null`.

Returns

Boolean

`true` if `obj` and this instance are of the same type and have identical field values; otherwise, `false`.

Examples

The following example defines two custom parameter Attribute classes, then creates several objects of each class and uses the Equals method to compare them.

C#

```
using System;
using System.Reflection;

// Define a custom parameter attribute that takes a single message argument.
[AttributeUsage( AttributeTargets.Parameter )]
public class ArgumentUsageAttribute : Attribute
{
    // This is the attribute constructor.
    public ArgumentUsageAttribute( string UsageMsg )
```

```
    {
        this.usageMsg = UsageMsg;
    }

    // usageMsg is storage for the attribute message.
    protected string usageMsg;

    // Override ToString() to append the message to what the base generates.
    public override string ToString( )
    {
        return $"{base.ToString()}: {usageMsg}";
    }
}

// Define a custom parameter attribute that generates a GUID for each
instance.
[AttributeUsage( AttributeTargets.Parameter )]
public class ArgumentIDAttribute : Attribute
{
    // This is the attribute constructor, which generates the GUID.
    public ArgumentIDAttribute( )
    {
        this.instanceGUID = Guid.NewGuid( );
    }

    // instanceGUID is storage for the generated GUID.
    protected Guid instanceGUID;

    // Override ToString() to append the GUID to what the base generates.
    public override string ToString( )
    {
        return $"{base.ToString()}.{instanceGUID.ToString()}";
    }
}

public class TestClass
{
    // Assign an ArgumentID attribute to each parameter.
    // Assign an ArgumentUsage attribute to each parameter.
    public void TestMethod(
        [ArgumentID]
        [ArgumentUsage("Must pass an array here.")]
        String[] strArray,
        [ArgumentID]
        [ArgumentUsage("Can pass param list or array here.")]
        params String[] strList)
    { }
}

class AttributeEqualsDemo
{
    // Create Attribute objects and compare them.
    static void Main()
    {
        // Get the class type, and then get the MethodInfo object
```

```
        // for TestMethod to access its metadata.
        Type clsType = typeof( TestClass );
        MethodInfo mInfo = clsType.GetMethod("TestMethod");

        // There will be two elements in pInfoArray, one for each parameter.
        ParameterInfo[] pInfoArray = mInfo.GetParameters();
        if (pInfoArray != null)
        {
            // Create an instance of the argument usage attribute on
strArray.
            ArgumentUsageAttribute arrayUsageAttr1 =
(ArgumentUsageAttribute)
                Attribute.GetCustomAttribute( pInfoArray[0],
                    typeof(ArgumentUsageAttribute) );

            // Create another instance of the argument usage attribute
            // on strArray.
            ArgumentUsageAttribute arrayUsageAttr2 =
(ArgumentUsageAttribute)
                Attribute.GetCustomAttribute( pInfoArray[0],
                    typeof(ArgumentUsageAttribute) );

            // Create an instance of the argument usage attribute on
strList.

                Attribute.GetCustomAttribute( pInfoArray[0],
                    typeof(ArgumentIDAttribute) );

            // Create another instance of the argument ID attribute on
strArray.
            ArgumentIDAttribute arrayIDAttr2 = (ArgumentIDAttribute)
                Attribute.GetCustomAttribute( pInfoArray[0],
                    typeof(ArgumentIDAttribute) );

            // Create an instance of the argument ID attribute on strList.
            ArgumentIDAttribute listIDAttr = (ArgumentIDAttribute)
                Attribute.GetCustomAttribute( pInfoArray[1],
                    typeof(ArgumentIDAttribute) );

            // Compare various pairs of attributes for equality.
            Console.WriteLine("\nCompare a usage attribute instance to " +
                "another instance of the same attribute:" );
            Console.WriteLine($"   \"{arrayUsageAttr1}\" == \n" +
                    $"   \"{arrayUsageAttr2}\"? {arrayUsageAttr1.Equals(
arrayUsageAttr2)}");

            Console.WriteLine("\nCompare a usage attribute to " +
                "another usage attribute:" );
            Console.WriteLine($"   \"{arrayUsageAttr1}\" == \n" +
                    $"   \"{listUsageAttr}\"?
```

```
{arrayUsageAttr1.Equals(listUsageAttr)}");

            Console.WriteLine("\nCompare an ID attribute instance to " +
                "another instance of the same attribute:" );
            Console.WriteLine($"   \"{ arrayIDAttr1}\" == \n" +
                    $"   \"{arrayIDAttr2}\"?
{arrayIDAttr1.Equals(arrayIDAttr2)}");

            Console.WriteLine("\nCompare an ID attribute to another ID
attribute:" );
            Console.WriteLine($"   \"{arrayIDAttr1}\" == \n" +
                    $"   \"{listIDAttr}\"?
{arrayIDAttr1.Equals(listIDAttr)}");
        }
        else
            Console.WriteLine( "The parameters information could " +
                "not be retrieved for method {0}.", mInfo.Name);
    }
    }
/*
The example displays an output similar to the following:
//         Compare a usage attribute instance to another instance of the
same attribute:
//            "ArgumentUsageAttribute: Must pass an array here." ==
//            "ArgumentUsageAttribute: Must pass an array here."? True
//
//         Compare a usage attribute to another usage attribute:
//            "ArgumentUsageAttribute: Must pass an array here." ==
//            "ArgumentUsageAttribute: Can pass param list or array here."?
False
//
//         Compare an ID attribute instance to another instance of the same
attribute:
//            "ArgumentIDAttribute.22d1a176-4aca-427b-8230-0c1563e13187" ==
//            "ArgumentIDAttribute.7fa94bba-c290-48e1-a0de-e22f6c1e64f1"?
False
//
//         Compare an ID attribute to another ID attribute:
//            "ArgumentIDAttribute.22d1a176-4aca-427b-8230-0c1563e13187" ==
//            "ArgumentIDAttribute.b9eea70d-9c0f-459e-a984-19c46b6c8789"?
False
*/
```

Remarks

The Equals method uses reflection to retrieve field information for the current instance and the `obj` argument. It then compares field values.

When implementing your own class derived from Attribute, you can override the Equals method. Because it uses reflection, we recommend that you do so. However, your override should perform a standard test for reference equality (the two arguments

represent the same object instance) or value equality (the two arguments are of the same type and have identical field values). If you want to perform a custom comparison to determine whether two attributes objects are equal, you can override the Match method.

Attribute.GetCustomAttribute Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves a custom attribute of a specified type applied to an assembly, module, type member, or method parameter.

Overloads

Expand table

GetCustomAttribute(ParameterInfo, Type, Boolean)	Retrieves a custom attribute applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.
GetCustomAttribute(MemberInfo, Type, Boolean)	Retrieves a custom attribute applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
GetCustomAttribute(Assembly, Type, Boolean)	Retrieves a custom attribute applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.
GetCustomAttribute(Module, Type, Boolean)	Retrieves a custom attribute applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.
GetCustomAttribute(Module, Type)	Retrieves a custom attribute applied to a module. Parameters specify the module, and the type of the custom attribute to search for.
GetCustomAttribute(MemberInfo, Type)	Retrieves a custom attribute applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.
GetCustomAttribute(Assembly, Type)	Retrieves a custom attribute applied to a specified assembly. Parameters specify the assembly and the type of the custom attribute to search for.

GetCustomAttribute(ParameterInfo, Type)	Retrieves a custom attribute applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.

GetCustomAttribute(ParameterInfo, Type, Boolean)

Retrieves a custom attribute applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.

C#

```
public static Attribute? GetCustomAttribute
(System.Reflection.ParameterInfo element, Type attributeType, bool
inherit);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

AmbiguousMatchException

More than one of the requested attributes was found.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example defines a custom parameter Attribute class and applies the custom attribute to a method in a derived class and the base of the derived class. The example shows the use of the GetCustomAttribute method to return the attributes.

C#

```
// Example for the Attribute.GetCustomAttribute( ParameterInfo, Type,
Boolean )
// method.
using System;
using System.Reflection;

namespace NDP_UE_CS
{
    // Define a custom parameter attribute that takes a single message
argument.
    [AttributeUsage( AttributeTargets.Parameter )]
    public class ArgumentUsageAttribute : Attribute
    {
        // This is the attribute constructor.
        public ArgumentUsageAttribute( string UsageMsg )
        {
            this.usageMsg = UsageMsg;
        }

        // usageMsg is storage for the attribute message.
        protected string usageMsg;

        // This is the Message property for the attribute.
        public string Message
        {
            get { return usageMsg; }
            set { usageMsg = value; }
        }
    }

    public class BaseClass
```

```
    {
        // Assign an ArgumentUsage attribute to the strArray parameter.
        // Assign a ParamArray attribute to strList using the params
keyword.
        public virtual void TestMethod(
            [ArgumentUsage("Must pass an array here.")]
            String[] strArray,
            params String[] strList)
        { }
    }

    public class DerivedClass : BaseClass
    {
        // Assign an ArgumentUsage attribute to the strList parameter.
        // Assign a ParamArray attribute to strList using the params
keyword.
        public override void TestMethod(
            String[] strArray,
            [ArgumentUsage("Can pass a parameter list or array here.")]
            params String[] strList)
        { }
    }

    class CustomParamDemo
    {
        static void Main( )
        {
            Console.WriteLine(
                "This example of Attribute.GetCustomAttribute( Parameter"
+
                "Info, Type, Boolean )\ngenerates the following output."
);

            // Get the class type, and then get the MethodInfo object
            // for TestMethod to access its metadata.
            Type clsType = typeof(DerivedClass);
            MethodInfo mInfo = clsType.GetMethod("TestMethod");

            // Iterate through the ParameterInfo array for the method
parameters.
            ParameterInfo[] pInfoArray = mInfo.GetParameters();
            if (pInfoArray != null)
            {
                DisplayParameterAttributes( mInfo, pInfoArray, false );
                DisplayParameterAttributes( mInfo, pInfoArray, true );
            }
            else
                Console.WriteLine("The parameters information could " +
                    "not be retrieved for method {0}.", mInfo.Name);
        }

        static void DisplayParameterAttributes( MethodInfo mInfo,
            ParameterInfo[] pInfoArray, bool includeInherited )
        {
            Console.WriteLine(
```

```
                "\nParameter attribute information for method \"" +
                "{0}\"\nincludes inheritance from base class: {1}.",
                mInfo.Name, includeInherited ? "Yes" : "No" );

            // Display the attribute information for the parameters.
            foreach( ParameterInfo paramInfo in pInfoArray )
            {
                // See if the ParamArray attribute is defined.
                bool isDef = Attribute.IsDefined( paramInfo,
                    typeof(ParamArrayAttribute));

                if( isDef )
                    Console.WriteLine(
                        "\n    The ParamArray attribute is defined " +
                        "for \n    parameter {0} of method {1}.",
                        paramInfo.Name, mInfo.Name);

                // See if ParamUsageAttribute is defined.
                // If so, display a message.
                ArgumentUsageAttribute usageAttr =
(ArgumentUsageAttribute)
                    Attribute.GetCustomAttribute( paramInfo,
                        typeof(ArgumentUsageAttribute),
                        includeInherited );

                if( usageAttr != null )
                {
                    Console.WriteLine(
                        "\n    The ArgumentUsage attribute is def" +
                        "ined for \n    parameter {0} of method {1}.",
                        paramInfo.Name, mInfo.Name );

                    Console.WriteLine( "\n        The usage " +
                        "message for {0} is:\n        \"{1}\".",
                        paramInfo.Name, usageAttr.Message);
                }
            }
        }
    }
}

/*
This example of Attribute.GetCustomAttribute( ParameterInfo, Type,
Boolean )
generates the following output.

Parameter attribute information for method "TestMethod"
includes inheritance from base class: No.

    The ParamArray attribute is defined for
    parameter strList of method TestMethod.

    The ArgumentUsage attribute is defined for
    parameter strList of method TestMethod.
```

```
        The usage message for strList is:
        "Can pass a parameter list or array here.".

Parameter attribute information for method "TestMethod"
includes inheritance from base class: Yes.

    The ArgumentUsage attribute is defined for
    parameter strArray of method TestMethod.

        The usage message for strArray is:
        "Must pass an array here.".

    The ParamArray attribute is defined for
    parameter strList of method TestMethod.

    The ArgumentUsage attribute is defined for
    parameter strList of method TestMethod.

        The usage message for strList is:
        "Can pass a parameter list or array here.".
*/
```

Remarks

If `element` represents a parameter in a method of a derived type, the return value includes the inheritable custom attributes applied to the same parameter in the overridden base methods.

.NET Standard	2.0, 2.1

GetCustomAttribute(MemberInfo, Type, Boolean)

Retrieves a custom attribute applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.

```
C#

public static Attribute? GetCustomAttribute (System.Reflection.MemberInfo
element, Type attributeType, bool inherit);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, or property member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

AmbiguousMatchException

More than one of the requested attributes was found.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example illustrates the use of the GetCustomAttribute method taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;

namespace IsDef4CS
{
    public class TestClass
    {
        // Assign the Obsolete attribute to a method.
        [Obsolete("This method is obsolete. Use Method2 instead.")]
        public void Method1()
        {}
        public void Method2()
        {}
    }

    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get the MethodInfo object for Method1.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // See if the Obsolete attribute is defined for this method.
            bool isDef = Attribute.IsDefined(mInfo,
typeof(ObsoleteAttribute));
            // Display the result.
            Console.WriteLine("The Obsolete Attribute {0} defined for {1}
of class {2}.",
                isDef ? "is" : "is not", mInfo.Name, clsType.Name);
            // If it's defined, display the attribute's message.
            if (isDef)
            {
                ObsoleteAttribute obsAttr =

(ObsoleteAttribute)Attribute.GetCustomAttribute(
                                                        mInfo,
typeof(ObsoleteAttribute));
                if (obsAttr != null)
                    Console.WriteLine("The message is: \"{0}\".",
                        obsAttr.Message);
                else
```

```
                    Console.WriteLine("The message could not be
retrieved.");
            }
        }
    }
}

/*
 * Output:
 * The Obsolete Attribute is defined for Method1 of class TestClass.
 * The message is: "This method is obsolete. Use Method2 instead.".
 */
```

Remarks

> **Note**
>
> Starting with the .NET Framework version 2.0, this method returns security attributes on types, methods, and constructors if the attributes are stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

.NET Standard	2.0, 2.1

GetCustomAttribute(Assembly, Type, Boolean)

Retrieves a custom attribute applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.

```
C#

public static Attribute? GetCustomAttribute (System.Reflection.Assembly
element, Type attributeType, bool inherit);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

AmbiguousMatchException

More than one of the requested attributes was found.

Examples

The following code example illustrates the use of the GetCustomAttribute method taking an Assembly as a parameter.

```
C#
```

```
using System;
using System.Reflection;

// Add an AssemblyDescription attribute
[assembly: AssemblyDescription("A sample description")]
namespace IsDef1CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // Get the assembly object.
            Assembly assy = clsType.Assembly;
            // Store the assembly's name.
            String assyName = assy.GetName().Name;
            // See if the Assembly Description is defined.
            bool isdef = Attribute.IsDefined(assy,
                typeof(AssemblyDescriptionAttribute));
            if (isdef)
            {
                // Affirm that the attribute is defined.
                Console.WriteLine("The AssemblyDescription attribute " +
                    "is defined for assembly {0}.", assyName);
                // Get the description attribute itself.
                AssemblyDescriptionAttribute adAttr =

(AssemblyDescriptionAttribute)Attribute.GetCustomAttribute(
                    assy, typeof(AssemblyDescriptionAttribute));
                // Display the description.
                if (adAttr != null)
                    Console.WriteLine("The description is \"{0}\".",
                        adAttr.Description);
                else
                    Console.WriteLine("The description could not " +
                        "be retrieved.");
            }
            else
                Console.WriteLine("The AssemblyDescription attribute is
not " +
                    "defined for assembly {0}.", assyName);
        }
    }
}

/*
 * Output:
 * The AssemblyDescription attribute is defined for assembly IsDef1CS.
 * The description is "A sample description".
 */
```

GetCustomAttribute(Module, Type, Boolean)

Retrieves a custom attribute applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.

C#

```
public static Attribute? GetCustomAttribute (System.Reflection.Module
element, Type attributeType, bool inherit);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

AmbiguousMatchException

More than one of the requested attributes was found.

Examples

The following code example illustrates the use of the GetCustomAttribute method taking a Module as a parameter.

C#

```
using System;
using System.Diagnostics;

// Add the Debuggable attribute to the module.
[module:Debuggable(true, false)]
namespace IsDef2CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // See if the Debuggable attribute is defined for this
module.
            bool isDef = Attribute.IsDefined(clsType.Module,
                typeof(DebuggableAttribute));
            // Display the result.
```

```
            Console.WriteLine("The Debuggable attribute {0} " +
                "defined for Module {1}.",
                isDef ? "is" : "is not",
                clsType.Module.Name);
            // If the attribute is defined, display the JIT settings.
            if (isDef)
            {
                // Retrieve the attribute itself.
                DebuggableAttribute dbgAttr = (DebuggableAttribute)
                    Attribute.GetCustomAttribute(clsType.Module,
                    typeof(DebuggableAttribute));
                if (dbgAttr != null)
                {
                    Console.WriteLine("JITTrackingEnabled is {0}.",
                        dbgAttr.IsJITTrackingEnabled);
                    Console.WriteLine("JITOptimizerDisabled is {0}.",
                        dbgAttr.IsJITOptimizerDisabled);
                }
                else
                    Console.WriteLine("The Debuggable attribute " +
                        "could not be retrieved.");
            }
        }
    }
}

/*
 * Output:
 * The Debuggable attribute is defined for Module IsDef2CS.exe.
 * JITTrackingEnabled is True.
 * JITOptimizerDisabled is False.
 */
```

GetCustomAttribute(Module, Type)

Retrieves a custom attribute applied to a module. Parameters specify the module, and the type of the custom attribute to search for.

```C#
public static Attribute? GetCustomAttribute (System.Reflection.Module element, Type attributeType);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

AmbiguousMatchException

More than one of the requested attributes was found.

Examples

The following code example illustrates the use of the GetCustomAttribute method taking a Module as a parameter.

```C#
```

```
using System;
using System.Diagnostics;

// Add the Debuggable attribute to the module.
[module:Debuggable(true, false)]
namespace IsDef2CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // See if the Debuggable attribute is defined for this
module.
            bool isDef = Attribute.IsDefined(clsType.Module,
                typeof(DebuggableAttribute));
            // Display the result.
            Console.WriteLine("The Debuggable attribute {0} " +
                "defined for Module {1}.",
                isDef ? "is" : "is not",
                clsType.Module.Name);
            // If the attribute is defined, display the JIT settings.
            if (isDef)
            {
                // Retrieve the attribute itself.
                DebuggableAttribute dbgAttr = (DebuggableAttribute)
                    Attribute.GetCustomAttribute(clsType.Module,
                    typeof(DebuggableAttribute));
                if (dbgAttr != null)
                {
                    Console.WriteLine("JITTrackingEnabled is {0}.",
                        dbgAttr.IsJITTrackingEnabled);
                    Console.WriteLine("JITOptimizerDisabled is {0}.",
                        dbgAttr.IsJITOptimizerDisabled);
                }
                else
                    Console.WriteLine("The Debuggable attribute " +
                        "could not be retrieved.");
            }
        }
    }
}

/*

.NET Standard	2.0, 2.1

GetCustomAttribute(MemberInfo, Type)

Retrieves a custom attribute applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.

C#

```
public static Attribute? GetCustomAttribute (System.Reflection.MemberInfo
element, Type attributeType);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, or property member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

AmbiguousMatchException

More than one of the requested attributes was found.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example illustrates the use of the GetCustomAttribute method taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;

namespace IsDef4CS
{
    public class TestClass
    {
        // Assign the Obsolete attribute to a method.
        [Obsolete("This method is obsolete. Use Method2 instead.")]
        public void Method1()
        {}
        public void Method2()
        {}
    }

    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get the MethodInfo object for Method1.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // See if the Obsolete attribute is defined for this method.
            bool isDef = Attribute.IsDefined(mInfo,
typeof(ObsoleteAttribute));
            // Display the result.
            Console.WriteLine("The Obsolete Attribute {0} defined for {1}
of class {2}.",
                isDef ? "is" : "is not", mInfo.Name, clsType.Name);
            // If it's defined, display the attribute's message.
```

```
            if (isDef)
            {
                ObsoleteAttribute obsAttr =

(ObsoleteAttribute)Attribute.GetCustomAttribute(
                                                        mInfo,
typeof(ObsoleteAttribute));
                if (obsAttr != null)
                    Console.WriteLine("The message is: \"{0}\".",
                        obsAttr.Message);
                else
                    Console.WriteLine("The message could not be
retrieved.");
            }
        }
    }
}

/*
 * Output:
 * The Obsolete Attribute is defined for Method1 of class TestClass.
 * The message is: "This method is obsolete. Use Method2 instead.".
 */
```

Remarks

A match is determined in the same way described in the Return Value section of Type.IsAssignableFrom.

> **Note**
>
> Starting with the .NET Framework version 2.0, this method returns security attributes on types, methods, and constructors if the attributes are stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

.NET Standard	2.0, 2.1

GetCustomAttribute(Assembly, Type)

Retrieves a custom attribute applied to a specified assembly. Parameters specify the assembly and the type of the custom attribute to search for.

```
C#

public static Attribute? GetCustomAttribute (System.Reflection.Assembly
element, Type attributeType);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

AmbiguousMatchException

More than one of the requested attributes was found.

Examples

The following code example illustrates the use of the GetCustomAttribute method taking an Assembly as a parameter.

C#

```
using System;
using System.Reflection;

// Add an AssemblyDescription attribute
[assembly: AssemblyDescription("A sample description")]
namespace IsDef1CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // Get the assembly object.
            Assembly assy = clsType.Assembly;
            // Store the assembly's name.
            String assyName = assy.GetName().Name;
            // See if the Assembly Description is defined.
            bool isdef = Attribute.IsDefined(assy,
                typeof(AssemblyDescriptionAttribute));
            if (isdef)
            {
                // Affirm that the attribute is defined.
                Console.WriteLine("The AssemblyDescription attribute " +
                    "is defined for assembly {0}.", assyName);
                // Get the description attribute itself.
                AssemblyDescriptionAttribute adAttr =

(AssemblyDescriptionAttribute)Attribute.GetCustomAttribute(
                    assy, typeof(AssemblyDescriptionAttribute));
                // Display the description.
                if (adAttr != null)
                    Console.WriteLine("The description is \"{0}\".",
                        adAttr.Description);
                else
                    Console.WriteLine("The description could not " +
                        "be retrieved.");
            }
            else
                Console.WriteLine("The AssemblyDescription attribute is
not " +
                    "defined for assembly {0}.", assyName);
        }
```

```
    }
}

/*
 * Output:
 * The AssemblyDescription attribute is defined for assembly IsDef1CS.
 * The description is "A sample description".
 */
```

Remarks

Use the GetCustomAttributes method if you expect more than one value to be returned, or AmbiguousMatchException will be thrown.

GetCustomAttribute(ParameterInfo, Type)

Retrieves a custom attribute applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.

C#

```
public static Attribute? GetCustomAttribute
(System.Reflection.ParameterInfo element, Type attributeType);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute

A reference to the single custom attribute of type `attributeType` that is applied to `element`, or `null` if there is no such attribute.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

AmbiguousMatchException

More than one of the requested attributes was found.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example defines a custom parameter Attribute class and applies the custom attribute to a method in a derived class and the base of the derived class. The example shows the use of the GetCustomAttribute method to return the attributes.

C#

```
// Example for the Attribute.GetCustomAttribute( ParameterInfo, Type )
method.
using System;
using System.Reflection;

namespace NDP_UE_CS
{
    // Define a custom parameter attribute that takes a single message
argument.
    [AttributeUsage( AttributeTargets.Parameter )]
    public class ArgumentUsageAttribute : Attribute
    {
        // This is the attribute constructor.
        public ArgumentUsageAttribute( string UsageMsg )
        {
            this.usageMsg = UsageMsg;
        }

        // usageMsg is storage for the attribute message.
        protected string usageMsg;

        // This is the Message property for the attribute.
        public string Message
        {
            get { return usageMsg; }
            set { usageMsg = value; }
        }
    }

    public class BaseClass
    {
        // Assign an ArgumentUsage attribute to the strArray parameter.
        // Assign a ParamArray attribute to strList using the params
keyword.
        public virtual void TestMethod(
            [ArgumentUsage("Must pass an array here.")]
            String[] strArray,
            params String[] strList)
        { }
    }

    public class DerivedClass : BaseClass
    {
        // Assign an ArgumentUsage attribute to the strList parameter.
        // Assign a ParamArray attribute to strList using the params
keyword.
        public override void TestMethod(
            String[] strArray,
            [ArgumentUsage("Can pass a parameter list or array here.")]
            params String[] strList)
        { }
    }
```

```
    class CustomParamDemo
    {
        static void Main( )
        {
            Console.WriteLine(
                "This example of Attribute.GetCustomAttribute( Param" +
                "eterInfo, Type )\ngenerates the following output." );

            // Get the class type, and then get the MethodInfo object
            // for TestMethod to access its metadata.
            Type clsType = typeof( DerivedClass );
            MethodInfo mInfo = clsType.GetMethod("TestMethod");

            // Iterate through the ParameterInfo array for the method
parameters.
            ParameterInfo[] pInfoArray = mInfo.GetParameters();
            if (pInfoArray != null)
            {
                foreach( ParameterInfo paramInfo in pInfoArray )
                {
                    // See if the ParamArray attribute is defined.
                    bool isDef = Attribute.IsDefined(
                        paramInfo, typeof(ParamArrayAttribute));

                    if( isDef )
                        Console.WriteLine(
                            "\nThe ParamArray attribute is defined " +
                            "for \nparameter {0} of method {1}.",
                            paramInfo.Name, mInfo.Name);

                    // See if ParamUsageAttribute is defined.
                    // If so, display a message.
                    ArgumentUsageAttribute usageAttr =
(ArgumentUsageAttribute)
                        Attribute.GetCustomAttribute(
                            paramInfo, typeof(ArgumentUsageAttribute) );

                    if( usageAttr != null )
                    {
                        Console.WriteLine(
                            "\nThe ArgumentUsage attribute is defined " +
                            "for \nparameter {0} of method {1}.",
                            paramInfo.Name, mInfo.Name );

                        Console.WriteLine( "\n    The usage " +
                            "message for {0} is:\n    \"{1}\".",
                            paramInfo.Name, usageAttr.Message);
                    }
                }
            }
            else
                Console.WriteLine(
                    "The parameters information could not " +
                    "be retrieved for method {0}.", mInfo.Name);
```

```
        }
    }
}

/*
This example of Attribute.GetCustomAttribute( ParameterInfo, Type )
generates the following output.

The ArgumentUsage attribute is defined for
parameter strArray of method TestMethod.

    The usage message for strArray is:
    "Must pass an array here.".

The ParamArray attribute is defined for
parameter strList of method TestMethod.

The ArgumentUsage attribute is defined for
parameter strList of method TestMethod.

    The usage message for strList is:
    "Can pass a parameter list or array here.".
*/
```

Remarks

If `element` represents a parameter in a method of a derived type, the return value includes the inheritable custom attributes applied to the same parameter in the overridden base methods.

Attribute.GetCustomAttributes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves an array of the custom attributes applied to an assembly, module, type member, or method parameter.

Overloads

Expand table

GetCustomAttributes(ParameterInfo, Boolean)	Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, and whether to search ancestors of the method parameter.
GetCustomAttributes(MemberInfo, Type, Boolean)	Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
GetCustomAttributes(ParameterInfo, Type, Boolean)	Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.
GetCustomAttributes(Module, Type, Boolean)	Retrieves an array of the custom attributes applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.
GetCustomAttributes(MemberInfo, Type)	Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.
GetCustomAttributes(Assembly, Type, Boolean)	Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.

GetCustomAttributes(Module, Type)	Retrieves an array of the custom attributes applied to a module. Parameters specify the module, and the type of the custom attribute to search for.
GetCustomAttributes(ParameterInfo, Type)	Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.
GetCustomAttributes(MemberInfo, Boolean)	Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
GetCustomAttributes(Assembly, Type)	Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, and the type of the custom attribute to search for.
GetCustomAttributes(Assembly, Boolean)	Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, and an ignored search option.
GetCustomAttributes(ParameterInfo)	Retrieves an array of the custom attributes applied to a method parameter. A parameter specifies the method parameter.
GetCustomAttributes(Module)	Retrieves an array of the custom attributes applied to a module. A parameter specifies the module.
GetCustomAttributes(MemberInfo)	Retrieves an array of the custom attributes applied to a member of a type. A parameter specifies the member.
GetCustomAttributes(Assembly)	Retrieves an array of the custom attributes applied to an assembly. A parameter specifies the assembly.
GetCustomAttributes(Module, Boolean)	Retrieves an array of the custom attributes applied to a module. Parameters specify the module, and an ignored search option.

GetCustomAttributes(ParameterInfo, Boolean)

Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, and whether to search ancestors of the method parameter.

```
C#
```

```
public static Attribute[] GetCustomAttributes
(System.Reflection.ParameterInfo element, bool inherit);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentException

The Member property of `element` is `null`.

ArgumentNullException

`element` is `null`.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a ParameterInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

namespace CustAttrs5CS {
```

```
    public class AClass {
        public void ParamArrayAndDesc(
            // Add ParamArray (with the keyword) and Description
attributes.
            [Description("This argument is a ParamArray")]
            params int[] args)
        {}
    }

    class DemoClass {
        static void Main(string[] args) {
            // Get the Class type to access its metadata.
            Type clsType = typeof(AClass);
            // Get the type information for the method.
            MethodInfo mInfo = clsType.GetMethod("ParamArrayAndDesc");
            if (mInfo != null) {

                            Console.WriteLine("The description is: \"
{0}\"",

((DescriptionAttribute)attr).Description);
                        }
                    }
                }
            }
        }
    }
}

/*
 * Output:
 * Parameter args for method ParamArrayAndDesc has the ParamArray
attribute.
 * Parameter args for method ParamArrayAndDesc has a description
attribute.
```

```
  * The description is: "This argument is a ParamArray"
  */
```

Remarks

If `element` represents a parameter in a method of a derived type, the return value includes the inheritable custom attributes applied to the same parameter in the overridden base methods.

.NET Standard	2.0, 2.1

GetCustomAttributes(MemberInfo, Type, Boolean)

Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.

C#

```
public static Attribute[] GetCustomAttributes
(System.Reflection.MemberInfo element, Type attributeType, bool inherit);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, or property member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `type` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `type` is `null`.

ArgumentException

`type` is not derived from Attribute.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.Security;
using System.Runtime.InteropServices;

namespace CustAttrs4CS
{

    // Define an enumeration of Win32 unmanaged types
    public enum UnmanagedType
    {
```

```
        User,
        GDI,
        Kernel,
        Shell,
        Networking,
        Multimedia
    }

    // Define the Unmanaged attribute.
    public class UnmanagedAttribute : Attribute
    {
        // Storage for the UnmanagedType value.
        protected UnmanagedType thisType;

        // Set the unmanaged type in the constructor.
        public UnmanagedAttribute(UnmanagedType type)
        {
            thisType = type;
        }

        // Define a property to get and set the UnmanagedType value.
        public UnmanagedType Win32Type
        {
            get { return thisType; }
            set { thisType = Win32Type; }
        }
    }

    // Create a class for an imported Win32 unmanaged function.
    public class Win32 {
        [DllImport("user32.dll", CharSet = CharSet.Unicode)]
        public static extern int MessageBox(int hWnd, String text,
            String caption, uint type);
    }

    public class AClass {
        // Add some attributes to Win32CallMethod.
        [Obsolete("This method is obsolete. Use managed MsgBox
instead.")]
        [Unmanaged(UnmanagedType.User)]
        public void Win32CallMethod()
        {
            Win32.MessageBox(0, "This is an unmanaged call.", "Caution!",
0);
        }
    }

    class DemoClass {
        static void Main(string[] args)
            {
            // Get the AClass type to access its metadata.
            Type clsType = typeof(AClass);
            // Get the type information for Win32CallMethod.
            MethodInfo mInfo = clsType.GetMethod("Win32CallMethod");
            if (mInfo != null)
```

```
            {
                // Iterate through all the attributes of the method.
                foreach(Attribute attr in
                    Attribute.GetCustomAttributes(mInfo)) {
                    // Check for the Obsolete attribute.
                    if (attr.GetType() == typeof(ObsoleteAttribute))
                    {
                        Console.WriteLine("Method {0} is obsolete. " +
                            "The message is:",
                            mInfo.Name);
                        Console.WriteLine("  \"{0}\"",
                            ((ObsoleteAttribute)attr).Message);
                    }

                    // Check for the Unmanaged attribute.
                    else if (attr.GetType() ==
typeof(UnmanagedAttribute))
                    {
                        Console.WriteLine(
                            "This method calls unmanaged code.");
                        Console.WriteLine(
                            String.Format("The Unmanaged attribute type
is {0}.",

((UnmanagedAttribute)attr).Win32Type));
                        AClass myCls = new AClass();
                        myCls.Win32CallMethod();
                    }
                }
            }
        }
    }
}

/*

This code example produces the following results.

First, the compilation yields the warning, "... This method is
obsolete. Use managed MsgBox instead."
Second, execution yields a message box with a title of "Caution!"
and message text of "This is an unmanaged call."
Third, the following text is displayed in the console window:

Method Win32CallMethod is obsolete. The message is:
  "This method is obsolete. Use managed MsgBox instead."
This method calls unmanaged code.
The Unmanaged attribute type is User.

*/
```

Remarks

The return value contains the custom attributes for ancestors of `element` if `inherit` is `true`.

> ⓘ **Note**
>
> Starting with the .NET Framework version 2.0, this method returns security attributes on methods, constructors, and types if the attributes are stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

GetCustomAttributes(ParameterInfo, Type, Boolean)

Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.

C#

```
public static Attribute[] GetCustomAttributes
(System.Reflection.ParameterInfo element, Type attributeType, bool
inherit);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `attributeType` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a ParameterInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

namespace CustAttrs5CS {
    public class AClass {
        public void ParamArrayAndDesc(
            // Add ParamArray (with the keyword) and Description
attributes.
            [Description("This argument is a ParamArray")]
```

```
            params int[] args)
        {}
    }

    class DemoClass {
        static void Main(string[] args) {
            // Get the Class type to access its metadata.
            Type clsType = typeof(AClass);
            // Get the type information for the method.
            MethodInfo mInfo = clsType.GetMethod("ParamArrayAndDesc");
            if (mInfo != null) {
                // Get the parameter information.
                ParameterInfo[] pInfo = mInfo.GetParameters();
                if (pInfo != null) {
                    // Iterate through all the attributes for the
parameter.
                    foreach(Attribute attr in
                        Attribute.GetCustomAttributes(pInfo[0])) {
                        // Check for the ParamArray attribute.
                        if (attr.GetType() ==
typeof(ParamArrayAttribute))
                            Console.WriteLine("Parameter {0} for method
{1} " +
                                "has the ParamArray attribute.",
                                pInfo[0].Name, mInfo.Name);
                        // Check for the Description attribute.
                        else if (attr.GetType() ==
                            typeof(DescriptionAttribute)) {
                            Console.WriteLine("Parameter {0} for method
{1} " +
                                "has a description attribute.",
                                pInfo[0].Name, mInfo.Name);
                            Console.WriteLine("The description is: \"
{0}\"",

((DescriptionAttribute)attr).Description);
                        }
                    }
                }
            }
        }
    }
}

/*
 * Output:
 * Parameter args for method ParamArrayAndDesc has the ParamArray
attribute.
 * Parameter args for method ParamArrayAndDesc has a description
attribute.
 * The description is: "This argument is a ParamArray"
 */
```

Remarks

If `element` represents a parameter in a method of a derived type, the return value includes the inheritable custom attributes applied to the same parameter in the overridden base methods.

.NET Standard	2.0, 2.1

GetCustomAttributes(Module, Type, Boolean)

Retrieves an array of the custom attributes applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.

C#

```
public static Attribute[] GetCustomAttributes (System.Reflection.Module
element, Type attributeType, bool inherit);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `attributeType` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a Module as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

// Assign some attributes to the module.
[module:Description("A sample description")]

// Set the module's CLSCompliant attribute to false
// The CLSCompliant attribute is applicable for /target:module.
[module:CLSCompliant(false)]

namespace CustAttrs2CS {
    class DemoClass {
        static void Main(string[] args) {
            Type clsType = typeof(DemoClass);
            // Get the Module type to access its metadata.
            Module module = clsType.Module;

            // Iterate through all the attributes for the module.
            foreach(Attribute attr in
Attribute.GetCustomAttributes(module)) {
                // Check for the Description attribute.
                if (attr.GetType() == typeof(DescriptionAttribute))
                    Console.WriteLine("Module {0} has the description " +
                        "\"{1}\".", module.Name,
                        ((DescriptionAttribute)attr).Description);
                // Check for the CLSCompliant attribute.
```

```
                else if (attr.GetType() == typeof(CLSCompliantAttribute))
                    Console.WriteLine("Module {0} {1} CLSCompliant.",
                        module.Name,
                        ((CLSCompliantAttribute)attr).IsCompliant ?
                            "is" : "is not");
            }
        }
    }
}

/*
 * Output:
 * Module CustAttrs2CS.exe is not CLSCompliant.
 * Module CustAttrs2CS.exe has the description "A sample description".
 */
```

Remarks

The return value contains the custom attributes for ancestors of `element` if `inherit` is `true`.

GetCustomAttributes(MemberInfo, Type)

Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.

C#

```
public static Attribute[] GetCustomAttributes
(System.Reflection.MemberInfo element, Type attributeType);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, or property member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `type` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `type` is `null`.

ArgumentException

`type` is not derived from Attribute.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttribute, taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.Security;
using System.Runtime.InteropServices;

namespace CustAttrs4CS
{
```

```
    // Define an enumeration of Win32 unmanaged types
    public enum UnmanagedType
    {
        User,
        GDI,
        Kernel,
        Shell,
        Networking,
        Multimedia
    }

    // Define the Unmanaged attribute.
    public class UnmanagedAttribute : Attribute
    {
        // Storage for the UnmanagedType value.
        protected UnmanagedType thisType;

is {0}.",

((UnmanagedAttribute)attr).Win32Type));
                        AClass myCls = new AClass();
                        myCls.Win32CallMethod();
                    }
                }
            }
        }
    }
}

/*

This code example produces the following results.

First, the compilation yields the warning, "... This method is
obsolete. Use managed MsgBox instead."
Second, execution yields a message box with a title of "Caution!"
and message text of "This is an unmanaged call."
Third, the following text is displayed in the console window:

Method Win32CallMethod is obsolete. The message is:
  "This method is obsolete. Use managed MsgBox instead."
This method calls unmanaged code.
The Unmanaged attribute type is User.

*/
```

Remarks

The return value contains the custom attributes for ancestors of `element`.

GetCustomAttributes(Assembly, Type, Boolean)

Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.

C#

```
public static Attribute[] GetCustomAttributes (System.Reflection.Assembly
element, Type attributeType, bool inherit);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `attributeType` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking an Assembly as a parameter.

C#

```
using System;
using System.Reflection;

[assembly: AssemblyTitle("CustAttrs1CS")]
[assembly: AssemblyDescription("GetCustomAttributes() Demo")]
[assembly: AssemblyCompany("Microsoft")]

class Example {
    static void Main() {
        // Get the Assembly object to access its metadata.
        Assembly assy = typeof(Example).Assembly;

        // Iterate through the attributes for the assembly.
        foreach(Attribute attr in Attribute.GetCustomAttributes(assy)) {
```

```
            // Check for the AssemblyTitle attribute.
            if (attr.GetType() == typeof(AssemblyTitleAttribute))
                Console.WriteLine("Assembly title is \"{0}\".",
                    ((AssemblyTitleAttribute)attr).Title);

            // Check for the AssemblyDescription attribute.
            else if (attr.GetType() ==
                typeof(AssemblyDescriptionAttribute))
                Console.WriteLine("Assembly description is \"{0}\".",
                    ((AssemblyDescriptionAttribute)attr).Description);

            // Check for the AssemblyCompany attribute.
            else if (attr.GetType() == typeof(AssemblyCompanyAttribute))
                Console.WriteLine("Assembly company is {0}.",
                    ((AssemblyCompanyAttribute)attr).Company);
        }
    }
}
// The example displays the following output:
//     Assembly title is "CustAttrs1CS".
//     Assembly description is "GetCustomAttributes() Demo".
//     Assembly company is Microsoft.
```

Remarks

GetCustomAttributes(Module, Type)

Retrieves an array of the custom attributes applied to a module. Parameters specify the module, and the type of the custom attribute to search for.

```
C#

public static Attribute[] GetCustomAttributes (System.Reflection.Module
element, Type attributeType);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `attributeType` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a Module as a parameter.

```
C#

using System;
using System.Reflection;
```

```
using System.ComponentModel;

// Assign some attributes to the module.
[module:Description("A sample description")]

// Set the module's CLSCompliant attribute to false
// The CLSCompliant attribute is applicable for /target:module.
[module:CLSCompliant(false)]

namespace CustAttrs2CS {
    class DemoClass {
        static void Main(string[] args) {
            Type clsType = typeof(DemoClass);
            // Get the Module type to access its metadata.
            Module module = clsType.Module;

            // Iterate through all the attributes for the module.
            foreach(Attribute attr in
Attribute.GetCustomAttributes(module)) {
                // Check for the Description attribute.
                if (attr.GetType() == typeof(DescriptionAttribute))
                    Console.WriteLine("Module {0} has the description " +
                        "\"{1}\".", module.Name,
                        ((DescriptionAttribute)attr).Description);
                // Check for the CLSCompliant attribute.
                else if (attr.GetType() == typeof(CLSCompliantAttribute))
                    Console.WriteLine("Module {0} {1} CLSCompliant.",
                        module.Name,
                        ((CLSCompliantAttribute)attr).IsCompliant ?
                            "is" : "is not");
            }
        }
    }
}

/*
 * Output:
 * Module CustAttrs2CS.exe is not CLSCompliant.
 * Module CustAttrs2CS.exe has the description "A sample description".
 */
```

GetCustomAttributes(ParameterInfo, Type)

Retrieves an array of the custom attributes applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.

C#

```
public static Attribute[] GetCustomAttributes
(System.Reflection.ParameterInfo element, Type attributeType);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `attributeType` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a ParameterInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

namespace CustAttrs5CS {
    public class AClass {
        public void ParamArrayAndDesc(
            // Add ParamArray (with the keyword) and Description
attributes.
            [Description("This argument is a ParamArray")]
            params int[] args)
        {}
    }

    class DemoClass {
        static void Main(string[] args) {
            // Get the Class type to access its metadata.
            Type clsType = typeof(AClass);
            // Get the type information for the method.
            MethodInfo mInfo = clsType.GetMethod("ParamArrayAndDesc");
            if (mInfo != null) {
                // Get the parameter information.
                ParameterInfo[] pInfo = mInfo.GetParameters();
                if (pInfo != null) {
                    // Iterate through all the attributes for the
parameter.
                    foreach(Attribute attr in
                        Attribute.GetCustomAttributes(pInfo[0])) {
                        // Check for the ParamArray attribute.
                        if (attr.GetType() ==
typeof(ParamArrayAttribute))
                            Console.WriteLine("Parameter {0} for method
{1} " +
                                "has the ParamArray attribute.",
                                pInfo[0].Name, mInfo.Name);
                        // Check for the Description attribute.
                        else if (attr.GetType() ==
                            typeof(DescriptionAttribute)) {
                            Console.WriteLine("Parameter {0} for method
{1} " +
                                "has a description attribute.",
                                pInfo[0].Name, mInfo.Name);
                            Console.WriteLine("The description is: \"
{0}\"",

((DescriptionAttribute)attr).Description);
```

```
                        }
                    }
                }
            }
        }
    }
}

/*
 * Output:
 * Parameter args for method ParamArrayAndDesc has the ParamArray
attribute.
 * Parameter args for method ParamArrayAndDesc has a description
attribute.
 * The description is: "This argument is a ParamArray"
 */
```

Remarks

If `element` represents a parameter in a method of a derived type, the return value includes the inheritable custom attributes applied to the same parameter in the overridden base methods.

GetCustomAttributes(MemberInfo, Boolean)

Retrieves an array of the custom attributes applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.

C#

```
public static Attribute[] GetCustomAttributes
```

```
(System.Reflection.MemberInfo element, bool inherit);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, or property member of a class.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` is `null`.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.Security;
using System.Runtime.InteropServices;

namespace CustAttrs4CS
{
```

```
    // Define an enumeration of Win32 unmanaged types
    public enum UnmanagedType
    {
        User,
        GDI,
        Kernel,
        Shell,
        Networking,
        Multimedia
    }

    // Define the Unmanaged attribute.
    public class UnmanagedAttribute : Attribute
    {
        // Storage for the UnmanagedType value.
        protected UnmanagedType thisType;

        // Set the unmanaged type in the constructor.
        public UnmanagedAttribute(UnmanagedType type)
        {
            thisType = type;
        }

        // Define a property to get and set the UnmanagedType value.
        public UnmanagedType Win32Type
        {
            get { return thisType; }
            set { thisType = Win32Type; }
        }
    }

    // Create a class for an imported Win32 unmanaged function.
    public class Win32 {
        [DllImport("user32.dll", CharSet = CharSet.Unicode)]
        public static extern int MessageBox(int hWnd, String text,
            String caption, uint type);
    }

    public class AClass {
        // Add some attributes to Win32CallMethod.
        [Obsolete("This method is obsolete. Use managed MsgBox
instead.")]
        [Unmanaged(UnmanagedType.User)]
        public void Win32CallMethod()
        {
            Win32.MessageBox(0, "This is an unmanaged call.", "Caution!",
0);
        }
    }

    class DemoClass {
        static void Main(string[] args)
            {
            // Get the AClass type to access its metadata.
```

```
            Type clsType = typeof(AClass);
            // Get the type information for Win32CallMethod.
            MethodInfo mInfo = clsType.GetMethod("Win32CallMethod");
            if (mInfo != null)
            {
                // Iterate through all the attributes of the method.
                foreach(Attribute attr in
                    Attribute.GetCustomAttributes(mInfo)) {
                    // Check for the Obsolete attribute.
                    if (attr.GetType() == typeof(ObsoleteAttribute))
                    {
                        Console.WriteLine("Method {0} is obsolete. " +
                            "The message is:",
                            mInfo.Name);
                        Console.WriteLine("  \"{0}\"",
                            ((ObsoleteAttribute)attr).Message);
                    }

                    // Check for the Unmanaged attribute.
                    else if (attr.GetType() ==
typeof(UnmanagedAttribute))
                    {
                        Console.WriteLine(
                            "This method calls unmanaged code.");
                        Console.WriteLine(
                            String.Format("The Unmanaged attribute type
is {0}.",

((UnmanagedAttribute)attr).Win32Type));
                        AClass myCls = new AClass();
                        myCls.Win32CallMethod();
                    }
                }
            }
        }
    }
}

/*

This code example produces the following results.

First, the compilation yields the warning, "... This method is
obsolete. Use managed MsgBox instead."
Second, execution yields a message box with a title of "Caution!"
and message text of "This is an unmanaged call."

GetCustomAttributes(Assembly, Type)

Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, and the type of the custom attribute to search for.

C#

```
public static Attribute[] GetCustomAttributes (System.Reflection.Assembly
element, Type attributeType);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Attribute[]

An Attribute array that contains the custom attributes of type `attributeType` applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking an Assembly as a parameter.

C#

```
using System;
using System.Reflection;

[assembly: AssemblyTitle("CustAttrs1CS")]
[assembly: AssemblyDescription("GetCustomAttributes() Demo")]
[assembly: AssemblyCompany("Microsoft")]

class Example {
    static void Main() {
        // Get the Assembly object to access its metadata.
        Assembly assy = typeof(Example).Assembly;

        // Iterate through the attributes for the assembly.
        foreach(Attribute attr in Attribute.GetCustomAttributes(assy)) {
            // Check for the AssemblyTitle attribute.
            if (attr.GetType() == typeof(AssemblyTitleAttribute))
                Console.WriteLine("Assembly title is \"{0}\".",
                    ((AssemblyTitleAttribute)attr).Title);
```

```
            // Check for the AssemblyDescription attribute.
            else if (attr.GetType() ==
                typeof(AssemblyDescriptionAttribute))
                Console.WriteLine("Assembly description is \"{0}\".",
                    ((AssemblyDescriptionAttribute)attr).Description);

            // Check for the AssemblyCompany attribute.
            else if (attr.GetType() == typeof(AssemblyCompanyAttribute))
                Console.WriteLine("Assembly company is {0}.",
                    ((AssemblyCompanyAttribute)attr).Company);
        }
    }
}
// The example displays the following output:
//     Assembly title is "CustAttrs1CS".
//     Assembly description is "GetCustomAttributes() Demo".
//     Assembly company is Microsoft.
```

GetCustomAttributes(Assembly, Boolean)

Retrieves an array of the custom attributes applied to an assembly. Parameters specify the assembly, and an ignored search option.

```C#
public static Attribute[] GetCustomAttributes (System.Reflection.Assembly element, bool inherit);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking an Assembly as a parameter.

```C#
using System;
using System.Reflection;

[assembly: AssemblyTitle("CustAttrs1CS")]
[assembly: AssemblyDescription("GetCustomAttributes() Demo")]
[assembly: AssemblyCompany("Microsoft")]

class Example {
```

```
    static void Main() {
        // Get the Assembly object to access its metadata.
        Assembly assy = typeof(Example).Assembly;

        // Iterate through the attributes for the assembly.
        foreach(Attribute attr in Attribute.GetCustomAttributes(assy)) {
            // Check for the AssemblyTitle attribute.
            if (attr.GetType() == typeof(AssemblyTitleAttribute))
                Console.WriteLine("Assembly title is \"{0}\".",
                    ((AssemblyTitleAttribute)attr).Title);

            // Check for the AssemblyDescription attribute.
            else if (attr.GetType() ==
                typeof(AssemblyDescriptionAttribute))
                Console.WriteLine("Assembly description is \"{0}\".",
                    ((AssemblyDescriptionAttribute)attr).Description);

            // Check for the AssemblyCompany attribute.
            else if (attr.GetType() == typeof(AssemblyCompanyAttribute))
                Console.WriteLine("Assembly company is {0}.",
                    ((AssemblyCompanyAttribute)attr).Company);
        }
    }
}
// The example displays the following output:
//     Assembly title is "CustAttrs1CS".
//     Assembly description is "GetCustomAttributes() Demo".
//     Assembly company is Microsoft.
```

Remarks

> **Note**
>
> Starting with the .NET Framework version 2.0, this method returns security attributes if the attributes are stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

.NET Standard	2.0, 2.1

GetCustomAttributes(ParameterInfo)

Retrieves an array of the custom attributes applied to a method parameter. A parameter specifies the method parameter.

```
C#

public static Attribute[] GetCustomAttributes
(System.Reflection.ParameterInfo element);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` is `null`.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a ParameterInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

namespace CustAttrs5CS {
    public class AClass {
        public void ParamArrayAndDesc(
            // Add ParamArray (with the keyword) and Description
attributes.
            [Description("This argument is a ParamArray")]
            params int[] args)
        {}
    }

    class DemoClass {
        static void Main(string[] args) {
            // Get the Class type to access its metadata.
            Type clsType = typeof(AClass);
            // Get the type information for the method.
            MethodInfo mInfo = clsType.GetMethod("ParamArrayAndDesc");
            if (mInfo != null) {
                // Get the parameter information.
                ParameterInfo[] pInfo = mInfo.GetParameters();
                if (pInfo != null) {
                    // Iterate through all the attributes for the
parameter.
                    foreach(Attribute attr in
                        Attribute.GetCustomAttributes(pInfo[0])) {
                        // Check for the ParamArray attribute.
                        if (attr.GetType() ==
typeof(ParamArrayAttribute))
                            Console.WriteLine("Parameter {0} for method
{1} " +
                                "has the ParamArray attribute.",
                                pInfo[0].Name, mInfo.Name);
                        // Check for the Description attribute.
                        else if (attr.GetType() ==
                            typeof(DescriptionAttribute)) {
                            Console.WriteLine("Parameter {0} for method
{1} " +
                                "has a description attribute.",
                                pInfo[0].Name, mInfo.Name);
                            Console.WriteLine("The description is: \"
{0}\"",

((DescriptionAttribute)attr).Description);
                        }
                    }
                }
            }
        }
    }
```

```
}

/*
 * Output:
 * Parameter args for method ParamArrayAndDesc has the ParamArray
attribute.
 * Parameter args for method ParamArrayAndDesc has a description
attribute.
 * The description is: "This argument is a ParamArray"
 */
```

Remarks

If `element` represents a parameter in a method of a derived type, the return value includes the inheritable custom attributes applied to the same parameter in the overridden base methods.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetCustomAttributes(Module)

Retrieves an array of the custom attributes applied to a module. A parameter specifies the module.

```C#
public static Attribute[] GetCustomAttributes (System.Reflection.Module
element);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` is `null`.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a Module as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

// Assign some attributes to the module.
[module:Description("A sample description")]

// Set the module's CLSCompliant attribute to false
// The CLSCompliant attribute is applicable for /target:module.
[module:CLSCompliant(false)]

namespace CustAttrs2CS {
    class DemoClass {
        static void Main(string[] args) {
            Type clsType = typeof(DemoClass);
            // Get the Module type to access its metadata.
            Module module = clsType.Module;

            // Iterate through all the attributes for the module.
            foreach(Attribute attr in
Attribute.GetCustomAttributes(module)) {
                // Check for the Description attribute.
                if (attr.GetType() == typeof(DescriptionAttribute))
                    Console.WriteLine("Module {0} has the description " +
                        "\"{1}\".", module.Name,
                        ((DescriptionAttribute)attr).Description);
                // Check for the CLSCompliant attribute.
                else if (attr.GetType() == typeof(CLSCompliantAttribute))
```

```
                        Console.WriteLine("Module {0} {1} CLSCompliant.",
                            module.Name,
                            ((CLSCompliantAttribute)attr).IsCompliant ?
                                "is" : "is not");
                }
            }
        }
    }

    /*
     * Output:
     * Module CustAttrs2CS.exe is not CLSCompliant.
     * Module CustAttrs2CS.exe has the description "A sample description".
     */
```

.NET Standard	2.0, 2.1

GetCustomAttributes(MemberInfo)

Retrieves an array of the custom attributes applied to a member of a type. A parameter specifies the member.

C#

```
public static Attribute[] GetCustomAttributes
(System.Reflection.MemberInfo element);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, or property member of a class.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` is `null`.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

TypeLoadException

A custom attribute type cannot be loaded.

Examples

The following code example demonstrates the use of GetCustomAttribute, taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;
using System.Security;
using System.Runtime.InteropServices;

namespace CustAttrs4CS
{

    // Define an enumeration of Win32 unmanaged types
    public enum UnmanagedType
    {
        User,
        GDI,
        Kernel,
        Shell,
        Networking,
        Multimedia
    }

    // Define the Unmanaged attribute.
    public class UnmanagedAttribute : Attribute
    {
        // Storage for the UnmanagedType value.
```

```
        protected UnmanagedType thisType;

        // Set the unmanaged type in the constructor.
        public UnmanagedAttribute(UnmanagedType type)
        {
            thisType = type;
        }

        // Define a property to get and set the UnmanagedType value.
        public UnmanagedType Win32Type
        {
            get { return thisType; }
            set { thisType = Win32Type; }
        }
    }

    // Create a class for an imported Win32 unmanaged function.
    public class Win32 {
        [DllImport("user32.dll", CharSet = CharSet.Unicode)]
        public static extern int MessageBox(int hWnd, String text,
            String caption, uint type);
    }

    public class AClass {
        // Add some attributes to Win32CallMethod.
        [Obsolete("This method is obsolete. Use managed MsgBox
instead.")]
        [Unmanaged(UnmanagedType.User)]
        public void Win32CallMethod()
        {
            Win32.MessageBox(0, "This is an unmanaged call.", "Caution!",
0);
        }
    }

    class DemoClass {
        static void Main(string[] args)
            {
            // Get the AClass type to access its metadata.
            Type clsType = typeof(AClass);
            // Get the type information for Win32CallMethod.
            MethodInfo mInfo = clsType.GetMethod("Win32CallMethod");
            if (mInfo != null)
            {
                // Iterate through all the attributes of the method.
                foreach(Attribute attr in
                    Attribute.GetCustomAttributes(mInfo)) {
                    // Check for the Obsolete attribute.
                    if (attr.GetType() == typeof(ObsoleteAttribute))
                    {
                        Console.WriteLine("Method {0} is obsolete. " +
                            "The message is:",
                            mInfo.Name);
                        Console.WriteLine("  \"{0}\"",
                            ((ObsoleteAttribute)attr).Message);
```

```
                    }

                    // Check for the Unmanaged attribute.
                    else if (attr.GetType() ==
typeof(UnmanagedAttribute))
                    {
                        Console.WriteLine(
                            "This method calls unmanaged code.");
                        Console.WriteLine(
                            String.Format("The Unmanaged attribute type
is {0}.",

((UnmanagedAttribute)attr).Win32Type));
                        AClass myCls = new AClass();
                        myCls.Win32CallMethod();
                    }
                }
            }
        }
    }
}

/*

This code example produces the following results.

First, the compilation yields the warning, "... This method is
obsolete. Use managed MsgBox instead."
Second, execution yields a message box with a title of "Caution!"
and message text of "This is an unmanaged call."
Third, the following text is displayed in the console window:

Method Win32CallMethod is obsolete. The message is:
  "This method is obsolete. Use managed MsgBox instead."
This method calls unmanaged code.
The Unmanaged attribute type is User.

*/
```

Remarks

The return value contains the custom attributes for ancestors of `element`.

> **Note**
>
> Starting with the .NET Framework version 2.0, this method returns security attributes on methods, constructors, and types if the attributes are stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions

of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

GetCustomAttributes(Assembly)

Retrieves an array of the custom attributes applied to an assembly. A parameter specifies the assembly.

C#

```
public static Attribute[] GetCustomAttributes (System.Reflection.Assembly
element);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` is `null`.

Examples

The following example retrieves the custom attributes found in the current assembly.

C#

```
using System;
using System.Reflection;

[assembly: AssemblyTitle("CustAttrs1CS")]
[assembly: AssemblyDescription("GetCustomAttributes() Demo")]
[assembly: AssemblyCompany("Microsoft")]

class Example {
    static void Main() {
        // Get the Assembly object to access its metadata.
        Assembly assy = typeof(Example).Assembly;

        // Iterate through the attributes for the assembly.
        foreach(Attribute attr in Attribute.GetCustomAttributes(assy)) {
            // Check for the AssemblyTitle attribute.
            if (attr.GetType() == typeof(AssemblyTitleAttribute))
                Console.WriteLine("Assembly title is \"{0}\".",
                    ((AssemblyTitleAttribute)attr).Title);

            // Check for the AssemblyDescription attribute.
            else if (attr.GetType() ==
                typeof(AssemblyDescriptionAttribute))
                Console.WriteLine("Assembly description is \"{0}\".",
                    ((AssemblyDescriptionAttribute)attr).Description);

            // Check for the AssemblyCompany attribute.
            else if (attr.GetType() == typeof(AssemblyCompanyAttribute))
                Console.WriteLine("Assembly company is {0}.",
                    ((AssemblyCompanyAttribute)attr).Company);
        }
    }
}
// The example displays the following output:
//     Assembly title is "CustAttrs1CS".
//     Assembly description is "GetCustomAttributes() Demo".
//     Assembly company is Microsoft.
```

Remarks

ⓘ Note

Starting with the .NET Framework version 2.0, this method returns security attributes if the attributes are stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. GetCustomAttributes(Module, Boolean)

Retrieves an array of the custom attributes applied to a module. Parameters specify the module, and an ignored search option.

C#

```
public static Attribute[] GetCustomAttributes (System.Reflection.Module
element, bool inherit);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Attribute[]

An Attribute array that contains the custom attributes applied to `element`, or an empty array if no such custom attributes exist.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

Examples

The following code example demonstrates the use of GetCustomAttributes, taking a Module as a parameter.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;

// Assign some attributes to the module.
[module:Description("A sample description")]

// Set the module's CLSCompliant attribute to false
// The CLSCompliant attribute is applicable for /target:module.
[module:CLSCompliant(false)]

namespace CustAttrs2CS {
    class DemoClass {
        static void Main(string[] args) {
            Type clsType = typeof(DemoClass);
            // Get the Module type to access its metadata.
            Module module = clsType.Module;

            // Iterate through all the attributes for the module.
            foreach(Attribute attr in
Attribute.GetCustomAttributes(module)) {
                // Check for the Description attribute.
                if (attr.GetType() == typeof(DescriptionAttribute))
                    Console.WriteLine("Module {0} has the description " +
                        "\"{1}\".", module.Name,
                        ((DescriptionAttribute)attr).Description);
                // Check for the CLSCompliant attribute.
                else if (attr.GetType() == typeof(CLSCompliantAttribute))
                    Console.WriteLine("Module {0} {1} CLSCompliant.",
                        module.Name,
                        ((CLSCompliantAttribute)attr).IsCompliant ?
                            "is" : "is not");
            }
        }
    }
```

```
}

/*
 * Output:
 * Module CustAttrs2CS.exe is not CLSCompliant.
 * Module CustAttrs2CS.exe has the description "A sample description".
 */
```

Remarks

The return value contains the custom attributes for ancestors of `element` if `inherit` is `true`.

Attribute.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Examples

The following code example illustrates the use of GetHashCode in the context of Attribute.

C#

```
using System;
using System.Reflection;
using System.Collections.Generic;

// A custom attribute to allow two authors per method.
public class AuthorsAttribute : Attribute
{
   protected string _authorName1;
   protected string _authorName2;

   public AuthorsAttribute(string name1, string name2)
   {
      _authorName1 = name1;
      _authorName2 = name2;
   }

   public string AuthorName1
```

```
    {
       get { return _authorName1; }
       set { _authorName1 = value; }
    }

    public string AuthorName2
    {
       get { return _authorName2; }
       set { _authorName2 = value; }
    }

    // Use the hash code of the string objects and xor them together.
    public override int GetHashCode()
    {
       return _authorName1.GetHashCode() ^ _authorName2.GetHashCode();
    }
}

// Provide the author names for each method of the class.
public class TestClass
{
  [Authors("Immanuel Kant", "Lao Tzu")]
  public void Method1()
  {}

  [Authors("Jean-Paul Sartre", "Friedrich Nietzsche")]
  public void Method2()
  {}

  [Authors("Immanuel Kant", "Lao Tzu")]
  public void Method3()
  {}

  [Authors("Jean-Paul Sartre", "Friedrich Nietzsche")]
  public void Method4()
  {}

  [Authors("Immanuel Kant", "Friedrich Nietzsche")]
  public void Method5()
  {}
}

class Example
{
    static void Main()
    {
       // Get the class type to access its metadata.
       Type clsType = typeof(TestClass);

       // Store author information in a list of tuples.
       var authorsInfo = new List<Tuple<String, AuthorsAttribute>>();

       // Iterate through all the methods of the class.
       foreach(var method in clsType.GetMethods())
       {
```

```
            // Get the Authors attribute for the method if it exists.
            AuthorsAttribute authAttr =
                (AuthorsAttribute)Attribute.GetCustomAttribute(
                method, typeof(AuthorsAttribute));
            if (authAttr != null)
               // Add the information to the author list.
               authorsInfo.Add(Tuple.Create(clsType.Name + "." + method.Name,
                                            authAttr));
        }

        // Iterate through the list
        bool[] listed = new bool[authorsInfo.Count];
        Console.WriteLine("Method authors:\n");

        for (int ctr = 0; ctr < authorsInfo.Count; ctr++) {
           var authorInfo = authorsInfo[ctr];
           if (!listed[ctr]) {
               Console.WriteLine("{0} and {1}", authorInfo.Item2.AuthorName1,
                                                authorInfo.Item2.AuthorName2);
               listed[ctr] = true;
               Console.WriteLine("   {0}", authorInfo.Item1);
               for (int ctr2 = ctr + 1; ctr2 < authorsInfo.Count; ctr2++) {
                   if (!listed[ctr2])
                      if (authorInfo.Item2.Equals(authorsInfo[ctr2].Item2)) {
                         Console.WriteLine("   {0}", authorsInfo[ctr2].Item1);
                         listed[ctr2] = true;
                      }
               }
           }
        }
    }
}
// The example displays the following output:
//       Method authors:
//
//       Immanuel Kant and Lao Tzu
//          TestClass.Method1
//          TestClass.Method3
//       Jean-Paul Sartre and Friedrich Nietzsche
//          TestClass.Method2
//          TestClass.Method4
//       Immanuel Kant and Friedrich Nietzsche
//          TestClass.Method5
```

Attribute.IsDefaultAttribute Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class.

C#

```
public virtual bool IsDefaultAttribute ();
```

Returns

Boolean

`true` if this instance is the default attribute for the class; otherwise, `false`.

Examples

The following code example illustrates the use of IsDefaultAttribute.

C#

```
using System;
using System.Reflection;

namespace DefAttrCS
{
    // An enumeration of animals. Start at 1 (0 = uninitialized).
    public enum Animal
    {
        // Pets.
        Dog = 1,
        Cat,
        Bird,
    }

    // A custom attribute to allow a target to have a pet.
    public class AnimalTypeAttribute : Attribute
    {
```

```
        // The constructor is called when the attribute is set.
        public AnimalTypeAttribute(Animal pet)
        {
            thePet = pet;
        }

        // Provide a default constructor and make Dog the default.
        public AnimalTypeAttribute()
        {
            thePet = Animal.Dog;
        }

        // Keep a variable internally ...
        protected Animal thePet;

        // .. and show a copy to the outside world.
        public Animal Pet
        {
            get { return thePet; }
            set { thePet = Pet; }
        }

        // Override IsDefaultAttribute to return the correct response.
        public override bool IsDefaultAttribute()
        {
            if (thePet == Animal.Dog)
                return true;

            return false;
        }
    }

    public class TestClass
    {
        // Use the default constructor.
        [AnimalType]
        public void Method1()
        {}
    }

    class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get type information for the method.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // Get the AnimalType attribute for the method.
            AnimalTypeAttribute atAttr =
                (AnimalTypeAttribute)Attribute.GetCustomAttribute(mInfo,
                typeof(AnimalTypeAttribute));
            // Check to see if the default attribute is applied.
            Console.WriteLine("The attribute {0} for method {1} in class
{2}",
```

```
                atAttr.Pet, mInfo.Name, clsType.Name);
            Console.WriteLine("{0} the default for the AnimalType
attribute.",
                atAttr.IsDefaultAttribute() ? "is" : "is not");
        }
    }
}
```

Remarks

The default implementation of this class returns `false`, and must be implemented in the derived class to be useful to that class.

The implementation of this method in a derived class compares the value of this instance to a standard default value, then returns a Boolean value that indicates whether the value of this instance is equal to the standard value. The standard value is typically coded as a constant in the implementation, or stored programmatically in a field used by the implementation.

Attribute.IsDefined Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether any custom attributes of a specified type are applied to an assembly, module, type member, or method parameter.

Overloads

Expand table

IsDefined(ParameterInfo, Type, Boolean)	Determines whether any custom attributes are applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.
IsDefined(Module, Type, Boolean)	Determines whether any custom attributes are applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.
IsDefined(MemberInfo, Type, Boolean)	Determines whether any custom attributes are applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.
IsDefined(Assembly, Type, Boolean)	Determines whether any custom attributes are applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.
IsDefined(MemberInfo, Type)	Determines whether any custom attributes are applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.
IsDefined(Module, Type)	Determines whether any custom attributes of a specified type are applied to a module. Parameters specify the module, and the type of the custom attribute to search for.
IsDefined(Assembly, Type)	Determines whether any custom attributes are applied to an assembly. Parameters specify the assembly, and the type of the custom attribute to search for.

IsDefined(ParameterInfo, Type)	Determines whether any custom attributes are applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.

IsDefined(ParameterInfo, Type, Boolean)

Determines whether any custom attributes are applied to a method parameter. Parameters specify the method parameter, the type of the custom attribute to search for, and whether to search ancestors of the method parameter.

```
C#

public static bool IsDefined (System.Reflection.ParameterInfo element,
Type attributeType, bool inherit);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

ExecutionEngineException

`element` is not a method, constructor, or type.

Examples

The following code example illustrates the use of IsDefined, taking a ParameterInfo as a parameter.

C#

```
using System;
using System.Reflection;

namespace IsDef5CS
{
    public class TestClass
    {
        // Assign a ParamArray attribute to the parameter using the
keyword.
        public void Method1(params String[] args)
        {}
    }

    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get the MethodInfo object for Method1.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // Get the ParameterInfo array for the method parameters.
            ParameterInfo[] pInfo = mInfo.GetParameters();
            if (pInfo != null)
            {
                // See if the ParamArray attribute is defined.
                bool isDef = Attribute.IsDefined(pInfo[0],

typeof(ParamArrayAttribute));
                // Display the result.
                Console.WriteLine("The ParamArray attribute {0} defined
for " +
                                  "parameter {1} of method {2}.",
                                  isDef ? "is" : "is not",
                                  pInfo[0].Name,
                                  mInfo.Name);
            }
            else
                Console.WriteLine("The parameters information could " +
```

```
                                "not be retrieved for method {0}.",
mInfo.Name);
        }
    }
}

/*
 * Output:
 * The ParamArray attribute is defined for parameter args of method
Method1.
 */
```

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

IsDefined(Module, Type, Boolean)

Determines whether any custom attributes are applied to a module. Parameters specify the module, the type of the custom attribute to search for, and an ignored search option.

C#

```
public static bool IsDefined (System.Reflection.Module element, Type
attributeType, bool inherit);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example illustrates the use of IsDefined, taking a Module as a parameter.

C#

```
using System;
using System.Diagnostics;

// Add the Debuggable attribute to the module.
[module:Debuggable(true, false)]
namespace IsDef2CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // See if the Debuggable attribute is defined for this
module.
            bool isDef = Attribute.IsDefined(clsType.Module,
                typeof(DebuggableAttribute));
            // Display the result.
            Console.WriteLine("The Debuggable attribute {0} " +
                "defined for Module {1}.",
                isDef ? "is" : "is not",
                clsType.Module.Name);
```

```
            // If the attribute is defined, display the JIT settings.
            if (isDef)
            {
                // Retrieve the attribute itself.
                DebuggableAttribute dbgAttr = (DebuggableAttribute)
                    Attribute.GetCustomAttribute(clsType.Module,
                    typeof(DebuggableAttribute));
                if (dbgAttr != null)
                {
                    Console.WriteLine("JITTrackingEnabled is {0}.",
                        dbgAttr.IsJITTrackingEnabled);
                    Console.WriteLine("JITOptimizerDisabled is {0}.",
                        dbgAttr.IsJITOptimizerDisabled);
                }
                else
                    Console.WriteLine("The Debuggable attribute " +
                        "could not be retrieved.");
            }
        }
    }
}

/*
 * Output:
 * The Debuggable attribute is defined for Module IsDef2CS.exe.
 * JITTrackingEnabled is True.
 * JITOptimizerDisabled is False.
 */
```

Remarks

This method ignores the `inherit` parameter and does not search the ancestors of `element` for custom attributes.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

IsDefined(MemberInfo, Type, Boolean)

Determines whether any custom attributes are applied to a member of a type. Parameters specify the member, the type of the custom attribute to search for, and whether to search ancestors of the member.

```C#
public static bool IsDefined (System.Reflection.MemberInfo element, Type attributeType, bool inherit);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, type, or property member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

If `true`, specifies to also search the ancestors of `element` for custom attributes.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

Examples

The following code example illustrates the use of IsDefined, taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;

namespace IsDef4CS
{
    public class TestClass
    {
        // Assign the Obsolete attribute to a method.
        [Obsolete("This method is obsolete. Use Method2 instead.")]
        public void Method1()
        {}
        public void Method2()
        {}
    }

    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get the MethodInfo object for Method1.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // See if the Obsolete attribute is defined for this method.
            bool isDef = Attribute.IsDefined(mInfo,
typeof(ObsoleteAttribute));
            // Display the result.
            Console.WriteLine("The Obsolete Attribute {0} defined for {1}
of class {2}.",
                isDef ? "is" : "is not", mInfo.Name, clsType.Name);
            // If it's defined, display the attribute's message.
            if (isDef)
            {
                ObsoleteAttribute obsAttr =

(ObsoleteAttribute)Attribute.GetCustomAttribute(
                                                        mInfo,
typeof(ObsoleteAttribute));
                if (obsAttr != null)
                    Console.WriteLine("The message is: \"{0}\".",
                        obsAttr.Message);
                else
                    Console.WriteLine("The message could not be
retrieved.");
            }
        }
    }
}
```

```
/*
 * Output:
 * The Obsolete Attribute is defined for Method1 of class TestClass.
 * The message is: "This method is obsolete. Use Method2 instead.".
 */
```

Remarks

> **Note**
>
> Starting with the .NET Framework version 2.0, this method returns `true` if a type, method, or constructor has security attributes stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

IsDefined(Assembly, Type, Boolean)

Determines whether any custom attributes are applied to an assembly. Parameters specify the assembly, the type of the custom attribute to search for, and an ignored search option.

C#

```
public static bool IsDefined (System.Reflection.Assembly element, Type
attributeType, bool inherit);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

`inherit` Boolean

This parameter is ignored, and does not affect the operation of this method.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example illustrates the use of IsDefined, taking an Assembly as a parameter.

C#

```
using System;
using System.Reflection;

// Add an AssemblyDescription attribute
[assembly: AssemblyDescription("A sample description")]
namespace IsDef1CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
```

```
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // Get the assembly object.
            Assembly assy = clsType.Assembly;
            // Store the assembly's name.
            String assyName = assy.GetName().Name;
            // See if the Assembly Description is defined.
            bool isdef = Attribute.IsDefined(assy,
                typeof(AssemblyDescriptionAttribute));
            if (isdef)
            {
                // Affirm that the attribute is defined.
                Console.WriteLine("The AssemblyDescription attribute " +
                    "is defined for assembly {0}.", assyName);
                // Get the description attribute itself.
                AssemblyDescriptionAttribute adAttr =

(AssemblyDescriptionAttribute)Attribute.GetCustomAttribute(
                    assy, typeof(AssemblyDescriptionAttribute));
                // Display the description.
                if (adAttr != null)
                    Console.WriteLine("The description is \"{0}\".",
                        adAttr.Description);
                else
                    Console.WriteLine("The description could not " +
                        "be retrieved.");
            }
            else
                Console.WriteLine("The AssemblyDescription attribute is

.NET Standard	2.0, 2.1

IsDefined(MemberInfo, Type)

Determines whether any custom attributes are applied to a member of a type. Parameters specify the member, and the type of the custom attribute to search for.

C#

```
public static bool IsDefined (System.Reflection.MemberInfo element, Type
attributeType);
```

Parameters

`element` MemberInfo

An object derived from the MemberInfo class that describes a constructor, event, field, method, type, or property member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

NotSupportedException

`element` is not a constructor, method, property, event, type, or field.

Examples

The following code example illustrates the use of IsDefined, taking a MemberInfo as a parameter.

C#

```
using System;
using System.Reflection;

namespace IsDef4CS
{
    public class TestClass
    {
        // Assign the Obsolete attribute to a method.
        [Obsolete("This method is obsolete. Use Method2 instead.")]
        public void Method1()
        {}
        public void Method2()
        {}
    }

    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get the MethodInfo object for Method1.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // See if the Obsolete attribute is defined for this method.
            bool isDef = Attribute.IsDefined(mInfo,
typeof(ObsoleteAttribute));
            // Display the result.
            Console.WriteLine("The Obsolete Attribute {0} defined for {1}
of class {2}.",
                isDef ? "is" : "is not", mInfo.Name, clsType.Name);
            // If it's defined, display the attribute's message.
            if (isDef)
```

```
            {
                ObsoleteAttribute obsAttr =

(ObsoleteAttribute)Attribute.GetCustomAttribute(
                                                        mInfo,
typeof(ObsoleteAttribute));
                if (obsAttr != null)
                    Console.WriteLine("The message is: \"{0}\".",
                        obsAttr.Message);
                else
                    Console.WriteLine("The message could not be
retrieved.");
            }
        }
    }
}

/*
 * Output:
 * The Obsolete Attribute is defined for Method1 of class TestClass.
 * The message is: "This method is obsolete. Use Method2 instead.".
 */
```

Remarks

The ancestors of `element` are searched for custom attributes.

IsDefined(Module, Type)

Determines whether any custom attributes of a specified type are applied to a module. Parameters specify the module, and the type of the custom attribute to search for.

C#

```
public static bool IsDefined (System.Reflection.Module element, Type
attributeType);
```

Parameters

`element` Module

An object derived from the Module class that describes a portable executable file.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example illustrates the use of IsDefined, taking a Module as a parameter.

C#

```
using System;
using System.Diagnostics;

// Add the Debuggable attribute to the module.
[module:Debuggable(true, false)]
namespace IsDef2CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // See if the Debuggable attribute is defined for this
module.
            bool isDef = Attribute.IsDefined(clsType.Module,
                typeof(DebuggableAttribute));
            // Display the result.
            Console.WriteLine("The Debuggable attribute {0} " +
                "defined for Module {1}.",
                isDef ? "is" : "is not",
                clsType.Module.Name);
            // If the attribute is defined, display the JIT settings.
            if (isDef)
            {
                // Retrieve the attribute itself.
                DebuggableAttribute dbgAttr = (DebuggableAttribute)
                    Attribute.GetCustomAttribute(clsType.Module,
                    typeof(DebuggableAttribute));
                if (dbgAttr != null)
                {
                    Console.WriteLine("JITTrackingEnabled is {0}.",
                        dbgAttr.IsJITTrackingEnabled);
                    Console.WriteLine("JITOptimizerDisabled is {0}.",
                        dbgAttr.IsJITOptimizerDisabled);
                }
                else
                    Console.WriteLine("The Debuggable attribute " +
                        "could not be retrieved.");
            }
        }
    }
}

/*
 * Output:
 * The Debuggable attribute is defined for Module IsDef2CS.exe.
 * JITTrackingEnabled is True.
```

```
  * JITOptimizerDisabled is False.
  */
```

Remarks

The ancestors of `element` are not searched for custom attributes.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

IsDefined(Assembly, Type)

Determines whether any custom attributes are applied to an assembly. Parameters specify the assembly, and the type of the custom attribute to search for.

C#

```
public static bool IsDefined (System.Reflection.Assembly element, Type
attributeType);
```

Parameters

`element` Assembly

An object derived from the Assembly class that describes a reusable collection of modules.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example illustrates the use of IsDefined, taking an Assembly as a parameter.

C#

```
using System;
using System.Reflection;

// Add an AssemblyDescription attribute
[assembly: AssemblyDescription("A sample description")]
namespace IsDef1CS
{
    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(DemoClass);
            // Get the assembly object.
            Assembly assy = clsType.Assembly;
            // Store the assembly's name.
            String assyName = assy.GetName().Name;
            // See if the Assembly Description is defined.
            bool isdef = Attribute.IsDefined(assy,
                typeof(AssemblyDescriptionAttribute));
            if (isdef)
            {
                // Affirm that the attribute is defined.
                Console.WriteLine("The AssemblyDescription attribute " +
                    "is defined for assembly {0}.", assyName);
                // Get the description attribute itself.
                AssemblyDescriptionAttribute adAttr =

(AssemblyDescriptionAttribute)Attribute.GetCustomAttribute(
                    assy, typeof(AssemblyDescriptionAttribute));
                // Display the description.
```

```
                if (adAttr != null)
                    Console.WriteLine("The description is \"{0}\".",
                        adAttr.Description);
                else
                    Console.WriteLine("The description could not " +
                        "be retrieved.");
            }
            else
                Console.WriteLine("The AssemblyDescription attribute is
not " +
                    "defined for assembly {0}.", assyName);
        }
    }
}

/*
 * Output:
 * The AssemblyDescription attribute is defined for assembly IsDef1CS.
 * The description is "A sample description".
 */
```

Remarks

> **Note**
>
> Starting with the .NET Framework version 2.0, this method returns `true` if the assembly has security attributes stored in the new metadata format. Assemblies compiled with version 2.0 or later use the new format. Dynamic assemblies and assemblies compiled with earlier versions of the .NET Framework use the old XML format. See **Emitting Declarative Security Attributes**.

.NET Standard	2.0, 2.1

IsDefined(ParameterInfo, Type)

Determines whether any custom attributes are applied to a method parameter. Parameters specify the method parameter, and the type of the custom attribute to search for.

```
C#

public static bool IsDefined (System.Reflection.ParameterInfo element,
Type attributeType);
```

Parameters

`element` ParameterInfo

An object derived from the ParameterInfo class that describes a parameter of a member of a class.

`attributeType` Type

The type, or a base type, of the custom attribute to search for.

Returns

Boolean

`true` if a custom attribute of type `attributeType` is applied to `element`; otherwise, `false`.

Exceptions

ArgumentNullException

`element` or `attributeType` is `null`.

ArgumentException

`attributeType` is not derived from Attribute.

Examples

The following code example illustrates the use of IsDefined, taking a ParameterInfo as a parameter.

```
C#

using System;
using System.Reflection;
```

```
namespace IsDef5CS
{
    public class TestClass
    {
        // Assign a ParamArray attribute to the parameter using the
keyword.
        public void Method1(params String[] args)
        {}
    }

    public class DemoClass
    {
        static void Main(string[] args)
        {
            // Get the class type to access its metadata.
            Type clsType = typeof(TestClass);
            // Get the MethodInfo object for Method1.
            MethodInfo mInfo = clsType.GetMethod("Method1");
            // Get the ParameterInfo array for the method parameters.
            ParameterInfo[] pInfo = mInfo.GetParameters();
            if (pInfo != null)
            {
                // See if the ParamArray attribute is defined.
                bool isDef = Attribute.IsDefined(pInfo[0],

typeof(ParamArrayAttribute));
                // Display the result.
                Console.WriteLine("The ParamArray attribute {0} defined
for " +
                                  "parameter {1} of method {2}.",
                                  isDef ? "is" : "is not",
                                  pInfo[0].Name,
                                  mInfo.Name);
            }
            else
                Console.WriteLine("The parameters information could " +
                            "not be retrieved for method {0}.",
mInfo.Name);
        }
    }
}

/*
 * Output:
 * The ParamArray attribute is defined for parameter args of method
Method1.
 */
```

Remarks

The ancestors of `element` are searched for custom attributes.

Attribute.Match(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns a value that indicates whether this instance equals a specified object.

```
C#
public virtual bool Match (object? obj);
```

Parameters

obj Object

An Object to compare with this instance of Attribute.

Returns

Boolean

`true` if this instance equals `obj`; otherwise, `false`.

Remarks

This method determines if one Attribute equals another. Its default implementation is the same as Equals, which determines whether two attributes are of the same type and have the same field values.

In general, the Equals method is intended to perform a standard test for reference or value equality. You can override the Match method when you want to perform a custom comparison for equality that is based on some criteria other than that two attribute instances are of the same type and have identical values. For example, you can override the Match method to compare attributes in the following scenarios:

- An attribute includes a bit field, and you consider two attribute instances equal if a particular bit is set. For example, a `NumericDisplay` attribute might include a bit

field that indicates what numeric formats (such as binary, octal, decimal, and hexadecimal) a client supports. The overridden Match method might consider two instances equal if they support the same numeric format.

- An attribute includes multiple fields that contain the same kind of information, or it contains an array in which values can be in any order. For example, an `Author` attribute might include multiple fields for author names. The overridden Match method might consider two instances equal if they have the same authors regardless of whether each field is equal to the corresponding field.

Example

The following example illustrates the use of Match to create a custom comparison method for attribute values. If defines an `AuthorsAttribute` that internally contains a `List<String>` that stores authors' names. Because the names can occur in any order in the list, it overrides the Match method to compare author names regardless of their position in the list. Note the Equals method, which performs a test for value equality, returns different results from the Match method.

C#

```
using System;
using System.Collections.Generic;
using System.Reflection;

// A custom attribute to allow multiple authors per method.
[AttributeUsage(AttributeTargets.Method)]
public class AuthorsAttribute : Attribute
{
   protected List<string> _authors;

    public AuthorsAttribute(params string[] names)
   {
      _authors = new List<string>(names);
    }

   public List<string> Authors
   {
       get { return _authors; }
   }

    // Determine if the object is a match to this one.
    public override bool Match(object obj)
   {
      // Return false if obj is null or not an AuthorsAttribute.
      AuthorsAttribute authors2 = obj as AuthorsAttribute;
      if (authors2 == null) return false;
```

```
        // Return true if obj and this instance are the same object
reference.
      if (Object.ReferenceEquals(this, authors2))
         return true;

      // Return false if obj and this instance have different numbers of
authors
      if (_authors.Count != authors2._authors.Count)
         return false;

      bool matches = false;
      foreach (var author in _authors)
      {
         for (int ctr = 0; ctr < authors2._authors.Count; ctr++)
         {
            if (author == authors2._authors[ctr])
            {
               matches = true;
               break;
            }
            if (ctr == authors2._authors.Count)
            {
               matches = false;
            }
         }
      }
      return matches;
   }

   public override string ToString()
   {
      string retval = "";
      for (int ctr = 0; ctr < _authors.Count; ctr++)
      {
         retval += $"{_authors[ctr]}{(ctr < _authors.Count - 1 ? ", " :
String.Empty)}";
      }
      if (retval.Trim().Length == 0)
      {
         return "<unknown>";
      }
      return retval;
   }
}

// Add some authors to methods of a class.
public class TestClass {
    [Authors("Leo Tolstoy", "John Milton")]
    public void Method1()
    {}

    [Authors("Anonymous")]
    public void Method2()
    {}
```

```
    [Authors("Leo Tolstoy", "John Milton", "Nathaniel Hawthorne")]
    public void Method3()
    {}

    [Authors("John Milton", "Leo Tolstoy")]
    public void Method4()
    {}
}

class Example
{
    static void Main()
   {
        // Get the type for TestClass to access its metadata.
        Type clsType = typeof(TestClass);

        // Iterate through each method of the class.
      AuthorsAttribute authors = null;
        foreach(var method in clsType.GetMethods())
      {
            // Check each method for the Authors attribute.
            AuthorsAttribute authAttr = (AuthorsAttribute)
Attribute.GetCustomAttribute(method,
                                          typeof(AuthorsAttribute));
            if (authAttr != null)
         {
            // Display the authors.
                Console.WriteLine($"{clsType.Name}.{method.Name} was
authored by {authAttr}.");

            // Select Method1's authors as the basis for comparison.
            if (method.Name == "Method1")
            {
                   authors = authAttr;
               Console.WriteLine();
               continue;
            }

            // Compare first authors with the authors of this method.
            if (authors.Match(authAttr))
            {
                    Console.WriteLine("TestClass.Method1 was also authored
by the same team.");
            }

            // Perform an equality comparison of the two attributes.
            Console.WriteLine($"{authors} {(authors.Equals(authAttr) ? "=" :
"<>")} {authAttr}");
            Console.WriteLine();
            }
        }
    }
}
// The example displays the following output:
//       TestClass.Method1 was authored by Leo Tolstoy, John Milton.
```

```
//
//       TestClass.Method2 was authored by Anonymous.
//       Leo Tolstoy, John Milton <> Anonymous
//
//       TestClass.Method3 was authored by Leo Tolstoy, John Milton,
Nathaniel Hawthorne.
//       Leo Tolstoy, John Milton <> Leo Tolstoy, John Milton, Nathaniel
Hawthorne
//
//       TestClass.Method4 was authored by John Milton, Leo Tolstoy.
//       TestClass.Method1 was also authored by the same team.
//       Leo Tolstoy, John Milton <> John Milton, Leo Tolstoy
```

AttributeTargets Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the application elements on which it is valid to apply an attribute.

This enumeration supports a bitwise combination of its member values.

C#

```
[System.Flags]
public enum AttributeTargets
```

Inheritance Object → ValueType → Enum → AttributeTargets

Attributes FlagsAttribute

Fields

Expand table

All	32767	Attribute can be applied to any application element.
Assembly	1	Attribute can be applied to an assembly.
Class	4	Attribute can be applied to a class.
Constructor	32	Attribute can be applied to a constructor.
Delegate	4096	Attribute can be applied to a delegate.
Enum	16	Attribute can be applied to an enumeration.
Event	512	Attribute can be applied to an event.
Field	256	Attribute can be applied to a field.
GenericParameter	16384	Attribute can be applied to a generic parameter. Currently, this attribute can be applied only in C#, Microsoft intermediate language

		(MSIL), and emitted code.
Interface	1024	Attribute can be applied to an interface.
Method	64	Attribute can be applied to a method.
Module	2	Attribute can be applied to a module. `Module` refers to a portable executable file (.dll or.exe) and not a Visual Basic standard module.
Parameter	2048	Attribute can be applied to a parameter.
Property	128	Attribute can be applied to a property.
ReturnValue	8192	Attribute can be applied to a return value.
Struct	8	Attribute can be applied to a structure; that is, a value type.

Examples

The following example illustrates the application of attributes to various targets.

> **Note**
>
> Visual Basic and Visual C++ syntax currently do not support the application of attributes to type parameters.

C#

```
using System;

namespace AttTargsCS {
    // This attribute is only valid on a class.
    [AttributeUsage(AttributeTargets.Class)]
    public class ClassTargetAttribute : Attribute {
    }

    // This attribute is only valid on a method.
    [AttributeUsage(AttributeTargets.Method)]
    public class MethodTargetAttribute : Attribute {
    }

    // This attribute is only valid on a constructor.
    [AttributeUsage(AttributeTargets.Constructor)]
    public class ConstructorTargetAttribute : Attribute {
    }

    // This attribute is only valid on a field.
    [AttributeUsage(AttributeTargets.Field)]
    public class FieldTargetAttribute : Attribute {
```

```
    }

    // This attribute is valid on a class or a method.
    [AttributeUsage(AttributeTargets.Class|AttributeTargets.Method)]
    public class ClassMethodTargetAttribute : Attribute {
    }

    // This attribute is valid on a generic type parameter.
    [AttributeUsage(AttributeTargets.GenericParameter)]
    public class GenericParameterTargetAttribute : Attribute {
    }

    // This attribute is valid on any target.
    [AttributeUsage(AttributeTargets.All)]
    public class AllTargetsAttribute : Attribute {
    }

    [ClassTarget]
    [ClassMethodTarget]
    [AllTargets]
    public class TestClassAttribute {
        [ConstructorTarget]
        [AllTargets]
        TestClassAttribute() {
        }

        [MethodTarget]
        [ClassMethodTarget]
        [AllTargets]
        public void Method1() {
        }

        [FieldTarget]
        [AllTargets]
        public int myInt;

        public void GenericMethod<
            [GenericParameterTarget, AllTargets] T>(T x) {
        }

        static void Main(string[] args) {
        }
    }
}
```

Remarks

The AttributeUsageAttribute class uses this enumeration to specify the kind of element on which it is valid to apply an attribute.

AttributeTargets enumeration values can be combined with a bitwise OR operation to get the preferred combination.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

AttributeUsageAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the usage of another attribute class. This class cannot be inherited.

C#

```
[System.AttributeUsage(System.AttributeTargets.Class, Inherited=true)]
public sealed class AttributeUsageAttribute : Attribute
```

Inheritance Object → Attribute → AttributeUsageAttribute

Attributes AttributeUsageAttribute

Remarks

When you are defining your own attribute class, you can control the manner in which it is used by placing an AttributeUsageAttribute on your attribute class. The indicated attribute class must derive from Attribute, either directly or indirectly.

Attribute classes have positional and named parameters. Each public constructor for an attribute class defines a valid sequence of positional parameters for that class. Named parameters are defined by the non-static, public, and read-write fields or properties of the attribute class.

The three properties of AttributeUsageAttribute are set by defining the following parameters:

- ValidOn

This positional parameter specifies the program elements that the indicated attribute can be placed on. The set of all possible elements that you can place an attribute on is listed in the AttributeTargets enumeration. You can combine several AttributeTargets values using a bitwise OR operation to get the desired combination of valid program elements.

- AllowMultiple

This named parameter specifies whether the indicated attribute can be specified more than once for a given program element.

- Inherited

This named parameter specifies whether the indicated attribute can be inherited by derived classes and overriding members.

For more information about using attributes, see Attribute and Attributes.

Constructors

Expand table

AttributeUsageAttribute(AttributeTargets)	Initializes a new instance of the AttributeUsageAttribute class with the specified list of AttributeTargets, the AllowMultiple value, and the Inherited value.

Properties

Expand table

AllowMultiple	Gets or sets a Boolean value indicating whether more than one instance of the indicated attribute can be specified for a single program element.
Inherited	Gets or sets a Boolean value that determines whether the indicated attribute is inherited by derived classes and overriding members.
TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)
ValidOn	Gets a set of values identifying which program elements that the indicated attribute can be applied to.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)

GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

AttributeUsage Attribute(AttributeTargets) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the AttributeUsageAttribute class with the specified list of AttributeTargets, the AllowMultiple value, and the Inherited value.

C#

```
public AttributeUsageAttribute (AttributeTargets validOn);
```

Parameters

validOn AttributeTargets

The set of values combined using a bitwise OR operation to indicate which program elements are valid.

Examples

The definition of the DispId attribute illustrates the use of a bitwise OR operation to combine several AttributeTargets values.

C#

```
namespace System.Runtime.InteropServices
{
   [AttributeUsage(AttributeTargets.Method | AttributeTargets.Field |
    AttributeTargets.Property)]
   public class DispIdAttribute: System.Attribute
   {
      public DispIdAttribute(int value) {
        // . . .
      }

      public int Value {
         get {
            // . . .
```

```
            return 0;
        }
    }
  }
}
```

Remarks

You can combine several AttributeTargets values using a bitwise OR operation to get the desired combination of valid program elements.

For default property values, see the ValidOn, AllowMultiple, and Inherited properties.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

AttributeUsageAttribute.AllowMultiple Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets a Boolean value indicating whether more than one instance of the indicated attribute can be specified for a single program element.

```
C#
public bool AllowMultiple { get; set; }
```

Property Value

Boolean

`true` if more than one instance is allowed to be specified; otherwise, `false`. The default is `false`.

Remarks

An attribute that can be specified more than once for a program element is called a multi-use attribute. An attribute that can be specified only once is called a single-use attribute.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

AttributeUsageAttribute.Inherited Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets a Boolean value that determines whether the indicated attribute is inherited by derived classes and overriding members.

```
C#
public bool Inherited { get; set; }
```

Property Value

Boolean

`true` if the attribute can be inherited by derived classes and overriding members; otherwise, `false`. The default is `true`.

Examples

The following example illustrates the difference between an attribute to which an AttributeUsageAttribute attribute with an Inherited property value of `true` is applied and one to which AttributeUsageAttribute attribute with an Inherited property value of `false` is applied. The example defines two attributes, `InheritedAttribute` and `NotInheritedAttribute`. Both attributes can apply to classes and methods. Because the Inherited property of the AttributeUsageAttribute attribute applied to `InheritedAttribute` is `true`, it is inherited by derived classes and the members of derived classes that override the base class method. On the other hand, because the Inherited property of the AttributeUsageAttribute attribute applied to `NotInheritedAttribute` is `false`, it is not inherited by derived classes and the members of derived classes that override the base class method.

```
C#
```

```
[AttributeUsage(AttributeTargets.Class | AttributeTargets.Method |
                AttributeTargets.Property | AttributeTargets.Field,
                Inherited = true)]
public class InheritedAttribute : Attribute
{ }

[AttributeUsage(AttributeTargets.Class | AttributeTargets.Method |
                AttributeTargets.Property | AttributeTargets.Field,
                Inherited = false)]
public class NotInheritedAttribute : Attribute
{ }
```

The example then defines two base classes. The first, `BaseA`, has a single method, `MethodA`. The second, `BaseB`, has a single method, `MethodB`. `BaseA` and `MethodA` are tagged with the `InheritedAttribute` attribute, and `BaseB` and `MethodB` are tagged with the `NotInheritedAttribute` attribute. `DerivedA` inherits from `BaseA` and overrides its `MethodA` method. `DerivedB` inherits from `BaseB` and overrides its `MethodB` method.

C#

```
using System;
using System.Reflection;

[InheritedAttribute]
public class BaseA
{
    [InheritedAttribute]
    public virtual void MethodA()
    { }
}

public class DerivedA : BaseA
{
    public override void MethodA()
    { }
}

[NotInheritedAttribute]
public class BaseB
{
    [NotInheritedAttribute]
    public virtual void MethodB()
    { }
}

public class DerivedB : BaseB
{
    public override void MethodB()
    { }
}
```

```
public class Example
{
    public static void Main()
    {
        Type typeA = typeof(DerivedA);
        Console.WriteLine($"DerivedA has Inherited attribute:
{typeA.GetCustomAttributes(typeof(InheritedAttribute), true).Length > 0}");
        MethodInfo memberA = typeA.GetMethod(nameof(DerivedA.MethodA));
        Console.WriteLine($"DerivedA.MemberA has Inherited attribute:
{memberA.GetCustomAttributes(typeof(InheritedAttribute), true).Length >
0}\n");

        Type typeB = typeof(DerivedB);
        Console.WriteLine($"DerivedB has NotInherited attribute:
{typeB.GetCustomAttributes(typeof(NotInheritedAttribute), true).Length >
0}");
        MethodInfo memberB = typeB.GetMethod(nameof(DerivedB.MethodB));
        Console.WriteLine($"DerivedB.MemberB has NotInherited attribute:
{memberB.GetCustomAttributes(typeof(NotInheritedAttribute), true).Length >
0}");
    }
}
// The example displays the following output:
//       DerivedA has Inherited attribute: True
//       DerivedA.MemberA has Inherited attribute: True
//
//       DerivedB has NotInherited attribute: False
//       DerivedB.MemberB has NotInherited attribute: False
```

As the output from the example shows, `DerivedA` and `DerivedA.MethodA` inherit the `InheritedAttribute` attribute, but `DerivedB` and `DerivedB.MethodB` do not inherit the `NotInheritedAttribute` attribute.

Remarks

The Inherited property determines:

- Whether classes derived from a base class tagged with the attribute to which the AttributeUsageAttribute attribute is applied inherit that attribute.
- Whether methods of derived classes that override a base class method tagged with the attribute to which the AttributeUsageAttribute attribute is applied inherit that attribute. (If a class inherits a base class member, it also inherits any attributes applied to that member.)

BadImageFormatException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when the file image of a dynamic link library (DLL) or an executable program is invalid.

C#

```
public class BadImageFormatException : SystemException
```

Inheritance Object → Exception → SystemException → BadImageFormatException

Remarks

This exception is thrown when the file format of a dynamic link library (.dll file) or an executable (.exe file) doesn't conform to the format that the common language runtime expects. In particular, the exception is thrown under the following conditions:

- An earlier version of a .NET utility, such as ILDasm.exe or installutil.exe, is used with an assembly that was developed with a later version of .NET.

  To address this exception, use the version of the tool that corresponds to the version of .NET that was used to develop the assembly. This may require modifying the `Path` environment variable or providing a fully qualified path to the correct executable.

- You are trying to load an unmanaged dynamic link library or executable (such as a Windows system DLL) as if it were a .NET assembly. The following example illustrates this by using the Assembly.LoadFile method to load Kernel32.dll.

  C#

  ```
  // Windows DLL (non-.NET assembly)
  string filePath = Environment.ExpandEnvironmentVariables("%windir%");
  if (! filePath.Trim().EndsWith(@"\"))
     filePath += @"\";
  filePath += @"System32\Kernel32.dll";
  ```

```
try {
   Assembly assem = Assembly.LoadFile(filePath);
}
catch (BadImageFormatException e) {
   Console.WriteLine("Unable to load {0}.", filePath);
   Console.WriteLine(e.Message.Substring(0,
                     e.Message.IndexOf(".") + 1));
}
// The example displays an error message like the following:
//       Unable to load C:\WINDOWS\System32\Kernel32.dll.
//       The module was expected to contain an assembly manifest.
```

To address this exception, access the methods defined in the DLL by using the features provided by your development language, such as the `Declare` statement in Visual Basic or the DllImportAttribute attribute with the `extern` keyword in C# and F#.

- You are trying to load a reference assembly in a context other than the reflection-only context. You can address this issue in either of two ways:
  - You can load the implementation assembly rather than the reference assembly.
  - You can load the reference assembly in the reflection-only context by calling the Assembly.ReflectionOnlyLoad method.

- A DLL or executable is loaded as a 64-bit assembly, but it contains 32-bit features or resources. For example, it relies on COM interop or calls methods in a 32-bit dynamic link library.

  To address this exception, set the project's **Platform target** property to x86 (instead of x64 or AnyCPU) and recompile.

- Your application's components were created using different versions of .NET. Typically, this exception occurs when an application or component that was developed using the .NET Framework 1.0 or the .NET Framework 1.1 tries to load an assembly that was developed using the .NET Framework 2.0 SP1 or later, or when an application that was developed using the .NET Framework 2.0 SP1 or .NET Framework 3.5 tries to load an assembly that was developed using the .NET Framework 4 or later. The BadImageFormatException may be reported as a compile-time error, or the exception may be thrown at run time. The following example defines a `StringLib` class that has a single member, `ToProperCase`, and that resides in an assembly named StringLib.dll.

```
C#
```

```
using System;

public class StringLib
{
   private string[] exceptionList = { "a", "an", "the", "in", "on",
"of" };
   private char[] separators = { ' ' };

   public string ToProperCase(string title)
   {
      bool isException = false;

      string[] words = title.Split( separators,
StringSplitOptions.RemoveEmptyEntries);
      string[] newWords = new string[words.Length];

      for (int ctr = 0; ctr <= words.Length - 1; ctr++)
      {
         isException = false;

         foreach (string exception in exceptionList)
         {
            if (words[ctr].Equals(exception) && ctr > 0)
            {
               isException = true;
               break;
            }
         }

         if (! isException)
            newWords[ctr] = words[ctr].Substring(0, 1).ToUpper() +
words[ctr].Substring(1);
         else
            newWords[ctr] = words[ctr];
      }
      return string.Join(" ", newWords);
   }
}
// Attempting to load the StringLib.dll assembly produces the following
output:
//    Unhandled Exception: System.BadImageFormatException:
//                         The format of the file 'StringLib.dll' is
invalid.
```

The following example uses reflection to load an assembly named StringLib.dll. If the source code is compiled with a .NET Framework 1.1 compiler, a BadImageFormatException is thrown by the Assembly.LoadFrom method.

C#

```
using System;
using System.Reflection;
```

```
public class Example
{
   public static void Main()
   {
      string title = "a tale of two cities";
//      object[] args = { title}
      // Load assembly containing StateInfo type.
      Assembly assem = Assembly.LoadFrom(@".\StringLib.dll");
      // Get type representing StateInfo class.
      Type stateInfoType = assem.GetType("StringLib");
      // Get Display method.
      MethodInfo mi = stateInfoType.GetMethod("ToProperCase");
      // Call the Display method.
      string properTitle = (string) mi.Invoke(null, new object[] {
title } );
      Console.WriteLine(properTitle);
   }
}
```

To address this exception, make sure that the assembly whose code is executing and that throws the exception, and the assembly to be loaded, both target compatible versions of .NET.

- The components of your application target different platforms. For example, you are trying to load ARM assemblies in an x86 application. You can use the following command-line utility to determine the target platforms of individual .NET assemblies. The list of files should be provided as a space-delimited list at the command line.

C#

```
using System;
using System.IO;
using System.Reflection;

public class Example
{
   public static void Main()
   {
      String[] args = Environment.GetCommandLineArgs();
      if (args.Length == 1) {
         Console.WriteLine("\nSyntax:   PlatformInfo <filename>\n");
         return;
      }
      Console.WriteLine();

      // Loop through files and display information about their
platform.
      for (int ctr = 1; ctr < args.Length; ctr++) {
         string fn = args[ctr];
```

```
            if (! File.Exists(fn)) {
               Console.WriteLine("File: {0}", fn);
               Console.WriteLine("The file does not exist.\n");
            }
            else {
               try {
                  AssemblyName an = AssemblyName.GetAssemblyName(fn);
                  Console.WriteLine("Assembly: {0}", an.Name);
                  if (an.ProcessorArchitecture ==
ProcessorArchitecture.MSIL)
                     Console.WriteLine("Architecture: AnyCPU");
                  else
                     Console.WriteLine("Architecture: {0}",
an.ProcessorArchitecture);

                  Console.WriteLine();
               }
               catch (BadImageFormatException) {
                  Console.WriteLine("File: {0}", fn);
                  Console.WriteLine("Not a valid assembly.\n");
               }
            }
         }
      }
   }
```

- Reflecting on C++ executable files may throw this exception. This is most likely caused by the C++ compiler stripping the relocation addresses or the .Reloc section from the executable file. To preserve the .relocation address in a C++ executable file, specify /fixed:no when linking.

BadImageFormatException uses the HRESULT `COR_E_BADIMAGEFORMAT`, which has the value 0x8007000B.

For a list of initial property values for an instance of BadImageFormatException, see the BadImageFormatException constructors.

Constructors

Expand table

BadImageFormatException()	Initializes a new instance of the BadImageFormatException class.
BadImageFormat Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the BadImageFormatException class with serialized data.

BadImageFormatException(String)	Initializes a new instance of the BadImageFormatException class with a specified error message.
BadImageFormatException(String, Exception)	Initializes a new instance of the BadImageFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.
BadImageFormatException(String, String)	Initializes a new instance of the BadImageFormatException class with a specified error message and file name.
BadImageFormatException(String, String, Exception)	Initializes a new instance of the BadImageFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
FileName	Gets the name of the file that causes this exception.
FusionLog	Gets the log file that describes why an assembly load failed.
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message and the name of the file that caused this exception.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the file name, assembly cache log, and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns the fully qualified name of this exception and possibly the error message, the name of the inner exception, and the stack trace.

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

BadImageFormatException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the BadImageFormatException class.

Overloads

Expand table

BadImageFormatException()	Initializes a new instance of the BadImageFormatException class.
BadImageFormatException(String)	Initializes a new instance of the BadImageFormatException class with a specified error message.
BadImageFormatException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the BadImageFormatException class with serialized data.
BadImageFormatException(String, Exception)	Initializes a new instance of the BadImageFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.
BadImageFormatException(String, String)	Initializes a new instance of the BadImageFormatException class with a specified error message and file name.
BadImageFormatException(String, String, Exception)	Initializes a new instance of the BadImageFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

BadImageFormatException()

Initializes a new instance of the BadImageFormatException class.

```
C#

public BadImageFormatException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Format of the executable or library is invalid." This message takes into account the current system culture.

The following table shows the initial property values for an instance of BadImageFormatException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

BadImageFormatException(String)

Initializes a new instance of the BadImageFormatException class with a specified error message.

```
C#
public BadImageFormatException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of BadImageFormatException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

BadImageFormatException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the BadImageFormatException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected BadImageFormatException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

BadImageFormatException(String, Exception)

Initializes a new instance of the BadImageFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public BadImageFormatException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of BadImageFormatException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

UWP	10.0

BadImageFormatException(String, String)

Initializes a new instance of the BadImageFormatException class with a specified error message and file name.

C#

```
public BadImageFormatException (string? message, string? fileName);
```

Parameters

`message` String

A message that describes the error.

`fileName` String

The full name of the file with the invalid image.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Expand table

Property	Value
FileName	The full name of the file with the invalid image.
Message	The error message string.

Applies to

BadImageFormatException.FileName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the file that causes this exception.

```
C#
public string? FileName { get; }
```

Property Value

String

The name of the file with the invalid image, or a null reference if no file name was passed to the constructor for the current instance.

Remarks

This property returns the name of the file supplied to the constructor for the current instance, if any. If the file name was not specified or is a null reference (`Nothing` in Visual Basic), this property returns a null reference.

This property is read-only.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

BadImageFormatException.FusionLog Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the log file that describes why an assembly load failed.

C#

```
public string? FusionLog { get; }
```

Property Value

String

A `String` containing errors reported by the assembly cache.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

BadImageFormatException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the error message and the name of the file that caused this exception.

```
C#
public override string Message { get; }
```

Property Value

String

A string containing the error message and the name of the file that caused this exception.

Remarks

If no message was supplied to the constructor for the current exception, this property returns a system-supplied error message. If the FileName property is not a null reference (`Nothing` in Visual Basic), the message includes the file name.

This property is read-only.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

BadImageFormatException.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the file name, assembly cache log, and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

SecurityException

The caller does not have the required permission.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

BadImageFormatException.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the fully qualified name of this exception and possibly the error message, the name of the inner exception, and the stack trace.

C#

```
public override string ToString ();
```

Returns

String

A string containing the fully qualified name of this exception and possibly the error message, the name of the inner exception, and the stack trace.

Remarks

The string representation returned by this method includes the name of the exception, the value of the Message property, the result of calling `ToString` on the inner exception, the value of the FileName property, and the result of calling StackTrace. If any of these members is a null reference (`Nothing` in Visual Basic), its value is not included in the returned string.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Base64FormattingOptions Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies whether relevant ToBase64CharArray and ToBase64String methods insert line breaks in their output.

This enumeration supports a bitwise combination of its member values.

C#

```
[System.Flags]
public enum Base64FormattingOptions
```

Inheritance Object → ValueType → Enum → Base64FormattingOptions

Attributes FlagsAttribute

Fields

Expand table

InsertLineBreaks	1	Inserts line breaks after every 76 characters in the string representation.
None	0	Does not insert line breaks after every 76 characters in the string representation.

Examples

The following example calls the Convert.ToBase64String(Byte[], Base64FormattingOptions) method with a `InsertLineBreaks` argument to insert line breaks in the string that is produced by encoding a 100-element byte array:

C#

```
using System;

public class Example
{
   public static void Main()
   {
       // Define a byte array.
       var bytes = new byte[100];
       int originalTotal = 0;
       for (int ctr = 0; ctr <= bytes.GetUpperBound(0); ctr++) {
          bytes[ctr] = (byte)(ctr + 1);
          originalTotal += bytes[ctr];
       }
       // Display summary information about the array.
       Console.WriteLine("The original byte array:");
       Console.WriteLine("   Total elements: {0}", bytes.Length);
       Console.WriteLine("   Length of String Representation: {0}",
                         BitConverter.ToString(bytes).Length);
       Console.WriteLine("   Sum of elements: {0:N0}", originalTotal);
       Console.WriteLine();

       // Convert the array to a base 64 string.
       string s = Convert.ToBase64String(bytes,

Base64FormattingOptions.InsertLineBreaks);
       Console.WriteLine("The base 64 string:\n   {0}\n", s);

       // Restore the byte array.
       Byte[] newBytes = Convert.FromBase64String(s);
       int newTotal = 0;
       foreach (var newByte in newBytes)
          newTotal += newByte;

       // Display summary information about the restored array.
       Console.WriteLine("   Total elements: {0}", newBytes.Length);
       Console.WriteLine("   Length of String Representation: {0}",
                         BitConverter.ToString(newBytes).Length);
       Console.WriteLine("   Sum of elements: {0:N0}", newTotal);
   }
}
// The example displays the following output:
//   The original byte array:
//      Total elements: 100
//      Length of String Representation: 299
//      Sum of elements: 5,050
//
//   The base 64 string:
//
AQIDBAUGBwgJCgsMDQ4PEBESExQVFhcYGRobHB0eHyAhIiMkJSYnKCkqKywtLi8wMTIzNDU2Nzg5
//   Ojs8PT4/QEFCQ0RFRkdISUpLTE1OT1BRUlNUVVZXWFlaW1xdXl9gYWJjZA==
//
//      Total elements: 100
```

```
//      Length of String Representation: 299
//      Sum of elements: 5,050
```

As the output from the example shows, the Convert.FromBase64String succeeds in restoring the original byte array; the line break characters are ignored during the conversion.

Remarks

The Convert.ToBase64CharArray and Convert.ToBase64String methods convert the value of an array of 8-bit unsigned integers to an equivalent string representation that consists of base 64 digits. The string representation can contain one or more line breaks, where a line break is defined as a carriage return character (U+000D) followed by a line feed character (U+000A). Because line breaks are considered white-space characters in a base-64 encoding, they are ignored when converting a base-64 encoded string back to a byte array. The line breaks are simply convenient when displaying the encoded string to a control or a device such as a console window.

The `None` and `InsertLineBreaks` values are mutually exclusive. Therefore, although the `Base64FormattingOptions` enumeration is marked with the FlagsAttribute attribute, it makes no sense to perform a bitwise combination of these two values.

BitConverter Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts base data types to an array of bytes, and an array of bytes to base data types.

C#

```
public static class BitConverter
```

Inheritance Object → BitConverter

Examples

The following code example illustrates the use of several BitConverter class methods.

C#

```
// Example of BitConverter class methods.
using System;

class BitConverterDemo
{
    public static void Main( )
    {
        const string formatter = "{0,25}{1,30}";

        double  aDoubl  = 0.1111111111111111111;
        float   aSingl  = 0.1111111111111111111F;
        long    aLong   = 1111111111111111111;
        int     anInt   = 1111111111;
        short   aShort  = 11111;
        char    aChar   = '*';
        bool    aBool   = true;

        Console.WriteLine(
            "This example of methods of the BitConverter class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( formatter, "argument", "byte array" );
        Console.WriteLine( formatter, "--------", "----------" );
```

```
        // Convert values to Byte arrays and display them.
        Console.WriteLine( formatter, aDoubl,
            BitConverter.ToString( BitConverter.GetBytes( aDoubl ) ) );
        Console.WriteLine( formatter, aSingl,
            BitConverter.ToString( BitConverter.GetBytes( aSingl ) ) );
        Console.WriteLine( formatter, aLong,
            BitConverter.ToString( BitConverter.GetBytes( aLong ) ) );
        Console.WriteLine( formatter, anInt,
            BitConverter.ToString( BitConverter.GetBytes( anInt ) ) );
        Console.WriteLine( formatter, aShort,
            BitConverter.ToString( BitConverter.GetBytes( aShort ) ) );
        Console.WriteLine( formatter, aChar,
            BitConverter.ToString( BitConverter.GetBytes( aChar ) ) );
        Console.WriteLine( formatter, aBool,
            BitConverter.ToString( BitConverter.GetBytes( aBool ) ) );
    }
}

/*
This example of methods of the BitConverter class
generates the following output.

                 argument                    byte array
                 --------                    ----------
        0.111111111111111       1C-C7-71-1C-C7-71-BC-3F
                0.1111111                   39-8E-E3-3D
      1111111111111111111       C7-71-C4-2B-AB-75-6B-0F
               1111111111                   C7-35-3A-42
                    11111                         67-2B
                        *                         2A-00
                     True                            01
*/
```

Remarks

The BitConverter class helps manipulate value types in their fundamental form, as a series of bytes. A byte is defined as an 8-bit unsigned integer. The BitConverter class includes static methods to convert each of the primitive types to and from an array of bytes, as the following table illustrates.

Expand table

Type	To byte conversion	From byte conversion
Boolean	GetBytes(Boolean)	ToBoolean
Char	GetBytes(Char)	ToChar
Double	GetBytes(Double)	ToDouble

Type	To byte conversion	From byte conversion
	-or- DoubleToInt64Bits(Double)	-or- Int64BitsToDouble
Int16	GetBytes(Int16)	ToInt16
Int32	GetBytes(Int32)	ToInt32
Int64	GetBytes(Int64)	ToInt64
Single	GetBytes(Single)	ToSingle
UInt16	GetBytes(UInt16)	ToUInt16
UInt32	GetBytes(UInt32)	ToUInt32
UInt64	GetBytes(UInt64)	ToUInt64

If you use BitConverter methods to round-trip data, make sure that the GetBytes overload and the `To`*Type* method specify the same type. As the following example illustrates, restoring an array that represents a signed integer by calling the ToUInt32 method can result in a value that is different from the original. For more information, see Working with Signed Non-Decimal and Bitwise Values.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int value = -16;
      Byte[] bytes = BitConverter.GetBytes(value);

      // Convert bytes back to int.
      int intValue = BitConverter.ToInt32(bytes, 0);
      Console.WriteLine("{0} = {1}: {2}",
                        value, intValue,
                        value.Equals(intValue) ? "Round-trips" : "Does not
round-trip");
      // Convert bytes to UInt32.
      uint uintValue = BitConverter.ToUInt32(bytes, 0);
      Console.WriteLine("{0} = {1}: {2}", value, uintValue,
                        value.Equals(uintValue) ? "Round-trips" : "Does not
round-trip");
   }
}
// The example displays the following output:
```

```
//        -16 = -16: Round-trips
//        -16 = 4294967280: Does not round-trip
```

The order of bytes in the array returned by the GetBytes method overloads (as well as the order of bits in the integer returned by the DoubleToInt64Bits method) depends on whether the computer architecture is little-endian or big-endian. Similarly, the order of bytes in the array and returned by the `To`*IntegerValue* methods and the ToChar method depends on whether the computer architecture is little-endian or big-endian. The endianness of an architecture is indicated by the IsLittleEndian property, which returns `true` on little-endian systems and `false` on big-endian systems. On little-endian systems, lower-order bytes precede higher-order bytes. On big-endian system, higher-order bytes precede lower-order bytes. The following table illustrates the difference in the byte arrays that result from passing the integer 1,234,567,890 (0x499602D2) to the GetBytes(Int32) method. The bytes are listed in order from the byte at index 0 to the byte at index 3.

Expand table

Little-endian	D2-02-96-49
Big-endian	49-96-02-D2

Because the return value of some methods depends on system architecture, be careful when transmitting byte data beyond machine boundaries:

- If all systems sending and receiving data are guaranteed to have the same endianness, nothing has be done to the data.
- If systems sending and receiving data can have different endianness, always transmit data in a particular order. This means that the order of bytes in the array may have to be reversed either before sending them or after receiving them. A common convention is to transmit data in network byte order (big-endian order). The following example provides an implementation for sending an integer value in network byte order.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int value = 12345678;
```

```
        byte[] bytes = BitConverter.GetBytes(value);
        Console.WriteLine(BitConverter.ToString(bytes));

        if (BitConverter.IsLittleEndian)
           Array.Reverse(bytes);

        Console.WriteLine(BitConverter.ToString(bytes));
        // Call method to send byte stream across machine boundaries.

        // Receive byte stream from beyond machine boundaries.
        Console.WriteLine(BitConverter.ToString(bytes));
        if (BitConverter.IsLittleEndian)
           Array.Reverse(bytes);

        Console.WriteLine(BitConverter.ToString(bytes));
        int result = BitConverter.ToInt32(bytes, 0);
        Console.WriteLine("Original value: {0}", value);
        Console.WriteLine("Returned value: {0}", result);
    }
}
// The example displays the following output on a little-endian system:
//       4E-61-BC-00
//       00-BC-61-4E
//       00-BC-61-4E
//       4E-61-BC-00
//       Original value: 12345678
//       Returned value: 12345678
```

- If systems sending and receiving data can have different endianness and the data to be transmitted consists of signed integers, call the IPAddress.HostToNetworkOrder method to convert the data to network byte order and the IPAddress.NetworkToHostOrder method to convert it to the order required by the recipient.

Fields

Expand table

IsLittleEndian	Indicates the byte order ("endianness") in which data is stored in this computer architecture.

Methods

Expand table

DoubleToInt64Bits(Double)	Converts the specified double-precision floating point number to a 64-bit signed integer.
DoubleToUInt64Bits(Double)	Converts the specified double-precision floating point number to a 64-bit unsigned integer.
GetBytes(Boolean)	Returns the specified Boolean value as a byte array.
GetBytes(Char)	Returns the specified Unicode character value as an array of bytes.
GetBytes(Double)	Returns the specified double-precision floating-point value as an array of bytes.
GetBytes(Half)	Returns the specified half-precision floating-point value as an array of bytes.
GetBytes(Int16)	Returns the specified 16-bit signed integer value as an array of bytes.
GetBytes(Int32)	Returns the specified 32-bit signed integer value as an array of bytes.
GetBytes(Int64)	Returns the specified 64-bit signed integer value as an array of bytes.
GetBytes(Single)	Returns the specified single-precision floating point value as an array of bytes.
GetBytes(UInt16)	Returns the specified 16-bit unsigned integer value as an array of bytes.
GetBytes(UInt32)	Returns the specified 32-bit unsigned integer value as an array of bytes.
GetBytes(UInt64)	Returns the specified 64-bit unsigned integer value as an array of bytes.
HalfToInt16Bits(Half)	Converts a half-precision floating-point value into a 16-bit integer.
HalfToUInt16Bits(Half)	Converts the specified half-precision floating point number to a 16-bit unsigned integer.
Int16BitsToHalf(Int16)	Reinterprets the specified 16-bit signed integer value as a half-precision floating-point value.
Int32BitsToSingle(Int32)	Reinterprets the specified 32-bit integer as a single-precision floating-point value.
Int64BitsToDouble(Int64)	Reinterprets the specified 64-bit signed integer to a double-precision floating point number.
SingleToInt32Bits(Single)	Converts a single-precision floating-point value into an integer.

SingleToUInt32Bits(Single)	Converts the specified single-precision floating point number to a 32-bit unsigned integer.
ToBoolean(Byte[], Int32)	Returns a Boolean value converted from the byte at a specified position in a byte array.
ToBoolean(ReadOnlySpan<Byte>)	Converts a read-only byte span to a Boolean value.
ToChar(Byte[], Int32)	Returns a Unicode character converted from two bytes at a specified position in a byte array.
ToChar(ReadOnlySpan<Byte>)	Converts a read-only byte span into a character.
ToDouble(Byte[], Int32)	Returns a double-precision floating point number converted from eight bytes at a specified position in a byte array.
ToDouble(ReadOnlySpan<Byte>)	Converts a read-only byte span into a double-precision floating-point value.
ToHalf(Byte[], Int32)	Returns a laft-precision floating point number converted from two bytes at a specified position in a byte array.
ToHalf(ReadOnlySpan<Byte>)	Converts a read-only byte span into a half-precision floating-point value.
ToInt16(Byte[], Int32)	Returns a 16-bit signed integer converted from two bytes at a specified position in a byte array.
ToInt16(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 16-bit signed integer.
ToInt32(Byte[], Int32)	Returns a 32-bit signed integer converted from four bytes at a specified position in a byte array.
ToInt32(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 32-bit signed integer.
ToInt64(Byte[], Int32)	Returns a 64-bit signed integer converted from eight bytes at a specified position in a byte array.
ToInt64(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 64-bit signed integer.
ToSingle(Byte[], Int32)	Returns a single-precision floating point number converted from four bytes at a specified position in a byte array.
ToSingle(ReadOnlySpan<Byte>)	Converts a read-only byte span into a single-precision floating-point value.

ToString(Byte[])	Converts the numeric value of each element of a specified array of bytes to its equivalent hexadecimal string representation.
ToString(Byte[], Int32)	Converts the numeric value of each element of a specified subarray of bytes to its equivalent hexadecimal string representation.
ToString(Byte[], Int32, Int32)	Converts the numeric value of each element of a specified subarray of bytes to its equivalent hexadecimal string representation.
ToUInt16(Byte[], Int32)	Returns a 16-bit unsigned integer converted from two bytes at a specified position in a byte array.
ToUInt16(ReadOnlySpan<Byte>)	Converts a read-only byte-span into a 16-bit unsigned integer.
ToUInt32(Byte[], Int32)	Returns a 32-bit unsigned integer converted from four bytes at a specified position in a byte array.
ToUInt32(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 32-bit unsigned integer.
ToUInt64(Byte[], Int32)	Returns a 64-bit unsigned integer converted from eight bytes at a specified position in a byte array.
ToUInt64(ReadOnlySpan<Byte>)	Converts bytes into an unsigned long.
TryWriteBytes(Span<Byte>, Boolean)	Converts a Boolean into a span of bytes.
TryWriteBytes(Span<Byte>, Char)	Converts a character into a span of bytes.
TryWriteBytes(Span<Byte>, Double)	Converts a double-precision floating-point value into a span of bytes.
TryWriteBytes(Span<Byte>, Half)	Converts a half-precision floating-point value into a span of bytes.
TryWriteBytes(Span<Byte>, Int16)	Converts a 16-bit signed integer into a span of bytes.
TryWriteBytes(Span<Byte>, Int32)	Converts a 32-bit signed integer into a span of bytes.
TryWriteBytes(Span<Byte>, Int64)	Converts a 64-bit signed integer into a span of bytes.
TryWriteBytes(Span<Byte>, Single)	Converts a single-precision floating-point value into a span of bytes.

TryWriteBytes(Span<Byte>, UInt16)	Converts an unsigned 16-bit integer into a span of bytes.
TryWriteBytes(Span<Byte>, UInt32)	Converts a 32-bit unsigned integer into a span of bytes.
TryWriteBytes(Span<Byte>, UInt64)	Converts an unsigned 64-bit integer into a span of bytes.
UInt16BitsToHalf(UInt16)	Converts the specified 16-bit unsigned integer to a half-precision floating point number.
UInt32BitsToSingle(UInt32)	Converts the specified 32-bit unsigned integer to a single-precision floating point number.
UInt64BitsToDouble(UInt64)	Converts the specified 64-bit unsigned integer to a double-precision floating point number.

Applies to

BitConverter.IsLittleEndian Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates the byte order ("endianness") in which data is stored in this computer architecture.

C#

```
public static readonly bool IsLittleEndian;
```

Field Value

Boolean

Examples

The following code example illustrates the use of the `IsLittleEndian` field.

C#

```
// Example of the BitConverter.IsLittleEndian field.
using System;

class LittleEndDemo
{
    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.IsLittleEndian field " +
            "generates \nthe following output when run on " +
            "x86-class computers.\n");
        Console.WriteLine( "IsLittleEndian:  {0}",
            BitConverter.IsLittleEndian );
    }
}

/*
This example of the BitConverter.IsLittleEndian field generates
the following output when run on x86-class computers.
```

```
IsLittleEndian:  True
*/
```

Remarks

Different computer architectures store data using different byte orders. "Big-endian" means the most significant byte is on the left end of a word. "Little-endian" means the most significant byte is on the right end of a word.

> **Note**
>
> You can convert from network byte order to the byte order of the host computer without retrieving the value of the **BitConverter.IsLittleEndian** field by passing a 16-bit, 32-bit, or 64 bit integer to the **IPAddress.HostToNetworkOrder** method.

Applies to

BitConverter.DoubleToInt64Bits(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified double-precision floating point number to a 64-bit signed integer.

```
C#

public static long DoubleToInt64Bits (double value);
```

Parameters

`value` Double

The number to convert.

Returns

Int64

A 64-bit signed integer whose value is equivalent to `value`.

Examples

The following code example converts the bit patterns of several Double values to Int64 values with the `DoubleToInt64Bits` method.

```
C#

// Example of the BitConverter.DoubleToInt64Bits method.
using System;

class DoubleToInt64BitsDemo
{
    const string formatter = "{0,25:E16}{1,23:X16}";
```

```
    // Reinterpret the double argument as a long.
    public static void DoubleToLongBits( double argument )
    {
        long longValue;
        longValue = BitConverter.DoubleToInt64Bits( argument );

        // Display the resulting long in hexadecimal.
        Console.WriteLine( formatter, argument, longValue );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.DoubleToInt64Bits( " +
            "double ) \nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "double argument",
            "hexadecimal value" );
        Console.WriteLine( formatter, "---------------",
            "-----------------" );

        // Convert double values and display the results.
        DoubleToLongBits( 1.0 );
        DoubleToLongBits( 15.0 );
        DoubleToLongBits( 255.0 );
        DoubleToLongBits( 4294967295.0 );
        DoubleToLongBits( 0.00390625 );
        DoubleToLongBits( 0.0000000002328306436538696289062 5 );
        DoubleToLongBits( 1.234567890123E-300 );
        DoubleToLongBits( 1.23456789012345E-150 );
        DoubleToLongBits( 1.2345678901234565 );
        DoubleToLongBits( 1.2345678901234567 );
        DoubleToLongBits( 1.2345678901234569 );
        DoubleToLongBits( 1.23456789012345678E+150 );
        DoubleToLongBits( 1.234567890123456789E+300 );
        DoubleToLongBits( double.MinValue );
        DoubleToLongBits( double.MaxValue );
        DoubleToLongBits( double.Epsilon );
        DoubleToLongBits( double.NaN );
        DoubleToLongBits( double.NegativeInfinity );
        DoubleToLongBits( double.PositiveInfinity );
    }
}

/*
This example of the BitConverter.DoubleToInt64Bits( double )
method generates the following output.

          double argument      hexadecimal value
          ---------------      -----------------

BitConverter.DoubleToUInt64Bits(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified double-precision floating point number to a 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong DoubleToUInt64Bits (double value);
```

Parameters

`value` Double

The number to convert.

Returns

UInt64

A 64-bit unsigned integer whose bits are identical to `value`.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.GetBytes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified data to an array of bytes.

Overloads

Expand table

GetBytes(Boolean)	Returns the specified Boolean value as a byte array.
GetBytes(Char)	Returns the specified Unicode character value as an array of bytes.
GetBytes(Double)	Returns the specified double-precision floating-point value as an array of bytes.
GetBytes(Half)	Returns the specified half-precision floating-point value as an array of bytes.
GetBytes(Int16)	Returns the specified 16-bit signed integer value as an array of bytes.
GetBytes(Int32)	Returns the specified 32-bit signed integer value as an array of bytes.
GetBytes(Int64)	Returns the specified 64-bit signed integer value as an array of bytes.
GetBytes(Single)	Returns the specified single-precision floating point value as an array of bytes.
GetBytes(UInt16)	Returns the specified 16-bit unsigned integer value as an array of bytes.
GetBytes(UInt32)	Returns the specified 32-bit unsigned integer value as an array of bytes.
GetBytes(UInt64)	Returns the specified 64-bit unsigned integer value as an array of bytes.

GetBytes(Boolean)

Returns the specified Boolean value as a byte array.

```
C#
```

```
public static byte[] GetBytes (bool value);
```

Parameters

`value` Boolean

The value to convert.

Returns

Byte[]

A byte array with length 1.

Examples

The following example converts the bit patterns of Boolean values to Byte arrays with the `GetBytes` method.

C#

```
using System;

class Example
{
   public static void Main( )
   {
      // Define Boolean true and false values.
      bool[] values = { true, false };

      // Display the value and its corresponding byte array.
      Console.WriteLine("{0,10}{1,16}\n", "Boolean", "Bytes");
      foreach (var value in values) {
         byte[] bytes = BitConverter.GetBytes(value);
         Console.WriteLine("{0,10}{1,16}", value,
                           BitConverter.ToString(bytes));
      }
   }
}
// The example displays the following output:
//        Boolean           Bytes
//
//           True              01
//          False              00
```

Remarks

You can convert a byte array back to a Boolean value by calling the ToBoolean method.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetBytes(Char)

Returns the specified Unicode character value as an array of bytes.

C#

```
public static byte[] GetBytes (char value);
```

Parameters

`value` Char

The character to convert.

Returns

Byte[]

An array of bytes with length 2.

Examples

The following code example converts the bit patterns of Char values (Unicode characters) to Byte arrays with the `GetBytes` method.

C#

```
// Example of the BitConverter.GetBytes( char ) method.
using System;

class GetBytesCharDemo
{
    const string formatter = "{0,10}{1,16}";

    // Convert a char argument to a byte array and display it.
    public static void GetBytesChar( char argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( char ) " +
            "\nmethod generates the following output.\r\n" );
        Console.WriteLine( formatter, "char", "byte array" );
        Console.WriteLine( formatter, "----", "----------" );

        // Convert char values and display the results.
        GetBytesChar( '\0' );
        GetBytesChar( ' ' );
        GetBytesChar( '*' );
        GetBytesChar( '3' );
        GetBytesChar( 'A' );
        GetBytesChar( '[' );
        GetBytesChar( 'a' );
        GetBytesChar( '{' );
    }
}

/*
This example of the BitConverter.GetBytes( char )
method generates the following output.

      char      byte array
      ----      ----------
                     00-00
                     20-00
         *           2A-00
         3           33-00
         A           41-00
```

```
        [           5B-00
        a           61-00
        {           7B-00
*/
```

Remarks

The order of bytes in the array returned by the GetBytes method depends on whether the computer architecture is little-endian or big-endian.

GetBytes(Double)

Returns the specified double-precision floating-point value as an array of bytes.

C#

```
public static byte[] GetBytes (double value);
```

Parameters

`value` Double

The number to convert.

Returns

Byte[]

An array of bytes with length 8.

Examples

The following code example converts the bit patterns of Double values to Byte arrays with the `GetBytes` method.

C#

```
// Example of the BitConverter.GetBytes( double ) method.
using System;

class GetBytesDoubleDemo
{
    const string formatter = "{0,25:E16}{1,30}";

    // Convert a double argument to a byte array and display it.
    public static void GetBytesDouble( double argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( double ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "double", "byte array" );
        Console.WriteLine( formatter, "------", "----------" );

        // Convert double values and display the results.
        GetBytesDouble( 0.0 );
        GetBytesDouble( 1.0 );

GetBytes(Half)

Returns the specified half-precision floating-point value as an array of bytes.

C#

```
public static byte[] GetBytes (Half value);
```

Parameters

`value` Half

The number to convert.

Returns

Byte[]

An array of bytes with length 2.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

GetBytes(Int16)

Returns the specified 16-bit signed integer value as an array of bytes.

C#

```
public static byte[] GetBytes (short value);
```

Parameters

`value` Int16

The number to convert.

Returns

Byte[]

An array of bytes with length 2.

Examples

The following code example converts the bit patterns of Int16 values to Byte arrays with the `GetBytes` method.

C#

```
// Example of the BitConverter.GetBytes( short ) method.
using System;

class GetBytesInt16Demo
{
    const string formatter = "{0,10}{1,13}";

    // Convert a short argument to a byte array and display it.
    public static void GetBytesInt16( short argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( short ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "short", "byte array" );
        Console.WriteLine( formatter, "-----", "----------" );

        // Convert short values and display the results.
        GetBytesInt16( 0 );
        GetBytesInt16( 15 );
        GetBytesInt16( -15 );
        GetBytesInt16( 10000 );
```

```
        GetBytesInt16( -10000 );
        GetBytesInt16( short.MinValue );
        GetBytesInt16( short.MaxValue );
    }
}

/*
This example of the BitConverter.GetBytes( short )
method generates the following output.

     short   byte array
     -----   ----------
         0        00-00
        15        0F-00
       -15        F1-FF
     10000        10-27
    -10000        F0-D8
    -32768        00-80
     32767        FF-7F
*/
```

Remarks

The order of bytes in the array returned by the GetBytes method depends on whether the computer architecture is little-endian or big-endian.

GetBytes(Int32)

Returns the specified 32-bit signed integer value as an array of bytes.

C#

```
public static byte[] GetBytes (int value);
```

Parameters

`value` Int32

The number to convert.

Returns

Byte[]

An array of bytes with length 4.

Examples

The following code example converts the bit patterns of Int32 values to Byte arrays with the `GetBytes` method.

C#

```
using System;

class Example
{
    public static void Main( )
    {
        // Define an array of integers.
        int[] values = { 0, 15, -15, 0x100000,  -0x100000, 1000000000,
                         -1000000000, int.MinValue, int.MaxValue };

        // Convert each integer to a byte array.
        Console.WriteLine("{0,16}{1,10}{2,17}", "Integer",
                          "Endian", "Byte Array");
        Console.WriteLine("{0,16}{1,10}{2,17}", "---", "------",
                          "----------" );
        foreach (var value in values) {
          byte[] byteArray = BitConverter.GetBytes(value);
          Console.WriteLine("{0,16}{1,10}{2,17}", value,
                            BitConverter.IsLittleEndian ? "Little" : "
Big",
                            BitConverter.ToString(byteArray));
```

```
        }
    }
}
// This example displays output like the following:
//              Integer    Endian       Byte Array
//                  ---    ------       ----------
//                    0    Little      00-00-00-00
//                   15    Little      0F-00-00-00
//                  -15    Little      F1-FF-FF-FF
//              1048576    Little      00-00-10-00
//             -1048576    Little      00-00-F0-FF
//           1000000000    Little      00-CA-9A-3B
//          -1000000000    Little      00-36-65-C4
//          -2147483648    Little      00-00-00-80
//           2147483647    Little      FF-FF-FF-7F
```

Remarks

GetBytes(Int64)

Returns the specified 64-bit signed integer value as an array of bytes.

C#

```
public static byte[] GetBytes (long value);
```

Parameters

`value` Int64

The number to convert.

Returns

Byte[]

An array of bytes with length 8.

Examples

The following example calls the GetBytes method to convert each element in an Int64 array to a Byte arrays.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of Int64 values.
        long[] values = { 0, 0xFFFFFF, -0xFFFFFF, 1000000000,
-1000000000,
                          0x100000000, -0x100000000, 0xAAAAAAAAAAAA,
                          -0xAAAAAAAAAAAA, 1000000000000000000,
                          -1000000000000000000, long.MinValue,
                          long.MaxValue };

        Console.WriteLine( "{0,22}{1,10} {2,30}", "Int64", "Endian",
"Byte Array");
        Console.WriteLine( "{0,22}{1,10} {2,30}", "----", "------", "----
------" );

        foreach (var value in values) {
            // Convert each Int64 value to a byte array.
            byte[] byteArray = BitConverter.GetBytes(value);
            // Display the result.
            Console.WriteLine("{0,22}{1,10}{2,30}", value,
                              BitConverter.IsLittleEndian ? "Little" :
"Big",
```

```
                                BitConverter.ToString(byteArray));
        }
    }
}
// The example displays output like the following:
//                     Int64    Endian                     Byte Array
//                      ----    ------                     ----------
//                         0    Little       00-00-00-00-00-00-00-00
//                  16777215    Little       FF-FF-FF-00-00-00-00-00
//                 -16777215    Little       01-00-00-FF-FF-FF-FF-FF
//                1000000000    Little       00-CA-9A-3B-00-00-00-00

GetBytes(Single)

Returns the specified single-precision floating point value as an array of bytes.

```
C#

public static byte[] GetBytes (float value);
```

Parameters

`value` Single

The number to convert.

Returns

Byte[]

An array of bytes with length 4.

Examples

The following code example converts the bit patterns of Single values to Byte arrays with the `GetBytes` method.

```
C#

// Example of the BitConverter.GetBytes( float ) method.
using System;

class GetBytesSingleDemo
{
    const string formatter = "{0,16:E7}{1,20}";

    // Convert a float argument to a byte array and display it.
    public static void GetBytesSingle( float argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( float ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "float", "byte array" );
```

```
        Console.WriteLine( formatter, "-----", "----------" );

        // Convert float values and display the results.
        GetBytesSingle( 0.0F );
        GetBytesSingle( 1.0F );
        GetBytesSingle( 15.0F );
        GetBytesSingle( 65535.0F );
        GetBytesSingle( 0.00390625F );
        GetBytesSingle( 0.00000000023283064365386962890625F );
        GetBytesSingle( 1.2345E-35F );
        GetBytesSingle( 1.2345671F );
        GetBytesSingle( 1.2345673F );
        GetBytesSingle( 1.2345677F );
        GetBytesSingle( 1.23456789E+35F );
        GetBytesSingle( float.MinValue );
        GetBytesSingle( float.MaxValue );
        GetBytesSingle( float.Epsilon );
        GetBytesSingle( float.NaN );
        GetBytesSingle( float.NegativeInfinity );
        GetBytesSingle( float.PositiveInfinity );
    }
}

/*

GetBytes(UInt16)

> Important
>
> This API is not CLS-compliant.

Returns the specified 16-bit unsigned integer value as an array of bytes.

C#

```
[System.CLSCompliant(false)]
public static byte[] GetBytes (ushort value);
```

Parameters

`value` UInt16

The number to convert.

Returns

Byte[]

An array of bytes with length 2.

Attributes CLSCompliantAttribute

Examples

The following code example converts the bit patterns of UInt16 values to Byte arrays with the `GetBytes` method.

C#

```
// Example of the BitConverter.GetBytes( ushort ) method.
using System;

class GetBytesUInt16Demo
{
    const string formatter = "{0,10}{1,13}";

    // Convert a ushort argument to a byte array and display it.
    public static void GetBytesUInt16( ushort argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( ushort ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "ushort", "byte array" );
        Console.WriteLine( formatter, "------", "----------" );

        // Convert ushort values and display the results.
        GetBytesUInt16( 15 );
        GetBytesUInt16( 1023 );
        GetBytesUInt16( 10000 );
        GetBytesUInt16( ushort.MinValue );
        GetBytesUInt16( (ushort)short.MaxValue );
        GetBytesUInt16( ushort.MaxValue );
    }
}

/*
This example of the BitConverter.GetBytes( ushort )
method generates the following output.

    ushort   byte array
    ------   ----------
        15       0F-00
      1023       FF-03
     10000       10-27
         0       00-00
```

```
     32767        FF-7F
     65535        FF-FF
*/
```

Remarks

The order of bytes in the array returned by the GetBytes method depends on whether the computer architecture is little-endian or big-endian.

GetBytes(UInt32)

> Important
>
> This API is not CLS-compliant.

Returns the specified 32-bit unsigned integer value as an array of bytes.

C#

```
[System.CLSCompliant(false)]
public static byte[] GetBytes (uint value);
```

Parameters

`value` UInt32

The number to convert.

Returns

Byte[]

An array of bytes with length 4.

Attributes CLSCompliantAttribute

Examples

The following code example converts the bit patterns of UInt32 values to Byte arrays with the `GetBytes` method.

C#

```
// Example of the BitConverter.GetBytes( uint ) method.
using System;

class GetBytesUInt32Demo
{
    const string formatter = "{0,16}{1,20}";

    // Convert a uint argument to a byte array and display it.
    public static void GetBytesUInt32( uint argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( uint ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "uint", "byte array" );
        Console.WriteLine( formatter, "----", "----------" );

        // Convert uint values and display the results.
        GetBytesUInt32( 15 );
        GetBytesUInt32( 1023 );
        GetBytesUInt32( 0x100000 );
        GetBytesUInt32( 1000000000 );
        GetBytesUInt32( uint.MinValue );
        GetBytesUInt32( int.MaxValue );
```

```
        GetBytesUInt32( uint.MaxValue );
    }
}

/*
This example of the BitConverter.GetBytes( uint )
method generates the following output.

            uint          byte array
            ----          ----------
              15         0F-00-00-00
            1023         FF-03-00-00
         1048576         00-00-10-00
      1000000000         00-CA-9A-3B
               0         00-00-00-00
      2147483647         FF-FF-FF-7F
      4294967295         FF-FF-FF-FF
*/
```

Remarks

The order of bytes in the array returned by the GetBytes method depends on whether the computer architecture is little-endian or big-endian.

GetBytes(UInt64)

> Important
>
> This API is not CLS-compliant.

Returns the specified 64-bit unsigned integer value as an array of bytes.

C#

```
[System.CLSCompliant(false)]
public static byte[] GetBytes (ulong value);
```

Parameters

`value` UInt64

The number to convert.

Returns

Byte[]

An array of bytes with length 8.

Attributes CLSCompliantAttribute

Examples

The following code example converts the bit patterns of UInt64 values to Byte arrays with the `GetBytes` method.

C#

```
// Example of the BitConverter.GetBytes( ulong ) method.
using System;

class GetBytesUInt64Demo
{
    const string formatter = "{0,22}{1,30}";

    // Convert a ulong argument to a byte array and display it.
    public static void GetBytesUInt64( ulong argument )
    {
        byte[ ] byteArray = BitConverter.GetBytes( argument );
        Console.WriteLine( formatter, argument,
            BitConverter.ToString( byteArray ) );
```

```
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.GetBytes( ulong ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "ulong", "byte array" );
        Console.WriteLine( formatter, "-----", "----------" );

        // Convert ulong values and display the results.
        GetBytesUInt64( 0xFFFFFF );
        GetBytesUInt64( 1000000000 );
        GetBytesUInt64( 0x100000000 );
        GetBytesUInt64( 0xAAAAAAAAAAAA );
        GetBytesUInt64( 1000000000000000000 );
        GetBytesUInt64( 10000000000000000000 );
        GetBytesUInt64( ulong.MinValue );
        GetBytesUInt64( long.MaxValue );
        GetBytesUInt64( ulong.MaxValue );
    }
}

/*
This example of the BitConverter.GetBytes( ulong )
method generates the following output.

                 ulong                    byte array
                 -----                    ----------
              16777215       FF-FF-FF-00-00-00-00-00

BitConverter.HalfToInt16Bits(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a half-precision floating-point value into a 16-bit integer.

C#

```
public static short HalfToInt16Bits (Half value);
```

Parameters

`value` Half

The half-precision floating-point value to convert.

Returns

Int16

An integer representing the converted half-precision floating-point value.

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.HalfToUInt16Bits(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified half-precision floating point number to a 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort HalfToUInt16Bits (Half value);
```

Parameters

`value` Half

The number to convert.

Returns

UInt16

A 16-bit unsigned integer whose bits are identical to `value`.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.Int16BitsToHalf(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reinterprets the specified 16-bit signed integer value as a half-precision floating-point value.

C#

```
public static Half Int16BitsToHalf (short value);
```

Parameters

`value` Int16

The 16-bit signed integer value to convert.

Returns

Half

A half-precision floating-point value that represents the converted integer.

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.Int32BitsToSingle(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reinterprets the specified 32-bit integer as a single-precision floating-point value.

C#

```
public static float Int32BitsToSingle (int value);
```

Parameters

`value` Int32

The integer to convert.

Returns

Single

A single-precision floating-point value that represents the converted integer.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

BitConverter.Int64BitsToDouble(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reinterprets the specified 64-bit signed integer to a double-precision floating point number.

C#

```
public static double Int64BitsToDouble (long value);
```

Parameters

`value` Int64

The number to convert.

Returns

Double

A double-precision floating point number whose value is equivalent to `value`.

Examples

The following code example converts the bit patterns of several Int64 values to Double values with the `Int64BitsToDouble` method.

C#

```
// Example of the BitConverter.Int64BitsToDouble method.
using System;

class Int64BitsToDoubleDemo
{
    const string formatter = "{0,20}{1,27:E16}";
```

```
    // Reinterpret the long argument as a double.
    public static void LongBitsToDouble( long argument )
    {
        double doubleValue;
        doubleValue = BitConverter.Int64BitsToDouble( argument );

        // Display the argument in hexadecimal.
        Console.WriteLine( formatter,
            string.Format( "0x{0:X16}", argument ), doubleValue );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the BitConverter.Int64BitsToDouble( " +
            "long ) \nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "long argument",
            "double value" );
        Console.WriteLine( formatter, "-------------",
            "------------" );

        // Convert long values and display the results.
        LongBitsToDouble( 0 );
        LongBitsToDouble( 0x3FF0000000000000 );
        LongBitsToDouble( 0x402E000000000000 );

*/
```

Remarks

Typically, `value` is an integer that is returned by the DoubleToInt64Bits method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

BitConverter.SingleToInt32Bits(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a single-precision floating-point value into an integer.

C#

```
public static int SingleToInt32Bits (float value);
```

Parameters

`value` Single

The single-precision floating-point value to convert.

Returns

Int32

An integer representing the converted single-precision floating-point value.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

BitConverter.SingleToUInt32Bits(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified single-precision floating point number to a 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint SingleToUInt32Bits (float value);
```

Parameters

`value` Single

The number to convert.

Returns

UInt32

A 32-bit unsigned integer whose bits are identical to `value`.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.ToBoolean Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToBoolean(ReadOnlySpan<Byte>)	Converts a read-only byte span to a Boolean value.
ToBoolean(Byte[], Int32)	Returns a Boolean value converted from the byte at a specified position in a byte array.

ToBoolean(ReadOnlySpan<Byte>)

Converts a read-only byte span to a Boolean value.

C#

```
public static bool ToBoolean (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

Boolean

A Boolean representing the converted bytes.

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToBoolean(Byte[], Int32)

Returns a Boolean value converted from the byte at a specified position in a byte array.

```
C#

public static bool ToBoolean (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

A byte array.

`startIndex` Int32

The index of the byte within `value` to convert.

Returns

Boolean

`true` if the byte at `startIndex` in `value` is nonzero; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to Boolean values with the `ToBoolean` method.

C#

```
using System;

class Example
{
    public static void Main( )
    {
        // Define an array of byte values.
        byte[] bytes = { 0, 1, 2, 4, 8, 16, 32, 64, 128, 255 };

        Console.WriteLine("{0,5}{1,16}{2,10}\n", "index", "array
element", "bool" );
        // Convert each array element to a Boolean value.
        for (int index = 0; index < bytes.Length; index++)
           Console.WriteLine("{0,5}{1,16:X2}{2,10}", index, bytes[index],
                             BitConverter.ToBoolean(bytes, index));
    }
}
// The example displays the following output:
//     index   array element      bool
//
//         0              00     False
//         1              01      True
//         2              02      True
//         3              04      True
//         4              08      True
//         5              10      True
//         6              20      True
//         7              40      True
//         8              80      True
//         9              FF      True
```

Remarks

To convert a Boolean value to its byte representation, call the GetBytes(Boolean) method.

BitConverter.ToChar Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToChar(Byte[], Int32)	Returns a Unicode character converted from two bytes at a specified position in a byte array.
ToChar(ReadOnlySpan<Byte>)	Converts a read-only byte span into a character.

ToChar(Byte[], Int32)

Returns a Unicode character converted from two bytes at a specified position in a byte array.

```
C#

public static char ToChar (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array that includes the two bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

Char

The character formed by two bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` equals the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to Char values (Unicode characters) with the `ToChar` method.

C#

```
// Example of the BitConverter.ToChar method.
using System;

class BytesToCharDemo
{
    const string formatter = "{0,5}{1,17}{2,8}";

    // Convert two byte array elements to a char and display it.
    public static void BAToChar( byte[] bytes, int index )
    {
        char value = BitConverter.ToChar( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 2 ), value );
    }

    public static void Main( )
    {
        byte[] byteArray = {
             32,   0,   0,  42,   0,  65,   0, 125,   0,
            197,   0, 168,   3,  41,   4, 172,  32 };

        Console.WriteLine(
            "This example of the BitConverter.ToChar( byte[ ], " +
            "int ) \nmethod generates the following output. It " +
            "converts \nelements of a byte array to char values.\n" );
        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );
        Console.WriteLine( BitConverter.ToString( byteArray ) );
        Console.WriteLine( );
        Console.WriteLine( formatter, "index", "array elements", "char"
```

```
);
        Console.WriteLine( formatter, "-----", "--------------", "----"
);

        // Convert byte array elements to char values.
        BAToChar( byteArray, 0 );
        BAToChar( byteArray, 1 );
        BAToChar( byteArray, 3 );
        BAToChar( byteArray, 5 );
        BAToChar( byteArray, 7 );
        BAToChar( byteArray, 9 );
        BAToChar( byteArray, 11 );
        BAToChar( byteArray, 13 );
        BAToChar( byteArray, 15 );
    }
}

/*
This example of the BitConverter.ToChar(byte[ ], int)
method generates the following output. It converts
elements of a byte array to char values.

initial byte array
------------------
20-00-00-2A-00-41-00-7D-00-C5-00-A8-03-29-04-AC-20

index   array elements    char
-----   --------------    ----
    0            20-00
    1            00-00
    3            2A-00       *
    5            41-00       A
    7            7D-00       }
    9            C5-00       Å
   11            A8-03       Ψ
   13            29-04       Щ
   15            AC-20       €
*/
```

Remarks

The ToChar method converts the bytes from index `startIndex` to `startIndex` + 1 to a Char value. The order of bytes in the array must reflect the endianness of the computer system's architecture. For more information, see the Remarks section of the BitConverter class topic.

BitConverter.ToDouble Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToDouble(ReadOnlySpan<Byte>)	Converts a read-only byte span into a double-precision floating-point value.
ToDouble(Byte[], Int32)	Returns a double-precision floating point number converted from eight bytes at a specified position in a byte array.

ToDouble(ReadOnlySpan<Byte>)

Converts a read-only byte span into a double-precision floating-point value.

C#

```
public static double ToDouble (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

Double

A double-precision floating-point value that represents the converted bytes.

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than the length of a Double value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToDouble(Byte[], Int32)

Returns a double-precision floating point number converted from eight bytes at a specified position in a byte array.

C#

```
public static double ToDouble (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes that includes the eight bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

Double

A double-precision floating point number formed by eight bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` is greater than or equal to the length of `value` minus 7, and is less than or equal to the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to Double values with the `ToDouble` method.

C#

```
// Example of the BitConverter.ToDouble method.
using System;

class BytesToDoubleDemo
{
    const string formatter = "{0,5}{1,27}{2,27:E16}";

    // Convert eight byte array elements to a double and display it.
    public static void BAToDouble( byte[ ] bytes, int index )
    {
        double value = BitConverter.ToDouble( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 8 ), value );
    }

    // Display a byte array, using multiple lines if necessary.
    public static void WriteMultiLineByteArray( byte[ ] bytes )
    {
        const int rowSize = 20;
        int iter;

        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );

        for( iter = 0; iter < bytes.Length - rowSize; iter += rowSize )
        {
            Console.Write(
                BitConverter.ToString( bytes, iter, rowSize ) );
            Console.WriteLine( "-" );
        }

        Console.WriteLine( BitConverter.ToString( bytes, iter ) );
        Console.WriteLine( );
    }

    public static void Main( )
```

```
    {
        byte[ ] byteArray = {
              0,   0,   0,   0,   0,   0,   0,   0, 240,  63,
              0,   0,   0,   0,   0, 224, 111,  64,   0,   0,
            224, 255, 255, 255, 239,  65,   0,   0,   0,   0,
              0,   0, 112,  63,   0,   0,   0,   0,   0,   0,
            240,  61, 223, 136,  30,  28, 254, 116, 170,   1,
            250,  89, 140,  66, 202, 192, 243,  63, 251,  89,

*/
```

Remarks

The ToDouble method converts the bytes from index `startIndex` to `startIndex` + 7 to a Double value. The order of bytes in the array must reflect the endianness of the computer system's architecture. For more information, see the Remarks section of the BitConverter class topic.

BitConverter.ToHalf Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToHalf(ReadOnlySpan<Byte>)	Converts a read-only byte span into a half-precision floating-point value.
ToHalf(Byte[], Int32)	Returns a laft-precision floating point number converted from two bytes at a specified position in a byte array.

ToHalf(ReadOnlySpan<Byte>)

Converts a read-only byte span into a half-precision floating-point value.

C#

```
public static Half ToHalf (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

Half

A half-precision floating-point value that represents the converted bytes.

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 2.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToHalf(Byte[], Int32)

Returns a laft-precision floating point number converted from two bytes at a specified position in a byte array.

```
C#

public static Half ToHalf (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes that includes the two bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

Half

A half-precision floating point number formed by two bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` equals the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

BitConverter.ToInt16 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToInt16(Byte[], Int32)	Returns a 16-bit signed integer converted from two bytes at a specified position in a byte array.
ToInt16(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 16-bit signed integer.

ToInt16(Byte[], Int32)

Returns a 16-bit signed integer converted from two bytes at a specified position in a byte array.

C#

```
public static short ToInt16 (byte[] value, int startIndex);
```

Parameters

value Byte[]

An array of bytes that includes the two bytes to convert.

startIndex Int32

The starting position within `value`.

Returns

Int16

A 16-bit signed integer formed by two bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` equals the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to Int16 values with the `ToInt16` method.

C#

```
// Example of the BitConverter.ToInt16 method.
using System;

class BytesToInt16Demo
{
    const string formatter = "{0,5}{1,17}{2,10}";

    // Convert two byte array elements to a short and display it.
    public static void BAToInt16( byte[ ] bytes, int index )
    {
        short value = BitConverter.ToInt16( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 2 ), value );
    }

    public static void Main( )
    {
        byte[ ] byteArray =
            { 15, 0, 0, 128, 16, 39, 240, 216, 241, 255, 127 };

        Console.WriteLine(
            "This example of the BitConverter.ToInt16( byte[ ], " +
            "int ) \nmethod generates the following output. It " +
            "converts elements \nof a byte array to short values.\n" );
        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );
        Console.WriteLine( BitConverter.ToString( byteArray ) );
        Console.WriteLine( );
        Console.WriteLine( formatter, "index", "array elements", "short"
);
```

```
        Console.WriteLine( formatter, "-----", "--------------", "-----"
);

        // Convert byte array elements to short values.
        BAToInt16( byteArray, 1 );
        BAToInt16( byteArray, 0 );
        BAToInt16( byteArray, 8 );
        BAToInt16( byteArray, 4 );
        BAToInt16( byteArray, 6 );
        BAToInt16( byteArray, 9 );
        BAToInt16( byteArray, 2 );
    }
}

/*
This example of the BitConverter.ToInt16( byte[ ], int )
method generates the following output. It converts elements
of a byte array to short values.

initial byte array
------------------
0F-00-00-80-10-27-F0-D8-F1-FF-7F

index   array elements     short
-----   --------------     -----
    1            00-00         0
    0            0F-00        15
    8            F1-FF       -15
    4            10-27     10000
    6            F0-D8    -10000
    9            FF-7F     32767
    2            00-80    -32768
*/
```

Remarks

The ToInt16 method converts the bytes from index `startIndex` to `startIndex` + 1 to an Int16 value. The order of bytes in the array must reflect the endianness of the computer system's architecture. For more information, see the Remarks section of the BitConverter class topic.

BitConverter.ToInt32 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToInt32(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 32-bit signed integer.
ToInt32(Byte[], Int32)	Returns a 32-bit signed integer converted from four bytes at a specified position in a byte array.

ToInt32(ReadOnlySpan<Byte>)

Converts a read-only byte span into a 32-bit signed integer.

C#

```
public static int ToInt32 (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

Int32

A 32-bit signed integer representing the converted bytes.

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 4.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToInt32(Byte[], Int32)

Returns a 32-bit signed integer converted from four bytes at a specified position in a byte array.

C#

```
public static int ToInt32 (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes that includes the four bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

Int32

A 32-bit signed integer formed by four bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` is greater than or equal to the length of `value` minus 3, and is less than or equal to the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following example uses the ToInt32 method to create Int32 values from a four-byte array and from the upper four bytes of an eight-byte array. It also uses the GetBytes(Int32) and ToInt32 methods to round-trip an Int32 value.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Create an Integer from a 4-byte array.
      Byte[] bytes1 = { 0xEC, 0x00, 0x00, 0x00 };
      Console.WriteLine("{0}--> 0x{1:X4} ({1:N0})", FormatBytes(bytes1),
                                     BitConverter.ToInt32(bytes1, 0));
      // Create an Integer from the upper four bytes of a byte array.
      Byte[] bytes2 = BitConverter.GetBytes(Int64.MaxValue / 2);
      Console.WriteLine("{0}--> 0x{1:X4} ({1:N0})", FormatBytes(bytes2),
                                     BitConverter.ToInt32(bytes2, 4));

      // Round-trip an integer value.
      int original = (int) Math.Pow(16, 3);
      Byte[] bytes3 = BitConverter.GetBytes(original);
      int restored = BitConverter.ToInt32(bytes3, 0);
      Console.WriteLine("0x{0:X4} ({0:N0}) --> {1} --> 0x{2:X4}
({2:N0})", original,
                        FormatBytes(bytes3), restored);
   }

   private static string FormatBytes(Byte[] bytes)
   {
       string value = "";
       foreach (var byt in bytes)
          value += string.Format("{0:X2} ", byt);

       return value;
   }
}
// The example displays the following output:
//       EC 00 00 00 --> 0x00EC (236)
```

```
//       FF FF FF FF FF FF FF 3F --> 0x3FFFFFFF (1,073,741,823)
//       0x1000 (4,096) --> 00 10 00 00  --> 0x1000 (4,096)
```

Remarks

The ToInt32 method converts the bytes from index `startIndex` to `startIndex` + 3 to an Int32 value. The order of bytes in the array must reflect the endianness of the computer system's architecture. For more information, see the Remarks section of BitConverter.

BitConverter.ToInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToInt64(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 64-bit signed integer.
ToInt64(Byte[], Int32)	Returns a 64-bit signed integer converted from eight bytes at a specified position in a byte array.

ToInt64(ReadOnlySpan<Byte>)

Converts a read-only byte span into a 64-bit signed integer.

C#

```
public static long ToInt64 (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

Int64

A 64-bit signed integer representing the converted bytes.

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 8.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToInt64(Byte[], Int32)

Returns a 64-bit signed integer converted from eight bytes at a specified position in a byte array.

C#

```
public static long ToInt64 (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes that includes the eight bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

Int64

A 64-bit signed integer formed by eight bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` is greater than or equal to the length of `value` minus 7, and is less than or equal to the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to Int64 values with the `ToInt64` method.

C#

```
// Example of the BitConverter.ToInt64 method.
using System;

class BytesToInt64Demo
{
    const string formatter = "{0,5}{1,27}{2,24}";

    // Convert eight byte array elements to a long and display it.
    public static void BAToInt64( byte[ ] bytes, int index )
    {
        long value = BitConverter.ToInt64( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 8 ), value );
    }

    // Display a byte array, using multiple lines if necessary.
    public static void WriteMultiLineByteArray( byte[ ] bytes )
    {
        const int rowSize = 20;
        int iter;

        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );

        for( iter = 0; iter < bytes.Length - rowSize; iter += rowSize )
        {
            Console.Write(
                BitConverter.ToString( bytes, iter, rowSize ) );
            Console.WriteLine( "-" );
        }

        Console.WriteLine( BitConverter.ToString( bytes, iter ) );
        Console.WriteLine( );
    }

    public static void Main( )
```

```
    {
        byte[ ] byteArray = {
              0,  54, 101, 196, 255, 255, 255, 255,   0,   0,
              0,   0,   0,   0,   0,   0, 128,   0, 202, 154,
             59,   0,   0,   0,   0,   1,   0,   0,   0,   0,
            255, 255, 255, 255,   1,   0,   0, 255, 255, 255,
            255, 255, 255, 255, 127,  86,  85,  85,  85,  85,
             85, 255, 255, 170, 170, 170, 170, 170, 170,   0,
              0, 100, 167, 179, 182, 224,  13,   0,   0, 156,
             88,  76,  73,  31, 242 };

        Console.WriteLine(
            "This example of the BitConverter.ToInt64( byte[ ], " +
            "int ) \nmethod generates the following output. It " +
            "converts elements \nof a byte array to long values.\r\n" );

        WriteMultiLineByteArray( byteArray );

        Console.WriteLine( formatter, "index", "array elements", "long"
);
        Console.WriteLine( formatter, "-----", "--------------", "----"
);

        // Convert byte array elements to long values.
        BAToInt64( byteArray, 8 );
        BAToInt64( byteArray, 5 );
        BAToInt64( byteArray, 34 );
        BAToInt64( byteArray, 17 );
        BAToInt64( byteArray, 0 );
        BAToInt64( byteArray, 21 );
        BAToInt64( byteArray, 26 );
        BAToInt64( byteArray, 53 );
        BAToInt64( byteArray, 45 );
        BAToInt64( byteArray, 59 );
        BAToInt64( byteArray, 67 );
        BAToInt64( byteArray, 37 );
        BAToInt64( byteArray, 9 );
    }
}

/*
This example of the BitConverter.ToInt64( byte[ ], int )
method generates the following output. It converts elements
of a byte array to long values.

initial byte array

*/
```

Remarks

The ToInt64 method converts the bytes from index `startIndex` to `startIndex` + 7 to a Int64 value. The order of bytes in the array must reflect the endianness of the computer system's architecture. For more information, see the Remarks section of the BitConverter class topic.

BitConverter.ToSingle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToSingle(ReadOnlySpan<Byte>)	Converts a read-only byte span into a single-precision floating-point value.
ToSingle(Byte[], Int32)	Returns a single-precision floating point number converted from four bytes at a specified position in a byte array.

ToSingle(ReadOnlySpan<Byte>)

Converts a read-only byte span into a single-precision floating-point value.

C#

```
public static float ToSingle (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

Single

A single-precision floating-point value representing the converted bytes.

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than the length of a Single value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToSingle(Byte[], Int32)

Returns a single-precision floating point number converted from four bytes at a specified position in a byte array.

C#

```
public static float ToSingle (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes.

`startIndex` Int32

The starting position within `value`.

Returns

Single

A single-precision floating point number formed by four bytes beginning at `startIndex`.

Exceptions

ArgumentException

`startIndex` is greater than or equal to the length of `value` minus 3, and is less than or equal to the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to Single values with the `ToSingle` method.

C#

```
// Example of the BitConverter.ToSingle method.
using System;

class BytesToSingleDemo
{
    const string formatter = "{0,5}{1,17}{2,18:E7}";

    // Convert four byte array elements to a float and display it.
    public static void BAToSingle( byte[ ] bytes, int index )
    {
        float value = BitConverter.ToSingle( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 4 ), value );
    }

    // Display a byte array, using multiple lines if necessary.
    public static void WriteMultiLineByteArray( byte[ ] bytes )
    {
        const int rowSize = 20;
        int iter;

        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );

        for( iter = 0; iter < bytes.Length - rowSize; iter += rowSize )
        {
            Console.Write(
                BitConverter.ToString( bytes, iter, rowSize ) );
            Console.WriteLine( "-" );
        }

        Console.WriteLine( BitConverter.ToString( bytes, iter ) );
        Console.WriteLine( );
    }

    public static void Main( )
```

```
    {
        byte[ ] byteArray = {
              0,   0,   0,   0, 128,  63,   0,   0, 112,  65,
              0, 255, 127,  71,   0,   0, 128,  59,   0,   0,
            128,  47,  73,  70, 131,   5,  75,   6, 158,  63,
             77,   6, 158,  63,  80,   6, 158,  63,  30,  55,
            190, 121, 255, 255, 127, 255, 255, 127, 127,   1,
              0,   0,   0, 192, 255,   0,   0, 128, 255,   0,
              0, 128, 127 };

        Console.WriteLine(
            "This example of the BitConverter.ToSingle( byte( ), " +
            "int ) \nmethod generates the following output. It " +
            "converts elements \nof a byte array to float values.\n" );

        WriteMultiLineByteArray( byteArray );

        Console.WriteLine( formatter, "index", "array elements",
            "float" );
        Console.WriteLine( formatter, "-----", "--------------",
            "-----" );

        // Convert byte array elements to float values.
        BAToSingle( byteArray, 0 );
        BAToSingle( byteArray, 2 );
        BAToSingle( byteArray, 6 );
        BAToSingle( byteArray, 10 );
        BAToSingle( byteArray, 14 );
        BAToSingle( byteArray, 18 );
        BAToSingle( byteArray, 22 );
        BAToSingle( byteArray, 26 );
        BAToSingle( byteArray, 30 );
        BAToSingle( byteArray, 34 );
        BAToSingle( byteArray, 38 );
        BAToSingle( byteArray, 42 );
        BAToSingle( byteArray, 45 );
        BAToSingle( byteArray, 49 );
        BAToSingle( byteArray, 51 );
        BAToSingle( byteArray, 55 );
        BAToSingle( byteArray, 59 );
    }
}

/*
This example of the BitConverter.ToSingle( byte( ), int )
method generates the following output. It converts elements
of a byte array to float values.

initial byte array

BitConverter.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of each element of a specified array of bytes to its equivalent hexadecimal string representation.

Overloads

Expand table

ToString(Byte[])	Converts the numeric value of each element of a specified array of bytes to its equivalent hexadecimal string representation.
ToString(Byte[], Int32)	Converts the numeric value of each element of a specified subarray of bytes to its equivalent hexadecimal string representation.
ToString(Byte[], Int32, Int32)	Converts the numeric value of each element of a specified subarray of bytes to its equivalent hexadecimal string representation.

ToString(Byte[])

Converts the numeric value of each element of a specified array of bytes to its equivalent hexadecimal string representation.

C#

```
public static string ToString (byte[] value);
```

Parameters

`value` Byte[]

An array of bytes.

Returns

String

A string of hexadecimal pairs separated by hyphens, where each pair represents the corresponding element in `value`; for example, "7F-2C-4A-00".

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following code example converts Byte arrays to String objects with the `ToString` method.

C#

```
// Example of the BitConverter.ToString( byte[ ] ) method.
using System;

class BytesToStringDemo
{
    // Display a byte array with a name.
    public static void WriteByteArray( byte[ ] bytes, string name )
    {
        const string underLine = "--------------------------------";

        Console.WriteLine( name );
        Console.WriteLine( underLine.Substring( 0,
            Math.Min( name.Length, underLine.Length ) ) );
        Console.WriteLine( BitConverter.ToString( bytes ) );
        Console.WriteLine( );
    }

    public static void Main( )
    {
        byte[ ] arrayOne = {
             0,   1,   2,   4,   8,  16,  32,  64, 128, 255 };

        byte[ ] arrayTwo = {
            32,   0,   0,  42,   0,  65,   0, 125,   0, 197,
             0, 168,   3,  41,   4, 172,  32 };

        byte[ ] arrayThree = {
            15,   0,   0, 128,  16,  39, 240, 216, 241, 255,
           127 };

        byte[ ] arrayFour = {
            15,   0,   0,   0,   0,  16,   0, 255,   3,   0,
             0, 202, 154,  59, 255, 255, 255, 255, 127 };
```

```
        Console.WriteLine( "This example of the " +
            "BitConverter.ToString( byte[ ] ) \n" +
            "method generates the following output.\n" );

        WriteByteArray( arrayOne, "arrayOne" );
        WriteByteArray( arrayTwo, "arrayTwo" );
        WriteByteArray( arrayThree, "arrayThree" );
        WriteByteArray( arrayFour, "arrayFour" );
    }
}

/*
This example of the BitConverter.ToString( byte[ ] )
method generates the following output.

arrayOne
--------
00-01-02-04-08-10-20-40-80-FF

arrayTwo
--------
20-00-00-2A-00-41-00-7D-00-C5-00-A8-03-29-04-AC-20

arrayThree
----------
0F-00-00-80-10-27-F0-D8-F1-FF-7F

arrayFour
---------
0F-00-00-00-00-10-00-FF-03-00-00-CA-9A-3B-FF-FF-FF-FF-7F
*/
```

Remarks

All the elements of `value` are converted.

ToString(Byte[], Int32)

Converts the numeric value of each element of a specified subarray of bytes to its equivalent hexadecimal string representation.

```
C#
public static string ToString (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes.

`startIndex` Int32

The starting position within `value`.

Returns

String

A string of hexadecimal pairs separated by hyphens, where each pair represents the corresponding element in a subarray of `value`; for example, "7F-2C-4A-00".

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts the part of a Byte array starting at the specified `startIndex` to a String with the `ToString` method.

C#

```
// Example of some BitConverter.ToString( ) method overloads.
using System;

class BytesToStringDemo
{
    // Display a byte array, using multiple lines if necessary.
    public static void WriteMultiLineByteArray( byte[ ] bytes,
        string name )
    {
        const int rowSize = 20;
        const string underLine = "--------------------------------";
        int iter;

        Console.WriteLine( name );
        Console.WriteLine( underLine.Substring( 0,
            Math.Min( name.Length, underLine.Length ) ) );

        for( iter = 0; iter < bytes.Length - rowSize; iter += rowSize )
        {
            Console.Write(
                BitConverter.ToString( bytes, iter, rowSize ) );
            Console.WriteLine( "-" );
        }

        Console.WriteLine( BitConverter.ToString( bytes, iter ) );
        Console.WriteLine( );
    }

    public static void Main( )
    {
        byte[ ] arrayOne = {
              0,   0,   0,   0, 128,  63,   0,   0, 112,  65,

*/
```

Remarks

The elements from array position `startIndex` to the end of the array are converted.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(Byte[], Int32, Int32)

Converts the numeric value of each element of a specified subarray of bytes to its equivalent hexadecimal string representation.

C#

```
public static string ToString (byte[] value, int startIndex, int length);
```

Parameters

`value` Byte[]

An array of bytes that includes the bytes to convert.

`startIndex` Int32

The starting position within `value`.

`length` Int32

The number of array elements in `value` to convert.

Returns

String

A string of hexadecimal pairs separated by hyphens, where each pair represents the corresponding element in a subarray of `value`; for example, "7F-2C-4A-00".

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` or `length` is less than zero.

-or-

`startIndex` is greater than zero and is greater than or equal to the length of `value`.

ArgumentException

The combination of `startIndex` and `length` does not specify a position within `value`; that is, the `startIndex` parameter is greater than the length of `value` minus the `length` parameter.

Examples

The following example uses the ToString method to convert part of a byte array, starting at the specified `startIndex` and with the specified `length`, to a string.

C#

```
// Example of some BitConverter.ToString( ) method overloads.
using System;

class BytesToStringDemo
{
    // Display a byte array, using multiple lines if necessary.
    public static void WriteMultiLineByteArray( byte[ ] bytes,
        string name )
    {
        const int rowSize = 20;
        const string underLine = "--------------------------------";
        int iter;

        Console.WriteLine( name );
        Console.WriteLine( underLine.Substring( 0,
            Math.Min( name.Length, underLine.Length ) ) );

        for( iter = 0; iter < bytes.Length - rowSize; iter += rowSize )
        {
            Console.Write(
                BitConverter.ToString( bytes, iter, rowSize ) );
            Console.WriteLine( "-" );
        }

        Console.WriteLine( BitConverter.ToString( bytes, iter ) );
        Console.WriteLine( );
```

```
    }

    public static void Main( )
    {
        byte[ ] arrayOne = {
              0,   0,   0,   0, 128,  63,   0,   0, 112,  65,

BitConverter.ToUInt16 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToUInt16(ReadOnlySpan<Byte>)	Converts a read-only byte-span into a 16-bit unsigned integer.
ToUInt16(Byte[], Int32)	Returns a 16-bit unsigned integer converted from two bytes at a specified position in a byte array.

ToUInt16(ReadOnlySpan<Byte>)

> Important
>
> This API is not CLS-compliant.

Converts a read-only byte-span into a 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

UInt16

An 16-bit unsigned integer representing the converted bytes.

Attributes CLSCompliantAttribute

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 2.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToUInt16(Byte[], Int32)

> Important
>
> This API is not CLS-compliant.

Returns a 16-bit unsigned integer converted from two bytes at a specified position in a byte array.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

The array of bytes that includes the two bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

UInt16

A 16-bit unsigned integer formed by two bytes beginning at `startIndex`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`startIndex` equals the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to UInt16 values with the `ToUInt16` method.

C#

```
// Example of the BitConverter.ToUInt16 method.
using System;

class BytesToUInt16Demo
{
    const string formatter = "{0,5}{1,17}{2,10}";

    // Convert two byte array elements to a ushort and display it.
    public static void BAToUInt16( byte[ ] bytes, int index )
    {
        ushort value = BitConverter.ToUInt16( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 2 ), value );
    }

    public static void Main( )
    {
        byte[] byteArray = {
            15, 0, 0, 255, 3, 16, 39, 255, 255, 127 };
```

```
        Console.WriteLine(
            "This example of the BitConverter.ToUInt16( byte[ ], " +
            "int ) \nmethod generates the following output. It " +
            "converts elements \nof a byte array to ushort values.\n" );
        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );
        Console.WriteLine( BitConverter.ToString( byteArray ) );
        Console.WriteLine( );
        Console.WriteLine( formatter, "index", "array elements",
            "ushort" );
        Console.WriteLine( formatter, "-----", "--------------",
            "------" );

        // Convert byte array elements to ushort values.
        BAToUInt16( byteArray, 1 );
        BAToUInt16( byteArray, 0 );
        BAToUInt16( byteArray, 3 );
        BAToUInt16( byteArray, 5 );
        BAToUInt16( byteArray, 8 );
        BAToUInt16( byteArray, 7 );
    }
}

/*
This example of the BitConverter.ToUInt16( byte[ ], int )
method generates the following output. It converts elements
of a byte array to ushort values.

initial byte array
------------------
0F-00-00-FF-03-10-27-FF-FF-7F

index   array elements    ushort
-----   --------------    ------
    1            00-00         0
    0            0F-00        15
    3            FF-03      1023
    5            10-27     10000
    8            FF-7F     32767
    7            FF-FF     65535
*/
```

Remarks

The ToUInt16 method converts the bytes from index `startIndex` to `startIndex` + 1 to a UInt16 value. The order of bytes in the array must reflect the endianness of the computer system's architecture. For more information, see the Remarks section of the BitConverter class topic.

BitConverter.ToUInt32 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToUInt32(ReadOnlySpan<Byte>)	Converts a read-only byte span into a 32-bit unsigned integer.
ToUInt32(Byte[], Int32)	Returns a 32-bit unsigned integer converted from four bytes at a specified position in a byte array.

ToUInt32(ReadOnlySpan<Byte>)

> Important
>
> This API is not CLS-compliant.

Converts a read-only byte span into a 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

UInt32

A 32-bit unsigned integer representing the converted bytes.

Attributes CLSCompliantAttribute

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 4.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToUInt32(Byte[], Int32)

> Important
>
> This API is not CLS-compliant.

Returns a 32-bit unsigned integer converted from four bytes at a specified position in a byte array.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes.

`startIndex` Int32

The starting position within `value`.

Returns

UInt32

A 32-bit unsigned integer formed by four bytes beginning at `startIndex`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`startIndex` is greater than or equal to the length of `value` minus 3, and is less than or equal to the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to UInt32 values with the `ToUInt32` method.

C#

```
// Example of the BitConverter.ToUInt32 method.
using System;

class BytesToUInt32Demo
{
    const string formatter = "{0,5}{1,17}{2,15}";

    // Convert four byte array elements to a uint and display it.
    public static void BAToUInt32( byte[ ] bytes, int index )
    {
        uint value = BitConverter.ToUInt32( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 4 ), value );
    }

    public static void Main( )
    {
        byte[ ] byteArray = {
             15,   0,   0,   0,   0,  16,   0, 255,   3,   0,
```

```
                0, 202, 154,  59, 255, 255, 255, 255, 127 };

        Console.WriteLine(
            "This example of the BitConverter.ToUInt32( byte[ ], " +
            "int ) \nmethod generates the following output. It " +
            "converts elements \nof a byte array to uint values.\n" );
        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );
        Console.WriteLine( BitConverter.ToString( byteArray ) );
        Console.WriteLine( );
        Console.WriteLine( formatter, "index", "array elements",
            "uint" );
        Console.WriteLine( formatter, "-----", "--------------",
            "----" );

        // Convert byte array elements to uint values.
        BAToUInt32( byteArray, 1 );
        BAToUInt32( byteArray, 0 );
        BAToUInt32( byteArray, 7 );
        BAToUInt32( byteArray, 3 );
        BAToUInt32( byteArray, 10 );
        BAToUInt32( byteArray, 15 );
        BAToUInt32( byteArray, 14 );
    }
}

/*
This example of the BitConverter.ToUInt32( byte[ ], int )
method generates the following output. It converts elements
of a byte array to uint values.

initial byte array
------------------
0F-00-00-00-00-10-00-FF-03-00-00-CA-9A-3B-FF-FF-FF-FF-7F

index   array elements           uint
-----   --------------           ----
    1      00-00-00-00              0
    0      0F-00-00-00             15
    7      FF-03-00-00           1023
    3      00-00-10-00        1048576
   10      00-CA-9A-3B     1000000000
   15      FF-FF-FF-7F     2147483647
   14      FF-FF-FF-FF     4294967295
*/
```

Remarks

The ToUInt32 method converts the bytes from index `startIndex` to `startIndex` + 3 to a UInt32 value. The order of bytes in the array must reflect the endianness of the

computer system's architecture. For more information, see the Remarks section of the BitConverter class topic.

BitConverter.ToUInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToUInt64(Byte[], Int32)	Returns a 64-bit unsigned integer converted from eight bytes at a specified position in a byte array.
ToUInt64(ReadOnlySpan<Byte>)	Converts bytes into an unsigned long.

ToUInt64(Byte[], Int32)

> Important
>
> This API is not CLS-compliant.

Returns a 64-bit unsigned integer converted from eight bytes at a specified position in a byte array.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (byte[] value, int startIndex);
```

Parameters

`value` Byte[]

An array of bytes that includes the eight bytes to convert.

`startIndex` Int32

The starting position within `value`.

Returns

UInt64

A 64-bit unsigned integer formed by the eight bytes beginning at `startIndex`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`startIndex` is greater than or equal to the length of `value` minus 7, and is less than or equal to the length of `value` minus 1.

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of `value` minus 1.

Examples

The following code example converts elements of Byte arrays to UInt64 values with the `ToUInt64` method.

C#

```
// Example of the BitConverter.ToUInt64 method.
using System;

class BytesToUInt64Demo
{
    const string formatter = "{0,5}{1,27}{2,24}";

    // Convert eight byte array elements to a ulong and display it.
    public static void BAToUInt64( byte[ ] bytes, int index )
    {
        ulong value = BitConverter.ToUInt64( bytes, index );

        Console.WriteLine( formatter, index,
            BitConverter.ToString( bytes, index, 8 ), value );
    }

    // Display a byte array, using multiple lines if necessary.
    public static void WriteMultiLineByteArray( byte[ ] bytes )
    {
        const int rowSize = 20;
```

```
        int iter;

        Console.WriteLine( "initial byte array" );
        Console.WriteLine( "------------------" );

        for( iter = 0; iter < bytes.Length - rowSize; iter += rowSize )
        {
            Console.Write(
                BitConverter.ToString( bytes, iter, rowSize ) );
            Console.WriteLine( "-" );
        }

        Console.WriteLine( BitConverter.ToString( bytes, iter ) );
        Console.WriteLine( );
    }

    public static void Main( )
    {
        byte[ ] byteArray = {
            255, 255, 255,   0,   0,   0,   0,   0,   0,   0,
              0,   1,   0,   0,   0, 100, 167, 179, 182, 224,
             13,   0, 202, 154,  59,   0,   0,   0,   0, 170,
            170, 170, 170, 170, 170,   0,   0, 232, 137,   4,
             35, 199, 138, 255, 255, 255, 255, 255, 255, 255,
            255, 127 };

        Console.WriteLine(
            "This example of the BitConverter.ToUInt64( byte[ ], " +
            "int ) \nmethod generates the following output. It " +
            "converts elements \nof a byte array to ulong values.\n" );

        WriteMultiLineByteArray( byteArray );

        Console.WriteLine( formatter, "index", "array elements",
            "ulong" );
        Console.WriteLine( formatter, "-----", "--------------",
            "------" );

        // Convert byte array elements to ulong values.
        BAToUInt64( byteArray, 3 );
        BAToUInt64( byteArray, 0 );
        BAToUInt64( byteArray, 21 );
        BAToUInt64( byteArray, 7 );
        BAToUInt64( byteArray, 29 );
        BAToUInt64( byteArray, 13 );
        BAToUInt64( byteArray, 35 );
        BAToUInt64( byteArray, 44 );
        BAToUInt64( byteArray, 43 );
    }
}

/*
This example of the BitConverter.ToUInt64( byte[ ], int )
method generates the following output. It converts elements
of a byte array to ulong values.
```

```
initial byte array
------------------

ToUInt64(ReadOnlySpan<Byte>)

> Important
>
> This API is not CLS-compliant.

Converts bytes into an unsigned long.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

A read-only span containing the bytes to convert.

Returns

UInt64

A 64-bit unsigned integer representing the converted bytes.

Attributes CLSCompliantAttribute

Exceptions

ArgumentOutOfRangeException

The length of `value` is less than 8.

BitConverter.TryWriteBytes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryWriteBytes(Span<Byte>, Int64)	Converts a 64-bit signed integer into a span of bytes.
TryWriteBytes(Span<Byte>, Boolean)	Converts a Boolean into a span of bytes.
TryWriteBytes(Span<Byte>, Char)	Converts a character into a span of bytes.
TryWriteBytes(Span<Byte>, Double)	Converts a double-precision floating-point value into a span of bytes.
TryWriteBytes(Span<Byte>, Half)	Converts a half-precision floating-point value into a span of bytes.
TryWriteBytes(Span<Byte>, Int16)	Converts a 16-bit signed integer into a span of bytes.
TryWriteBytes(Span<Byte>, Int32)	Converts a 32-bit signed integer into a span of bytes.
TryWriteBytes(Span<Byte>, Single)	Converts a single-precision floating-point value into a span of bytes.
TryWriteBytes(Span<Byte>, UInt16)	Converts an unsigned 16-bit integer into a span of bytes.
TryWriteBytes(Span<Byte>, UInt32)	Converts a 32-bit unsigned integer into a span of bytes.
TryWriteBytes(Span<Byte>, UInt64)	Converts an unsigned 64-bit integer into a span of bytes.

TryWriteBytes(Span<Byte>, Int64)

Converts a 64-bit signed integer into a span of bytes.

C#

```
public static bool TryWriteBytes (Span<byte> destination, long value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted 64-bit signed integer.

`value` Int64

The 64-bit signed integer to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Boolean)

Converts a Boolean into a span of bytes.

C#

```
public static bool TryWriteBytes (Span<byte> destination, bool value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted Boolean.

`value` Boolean

The Boolean to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Char)

Converts a character into a span of bytes.

C#

```
public static bool TryWriteBytes (Span<byte> destination, char value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted character.

`value` Char

The character to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Double)

Converts a double-precision floating-point value into a span of bytes.

C#

```
public static bool TryWriteBytes (Span<byte> destination, double value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted double-precision floating-point value.

`value` Double

The double-precision floating-point value to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Half)

Converts a half-precision floating-point value into a span of bytes.

```
C#
public static bool TryWriteBytes (Span<byte> destination, Half value);
```

Parameters

destination Span<Byte>

When this method returns, the bytes representing the converted half-precision floating-point value.

value Half

The half-precision floating-point value to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryWriteBytes(Span<Byte>, Int16)

Converts a 16-bit signed integer into a span of bytes.

```
C#
public static bool TryWriteBytes (Span<byte> destination, short value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted 16-bit signed integer.

`value` Int16

The 16-bit signed integer to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Int32)

Converts a 32-bit signed integer into a span of bytes.

C#

```
public static bool TryWriteBytes (Span<byte> destination, int value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted 32-bit signed integer.

`value` Int32

The 32-bit signed integer to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Single)

Converts a single-precision floating-point value into a span of bytes.

C#

```
public static bool TryWriteBytes (Span<byte> destination, float value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted single-precision floating-point value.

`value` Single

The single-precision floating-point value to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, UInt16)

> Important
>
> This API is not CLS-compliant.

Converts an unsigned 16-bit integer into a span of bytes.

C#

```
[System.CLSCompliant(false)]
public static bool TryWriteBytes (Span<byte> destination, ushort value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted unsigned 16-bit integer.

`value` UInt16

The unsigned 16-bit integer to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, UInt32)

> Important
>
> This API is not CLS-compliant.

Converts a 32-bit unsigned integer into a span of bytes.

C#

```
[System.CLSCompliant(false)]
public static bool TryWriteBytes (Span<byte> destination, uint value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted unsigned 32-bit integer.

`value` UInt32

The unsigned 32-bit integer to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, UInt64)

> Important
>
> This API is not CLS-compliant.

Converts an unsigned 64-bit integer into a span of bytes.

C#

```
[System.CLSCompliant(false)]
public static bool TryWriteBytes (Span<byte> destination, ulong value);
```

Parameters

`destination` Span<Byte>

When this method returns, the bytes representing the converted unsigned 64-bit integer.

`value` UInt64

The unsigned 64-bit integer to convert.

Returns

Boolean

`true` if the conversion was successful; `false` otherwise.

BitConverter.UInt16BitsToHalf(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified 16-bit unsigned integer to a half-precision floating point number.

C#

```
[System.CLSCompliant(false)]
public static Half UInt16BitsToHalf (ushort value);
```

Parameters

`value` UInt16

The number to convert.

Returns

Half

A half-precision floating point number whose bits are identical to `value`.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.UInt32BitsToSingle(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified 32-bit unsigned integer to a single-precision floating point number.

C#

```
[System.CLSCompliant(false)]
public static float UInt32BitsToSingle (uint value);
```

Parameters

value UInt32

The number to convert.

Returns

Single

A single-precision floating point number whose bits are identical to `value`.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	6, 7, 8, 9

BitConverter.UInt64BitsToDouble(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified 64-bit unsigned integer to a double-precision floating point number.

C#

```
[System.CLSCompliant(false)]
public static double UInt64BitsToDouble (ulong value);
```

Parameters

`value` UInt64

The number to convert.

Returns

Double

A double-precision floating point number whose bits are identical to `value`.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Boolean Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a Boolean (`true` or `false`) value.

```
C#

public readonly struct Boolean : IComparable, IComparable<bool>,
IConvertible, IEquatable<bool>, IParsable<bool>, ISpanParsable<bool>
```

Inheritance Object → ValueType → Boolean

Implements IComparable , IComparable<Boolean> , IConvertible , IEquatable<Boolean> , IParsable<Boolean> , IParsable<TSelf> , ISpanParsable<Boolean>

Remarks

For more information about this API, see Supplemental API remarks for Boolean.

Fields

Expand table

FalseString	Represents the Boolean value `false` as a string. This field is read-only.
TrueString	Represents the Boolean value `true` as a string. This field is read-only.

Methods

Expand table

CompareTo(Boolean)	Compares this instance to a specified Boolean object and returns an integer that indicates their relationship to one another.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates their relationship to one another.
Equals(Boolean)	Returns a value indicating whether this instance is equal to a specified Boolean object.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the type code for the Boolean value type.
Parse(ReadOnlySpan<Char>)	Converts the specified span representation of a logical value to its Boolean equivalent.
Parse(String)	Converts the specified string representation of a logical value to its Boolean equivalent.
ToString()	Converts the value of this instance to its equivalent string representation (either "True" or "False").
ToString(IFormatProvider)	Converts the value of this instance to its equivalent string representation (either "True" or "False").
TryFormat(Span<Char>, Int32)	Tries to format the value of the current boolean instance into the provided span of characters.
TryParse(ReadOnly Span<Char>, Boolean)	Tries to convert the specified span representation of a logical value to its Boolean equivalent.
TryParse(String, Boolean)	Tries to convert the specified string representation of a logical value to its Boolean equivalent.

Explicit Interface Implementations

Expand table

IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).

IConvertible.ToChar(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Boolean.FalseString Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the Boolean value `false` as a string. This field is read-only.

```
C#
public static readonly string FalseString;
```

Field Value

String

Remarks

This field is equal to the string `"False"`.

The FalseString property defines the string representation of a `false` Boolean value in formatting and parsing operations.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Boolean.TrueString Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the Boolean value `true` as a string. This field is read-only.

C#

```
public static readonly string TrueString;
```

Field Value

String

Remarks

This field is equal to the string `"True"`.

The TrueString property defines the string representation of a `true` Boolean value in formatting and parsing operations.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Boolean.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or Boolean object and returns an integer that indicates their relationship to one another.

Overloads

Expand table

CompareTo(Boolean)	Compares this instance to a specified Boolean object and returns an integer that indicates their relationship to one another.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates their relationship to one another.

CompareTo(Boolean)

Compares this instance to a specified Boolean object and returns an integer that indicates their relationship to one another.

C#

```
public int CompareTo (bool value);
```

Parameters

`value` Boolean

A Boolean object to compare to this instance.

Returns

Int32

A signed integer that indicates the relative values of this instance and `value`.

Expand table

Return Value	Condition
Less than zero	This instance is `false` and `value` is `true`.
Zero	This instance and `value` are equal (either both are `true` or both are `false`).
Greater than zero	This instance is `true` and `value` is `false`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
```

```
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;
    Int16    c1 = -2,    c2 = 2;
    Int32    d1 = 3,     d2 = 3;
    Int64    e1 = 4,     e2 = -4;
    Decimal  f1 = -5.5m, f2 = 5.5m;
    Single   g1 = 6.6f,  g2 = 6.6f;
    Double   h1 = 7.7d,  h2 = -7.7d;
    Char     i1 = 'A',   i2 = 'A';
    String   j1 = "abc", j2 = "abc";
    DateTime k1 = now,   k2 = now;
    TimeSpan l1 = tsX,   l2 = tsX;
    Version  m1 = versX, m2 = new Version("2.0");
    Guid     n1 = guidX, n2 = guidX;

// The following types are not CLS-compliant.
    SByte    w1 = 8,     w2 = 8;
    UInt16   x1 = 9,     x2 = 9;

e1.CompareTo((Object)e2));
        Show("Decimal:  ", f1, f2, f1.CompareTo(f2),
f1.CompareTo((Object)f2));
        Show("Single:   ", g1, g2, g1.CompareTo(g2),
g1.CompareTo((Object)g2));
        Show("Double:   ", h1, h2, h1.CompareTo(h2),
h1.CompareTo((Object)h2));
        Show("Char:     ", i1, i2, i1.CompareTo(i2),
i1.CompareTo((Object)i2));
        Show("String:   ", j1, j2, j1.CompareTo(j2),
j1.CompareTo((Object)j2));
        Show("DateTime: ", k1, k2, k1.CompareTo(k2),
k1.CompareTo((Object)k2));
        Show("TimeSpan: ", l1, l2, l1.CompareTo(l2),
```

```
l1.CompareTo((Object)l2));
        Show("Version:  ", m1, m2, m1.CompareTo(m2),
m1.CompareTo((Object)m2));
        Show("Guid:     ", n1, n2, n1.CompareTo(n2),
n1.CompareTo((Object)n2));
//
        Console.WriteLine("{0}The following types are not CLS-
compliant:", nl);
        Show("SByte:    ", w1, w2, w1.CompareTo(w2),
w1.CompareTo((Object)w2));
        Show("UInt16:   ", x1, x2, x1.CompareTo(x2),
x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:
```

```
Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Boolean.CompareTo method because it does not have to convert the `value` parameter to an object.

If `value` has fewer bits (is narrower) than the instance type, some programming languages perform an implicit widening conversion that transforms the value of the parameter into a value with more bits.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method to compare the Int32 instance and parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an integer that indicates their relationship to one another.

C#

```
public int CompareTo (object? obj);
```

Parameters

`obj` Object

An object to compare to this instance, or `null`.

Returns

Int32

A signed integer that indicates the relative order of this instance and `obj`.

Expand table

Return Value	Condition
Less than zero	This instance is `false` and `obj` is `true`.
Zero	This instance and `obj` are equal (either both are `true` or both are `false`).
Greater than zero	This instance is `true` and `obj` is `false`.

Return Value	Condition
	-or- `obj` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Boolean.

Remarks

`obj` must be `null` or an instance of `Boolean`; otherwise, an exception is thrown.

This method implements the IComparable interface.

Boolean.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or Boolean.

Overloads

Expand table

Equals(Boolean)	Returns a value indicating whether this instance is equal to a specified Boolean object.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(Boolean)

Returns a value indicating whether this instance is equal to a specified Boolean object.

C#

```
public bool Equals (bool obj);
```

Parameters

obj Boolean

A Boolean value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

An object to compare to this instance.

Returns

Boolean

`true` if `obj` is a Boolean and has the same value as this instance; otherwise, `false`.

Remarks

This method overrides Equals.

Boolean.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A hash code for the current Boolean.

Remarks

The Boolean class implements `true` as the integer, one, and `false` as the integer, zero. However, a particular programming language might represent `true` and `false` with other values.

Applies to

Product	Versions

Boolean.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(ReadOnlySpan<Char>)	Converts the specified span representation of a logical value to its Boolean equivalent.
Parse(String)	Converts the specified string representation of a logical value to its Boolean equivalent.

Parse(ReadOnlySpan<Char>)

Converts the specified span representation of a logical value to its Boolean equivalent.

C#

```
public static bool Parse (ReadOnlySpan<char> value);
```

Parameters

`value` ReadOnlySpan<Char>

A span containing the characters representing the value to convert.

Returns

Boolean

`true` if `value` is equivalent to TrueString; `false` if `value` is equivalent to FalseString.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(String)

Converts the specified string representation of a logical value to its Boolean equivalent.

```
C#
public static bool Parse (string value);
```

Parameters

`value` String

A string containing the value to convert.

Returns

Boolean

`true` if `value` is equivalent to TrueString; `false` if `value` is equivalent to FalseString.

Exceptions

ArgumentNullException

`value` is `null`.

FormatException

`value` is not equivalent to TrueString or FalseString.

Examples

The following code example illustrates the use of Parse method.

```
C#
```

```
bool val;
string input;

input = bool.TrueString;
val = bool.Parse(input);
Console.WriteLine("'{0}' parsed as {1}", input, val);
// The example displays the following output:
//       'True' parsed as True
```

Remarks

The `value` parameter, optionally preceded or trailed by white space, must contain either TrueString or FalseString; otherwise, an exception is thrown. The comparison is case-insensitive.

Boolean.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to its equivalent string representation (either "True" or "False").

Overloads

Expand table

ToString(IFormatProvider)	Converts the value of this instance to its equivalent string representation (either "True" or "False").
ToString()	Converts the value of this instance to its equivalent string representation (either "True" or "False").

ToString(IFormatProvider)

Converts the value of this instance to its equivalent string representation (either "True" or "False").

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

(Reserved) An IFormatProvider object.

Returns

String

TrueString if the value of this instance is `true`, or FalseString if the value of this instance is `false`.

Implements

ToString(IFormatProvider)

Remarks

The `provider` parameter is reserved. It does not participate in the execution of this method. This means that the Boolean.ToString(IFormatProvider) method, unlike most methods with a `provider` parameter, does not reflect culture-specific settings.

This method returns the constants "True" or "False". Note that XML is case-sensitive, and that the XML specification recognizes "true" and "false" as the valid set of Boolean values. If the String object returned by the ToString(IFormatProvider) method is to be written to an XML file, its String.ToLowerInvariant method should be called first to convert it to lowercase.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToString()

Converts the value of this instance to its equivalent string representation (either "True" or "False").

C#

```
public override string ToString ();
```

Returns

String

"True" (the value of the TrueString property) if the value of this instance is `true`, or "False" (the value of the FalseString property) if the value of this instance is `false`.

Examples

The following example illustrates the ToString method.

C#

```
bool raining = false;
bool busLate = true;

Console.WriteLine("raining.ToString() returns {0}", raining);
Console.WriteLine("busLate.ToString() returns {0}", busLate);
// The example displays the following output:
//       raining.ToString() returns False
//       busLate.ToString() returns True
```

Remarks

This method returns the constants "True" or "False".

Note that XML is case-sensitive, and that the XML specification recognizes "true" and "false" as the valid set of Boolean values. If the string returned by the ToString() method is to be written to an XML file, its String.ToLowerInvariant method should be called first to convert it to lowercase.

Boolean.TryFormat(Span<Char>, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current boolean instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Boolean.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, Boolean)	Tries to convert the specified span representation of a logical value to its Boolean equivalent.
TryParse(String, Boolean)	Tries to convert the specified string representation of a logical value to its Boolean equivalent.

TryParse(ReadOnlySpan<Char>, Boolean)

Tries to convert the specified span representation of a logical value to its Boolean equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<char> value, out bool result);
```

Parameters

`value` ReadOnlySpan<Char>

A span containing the characters representing the value to convert.

`result` Boolean

When this method returns, if the conversion succeeded, contains `true` if `value` is equal to TrueString or `false` if `value` is equal to FalseString. If the conversion failed, contains `false`. The conversion fails if `value` is `null` or is not equal to the value of either the TrueString or FalseString field.

Returns

Boolean

`true` if `value` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Boolean)

Tries to convert the specified string representation of a logical value to its Boolean equivalent.

C#

```
public static bool TryParse (string? value, out bool result);
```

Parameters

`value` String

A string containing the value to convert.

`result` Boolean

When this method returns, if the conversion succeeded, contains `true` if `value` is equal to TrueString or `false` if `value` is equal to FalseString. If the conversion failed, contains `false`. The conversion fails if `value` is `null` or is not equal to the value of either the TrueString or FalseString field.

Returns

Boolean

`true` if `value` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParse method to parse an array of strings. Note that the parse operation succeeds only if the string to be parsed is "True" (the value of the TrueString field) or "False" (the value of the FalseString field) in a case-insensitive comparison.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] values = { null, String.Empty, "True", "False",
                          "true", "false", "    true    ", "0",
                          "1", "-1", "string" };
      foreach (var value in values) {
         bool flag;
         if (Boolean.TryParse(value, out flag))
            Console.WriteLine("'{0}' --> {1}", value, flag);
         else
            Console.WriteLine("Unable to parse '{0}'.",
                              value == null ? "<null>" : value);
      }
   }
}
// The example displays the following output:
//       Unable to parse '<null>'.
//       Unable to parse ''.
//       'True' --> True
//       'False' --> False
//       'true' --> True
//       'false' --> False
//       '    true    ' --> True
//       Unable to parse '0'.
//       Unable to parse '1'.
//       Unable to parse '-1'.
//       Unable to parse 'string'.
```

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails.

The `value` parameter can be preceded or followed by white space. The comparison is ordinal and case-insensitive.

Boolean.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` or `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Boolean.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Byte

1 if the value of this instance is `true`; otherwise, 0.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Boolean.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

This conversion is not supported. No value is returned.

Implements

ToChar(IFormatProvider)

Exceptions

InvalidCastException

You attempt to convert a Boolean value to a Char value. This conversion is not supported.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Boolean.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

```
C#
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

1 if this instance is `true`; otherwise, 0.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Boolean.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Double

1 if this instance is `true`; otherwise, 0.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Boolean.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Single

1 if this instance is `true`; otherwise, 0.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(Boolean) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Boolean.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The desired type.

`provider` IFormatProvider

An IFormatProvider implementation that supplies culture-specific information about the format of the returned value.

Returns

Object

An object of the specified type, with a value that is equivalent to the value of this `Boolean` object.

Implements

ToType(Type, IFormatProvider)

Exceptions

ArgumentNullException

`type` is `null`.

InvalidCastException

The requested type conversion is not supported.

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Boolean.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

UInt16

1 if this instance is `true`; otherwise, 0.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative

is to call the Convert.ToUInt16(Boolean) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Boolean.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

UInt32

1 if this instance is `true`; otherwise, 0.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative

is to call the Convert.ToUInt32(Boolean) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Boolean.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

1 if this instance is `true`; otherwise, 0.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Boolean instance is cast to an IConvertible interface. The recommended alternative

is to call the Convert.ToUInt64(Boolean) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Boolean.IParsable<Boolean>.Parse(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a string into a value.

```
C#
static bool IParsable<bool>.Parse (string s, IFormatProvider provider);
```

Parameters

s String

The string to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Boolean

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Boolean.ISpanParsable<Boolean>.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a span of characters into a value.

```
C#

static bool ISpanParsable<bool>.Parse (ReadOnlySpan<char> s, IFormatProvider
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Boolean

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Buffer Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Manipulates arrays of primitive types.

C#

```
public static class Buffer
```

Inheritance Object → Buffer

Examples

The following code example illustrates the use of several `Buffer` class methods.

C#

```
// Example of the Buffer class methods.
using System;

class BufferClassDemo
{
    // Display the array elements from right to left in hexadecimal.
    public static void DisplayArray( short[ ] arr )
    {
        Console.Write( "  arr:" );
        for( int loopX = arr.Length - 1; loopX >= 0; loopX-- )
            Console.Write( " {0:X4}", arr[ loopX ] );
        Console.WriteLine( );
    }

    public static void Main( )
    {
        // This array is to be modified and displayed.
        short[ ] arr = { 258, 259, 260, 261, 262, 263, 264,
                         265, 266, 267, 268, 269, 270, 271 };

        Console.WriteLine( "This example of the Buffer class " +
            "methods generates the following output.\n" +
            "Note: The array is displayed from right to left.\n" );
```

```
        Console.WriteLine( "Initial values of array:\n" );

        // Display the initial array values and ByteLength.
        DisplayArray( arr );
        Console.WriteLine( "\nBuffer.ByteLength( arr ): {0}",
            Buffer.ByteLength( arr ) );

        // Copy a region of the array; set a byte within the array.
        Console.WriteLine( "\nCall these methods: \n" +
            "  Buffer.BlockCopy( arr, 5, arr, 16, 9 ),\n" +
            "  Buffer.SetByte( arr, 7, 170 ).\n" );

        Buffer.BlockCopy( arr, 5, arr, 16, 9 );
        Buffer.SetByte( arr, 7, 170 );

        // Display the array and a byte within the array.
        Console.WriteLine( "Final values of array:\n" );
        DisplayArray( arr );
        Console.WriteLine( "\nBuffer.GetByte( arr, 26 ): {0}",
            Buffer.GetByte( arr, 26 ) );
    }
}

/*
This example of the Buffer class methods generates the following output.
Note: The array is displayed from right to left.

Initial values of array:

  arr: 010F 010E 010D 010C 010B 010A 0109 0108 0107 0106 0105 0104 0103 0102

Buffer.ByteLength( arr ): 28

Call these methods:
  Buffer.BlockCopy( arr, 5, arr, 16, 9 ),
  Buffer.SetByte( arr, 7, 170 ).

Final values of array:

  arr: 010F 0101 0801 0701 0601 0501 0109 0108 0107 0106 AA05 0104 0103 0102

Buffer.GetByte( arr, 26 ): 15
*/
```

Remarks

Buffer only affects arrays of primitive types; this class does not apply to objects. Each primitive type is treated as a series of bytes without regard to any behavior or limitation associated with the primitive type.

Buffer provides methods to copy bytes from one array of primitive types to another array of primitive types, get a byte from an array, set a byte in an array, and obtain the length of an array. This class provides better performance for manipulating primitive types than similar methods in the System.Array class.

Buffer is applicable to the following primitive types: Boolean, Char, SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, UInt64, IntPtr, UIntPtr, Single, and Double.

Methods

Expand table

BlockCopy(Array, Int32, Array, Int32, Int32)	Copies a specified number of bytes from a source array starting at a particular offset to a destination array starting at a particular offset.
ByteLength(Array)	Returns the number of bytes in the specified array.
GetByte(Array, Int32)	Retrieves the byte at the specified location in the specified array.
MemoryCopy(Void*, Void*, Int64, Int64)	Copies a number of bytes specified as a long integer value from one address in memory to another. This API is not CLS-compliant.
MemoryCopy(Void*, Void*, UInt64, UInt64)	Copies a number of bytes specified as an unsigned long integer value from one address in memory to another. This API is not CLS-compliant.
SetByte(Array, Int32, Byte)	Assigns a specified value to a byte at a particular location in a specified array.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Buffer.BlockCopy(Array, Int32, Array, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies a specified number of bytes from a source array starting at a particular offset to a destination array starting at a particular offset.

C#

```
public static void BlockCopy (Array src, int srcOffset, Array dst, int
dstOffset, int count);
```

Parameters

src Array

The source buffer.

srcOffset Int32

The zero-based byte offset into `src`.

dst Array

The destination buffer.

dstOffset Int32

The zero-based byte offset into `dst`.

count Int32

The number of bytes to copy.

Exceptions

ArgumentNullException

`src` or `dst` is `null`.

ArgumentException

`src` or `dst` is not an array of primitives.

-or-

The number of bytes in `src` is less than `srcOffset` plus `count`.

-or-

The number of bytes in `dst` is less than `dstOffset` plus `count`.

ArgumentOutOfRangeException

`srcOffset`, `dstOffset`, or `count` is less than 0.

Examples

The following example copies regions of arrays by using the BlockCopy method. For each BlockCopy operation, it lists the source and destination arrays as both an array of values and as a sequence of bytes. The example illustrates the importance of considering a system's endianness when working with the BlockCopy method: Because Windows systems are little-endian, the lower-order bytes of a primitive data type's value precede the higher-order bytes.

C#

```
using System;

class Example
{
    // Display the individual bytes in the array in hexadecimal.
    public static void DisplayArray(Array arr, string name)
    {
        Console.WindowWidth = 120;
        Console.Write("{0,11}:", name);
        for (int ctr = 0; ctr < arr.Length; ctr++)
        {
            byte[] bytes;
            if (arr is long[])
               bytes = BitConverter.GetBytes((long) arr.GetValue(ctr));
            else
               bytes = BitConverter.GetBytes((short) arr.GetValue(ctr));

            foreach (byte byteValue in bytes)
               Console.Write(" {0:X2}", byteValue);
        }
        Console.WriteLine();
    }
```

```
    // Display the individual array element values in hexadecimal.
    public static void DisplayArrayValues(Array arr, string name)
    {
        // Get the length of one element in the array.
        int elementLength = Buffer.ByteLength(arr) / arr.Length;
        string formatString = String.Format(" {{0:X{0}}}", 2 *
elementLength);
        Console.Write( "{0,11}:", name);
        for (int ctr = 0; ctr < arr.Length; ctr++)
            Console.Write(formatString, arr.GetValue(ctr));

        Console.WriteLine();
    }

    public static void Main( )
    {
        // These are the source and destination arrays for BlockCopy.
        short[] src  = { 258, 259, 260, 261, 262, 263, 264,
                         265, 266, 267, 268, 269, 270 };
        long[] dest = { 17, 18, 19, 20 };

        // Display the initial value of the arrays in memory.
        Console.WriteLine( "Initial values of arrays:");
        Console.WriteLine("   Array values as Bytes:");
        DisplayArray(src, "src" );
        DisplayArray(dest, "dest");
        Console.WriteLine("   Array values:");
        DisplayArrayValues(src, "src");
        DisplayArrayValues(dest, "dest");
        Console.WriteLine();

        // Copy bytes 5-10 from source to index 7 in destination and display
the result.
        Buffer.BlockCopy(src, 5, dest, 7, 6);
        Console.WriteLine("Buffer.BlockCopy(src, 5, dest, 7, 6 )");
        Console.WriteLine("   Array values as Bytes:");
        DisplayArray(src, "src");
        DisplayArray(dest, "dest");
        Console.WriteLine("   Array values:");
        DisplayArrayValues(src, "src");
        DisplayArrayValues(dest, "dest");
        Console.WriteLine();

        // Copy bytes 16-20 from source to index 22 in destination and
display the result.
        Buffer.BlockCopy(src, 16, dest, 22, 5);
        Console.WriteLine("Buffer.BlockCopy(src, 16, dest, 22, 5)");
        Console.WriteLine("   Array values as Bytes:");
        DisplayArray(src, "src");
        DisplayArray(dest, "dest");
        Console.WriteLine("   Array values:");
        DisplayArrayValues(src, "src");
        DisplayArrayValues(dest, "dest");
        Console.WriteLine();
```

```
        // Copy overlapping range of bytes 4-10 to index 5 in source.
        Buffer.BlockCopy(src, 4, src, 5, 7 );
        Console.WriteLine("Buffer.BlockCopy( src, 4, src, 5, 7)");
        Console.WriteLine("   Array values as Bytes:");
        DisplayArray(src, "src");
        DisplayArray(dest, "dest");
        Console.WriteLine("   Array values:");
        DisplayArrayValues(src, "src");
        DisplayArrayValues(dest, "dest");
        Console.WriteLine();

        // Copy overlapping range of bytes 16-22 to index 15 in source.
        Buffer.BlockCopy(src, 16, src, 15, 7);
        Console.WriteLine("Buffer.BlockCopy( src, 16, src, 15, 7)");
        Console.WriteLine("   Array values as Bytes:");
        DisplayArray(src, "src");
        DisplayArray(dest, "dest");
        Console.WriteLine("   Array values:");
        DisplayArrayValues(src, "src");
        DisplayArrayValues(dest, "dest");
    }
}
// The example displays the following output:
//    Initial values of arrays:
//       Array values as Bytes:
//            src: 02 01 03 01 04 01 05 01 06 01 07 01 08 01 09 01 0A 01 0B

010D 010E
//           dest: 0100000000000011 0000000701060105 010A000000000013
00000000000C010B
```

Remarks

This method copies `count` bytes from `src`, beginning at `srcOffset`, to `dst`, beginning at `dstOffset`. Both `srcOffset` and `dstOffset` are zero-based; that is, the first byte in each buffer is at position 0, not position 1.

The BlockCopy method accesses the bytes in the `src` parameter array using offsets into memory, not programming constructs such as indexes or upper and lower array bounds. For example, if in the programming language of your application you declare an Int32 array with a zero-based lower bound of -50, and then pass the array and an offset of 5 to the BlockCopy method, the first array element the method will access is the second element of the array, which is at index -49. Furthermore, which byte of array element -49 is accessed first depends on the endianness of the computer that is executing your application.

As its name suggests, the BlockCopy method copies a block of bytes as a whole, rather than copying one byte at a time. Therefore, if `src` and `dst` reference the same array, and the range from `srcOffset` + `count` -1 overlaps the range from `dstOffset` + `count` - 1, the values of the overlapping bytes are not overwritten before they are copied to the

destination. In the following example, the values of bytes 0-16 in an array named `arr` are copied to bytes 12-28. Despite the overlapping range, the values of the source bytes are successfully copied.

C#

```
const int INT_SIZE = 4;
int[] arr = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
Buffer.BlockCopy(arr, 0 * INT_SIZE, arr, 3 * INT_SIZE, 4 * INT_SIZE);
foreach (int value in arr)
   Console.Write("{0}  ", value);
// The example displays the following output:
//       2  4  6  2  4  6  8  16  18  20
```

In the following example, the values of bytes 12-28 in an array named `arr` are copied to bytes 0-16. Again, despite the overlapping range, the values of the source bytes are successfully copied.

C#

```
const int INT_SIZE = 4;
int[] arr = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
Buffer.BlockCopy(arr, 3 * INT_SIZE, arr, 0 * INT_SIZE, 4 * INT_SIZE);
foreach (int value in arr)
   Console.Write("{0}  ", value);
// The example displays the following output:
//       8  10  12  14  10  12  14  16  18  20
```

Buffer.ByteLength(Array) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the number of bytes in the specified array.

```
C#
public static int ByteLength (Array array);
```

Parameters

array Array

An array.

Returns

Int32

The number of bytes in the array.

Exceptions

ArgumentNullException

`array` is `null`.

ArgumentException

`array` is not a primitive.

OverflowException

`array` is larger than 2 gigabytes (GB).

Examples

The following code example illustrates the use of the `ByteLength` method to return the number of bytes in an array.

C#

```
// Example of the Buffer.ByteLength method.
using System;

class ByteLengthDemo
{
    const string formatter = "{0,10}{1,20}{2,9}{3,12}";

    public static void ArrayInfo( Array arr, string name )
    {
        int byteLength = Buffer.ByteLength( arr );

        // Display the array name, type, Length, and ByteLength.
        Console.WriteLine( formatter, name, arr.GetType( ),
            arr.Length, byteLength );
    }

    public static void Main( )
    {
        byte[ ]   bytes   = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 0 };
        bool[ ]   bools   = { true, false, true, false, true };
        char[ ]   chars   = { ' ', '$', '\"', 'A', '{' };
        short[ ]  shorts  = { 258, 259, 260, 261, 262, 263 };
        float[ ]  singles = { 1, 678, 2.37E33F, .00415F, 8.9F };
        double[ ] doubles = { 2E-22, .003, 4.4E44, 555E55 };
        long[ ]   longs   = { 1, 10, 100, 1000, 10000, 100000 };

        Console.WriteLine(
            "This example of the Buffer.ByteLength( Array ) " +
            "\nmethod generates the following output.\n" );
        Console.WriteLine( formatter, "Array name", "Array type",
            "Length", "ByteLength" );
        Console.WriteLine( formatter, "----------", "----------",
            "------", "----------" );

        // Display the Length and ByteLength for each array.
        ArrayInfo( bytes, "bytes" );
        ArrayInfo( bools, "bools" );
        ArrayInfo( chars, "chars" );
        ArrayInfo( shorts, "shorts" );
        ArrayInfo( singles, "singles" );
        ArrayInfo( doubles, "doubles" );
        ArrayInfo( longs, "longs" );
    }
}

/*
This example of the Buffer.ByteLength( Array )
method generates the following output.
```

```
Array name          Array type   Length  ByteLength
----------          ----------   ------  ----------
     bytes       System.Byte[]       10          10
     bools    System.Boolean[]        5           5
     chars       System.Char[]        5          10
    shorts      System.Int16[]        6          12
   singles     System.Single[]        5          20
   doubles     System.Double[]        4          32
     longs      System.Int64[]        6          48
*/

Buffer.GetByte(Array, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves the byte at the specified location in the specified array.

C#

```
public static byte GetByte (Array array, int index);
```

Parameters

array Array

An array.

index Int32

A location in the array.

Returns

Byte

The byte at the specified location in the array.

Exceptions

ArgumentException

`array` is not a primitive.

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is negative or greater than the length of `array`.

OverflowException

`array` is larger than 2 gigabytes (GB).

Examples

The following code example displays the byte values at specified locations within arrays using the `GetByte` method.

C#

```
// Example of the Buffer.GetByte method.
using System;

class GetByteDemo
{
    const string formatter = "{0,10}{1,10}{2,9} {3}";

    // Display the array contents in hexadecimal.
    public static void DisplayArray( Array arr, string name )
    {
        // Get the array element width; format the formatting string.
        int elemWidth = Buffer.ByteLength( arr ) / arr.Length;
        string format = String.Format( " {{0:X{0}}}", 2 * elemWidth );

        // Display the array elements from right to left.
        Console.Write( "{0,5}:", name );
        for( int loopX = arr.Length - 1; loopX >= 0; loopX-- )
            Console.Write( format, arr.GetValue( loopX ) );
        Console.WriteLine( );
    }

    public static void ArrayInfo( Array arr, string name, int index )
    {
        byte value = Buffer.GetByte( arr, index );

        // Display the array name, index, and byte to be viewed.
        Console.WriteLine( formatter, name, index, value,
            String.Format( "0x{0:X2}", value ) );
    }

    public static void Main( )
    {
        // These are the arrays to be viewed with GetByte.
        long[ ] longs =
            { 333333333333333333, 666666666666666666, 999999999999999999 };
        int[ ]  ints  =
            { 111111111, 222222222, 333333333, 444444444, 555555555 };

        Console.WriteLine( "This example of the " +
            "Buffer.GetByte( Array, int ) \n" +
            "method generates the following output.\n" +
            "Note: The arrays are displayed from right to left.\n" );
        Console.WriteLine( "  Values of arrays:\n" );
```

```
        // Display the values of the arrays.
        DisplayArray( longs, "longs" );
        DisplayArray( ints, "ints" );
        Console.WriteLine( );

        Console.WriteLine( formatter, "Array", "index", "value", "" );
        Console.WriteLine( formatter, "-----", "-----", "-----",
            "----" );

        // Display the Length and ByteLength for each array.
        ArrayInfo( ints, "ints", 0 );
        ArrayInfo( ints, "ints", 7 );
        ArrayInfo( ints, "ints", 10 );
        ArrayInfo( ints, "ints", 17 );
        ArrayInfo( longs, "longs", 0 );
        ArrayInfo( longs, "longs", 6 );
        ArrayInfo( longs, "longs", 10 );
        ArrayInfo( longs, "longs", 17 );
        ArrayInfo( longs, "longs", 21 );
    }
}

/*
This example of the Buffer.GetByte( Array, int )
method generates the following output.
Note: The arrays are displayed from right to left.

  Values of arrays:

longs: 0DE0B6B3A763FFFF 094079CD1A42AAAA 04A03CE68D215555
 ints: 211D1AE3 1A7DAF1C 13DE4355 0D3ED78E 069F6BC7

     Array     index    value
     -----     -----    ----- ----
      ints         0      199 0xC7
      ints         7       13 0x0D
      ints        10      222 0xDE
      ints        17       26 0x1A
     longs         0       85 0x55
     longs         6      160 0xA0
     longs        10       66 0x42
     longs        17      255 0xFF
     longs        21      182 0xB6
*/
```

Remarks

The `GetByte` method gets a particular byte out of the array. The array must be an array of primitives.

Buffer.MemoryCopy Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies a block of memory.

Overloads

Expand table

MemoryCopy(Void*, Void*, Int64, Int64)	Copies a number of bytes specified as a long integer value from one address in memory to another. This API is not CLS-compliant.
MemoryCopy(Void*, Void*, UInt64, UInt64)	Copies a number of bytes specified as an unsigned long integer value from one address in memory to another. This API is not CLS-compliant.

MemoryCopy(Void*, Void*, Int64, Int64)

> Important
>
> This API is not CLS-compliant.

Copies a number of bytes specified as a long integer value from one address in memory to another.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static void MemoryCopy (void* source, void* destination, long
destinationSizeInBytes, long sourceBytesToCopy);
```

Parameters

`source` Void*

The address of the bytes to copy.

`destination` Void*

The target address.

`destinationSizeInBytes` Int64

The number of bytes available in the destination memory block.

`sourceBytesToCopy` Int64

The number of bytes to copy.

Attributes CLSCompliantAttribute

Exceptions

ArgumentOutOfRangeException

`sourceBytesToCopy` is greater than `destinationSizeInBytes`.

Remarks

This method copies `sourceBytesToCopy` bytes from the address specified by `source` to the address specified by `destination`. If some regions of the source area and the destination overlap, the function ensures that the original source bytes in the overlapping region are copied before being overwritten.

Applies to

Buffer.SetByte(Array, Int32, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Assigns a specified value to a byte at a particular location in a specified array.

C#

```
public static void SetByte (Array array, int index, byte value);
```

Parameters

array Array

An array.

index Int32

A location in the array.

value Byte

A value to assign.

Exceptions

ArgumentException

`array` is not a primitive.

ArgumentNullException

`array` is `null`.

ArgumentOutOfRangeException

`index` is negative or greater than the length of `array`.

OverflowException

`array` is larger than 2 gigabytes (GB).

Examples

The following code example assigns values to bytes at particular locations within arrays using the `SetByte` method.

C#

```
// Example of the Buffer.SetByte method.
using System;

class SetByteDemo
{
    // Display the array contents in hexadecimal.
    public static void DisplayArray( Array arr, string name )
    {
        // Get the array element width; format the formatting string.
        int elemWidth = Buffer.ByteLength( arr ) / arr.Length;
        string format = String.Format( " {{0:X{0}}}", 2 * elemWidth );

        // Display the array elements from right to left.
        Console.Write( "{0,7}:", name );
        for( int loopX = arr.Length - 1; loopX >= 0; loopX-- )
            Console.Write( format, arr.GetValue( loopX ) );
        Console.WriteLine( );
    }

    public static void Main( )
    {
        // These are the arrays to be modified with SetByte.
        short[ ] shorts = new short[ 10 ];
        long[ ]  longs  = new long[ 3 ];

        Console.WriteLine( "This example of the " +
            "Buffer.SetByte( Array, int, byte ) \n" +
            "method generates the following output.\n" +
            "Note: The arrays are displayed from right to left.\n" );
        Console.WriteLine( "  Initial values of arrays:\n" );

        // Display the initial values of the arrays.
        DisplayArray( shorts, "shorts" );
        DisplayArray( longs, "longs" );

        // Copy two regions of source array to destination array,
        // and two overlapped copies from source to source.
        Console.WriteLine( "\n" +
            "  Array values after setting byte 3 = 25, \n" +
            "  byte 6 = 64, byte 12 = 121, and byte 17 = 196:\n" );

        Buffer.SetByte( shorts, 3, 25 );
        Buffer.SetByte( shorts, 6, 64 );
```

```
        Buffer.SetByte( shorts, 12, 121 );
        Buffer.SetByte( shorts, 17, 196 );
        Buffer.SetByte( longs, 3, 25 );
        Buffer.SetByte( longs, 6, 64 );
        Buffer.SetByte( longs, 12, 121 );
        Buffer.SetByte( longs, 17, 196 );

        // Display the arrays again.
        DisplayArray( shorts, "shorts" );
        DisplayArray( longs, "longs" );
    }
}

/*
This example of the Buffer.SetByte( Array, int, byte )
method generates the following output.
Note: The arrays are displayed from right to left.

  Initial values of arrays:

 shorts: 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000
  longs: 0000000000000000 0000000000000000 0000000000000000

  Array values after setting byte 3 = 25,
  byte 6 = 64, byte 12 = 121, and byte 17 = 196:

 shorts: 0000 C400 0000 0079 0000 0000 0040 0000 1900 0000
  longs: 000000000000C400 0000007900000000 0040000019000000
*/
```

Remarks

`array` must be an array of primitives.

Byte Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an 8-bit unsigned integer.

C#

```
public readonly struct Byte : IComparable<byte>, IConvertible,
IEquatable<byte>, IParsable<byte>, ISpanParsable<byte>,
IUtf8SpanParsable<byte>, System.Numerics.IAdditionOperators<byte,byte,byte>,
System.Numerics.IAdditiveIdentity<byte,byte>,
System.Numerics.IBinaryInteger<byte>, System.Numerics.IBinaryNumber<byte>,
System.Numerics.IBitwiseOperators<byte,byte,byte>,
System.Numerics.IComparisonOperators<byte,byte,bool>,
System.Numerics.IDecrementOperators<byte>,
System.Numerics.IDivisionOperators<byte,byte,byte>,
System.Numerics.IEqualityOperators<byte,byte,bool>,
System.Numerics.IIncrementOperators<byte>,
System.Numerics.IMinMaxValue<byte>,

Fields

Expand table

MaxValue	Represents the largest possible value of a Byte. This field is constant.

MinValue	Represents the smallest possible value of a Byte. This field is constant.

Methods

Expand table

Clamp(Byte, Byte, Byte)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Byte)	Compares this instance to a specified 8-bit unsigned integer and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(Byte, Byte)	Computes the quotient and remainder of two values.
Equals(Byte)	Returns a value indicating whether this instance and a specified Byte object represent the same value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type Byte.
IsEvenInteger(Byte)	Determines if a value represents an even integral number.
IsOddInteger(Byte)	Determines if a value represents an odd integral number.
IsPow2(Byte)	Determines if a value is a power of two.
LeadingZeroCount(Byte)	Computes the number of leading zeros in a value.
Log2(Byte)	Computes the log2 of a value.

Max(Byte, Byte)	Compares two values to compute which is greater.
Min(Byte, Byte)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its Byte equivalent.
Parse(String)	Converts the string representation of a number to its Byte equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its Byte equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its Byte equivalent.
Parse(String, NumberStyles, IFormat Provider)	Converts the string representation of a number in a specified style and culture-specific format to its Byte equivalent.
PopCount(Byte)	Computes the number of bits that are set in a value.
RotateLeft(Byte, Int32)	Rotates a value left by a given amount.
RotateRight(Byte, Int32)	Rotates a value right by a given amount.
Sign(Byte)	Computes the sign of a value.
ToString()	Converts the value of the current Byte object to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of the current Byte object to its equivalent string representation using the specified culture-specific formatting information.
ToString(String)	Converts the value of the current Byte object to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the value of the current Byte object to its equivalent string representation using the specified format and culture-specific formatting information.

TrailingZeroCount(Byte)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current 8-bit unsigned integer instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, Byte)	Tries to convert a UTF-8 character span containing the string representation of a number to its 8-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Byte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Byte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Byte)	Tries to convert the span representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Byte)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Byte)	Converts the span representation of a number in a specified style and culture-specific format to its Byte equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Byte)	Tries to convert the string representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, Byte)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, Byte)	Converts the string representation of a number in a specified style and culture-specific format to its Byte equivalent. A return value indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<Byte,Byte,Byte>.Addition(Byte, Byte)	Adds two values together to compute their sum.

IAdditionOperators<Byte,Byte,Byte>.CheckedAddition(Byte, Byte)	Adds two values together to compute their sum.
IAdditiveIdentity<Byte,Byte>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<Byte>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<Byte>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<Byte>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, Byte)	
IBinaryInteger<Byte>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, Byte)	
IBinaryInteger<Byte>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<Byte>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<Byte>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<Byte,Byte,Byte>.BitwiseAnd(Byte, Byte)	Computes the bitwise-and of two values.
IBitwiseOperators<Byte,Byte,Byte>.BitwiseOr(Byte, Byte)	Computes the bitwise-or of two values.
IBitwiseOperators<Byte,Byte,Byte>.ExclusiveOr(Byte, Byte)	Computes the exclusive-or of two values.
IBitwiseOperators<Byte,Byte,Byte>.OnesComplement(Byte)	Computes the ones-complement representation of a given value.
IComparisonOperators<Byte,Byte,Boolean>.GreaterThan(Byte, Byte)	Compares two values to determine which is greater.
IComparisonOperators<Byte,Byte,Boolean>.GreaterThanOrEqual(Byte, Byte)	Compares two values to determine which is greater or equal.
IComparisonOperators<Byte,Byte,Boolean>.LessThan(Byte, Byte)	Compares two values to determine which is less.
IComparisonOperators<Byte,Byte,Boolean>.LessThanOrEqual(Byte, Byte)	Compares two values to determine which is less or equal.

IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<Byte>.Checked Decrement(Byte)	Decrements a value.
IDecrementOperators<Byte>.Decrement(Byte)	Decrements a value.

IDivisionOperators<Byte,Byte,Byte>.Division(Byte, Byte)	Divides one value by another to compute their quotient.
IEqualityOperators<Byte,Byte,Boolean>.Equality(Byte, Byte)	Compares two values to determine equality.
IEquality Operators<Byte,Byte,Boolean>.Inequality(Byte, Byte)	Compares two values to determine inequality.
IIncrementOperators<Byte>.CheckedIncrement(Byte)	Increments a value.
IIncrementOperators<Byte>.Increment(Byte)	Increments a value.
IMinMaxValue<Byte>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Byte>.MinValue	Gets the minimum value of the current type.
IModulusOperators<Byte,Byte,Byte>.Modulus(Byte, Byte)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Byte,Byte>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiplyOperators<Byte,Byte,Byte>.Checked Multiply(Byte, Byte)	Multiplies two values together to compute their product.
IMultiplyOperators<Byte,Byte,Byte>.Multiply(Byte, Byte)	Multiplies two values together to compute their product.
INumber<Byte>.CopySign(Byte, Byte)	Copies the sign of a value to the sign of another value.
INumber<Byte>.MaxNumber(Byte, Byte)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<Byte>.MinNumber(Byte, Byte)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<Byte>.Abs(Byte)	Computes the absolute of a value.
INumberBase<Byte>.IsCanonical(Byte)	Determines if a value is in its canonical representation.
INumberBase<Byte>.IsComplexNumber(Byte)	Determines if a value represents a complex number.
INumberBase<Byte>.IsFinite(Byte)	Determines if a value is finite.

INumberBase<Byte>.IsImaginaryNumber(Byte)	Determines if a value represents a pure imaginary number.
INumberBase<Byte>.IsInfinity(Byte)	Determines if a value is infinite.
INumberBase<Byte>.IsInteger(Byte)	Determines if a value represents an integral number.
INumberBase<Byte>.IsNaN(Byte)	Determines if a value is NaN.
INumberBase<Byte>.IsNegative(Byte)	Determines if a value is negative.
INumberBase<Byte>.IsNegativeInfinity(Byte)	Determines if a value is negative infinity.
INumberBase<Byte>.IsNormal(Byte)	Determines if a value is normal.
INumberBase<Byte>.IsPositive(Byte)	Determines if a value is positive.
INumberBase<Byte>.IsPositiveInfinity(Byte)	Determines if a value is positive infinity.
INumberBase<Byte>.IsRealNumber(Byte)	Determines if a value represents a real number.
INumberBase<Byte>.IsSubnormal(Byte)	Determines if a value is subnormal.
INumberBase<Byte>.IsZero(Byte)	Determines if a value is zero.
INumberBase<Byte>.MaxMagnitude(Byte, Byte)	Compares two values to compute which is greater.
INumberBase<Byte>.MaxMagnitudeNumber(Byte, Byte)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Byte>.MinMagnitude(Byte, Byte)	Compares two values to compute which is lesser.
INumberBase<Byte>.MinMagnitudeNumber(Byte, Byte)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<Byte>.One	Gets the value `1` for the type.
INumberBase<Byte>.Radix	Gets the radix, or base, for the type.
INumberBase<Byte>.TryConvertFromChecked<TOther>(TOther, Byte)	
INumberBase<Byte>.TryConvertFromSaturating<TOther>(TOther, Byte)	
INumberBase<Byte>.TryConvertFromTruncating<TOther>(TOther, Byte)	
INumberBase<Byte>.TryConvertToChecked<TOther>(Byte, TOther)	Tries to convert an instance of the the current type to another type, throwing an

	overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Byte>.TryConvertToSaturating<TOther>(Byte, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Byte>.TryConvertToTruncating<TOther>(Byte, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Byte>.Zero	Gets the value `0` for the type.
IShiftOperators<Byte,Int32,Byte>.LeftShift(Byte, Int32)	Shifts a value left by a given amount.
IShiftOperators<Byte,Int32,Byte>.RightShift(Byte, Int32)	Shifts a value right by a given amount.
IShiftOperators<Byte,Int32,Byte>.UnsignedRightShift(Byte, Int32)	Shifts a value right by a given amount.
ISubtractionOperators<Byte,Byte,Byte>.CheckedSubtraction(Byte, Byte)	Subtracts two values to compute their difference.
ISubtractionOperators<Byte,Byte,Byte>.Subtraction(Byte, Byte)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Byte,Byte>.CheckedUnaryNegation(Byte)	Computes the checked unary negation of a value.
IUnaryNegationOperators<Byte,Byte>.UnaryNegation(Byte)	Computes the unary negation of a value.
IUnaryPlusOperators<Byte,Byte>.UnaryPlus(Byte)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Byte.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of a Byte. This field is constant.

C#

```
public const byte MaxValue = 255;
```

Field Value

***Value* = 255**

Byte

Examples

The following example demonstrates how to use the MaxValue field to screen variable inputs for values that are outside the range of possible byte values.

C#

```
public void MinMaxFields(int numberToSet)
{
   if(numberToSet <= (int)Byte.MaxValue && numberToSet >=
(int)Byte.MinValue)
   {
      // You must explicitly convert an integer to a byte.
      MemberByte = (Byte)numberToSet;

      // Displays MemberByte using the ToString() method.
      Console.WriteLine("The MemberByte value is {0}",
MemberByte.ToString());
   }
   else
   {
      Console.WriteLine("The value {0} is outside of the range of possible
Byte values", numberToSet.ToString());
```

```
    }
}
```

Remarks

The value of this constant is 255 (hexadecimal 0xFF).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Byte.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of a Byte. This field is constant.

C#

```
public const byte MinValue = 0;
```

Field Value

Value* = *0

Byte

Examples

The following example demonstrates how to use the MinValue field to screen variable inputs for values that are outside the range of possible byte values.

C#

```
public void MinMaxFields(int numberToSet)
{
   if(numberToSet <= (int)Byte.MaxValue && numberToSet >=
(int)Byte.MinValue)
   {
      // You must explicitly convert an integer to a byte.
      MemberByte = (Byte)numberToSet;

      // Displays MemberByte using the ToString() method.
      Console.WriteLine("The MemberByte value is {0}",
MemberByte.ToString());
   }
   else
   {
      Console.WriteLine("The value {0} is outside of the range of possible
Byte values", numberToSet.ToString());
```

```
    }
}
```

Remarks

The value of this constant is 0.

Applies to

Product	Versions

Byte.Clamp(Byte, Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static byte Clamp (byte value, byte min, byte max);
```

Parameters

`value` Byte

The value to clamp.

`min` Byte

The inclusive minimum to which `value` should clamp.

`max` Byte

The inclusive maximum to which `value` should clamp.

Returns

Byte

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or Byte and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Byte)	Compares this instance to a specified 8-bit unsigned integer and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.

CompareTo(Byte)

Compares this instance to a specified 8-bit unsigned integer and returns an indication of their relative values.

C#

```
public int CompareTo (byte value);
```

Parameters

`value` Byte

An 8-bit unsigned integer to compare.

Returns

Int32

A signed integer that indicates the relative order of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and non-generic versions of the `CompareTo` method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");
```

```
    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;
    Int16    c1 = -2,    c2 = 2;
    Int32    d1 = 3,     d2 = 3;
    Int64    e1 = 4,     e2 = -4;
    Decimal  f1 = -5.5m, f2 = 5.5m;

        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                            resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
```

```
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Byte.CompareTo(Object) method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed integer that indicates the relative order of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.

Return Value	Description
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a Byte.

Examples

The following code example demonstrates the CompareTo method.

C#

```
public void Compare(Byte myByte)
{
   int myCompareResult;

   myCompareResult = MemberByte.CompareTo(myByte);

   if(myCompareResult > 0)
   {
      Console.WriteLine("{0} is less than the MemberByte value {1}",
myByte.ToString(), MemberByte.ToString());
   }
   else if(myCompareResult < 0)
   {
      Console.WriteLine("{0} is greater than the MemberByte value {1}",
myByte.ToString(), MemberByte.ToString());
   }
   else
   {
      Console.WriteLine("{0} is equal to the MemberByte value {1}",
myByte.ToString(), MemberByte.ToString());
   }
}
```

Remarks

`value` must be `null` or an instance of Byte; otherwise, an exception is thrown.

Any instance of Byte, regardless of its value, is considered greater than `null`.

This method is implemented to support the IComparable interface.

Byte.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static byte CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Byte

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static byte CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Byte

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static byte CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Byte

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.DivRem(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (byte Quotient, byte Remainder) DivRem (byte left, byte
right);
```

Parameters

`left` Byte

The value which `right` divides.

`right` Byte

The value which divides `left`.

Returns

ValueTuple<Byte,Byte>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two instances of Byte represent the same value.

Overloads

Expand table

Equals(Byte)	Returns a value indicating whether this instance and a specified Byte object represent the same value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Examples

The following code example determines whether the first Byte value is equal to the second Byte value, and whether the first Byte value is equal to the boxed version of the second Byte value.

C#

```
// This code example demonstrates the System.Byte.Equals(Object) and
// System.Byte.Equals(Byte) methods.

using System;

class Sample
{
    public static void Main()
    {
    byte   byteVal1 = 0x7f;
    byte   byteVal2 = 127;
    object objectVal3 = byteVal2;
//
    Console.WriteLine("byteVal1 = {0}, byteVal2 = {1}, objectVal3 = {2}\n",
                      byteVal1, byteVal2, objectVal3);
    Console.WriteLine("byteVal1 equals byteVal2?: {0}",
```

```
byteVal1.Equals(byteVal2));
    Console.WriteLine("byteVal1 equals objectVal3?: {0}",
byteVal1.Equals(objectVal3));
    }
}

/*
This code example produces the following results:

byteVal1 = 127, byteVal2 = 127, objectVal3 = 127

byteVal1 equals byteVal2?: True
byteVal1 equals objectVal3?: True

*/
```

Equals(Byte)

Returns a value indicating whether this instance and a specified Byte object represent the same value.

```
C#

public bool Equals (byte obj);
```

Parameters

`obj` Byte

An object to compare to this instance.

Returns

Boolean

`true` if `obj` is equal to this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals(Object) because it does not have to convert the `obj` parameter to

an object.

Byte.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A hash code for the current Byte.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Byte.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Byte.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Byte.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Byte.IsEvenInteger(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IsOddInteger(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (byte value);
```

Parameters

value Byte

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Byte.LeadingZeroCount(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static byte LeadingZeroCount (byte value);
```

Parameters

`value` Byte

The value whose leading zeroes are to be counted.

Returns

Byte

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.Max(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static byte Max (byte x, byte y);
```

Parameters

x Byte

The value to compare with `y`.

y Byte

The value to compare with `x`.

Returns

Byte

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf>, this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.Min(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static byte Min (byte x, byte y);
```

Parameters

x Byte

The value to compare with `y`.

y Byte

The value to compare with `x`.

Returns

Byte

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf>, this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Byte.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its Byte equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its Byte equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its Byte equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its Byte equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its Byte equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String)	Converts the string representation of a number to its Byte equivalent.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its Byte equivalent.

```C#
public static byte Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific information about the format of `s`. If `provider` is `null`, the thread current culture is used.

Returns

Byte

A byte value that is equivalent to the number contained in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not of the correct format.

OverflowException

`s` represents a number less than Byte.MinValue or greater than Byte.MaxValue.

-or-

`s` includes non-zero, fractional digits.

ArgumentException
`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following code example parses string representations of `Byte` values with this overload of the Byte.Parse(String, NumberStyles, IFormatProvider) method.

C#

```
NumberStyles style;
CultureInfo culture;
string value;
byte number;

// Parse number with decimals.
// NumberStyles.Float includes NumberStyles.AllowDecimalPoint.
style = NumberStyles.Float;
culture = CultureInfo.CreateSpecificCulture("fr-FR");
value = "12,000";

number = Byte.Parse(value, style, culture);
Console.WriteLine("Converted '{0}' to {1}.", value, number);

culture = CultureInfo.CreateSpecificCulture("en-GB");
try
{
   number = Byte.Parse(value, style, culture);
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
}
catch (FormatException) {
   Console.WriteLine("Unable to parse '{0}'.", value); }

value = "12.000";
number = Byte.Parse(value, style, culture);
Console.WriteLine("Converted '{0}' to {1}.", value, number);
// The example displays the following output to the console:
//       Converted '12,000' to 12.
```

```
//       Unable to parse '12,000'.
//       Converted '12.000' to 12.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign]digits[.fractional_digits][e[sign]digits][ws]

Or, if the `style` parameter includes AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional positive sign. (The method throws an OverflowException if a negative sign is present in `s`.) The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.

Element	Description
e	The e or E character, which indicates that the value is represented in exponential notation. The s parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The . and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or an OverflowException is thrown.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A positive sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A positive sign can appear after *digits*.
NumberStyles.AllowParentheses	Although this flag is supported, the use of parentheses in `s` results in an OverflowException.
NumberStyles.AllowThousands	Although the group separator symbol can appear in `s`, it can be preceded by only one or more 0 digits.

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.AllowCurrencySymbol	The $ element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "F3" parses successfully, but "0xF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null`, the thread current culture is used.

UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the span representation of a number in a specified style and culture-specific format to its Byte equivalent.

C#

```
public static byte Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the value to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific information about the format of `s`. If `provider` is `null`, the thread current culture is used.

Returns

Byte

A byte value that is equivalent to the number contained in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static byte Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Byte

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its Byte equivalent.

```
C#
public static byte Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert. The string is interpreted using the Integer style.

`provider` IFormatProvider

An object that supplies culture-specific parsing information about `s`. If `provider` is `null`, the thread current culture is used.

Returns

Byte

A byte value that is equivalent to the number contained in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not of the correct format.

OverflowException

`s` represents a number less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example parses string representations of `Byte` values with the Parse method.

C#

```
string stringToConvert;
byte byteValue;

stringToConvert = " 214 ";
try {
   byteValue = Byte.Parse(stringToConvert, CultureInfo.InvariantCulture);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert,
byteValue);
}
catch (FormatException) {
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert); }
catch (OverflowException) {
   Console.WriteLine("'{0}' is greater than {1} or less than {2}.",
                     stringToConvert, Byte.MaxValue, Byte.MinValue); }

stringToConvert = " + 214 ";
try {
   byteValue = Byte.Parse(stringToConvert, CultureInfo.InvariantCulture);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert,
byteValue);
}
catch (FormatException) {
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert); }
catch (OverflowException) {
   Console.WriteLine("'{0}' is greater than {1} or less than {2}.",
                     stringToConvert, Byte.MaxValue, Byte.MinValue); }

stringToConvert = " +214 ";
try {
   byteValue = Byte.Parse(stringToConvert, CultureInfo.InvariantCulture);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert,
byteValue);
}
catch (FormatException) {
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert); }
catch (OverflowException) {
   Console.WriteLine("'{0}' is greater than {1} or less than {2}.",
                     stringToConvert, Byte.MaxValue, Byte.MinValue); }
// The example displays the following output to the console:
```

```
//       Converted ' 214 ' to 214.
//       Unable to parse ' + 214 '.
//       Converted ' +214 ' to 214.
```

Remarks

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional positive sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the Integer style. In addition to the byte value's decimal digits, only leading and trailing spaces together with a leading sign are allowed. (If the sign is present, it must be a positive sign or the method throws an OverflowException.) To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Byte.Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object supplied by `provider`. The `provider` parameter is an IFormatProvider implementation such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null`, the thread current culture is used.

UWP	10.0

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its Byte equivalent.

C#

```
public static byte Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string that contains a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

Returns

Byte

A byte value that is equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not of the correct format.

OverflowException

`s` represents a number less than Byte.MinValue or greater than Byte.MaxValue.

-or-

`s` includes non-zero, fractional digits.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example parses string representations of `Byte` values with the Byte.Parse(String, NumberStyles) method. The current culture for the example is en-US.

C#

```
string value;
NumberStyles style;
byte number;

// Parse value with no styles allowed.
style = NumberStyles.None;
value = " 241 ";
try
{
   number = Byte.Parse(value, style);
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
}
catch (FormatException) {
   Console.WriteLine("Unable to parse '{0}'.", value); }
```

```
// Parse value with trailing sign.
style = NumberStyles.Integer | NumberStyles.AllowTrailingSign;
value = " 163+";
number = Byte.Parse(value, style);
Console.WriteLine("Converted '{0}' to {1}.", value, number);

// Parse value with leading sign.
value = "   +253  ";
number = Byte.Parse(value, style);
Console.WriteLine("Converted '{0}' to {1}.", value, number);
// This example displays the following output to the console:
//       Unable to parse ' 241 '.
//       Converted ' 163+' to 163.
//       Converted '   +253  ' to 253.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign]digits[.fractional_digits][e[sign]digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of s if style includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional positive sign. (The method throws an OverflowException if a negative sign is present in `s`.) The sign can appear at the beginning of `s` if

Element	Description
	`style` includes the NumberStyles.AllowLeadingSign flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The e or E character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The . and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or an OverflowException is thrown.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A positive sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A positive sign can appear after *digits*.
NumberStyles.AllowParentheses	Although this flag is supported, the use of parentheses in `s` results in an OverflowException.
NumberStyles.AllowThousands	Although the group separator symbol can appear in `s`, it can be preceded by only one or more 0 digits.
NumberStyles.AllowCurrencySymbol	The *$* element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "F3" parses successfully, but "0xF3" does not. The only other flags that can be combined with it are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To use the formatting information of some other culture, call the Byte.Parse(String, NumberStyles, IFormatProvider) overload.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#

public static byte Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Byte

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static byte Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Byte

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String)

Converts the string representation of a number to its Byte equivalent.

```
C#

public static byte Parse (string s);
```

Parameters

s String

A string that contains a number to convert. The string is interpreted using the Integer style.

Returns

Byte

A byte value that is equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not of the correct format.

OverflowException

`s` represents a number less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example demonstrates how to convert a string value into a byte value using the Byte.Parse(String) method. The resulting byte value is then displayed to the console.

```
C#

string stringToConvert = " 162";
byte byteValue;
try
{
   byteValue = Byte.Parse(stringToConvert);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert,
```

```
byteValue);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert);
}
catch (OverflowException)
{
   Console.WriteLine("'{0}' is greater than {1} or less than {2}.",
                     stringToConvert, Byte.MaxValue, Byte.MinValue);
}
// The example displays the following output to the console:
//       Converted ' 162' to 162.
```

Remarks

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional positive or negative sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to the byte value's decimal digits, only leading and trailing spaces together with a leading sign are allowed. (If the sign is present, it must be a positive sign or the method throws an OverflowException.) To explicitly define the style elements that can be present in `s`, use either the Byte.Parse(String, NumberStyles) or the Byte.Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see CurrentInfo. To parse a string using the formatting information of some other culture, use the Byte.Parse(String, NumberStyles, IFormatProvider) method.

Byte.Sign(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (byte value);
```

Parameters

`value` Byte

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Byte.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current Byte object to its equivalent string representation.

Overloads

Expand table

ToString(IFormatProvider)	Converts the numeric value of the current Byte object to its equivalent string representation using the specified culture-specific formatting information.
ToString(String)	Converts the value of the current Byte object to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the value of the current Byte object to its equivalent string representation using the specified format and culture-specific formatting information.
ToString()	Converts the value of the current Byte object to its equivalent string representation.

ToString(IFormatProvider)

Converts the numeric value of the current Byte object to its equivalent string representation using the specified culture-specific formatting information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this object in the format specified by the `provider` parameter.

Implements

ToString(IFormatProvider)

Examples

The following example iterates an array of byte values and displays each of them to the console by calling the ToString(IFormatProvider) method with different format providers.

C#

```
byte[] bytes = {0, 1, 14, 168, 255};
CultureInfo[] providers = {new CultureInfo("en-us"),
                           new CultureInfo("fr-fr"),
                           new CultureInfo("de-de"),
                           new CultureInfo("es-es")};
foreach (byte byteValue in bytes)
{
   foreach (CultureInfo provider in providers)
      Console.Write("{0,3} ({1})      ",
                    byteValue.ToString(provider), provider.Name);

   Console.WriteLine();
}
// The example displays the following output to the console:
//      0 (en-US)        0 (fr-FR)        0 (de-DE)        0 (es-ES)
//      1 (en-US)        1 (fr-FR)        1 (de-DE)        1 (es-ES)
//     14 (en-US)       14 (fr-FR)       14 (de-DE)       14 (es-ES)
//    168 (en-US)      168 (fr-FR)      168 (de-DE)      168 (es-ES)
//    255 (en-US)      255 (fr-FR)      255 (de-DE)      255 (es-ES)
```

Remarks

The return value is formatted with the general numeric format specifier ("G").

The `provider` parameter is an object that implements the IFormatProvider interface. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.
- A NumberFormatInfo object that contains specific numeric formatting information for this value.
- A custom object that implements IFormatProvider.

If `provider` is `null` or a NumberFormatInfo object cannot be obtained from `provider`, the return value is formatted using the NumberFormatInfo object for the thread current culture. For information about the thread current culture, see Thread.CurrentCulture.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the value of the current Byte object to its equivalent string representation using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the current Byte object, formatted as specified by the `format` parameter.

Exceptions

FormatException

`format` includes an unsupported specifier. Supported format specifiers are listed in the Remarks section.

Examples

The following example initializes a Byte value and displays it to the console using each of the supported standard format strings and a custom format string. The example is run with en-US as the current culture.

```
C#
```

```
string[] formats = {"C3", "D4", "e1", "E2", "F1", "G", "N1",
                    "P0", "X4", "0000.0000"};
byte number = 240;
foreach (string format in formats)
   Console.WriteLine("'{0}' format specifier: {1}",
                     format, number.ToString(format));

// The example displays the following output to the console if the
// current culture is en-us:
//       'C3' format specifier: $240.000
//       'D4' format specifier: 0240
//       'e1' format specifier: 2.4e+002
//       'E2' format specifier: 2.40E+002
//       'F1' format specifier: 240.0
//       'G' format specifier: 240
//       'N1' format specifier: 240.0
//       'P0' format specifier: 24,000 %
//       'X4' format specifier: 00F0
//       '0000.0000' format specifier: 0240.0000
```

Remarks

The `format` parameter can be either a standard or a custom numeric format string. All standard numeric format strings other than "R" (or "r") are supported, as are all custom numeric format characters. If `format` is `null` or an empty string (""), the return value is formatted with the general numeric format specifier ("G").

The return value of this function is formatted using the NumberFormatInfo object for the thread current culture. For information about the thread current culture, see Thread.CurrentCulture. To provide formatting information for cultures other than the current culture, call the Byte.ToString(String, IFormatProvider) method.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String, IFormatProvider)

Converts the value of the current Byte object to its equivalent string representation using the specified format and culture-specific formatting information.

```
C#
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A standard or custom numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the current Byte object, formatted as specified by the `format` and `provider` parameters.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` includes an unsupported specifier. Supported format specifiers are listed in the Remarks section.

Examples

The following example uses the standard "N" format string and four different CultureInfo objects to display the string representation of a byte value to the console.

C#

```
byte byteValue = 250;
CultureInfo[] providers = {new CultureInfo("en-us"),
                           new CultureInfo("fr-fr"),
                           new CultureInfo("es-es"),
                           new CultureInfo("de-de")};

foreach (CultureInfo provider in providers)
   Console.WriteLine("{0} ({1})",
                     byteValue.ToString("N2", provider), provider.Name);
// The example displays the following output to the console:
//       250.00 (en-US)
//       250,00 (fr-FR)
//       250,00 (es-ES)
//       250,00 (de-DE)
```

Remarks

The ToString(String, IFormatProvider) method formats a Byte value in a specified format of a specified culture. To format a number by using the default ("G") format of the current culture, call the ToString() method. To format a number by using a specified format of the current culture, call the ToString(String) method.

The `format` parameter can be either a standard or a custom numeric format string. All standard numeric format strings other than "R" (or "r") are supported, as are all custom numeric format characters. If `format` is `null` or an empty string ("), the return value of this method is formatted with the general numeric format specifier ("G").

The `provider` parameter is an object that implements the IFormatProvider interface. Its GetFormat method returns a NumberFormatInfo object that provides culture-

specific information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.
- A NumberFormatInfo object that contains specific numeric formatting information for this value.
- A custom object that implements IFormatProvider.

If `provider` is `null` or a NumberFormatInfo object cannot be obtained from `provider`, the return value is formatted using the NumberFormatInfo object for the thread current culture. For information about the thread current culture, see Thread.CurrentCulture.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString()

Converts the value of the current Byte object to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this object, which consists of a sequence of digits that range from 0 to 9 with no leading zeroes.

Examples

The following example displays an array of byte values. Note that the ToString() method is not called explicitly in the example. Instead, it is called implicitly, because of the use of the composite formatting feature, the F# example uses string interpolation.

C#

```
byte[] bytes = {0, 1, 14, 168, 255};
foreach (byte byteValue in bytes)
   Console.WriteLine(byteValue);
// The example displays the following output to the console if the
current
// culture is en-US:
//       0
//       1
//       14
```

```
//        168
//        255
```

Remarks

The return value is formatted with the general numeric format specifier ("G") and the NumberFormatInfo object for the thread current culture. To define the formatting of the Byte value's string representation, call the ToString method. To define both the format specifiers and culture used to create the string representation of a Byte value, call the ToString method.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

For information about the thread current culture, see Thread.CurrentCulture.

Byte.TrailingZeroCount(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static byte TrailingZeroCount (byte value);
```

Parameters

`value` Byte

The value whose trailing zeroes are to be counted.

Returns

Byte

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current 8-bit unsigned integer instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current 8-bit unsigned integer instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the charactes that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Byte.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the string representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Byte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Byte)	Tries to convert the span representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, Byte)	Tries to convert the string representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Byte)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Byte)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Byte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Byte)	Tries to convert a UTF-8 character span containing the string representation of a number to its 8-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Byte)	Converts the span representation of a number in a specified style and culture-specific format to its Byte equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Byte)	Converts the string representation of a number in a specified style and culture-specific format to its Byte

	equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Byte)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out byte result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Byte

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, Byte)

Tries to convert the span representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out byte result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`result` Byte

When this method returns, contains the Byte value equivalent to the number contained in `s` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Byte)

Tries to convert the string representation of a number to its Byte equivalent, and returns a value that indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParse (string? s, out byte result);
```

Parameters

s String

A string that contains a number to convert.

result Byte

When this method returns, contains the Byte value equivalent to the number contained in `s` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParse(String, Byte) method with a number of different string values.

C#

```
using System;

public class ByteConversion
{
   public static void Main()
   {
      string[] byteStrings = { null, string.Empty, "1024",
                               "100.1", "100", "+100", "-100",
                               "00000000000000100", "00,100",
                               "   20   ", "FF", "0x1F" };

      foreach (var byteString in byteStrings)
      {
          CallTryParse(byteString);
      }
   }

   private static void CallTryParse(string stringToConvert)
   {
```

```
        byte byteValue;
        bool success = Byte.TryParse(stringToConvert, out byteValue);
        if (success)
        {
           Console.WriteLine("Converted '{0}' to {1}",
                             stringToConvert, byteValue);
        }
        else
        {
           Console.WriteLine("Attempted conversion of '{0}' failed.",
                               stringToConvert);
        }
    }
}
// The example displays the following output to the console:
//       Attempted conversion of '' failed.
//       Attempted conversion of '' failed.
//       Attempted conversion of '1024' failed.
//       Attempted conversion of '100.1' failed.
//       Converted '100' to 100
//       Converted '+100' to 100
//       Attempted conversion of '-100' failed.
//       Converted '000000000000000100' to 100
//       Attempted conversion of '00,100' failed.
//       Converted '    20    ' to 20
//       Attempted conversion of 'FF' failed.
//       Attempted conversion of '0x1F' failed.
```

Remarks

The conversion fails and the method returns `false` if the `s` parameter is not in the correct format, if it is `null` or String.Empty, or if it represents a number less than MinValue or greater than MaxValue.

The Byte.TryParse(String, Byte) method is similar to the Byte.Parse(String) method, except that TryParse(String, Byte) does not throw an exception if the conversion fails.

The `s` parameter should be the string representation of a number in the following form:

```
[ws][sign]digits[ws]
```

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional positive sign, as specified by the NumberFormatInfo.PositiveSign property of the current culture.
digits	A sequence of decimal digits that range from 0 to 9.

The `s` parameter is interpreted using the Integer style. In addition to the byte value's decimal digits, only leading and trailing spaces together with a leading sign are allowed. (If the sign is present, it must be a positive sign or the method throws an OverflowException.) To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Byte.Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object for the current culture. For more information, see NumberFormatInfo.CurrentInfo.

This overload of the Byte.TryParse(String, Byte) method interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the Byte.TryParse(String, NumberStyles, IFormatProvider, Byte) overload.

UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, Byte)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out byte result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Byte

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Byte)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
byte result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Byte

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Byte)

Tries to parse a span of UTF-8 characters into a value.

```C#
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
byte result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Byte

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, Byte)

Tries to convert a UTF-8 character span containing the string representation of a number to its 8-bit unsigned integer equivalent.

```C#
```

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text, out byte
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` Byte

When this method returns, contains the 8-bit unsigned integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Byte)

Converts the span representation of a number in a specified style and culture-specific format to its Byte equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
byte result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert. The span is interpreted using the Integer style.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`. If `provider` is `null`, the thread current culture is used.

`result` Byte

When this method returns, contains the 8-bit unsigned integer value equivalent to the number contained in `s` if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than Byte.MinValue or greater than Byte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Byte)

Converts the string representation of a number in a specified style and culture-specific format to its Byte equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out byte result);
```

Parameters

`s` String

A string containing a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`. If `provider` is `null`, the thread current culture is used.

`result` Byte

When this method returns, contains the 8-bit unsigned integer value equivalent to the number contained in `s` if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than Byte.MinValue or greater than Byte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the TryParse(String, NumberStyles, IFormatProvider, Byte) method with a number of different string values.

C#

```
using System;
using System.Globalization;

public class ByteConversion2
{
   public static void Main()
   {
      string byteString;
      NumberStyles styles;

      byteString = "1024";
      styles = NumberStyles.Integer;
      CallTryParse(byteString, styles);

      byteString = "100.1";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(byteString, styles);

      byteString = "100.0";
      CallTryParse(byteString, styles);

      byteString = "+100";
      styles = NumberStyles.Integer | NumberStyles.AllowLeadingSign
               | NumberStyles.AllowTrailingSign;
      CallTryParse(byteString, styles);

      byteString = "-100";
      CallTryParse(byteString, styles);

      byteString = "000000000000000100";
      CallTryParse(byteString, styles);

      byteString = "00,100";
      styles = NumberStyles.Integer | NumberStyles.AllowThousands;
      CallTryParse(byteString, styles);

      byteString = "2E+3   ";
      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(byteString, styles);

      byteString = "FF";
```

```
      styles = NumberStyles.HexNumber;
      CallTryParse(byteString, styles);

      byteString = "0x1F";
      CallTryParse(byteString, styles);
   }

   private static void CallTryParse(string stringToConvert, NumberStyles
styles)
   {
      Byte byteValue;
      bool result = Byte.TryParse(stringToConvert, styles,
                                  null as IFormatProvider, out
byteValue);
      if (result)
         Console.WriteLine("Converted '{0}' to {1}",
                        stringToConvert, byteValue);
      else
         Console.WriteLine("Attempted conversion of '{0}' failed.",
                           stringToConvert.ToString());
   }
}
// The example displays the following output to the console:
//       Attempted conversion of '1024' failed.
//       Attempted conversion of '100.1' failed.
//       Converted '100.0' to 100
//       Converted '+100' to 100
//       Attempted conversion of '-100' failed.
//       Converted '000000000000000100' to 100
//       Converted '00,100' to 100
//       Attempted conversion of '2E+3   ' failed.
//       Converted 'FF' to 255
//       Attempted conversion of '0x1F' failed.
```

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object supplied by the `provider` parameter.

The style parameter defines the style elements (such as white space or the positive sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign]digits[.fractional_digits][e[sign]digits][ws]

Or, if the `style` parameter includes AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of s if style includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional positive sign. (The parse operation fails if a negative sign is present in `s`.) The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The e or E character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

Note

Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The . and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or the method returns `false`.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation. If `s` represents a number in exponential notation, it must represent an integer within the range of the Byte data type without a non-zero, fractional component.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A positive sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A positive sign can appear after *digits*.
NumberStyles.AllowParentheses	Although this flag is supported, the method returns `false` if parentheses are present in `s`.
NumberStyles.AllowThousands	Although the group separator symbol can appear in `s`, it can be preceded by only one or more 0 digits.
NumberStyles.AllowCurrencySymbol	The *$* element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "F3" parses successfully, but "0xF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a CultureInfo object or a NumberFormatInfo object, whose GetFormat method returns a

NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `s`.

Byte.IConvertible.To Boolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Byte.IConvertible.To Byte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, unchanged.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Byte.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

C#

```
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Byte.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions

Byte.IConvertible.To Decimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(Byte) method.

Applies to

Product	Versions

Byte.IConvertible.To Double(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(Byte) method.

Applies to

Product	Versions

Byte.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(Byte) method.

Applies to

Product	Versions

Byte.IConvertible.To Int64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Byte.IConvertible.To SByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToSByte(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Byte.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Byte.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to which to convert this Byte value.

provider IFormatProvider

An IFormatProvider implementation that supplies information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Exceptions

ArgumentNullException

`type` is `null`.

InvalidCastException

The requested type conversion is not supported.

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Byte.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt16(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Byte.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt32(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Byte.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Byte instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt64(Byte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Byte.IAdditionOperators<Byte,Byte,Byte>.Addition(Byte, Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static byte IAdditionOperators<byte,byte,byte>.operator + (byte left, byte right);
```

Parameters

`left` Byte

The value to which `right` is added.

`right` Byte

The value that's added to `left`.

Returns

Byte

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static byte IAdditionOperators<byte,byte,byte>.op_CheckedAddition (byte
left, byte right);
```

Parameters

`left` Byte

The value to which `right` is added.

`right` Byte

The value that's added to `left`.

Returns

Byte

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.IBinaryInteger<Byte>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

```
C#

bool IBinaryInteger<byte>.TryWriteBigEndian (Span<byte> destination, out int
bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IBinaryInteger<Byte>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<byte>.TryWriteLittleEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Byte.IBitwise Operators<Byte,Byte,Byte>.Bitwise And(Byte, Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static byte IBitwiseOperators<byte,byte,byte>.operator & (byte left, byte
right);
```

Parameters

`left` Byte

The value to `and` with `right`.

`right` Byte

The value to `and` with `left`.

Returns

Byte

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static byte IBitwiseOperators<byte,byte,byte>.operator | (byte left, byte
right);
```

Parameters

`left` Byte

The value to `or` with `right`.

`right` Byte

The value to `or` with `left`.

Returns

Byte

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static byte IBitwiseOperators<byte,byte,byte>.operator ^ (byte left, byte
right);
```

Parameters

`left` Byte

The value to xor with `right`.

`right` Byte

The value to xor with `left`.

Returns

Byte

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static byte IDivisionOperators<byte,byte,byte>.operator / (byte left, byte right);
```

Parameters

`left` Byte

The value that `right` divides.

`right` Byte

The value that divides `left`.

Returns

Byte

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.IEqualityOperators<Byte,Byte,Boolean>.Equality(Byte, Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<byte,byte,bool>.operator == (byte left, byte right);
```

Parameters

`left` Byte

The value to compare with `right`.

`right` Byte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.IEqualityOperators<Byte,Byte,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<byte,byte,bool>.operator != (byte left, byte right);
```

Parameters

`left` Byte

The value to compare with `right`.

`right` Byte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.IIncrementOperators<Byte>.CheckedIncrement(Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static byte IIncrementOperators<byte>.op_CheckedIncrement (byte value);
```

Parameters

`value` Byte

The value to increment.

Returns

Byte

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.IIncrementOperators<Byte>.Increment(Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static byte IIncrementOperators<byte>.operator ++ (byte value);
```

Parameters

`value` Byte

The value to increment.

Returns

Byte

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IMinMaxValue<Byte>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static byte System.Numerics.IMinMaxValue<System.Byte>.MaxValue { get; }
```

Property Value

Byte

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IMinMaxValue<Byte>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static byte System.Numerics.IMinMaxValue<System.Byte>.MinValue { get; }
```

Property Value

Byte

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.IModulusOperators<Byte,Byte,Byte>.Modulus(Byte, Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static byte IModulusOperators<byte,byte,byte>.operator % (byte left, byte
right);
```

Parameters

`left` Byte

The value that `right` divides.

`right` Byte

The value that divides `left`.

Returns

Byte

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.IMultiplicativeIdentity<Byte,Byte>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static byte
System.Numerics.IMultiplicativeIdentity<System.Byte,System.Byte>.MultiplicativeIdentity { get; }
```

Property Value

Byte

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IMultiplyOperators<Byte,Byte,Byte>.CheckedMultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static byte IMultiplyOperators<byte,byte,byte>.op_CheckedMultiply (byte
left, byte right);
```

Parameters

`left` Byte

The value that `right` multiplies.

`right` Byte

The value that multiplies `left`.

Returns

Byte

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.IMultiplyOperators<Byte,Byte,Byte>.Multiply(Byte, Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static byte IMultiplyOperators<byte,byte,byte>.operator * (byte left, byte
right);
```

Parameters

`left` Byte

The value that `right` multiplies.

`right` Byte

The value that multiplies `left`.

Returns

Byte

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumber<Byte>.CopySign(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
static byte INumber<byte>.CopySign (byte value, byte sign);
```

Parameters

`value` Byte

The value whose magnitude is used in the result.

`sign` Byte

The value whose sign is used in the result.

Returns

Byte

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumber<Byte>.MaxNumber(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

C#

```
static byte INumber<byte>.MaxNumber (byte x, byte y);
```

Parameters

x Byte

The value to compare with `y`.

y Byte

The value to compare with `x`.

Returns

Byte

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumber<Byte>.MinNumber(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

C#

```
static byte INumber<byte>.MinNumber (byte x, byte y);
```

Parameters

x Byte

The value to compare with `y`.

y Byte

The value to compare with `x`.

Returns

Byte

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.Abs(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static byte INumberBase<byte>.Abs (byte value);
```

Parameters

`value` Byte

The value for which to get its absolute.

Returns

Byte

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsCanonical(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<byte>.IsCanonical (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.IsComplexNumber(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<byte>.IsComplexNumber (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.IsFinite(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<byte>.IsFinite (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.IsImaginaryNumber(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<byte>.IsImaginaryNumber (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.IsInfinity(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<byte>.IsInfinity (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsInteger(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<byte>.IsInteger (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsNaN(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<byte>.IsNaN (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsNegative(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<byte>.IsNegative (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

```
C#
static bool INumberBase<byte>.IsNegativeInfinity (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsNormal(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<byte>.IsNormal (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsPositive(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
static bool INumberBase<byte>.IsPositive (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.IsRealNumber(Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<byte>.IsRealNumber (byte value);
```

Parameters

`value` Byte

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.Max Magnitude(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static byte INumberBase<byte>.MaxMagnitude (byte x, byte y);
```

Parameters

x Byte

The value to compare with `y`.

y Byte

The value to compare with `x`.

Returns

Byte

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Byte.INumberBase<Byte>.MinMagnitude(Byte, Byte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
static byte INumberBase<byte>.MinMagnitude (byte x, byte y);
```

Parameters

x Byte

The value to compare with `y`.

y Byte

The value to compare with `x`.

Returns

Byte

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.TryConvertFromChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<byte>.TryConvertFromChecked<TOther> (TOther value,
out byte result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Byte

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

Byte.INumberBase<Byte>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<byte>.TryConvertToChecked<TOther> (byte value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Byte

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.INumberBase<Byte>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<byte>.TryConvertToSaturating<TOther> (byte value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Byte

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.INumberBase<Byte>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<byte>.TryConvertToTruncating<TOther> (byte value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Byte

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Byte.IShift Operators<Byte,Int32,Byte>.Left Shift(Byte, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static byte IShiftOperators<byte,int,byte>.operator << (byte value, int
shiftAmount);
```

Parameters

`value` Byte

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

Byte

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IShift Operators<Byte,Int32,Byte>.Right Shift(Byte, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

C#

```
static byte IShiftOperators<byte,int,byte>.operator >> (byte value, int
shiftAmount);
```

Parameters

`value` Byte

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Byte

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.IShift Operators<Byte,Int32,Byte>.Unsigned RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static byte IShiftOperators<byte,int,byte>.op_UnsignedRightShift (byte
value, int shiftAmount);
```

Parameters

`value` Byte

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Byte

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.ISubtractionOperators<Byte,Byte,Byte>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static byte ISubtractionOperators<byte,byte,byte>.op_CheckedSubtraction
(byte left, byte right);
```

Parameters

`left` Byte

The value from which `right` is subtracted.

`right` Byte

The value that's subtracted from `left`.

Returns

Byte

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.ISubtraction Operators<Byte,Byte,Byte>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static byte ISubtractionOperators<byte,byte,byte>.operator - (byte left,
byte right);
```

Parameters

`left` Byte

The value from which `right` is subtracted.

`right` Byte

The value that's subtracted from `left`.

Returns

Byte

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Byte.IUnaryNegationOperators<Byte,Byte>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static byte IUnaryNegationOperators<byte,byte>.op_CheckedUnaryNegation (byte value);
```

Parameters

`value` Byte

The value for which to compute the unary negation.

Returns

Byte

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IUnaryNegationOperators<Byte,Byte>.UnaryNegation(Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static byte IUnaryNegationOperators<byte,byte>.operator - (byte value);
```

Parameters

`value` Byte

The value for which to compute the unary negation.

Returns

Byte

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Byte.IUnaryPlusOperators<Byte,Byte>.UnaryPlus(Byte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static byte IUnaryPlusOperators<byte,byte>.operator + (byte value);
```

Parameters

`value` Byte

The value for which to compute the unary plus.

Returns

Byte

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

CannotUnloadAppDomainException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt to unload an application domain fails.

```
C#
public class CannotUnloadAppDomainException : SystemException
```

Inheritance Object → Exception → SystemException → CannotUnloadAppDomainException

Remarks

CannotUnloadAppDomainException is thrown when there is an attempt to unload the following:

- The default application domain, which must remain loaded during the lifetime of the application.
- An application domain with a running thread that cannot immediately stop execution.
- An application domain that has already been unloaded.

CannotUnloadAppDomainException uses the HRESULT COR_E_CANNOTUNLOADAPPDOMAIN, which has the value 0x80131015.

For a list of initial property values for an instance of CannotUnloadAppDomainException, see the CannotUnloadAppDomainException constructors.

Constructors

Expand table

CannotUnloadAppDomainException()	Initializes a new instance of the CannotUnloadAppDomainException class.
CannotUnloadAppDomain Exception(SerializationInfo, Streaming Context)	**Obsolete.** Initializes a new instance of the CannotUnloadAppDomainException class from serialized data.
CannotUnloadAppDomain Exception(String)	Initializes a new instance of the CannotUnloadAppDomainException class with a specified error message.
CannotUnloadAppDomain Exception(String, Exception)	Initializes a new instance of the CannotUnloadAppDomainException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CannotUnloadAppDomainException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the CannotUnloadAppDomainException class.

Overloads

Expand table

CannotUnloadAppDomainException()	Initializes a new instance of the CannotUnloadAppDomainException class.
CannotUnloadAppDomainException(String)	Initializes a new instance of the CannotUnloadAppDomainException class with a specified error message.
CannotUnloadAppDomainException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the CannotUnloadAppDomainException class from serialized data.
CannotUnloadAppDomainException(String, Exception)	Initializes a new instance of the CannotUnloadAppDomainException class with a specified error message and a reference to the inner exception that is the cause of this exception.

CannotUnloadAppDomainException()

Initializes a new instance of the CannotUnloadAppDomainException class.

```
C#
```

```
public CannotUnloadAppDomainException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempt to unload the AppDomain failed." This message takes into account the current system culture.

The following table shows the initial property values for an instance of CannotUnloadAppDomainException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CannotUnloadAppDomainException(String)

Initializes a new instance of the CannotUnloadAppDomainException class with a specified error message.

C#

```
public CannotUnloadAppDomainException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of CannotUnloadAppDomainException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CannotUnloadAppDomainException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the CannotUnloadAppDomainException class from serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected CannotUnloadAppDomainException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CannotUnloadAppDomainException(String, Exception) *(Obsolete)*

Initializes a new instance of the CannotUnloadAppDomainException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public CannotUnloadAppDomainException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of CannotUnloadAppDomainException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

See also

- Exception
- Handling and throwing exceptions in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IUtf8SpanFormattable , IUtf8SpanParsable<Char> ,
IUtf8SpanParsable<TSelf>

Examples

The following code example demonstrates some of the methods in Char.

C#

```
using System;

public class CharStructureSample
{
    public static void Main()
```

```
    {
        char chA = 'A';
        char ch1 = '1';
        string str = "test string";

        Console.WriteLine(chA.CompareTo('B'));          //-----------
Output: "-1" (meaning 'A' is 1 less than 'B')
        Console.WriteLine(chA.Equals('A'));             //-----------
Output: "True"
        Console.WriteLine(Char.GetNumericValue(ch1));   //-----------
Output: "1"
        Console.WriteLine(Char.IsControl('\t'));        //-----------
Output: "True"
        Console.WriteLine(Char.IsDigit(ch1));           //-----------
Output: "True"
        Console.WriteLine(Char.IsLetter(','));          //-----------
Output: "False"
        Console.WriteLine(Char.IsLower('u'));           //-----------
Output: "True"
        Console.WriteLine(Char.IsNumber(ch1));          //-----------
Output: "True"
        Console.WriteLine(Char.IsPunctuation('.'));     //-----------
Output: "True"
        Console.WriteLine(Char.IsSeparator(str, 4));    //-----------
Output: "True"
        Console.WriteLine(Char.IsSymbol('+'));          //-----------
Output: "True"
        Console.WriteLine(Char.IsWhiteSpace(str, 4));   //-----------
Output: "True"
        Console.WriteLine(Char.Parse("S"));             //-----------
Output: "S"
        Console.WriteLine(Char.ToLower('M'));           //-----------
Output: "m"
        Console.WriteLine('x'.ToString());              //-----------
Output: "x"
    }
}
```

Remarks

For more information about this API, see Supplemental API remarks for Char.

Fields

Expand table

MaxValue	Represents the largest possible value of a Char. This field is constant.
MinValue	Represents the smallest possible value of a Char. This field is constant.

Methods

Expand table

CompareTo(Char)	Compares this instance to a specified Char object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Char object.
CompareTo(Object)	Compares this instance to a specified object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Object.
ConvertFromUtf32(Int32)	Converts the specified Unicode code point into a UTF-16 encoded string.
ConvertToUtf32(Char, Char)	Converts the value of a UTF-16 encoded surrogate pair into a Unicode code point.
ConvertToUtf32(String, Int32)	Converts the value of a UTF-16 encoded character or surrogate pair at a specified position in a string into a Unicode code point.
Equals(Char)	Returns a value that indicates whether this instance is equal to the specified Char object.
Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
GetNumericValue(Char)	Converts the specified numeric Unicode character to a double-precision floating point number.
GetNumericValue(String, Int32)	Converts the numeric Unicode character at the specified position in a specified string to a double-precision floating point number.
GetTypeCode()	Returns the TypeCode for value type Char.
GetUnicodeCategory(Char)	Categorizes a specified Unicode character into a group identified by one of the UnicodeCategory values.
GetUnicodeCategory(String, Int32)	Categorizes the character at the specified position in a specified string into a group identified by one of the UnicodeCategory values.
IsAscii(Char)	Returns `true` if `c` is an ASCII character ([U+0000..U+007F]).
IsAsciiDigit(Char)	Indicates whether a character is categorized as an ASCII digit.
IsAsciiHexDigit(Char)	Indicates whether a character is categorized as an ASCII hexademical digit.

IsAsciiHexDigitLower(Char)	Indicates whether a character is categorized as an ASCII lower-case hexademical digit.
IsAsciiHexDigitUpper(Char)	Indicates whether a character is categorized as an ASCII upper-case hexademical digit.
IsAsciiLetter(Char)	Indicates whether a character is categorized as an ASCII letter.
IsAsciiLetterLower(Char)	Indicates whether a character is categorized as a lowercase ASCII letter.
IsAsciiLetterOrDigit(Char)	Indicates whether a character is categorized as an ASCII letter or digit.
IsAsciiLetterUpper(Char)	Indicates whether a character is categorized as an uppercase ASCII letter.
IsBetween(Char, Char, Char)	Indicates whether a character is within the specified inclusive range.
IsControl(Char)	Indicates whether the specified Unicode character is categorized as a control character.
IsControl(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a control character.
IsDigit(Char)	Indicates whether the specified Unicode character is categorized as a decimal digit.
IsDigit(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a decimal digit.
IsHighSurrogate(Char)	Indicates whether the specified Char object is a high surrogate.
IsHighSurrogate(String, Int32)	Indicates whether the Char object at the specified position in a string is a high surrogate.
IsLetter(Char)	Indicates whether the specified Unicode character is categorized as a Unicode letter.
IsLetter(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a Unicode letter.
IsLetterOrDigit(Char)	Indicates whether the specified Unicode character is categorized as a letter or a decimal digit.
IsLetterOrDigit(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a letter or a decimal digit.
IsLower(Char)	Indicates whether the specified Unicode character is categorized as a lowercase letter.

IsLower(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a lowercase letter.
IsLowSurrogate(Char)	Indicates whether the specified Char object is a low surrogate.
IsLowSurrogate(String, Int32)	Indicates whether the Char object at the specified position in a string is a low surrogate.
IsNumber(Char)	Indicates whether the specified Unicode character is categorized as a number.
IsNumber(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a number.
IsPunctuation(Char)	Indicates whether the specified Unicode character is categorized as a punctuation mark.
IsPunctuation(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a punctuation mark.
IsSeparator(Char)	Indicates whether the specified Unicode character is categorized as a separator character.
IsSeparator(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a separator character.
IsSurrogate(Char)	Indicates whether the specified character has a surrogate code unit.
IsSurrogate(String, Int32)	Indicates whether the character at the specified position in a specified string has a surrogate code unit.
IsSurrogatePair(Char, Char)	Indicates whether the two specified Char objects form a surrogate pair.
IsSurrogatePair(String, Int32)	Indicates whether two adjacent Char objects at a specified position in a string form a surrogate pair.
IsSymbol(Char)	Indicates whether the specified Unicode character is categorized as a symbol character.
IsSymbol(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a symbol character.
IsUpper(Char)	Indicates whether the specified Unicode character is categorized as an uppercase letter.
IsUpper(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as an uppercase letter.
IsWhiteSpace(Char)	Indicates whether the specified Unicode character is categorized as white space.

IsWhiteSpace(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as white space.
Parse(String)	Converts the value of the specified string to its equivalent Unicode character.
ToLower(Char)	Converts the value of a Unicode character to its lowercase equivalent.
ToLower(Char, CultureInfo)	Converts the value of a specified Unicode character to its lowercase equivalent using specified culture-specific formatting information.
ToLowerInvariant(Char)	Converts the value of a Unicode character to its lowercase equivalent using the casing rules of the invariant culture.
ToString()	Converts the value of this instance to its equivalent string representation.
ToString(Char)	Converts the specified Unicode character to its equivalent string representation.
ToString(IFormatProvider)	Converts the value of this instance to its equivalent string representation using the specified culture-specific format information.
ToUpper(Char)	Converts the value of a Unicode character to its uppercase equivalent.
ToUpper(Char, CultureInfo)	Converts the value of a specified Unicode character to its uppercase equivalent using specified culture-specific formatting information.
ToUpperInvariant(Char)	Converts the value of a Unicode character to its uppercase equivalent using the casing rules of the invariant culture.
TryParse(String, Char)	Converts the value of the specified string to its equivalent Unicode character. A return code indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<Char,Char,Char>.Addition(Char, Char)	Adds two values together to compute their sum.
IAdditionOperators<Char,Char,Char>.CheckedAddition(Char, Char)	Adds two values together to compute their sum.
IAdditiveIdentity<Char,Char>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<Char>.GetByteCount()	Gets the number of bytes that will be written as part of

	TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<Char>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<Char>.LeadingZeroCount(Char)	Computes the number of leading zero bits in a value.
IBinaryInteger<Char>.PopCount(Char)	Computes the number of bits that are set in a value.
IBinaryInteger<Char>.RotateLeft(Char, Int32)	Rotates a value left by a given amount.
IBinaryInteger<Char>.RotateRight(Char, Int32)	Rotates a value right by a given amount.
IBinaryInteger<Char>.TrailingZeroCount(Char)	Computes the number of trailing zero bits in a value.
IBinaryInteger<Char>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, Char)	
IBinaryInteger<Char>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, Char)	
IBinaryInteger<Char>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<Char>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<Char>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBinaryNumber<Char>.IsPow2(Char)	Determines if a value is a power of two.
IBinaryNumber<Char>.Log2(Char)	Computes the log2 of a value.
IBitwiseOperators<Char,Char,Char>.BitwiseAnd(Char, Char)	Computes the bitwise-and of two values.
IBitwiseOperators<Char,Char,Char>.BitwiseOr(Char, Char)	Computes the bitwise-or of two values.
IBitwiseOperators<Char,Char,Char>.ExclusiveOr(Char, Char)	Computes the exclusive-or of two values.
IBitwiseOperators<Char,Char,Char>.Ones Complement(Char)	Computes the ones-complement representation of a given value.

IComparisonOperators<Char,Char,Boolean>.GreaterThan(Char, Char)	Compares two values to determine which is greater.
IComparisonOperators<Char,Char,Boolean>.GreaterThanOrEqual(Char, Char)	Compares two values to determine which is greater or equal.
IComparisonOperators<Char,Char,Boolean>.LessThan(Char, Char)	Compares two values to determine which is less.
IComparisonOperators<Char,Char,Boolean>.LessThanOrEqual(Char, Char)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	**Note** This conversion is not supported. Attempting to do so throws an InvalidCastException.
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	**Note** This conversion is not supported. Attempting to do so throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	**Note** This conversion is not supported. Attempting to do so throws an InvalidCastException.
IConvertible.ToDouble(IFormatProvider)	**Note** This conversion is not supported. Attempting to do so throws an InvalidCastException.
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	**Note** This conversion is not supported. Attempting to do so throws an InvalidCastException.
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).

IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<Char>.CheckedDecrement(Char)	Decrements a value.
IDecrementOperators<Char>.Decrement(Char)	Decrements a value.
IDivisionOperators<Char,Char,Char>.Division(Char, Char)	Divides one value by another to compute their quotient.
IEqualityOperators<Char,Char,Boolean>.Equality(Char, Char)	Compares two values to determine equality.
IEqualityOperators<Char,Char,Boolean>.Inequality(Char, Char)	Compares two values to determine inequality.
IFormattable.ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
IIncrementOperators<Char>.CheckedIncrement(Char)	Increments a value.
IIncrementOperators<Char>.Increment(Char)	Increments a value.
IMinMaxValue<Char>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Char>.MinValue	Gets the minimum value of the current type.
IModulusOperators<Char,Char,Char>.Modulus(Char, Char)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Char,Char>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
IMultiplyOperators<Char,Char,Char>.Checked Multiply(Char, Char)	Multiplies two values together to compute their product.
IMultiplyOperators<Char,Char,Char>.Multiply(Char, Char)	Multiplies two values together to compute their product.
INumberBase<Char>.Abs(Char)	Computes the absolute of a value.
INumberBase<Char>.IsCanonical(Char)	Determines if a value is in its canonical representation.

INumberBase<Char>.IsComplexNumber(Char)	Determines if a value represents a complex number.
INumberBase<Char>.IsEvenInteger(Char)	Determines if a value represents an even integral number.
INumberBase<Char>.IsFinite(Char)	Determines if a value is finite.
INumberBase<Char>.IsImaginaryNumber(Char)	Determines if a value represents a pure imaginary number.
INumberBase<Char>.IsInfinity(Char)	Determines if a value is infinite.
INumberBase<Char>.IsInteger(Char)	Determines if a value represents an integral number.
INumberBase<Char>.IsNaN(Char)	Determines if a value is NaN.
INumberBase<Char>.IsNegative(Char)	Determines if a value is negative.
INumberBase<Char>.IsNegativeInfinity(Char)	Determines if a value is negative infinity.
INumberBase<Char>.IsNormal(Char)	Determines if a value is normal.
INumberBase<Char>.IsOddInteger(Char)	Determines if a value represents an odd integral number.
INumberBase<Char>.IsPositive(Char)	Determines if a value is positive.
INumberBase<Char>.IsPositiveInfinity(Char)	Determines if a value is positive infinity.
INumberBase<Char>.IsRealNumber(Char)	Determines if a value represents a real number.
INumberBase<Char>.IsSubnormal(Char)	Determines if a value is subnormal.
INumberBase<Char>.IsZero(Char)	Determines if a value is zero.
INumberBase<Char>.MaxMagnitude(Char, Char)	Compares two values to compute which is greater.
INumberBase<Char>.MaxMagnitudeNumber(Char, Char)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Char>.MinMagnitude(Char, Char)	Compares two values to compute which is lesser.
INumberBase<Char>.MinMagnitudeNumber(Char, Char)	Compares two values to compute which has the lesser magnitude and

	returning the other value if an input is `NaN`.
INumberBase<Char>.One	Gets the value `1` for the type.
INumberBase<Char>.Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Parses a span of characters into a value.
INumberBase<Char>.Parse(String, NumberStyles, IFormatProvider)	Parses a string into a value.
INumberBase<Char>.Radix	Gets the radix, or base, for the type.
INumberBase<Char>.TryConvertFromChecked<TOther>(TOther, Char)	
INumberBase<Char>.TryConvertFromSaturating<TOther>(TOther, Char)	
INumberBase<Char>.TryConvertFromTruncating<TOther>(TOther, Char)	
INumberBase<Char>.TryConvertToChecked<TOther>(Char, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Char>.TryConvertToSaturating<TOther>(Char, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Char>.TryConvertToTruncating<TOther>(Char, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Char>.TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Char)	
INumberBase<Char>.TryParse(String, NumberStyles, IFormatProvider, Char)	
INumberBase<Char>.Zero	Gets the value `0` for the type.
IParsable<Char>.Parse(String, IFormatProvider)	Parses a string into a value.
IParsable<Char>.TryParse(String, IFormatProvider, Char)	
IShiftOperators<Char,Int32,Char>.LeftShift(Char, Int32)	Shifts a value left by a given amount.
IShiftOperators<Char,Int32,Char>.RightShift(Char, Int32)	Shifts a value right by a given amount.
IShiftOperators<Char,Int32,Char>.UnsignedRight	Shifts a value right by a given amount.

Shift(Char, Int32)	
ISpanFormattable.TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.
ISpanParsable<Char>.Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
ISpanParsable<Char>.TryParse(ReadOnlySpan<Char>, IFormatProvider, Char)	
ISubtractionOperators<Char,Char,Char>.CheckedSubtraction(Char, Char)	Subtracts two values to compute their difference.
ISubtractionOperators<Char,Char,Char>.Subtraction(Char, Char)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Char,Char>.CheckedUnaryNegation(Char)	Computes the checked unary negation of a value.
IUnaryNegationOperators<Char,Char>.UnaryNegation(Char)	Computes the unary negation of a value.
IUnaryPlusOperators<Char,Char>.UnaryPlus(Char)	Computes the unary plus of a value.
IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Char.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of a Char. This field is constant.

```
C#
public const char MaxValue;
```

Field Value

Char

Remarks

The value of this constant is hexadecimal 0xFFFF.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Char.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of a Char. This field is constant.

```
C#
public const char MinValue;
```

Field Value

Char

Remarks

The value of this constant is hexadecimal 0x00.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or value type, and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified object or value type.

Overloads

Expand table

CompareTo(Char)	Compares this instance to a specified Char object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Char object.
CompareTo(Object)	Compares this instance to a specified object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Object.

CompareTo(Char)

Compares this instance to a specified Char object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Char object.

C#

```
public int CompareTo (char value);
```

Parameters

`value` Char

A Char object to compare.

Returns

Int32

A signed number indicating the position of this instance in the sort order in relation to the `value` parameter.

Expand table

Return Value	Description
Less than zero	This instance precedes `value`.
Zero	This instance has the same position in the sort order as `value`.
Greater than zero	This instance follows `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and non-generic versions of the `CompareTo` method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
```

```
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

    Boolean  a1 = true,  a2 = true;

        Show("DateTime: ", k1, k2, k1.CompareTo(k2),
k1.CompareTo((Object)k2));
        Show("TimeSpan: ", l1, l2, l1.CompareTo(l2),
l1.CompareTo((Object)l2));
        Show("Version:  ", m1, m2, m1.CompareTo(m2),
m1.CompareTo((Object)m2));
        Show("Guid:     ", n1, n2, n1.CompareTo(n2),
n1.CompareTo((Object)n2));
//
        Console.WriteLine("{0}The following types are not CLS-
compliant:", nl);
        Show("SByte:    ", w1, w2, w1.CompareTo(w2),
w1.CompareTo((Object)w2));
        Show("UInt16:   ", x1, x2, x1.CompareTo(x2),
x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:
```

```
The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Char.CompareTo method because it does not have to convert the `value` parameter to an object.

The comparison performed by this method is based on the encoded values of this instance and `value`, not their lexicographical characteristics.

If the CompareTo method parameter type has fewer bits (is narrower) than the instance type, some programming languages perform an implicit widening conversion that transforms the value of the parameter into a value with more bits.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Typically, implicit widening conversions are performed on numeric types. Consult your programming language's documentation to determine if its compiler performs

widening conversions. If the instance and parameter types mismatch and a suitable conversion is not available, the compiler generates instructions to box the parameter and invoke the CompareTo overload that takes an Object parameter.

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare this instance to, or `null`.

Returns

Int32

A signed number indicating the position of this instance in the sort order in relation to the `value` parameter.

Expand table

Return Value	Description
Less than zero	This instance precedes `value`.
Zero	This instance has the same position in the sort order as `value`.
Greater than zero	This instance follows `value`. -or- `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a Char object.

Examples

The following code example demonstrates CompareTo.

C#

```
using System;

public class CompareToSample {
    public static void Main() {
        char chA = 'A';
        char chB = 'B';

        Console.WriteLine(chA.CompareTo('A'));  // Output: "0" (meaning
they're equal)
        Console.WriteLine('b'.CompareTo(chB));  // Output: "32" (meaning
'b' is greater than 'B' by 32)
        Console.WriteLine(chA.CompareTo(chB));  // Output: "-1" (meaning
'A' is less than 'B' by 1)
```

```
    }
}
```

Remarks

The CompareTo method implements the IComparable interface.

The `value` parameter must be `null` or an instance of Char; otherwise, an exception is thrown.

The comparison performed by this method is based on the encoded values of this instance and `value`, not necessarily their lexicographical characteristics. Any instance of Char, regardless of its value, is considered greater than `null`.

Char.ConvertFromUtf32(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified Unicode code point into a UTF-16 encoded string.

C#

```
public static string ConvertFromUtf32 (int utf32);
```

Parameters

`utf32` Int32

A 21-bit Unicode code point.

Returns

String

A string consisting of one Char object or a surrogate pair of Char objects equivalent to the code point specified by the `utf32` parameter.

Exceptions

ArgumentOutOfRangeException

`utf32` is not a valid 21-bit Unicode code point ranging from U+0 through U+10FFFF, excluding the surrogate pair range from U+D800 through U+DFFF.

Examples

The following code example demonstrates the ConvertToUtf32 and ConvertFromUtf32 methods.

C#

```
// This example demonstrates the Char.ConvertFromUtf32() method
//                            and Char.ConvertToUtf32() overloads.
```

```
using System;

class Sample
{
    public static void Main()
    {
    int letterA = 0x0041;  //U+00041 = LATIN CAPITAL LETTER A
    int music   = 0x1D161; //U+1D161 = MUSICAL SYMBOL SIXTEENTH NOTE
    string s1;
    string comment   = "Create a UTF-16 encoded string from a code point.";
    string comment1b = "Create a code point from a UTF-16 encoded string.";
    string comment2b = "Create a code point from a surrogate pair at a
certain position in a string.";
    string comment2c = "Create a code point from a high surrogate and a low
surrogate code point.";

//  Convert code point U+0041 to UTF-16. The UTF-16 equivalent of
//  U+0041 is a Char with hexadecimal value 0041.

    Console.WriteLine(comment);
    s1 = Char.ConvertFromUtf32(letterA);
    Console.Write("    1a) 0x{0:X} => ", letterA);
    Show(s1);
    Console.WriteLine();

//  Convert the lone UTF-16 character to a code point.

    Console.WriteLine(comment1b);
    letterA = Char.ConvertToUtf32(s1, 0);
    Console.Write("    1b) ");
    Show(s1);
    Console.WriteLine(" => 0x{0:X}", letterA);
    Console.WriteLine();

// ------------------------------------------------------------------

//  Convert the code point U+1D161 to UTF-16. The UTF-16 equivalent of
//  U+1D161 is a surrogate pair with hexadecimal values D834 and DD61.

    Console.WriteLine(comment);
    s1 = Char.ConvertFromUtf32(music);
    Console.Write("    2a) 0x{0:X} => ", music);
    Show(s1);
    Console.WriteLine();

//  Convert the surrogate pair in the string at index position
//  zero to a code point.

    Console.WriteLine(comment2b);
    music = Char.ConvertToUtf32(s1, 0);
    Console.Write("    2b) ");
    Show(s1);
    Console.WriteLine(" => 0x{0:X}", music);

//  Convert the high and low characters in the surrogate pair into a code
```

```
point.

    Console.WriteLine(comment2c);
    music = Char.ConvertToUtf32(s1[0], s1[1]);
    Console.Write("    2c) ");
    Show(s1);
    Console.WriteLine(" => 0x{0:X}", music);
    }

    private static void Show(string s)
    {
    for (int x = 0; x < s.Length; x++)
        {
        Console.Write("0x{0:X}{1}",
                      (int)s[x],
                      ((x == s.Length-1)? String.Empty : ", "));
        }
    }
}
/*
This example produces the following results:

Create a UTF-16 encoded string from a code point.
    1a) 0x41 => 0x41
Create a code point from a UTF-16 encoded string.
    1b) 0x41 => 0x41

Create a UTF-16 encoded string from a code point.
    2a) 0x1D161 => 0xD834, 0xDD61
Create a code point from a surrogate pair at a certain position in a string.
    2b) 0xD834, 0xDD61 => 0x1D161
Create a code point from a high surrogate and a low surrogate code point.
    2c) 0xD834, 0xDD61 => 0x1D161

*/
```

Remarks

Use this method to convert a 21-bit Unicode code point to a UTF-16 encoded string before testing the string with methods such as IsLowSurrogate(Char) and IsHighSurrogate(Char).

A valid code point outside the Basic Multilingual Plane (BMP) always yields a valid surrogate pair. However, a valid code point within the BMP might not yield a valid result according to the Unicode standard because no linguistic processing is used in the conversion. For that reason, use the System.Text.UTF32Encoding class to convert bulk UTF-32 data into bulk UTF-16 data.

class Sample
{
    public static void Main()
    {
    int letterA = 0x0041;  //U+00041 = LATIN CAPITAL LETTER A
    int music   = 0x1D161; //U+1D161 = MUSICAL SYMBOL SIXTEENTH NOTE
    string s1;
    string comment   = "Create a UTF-16 encoded string from a code point.";
    string comment1b = "Create a code point from a UTF-16 encoded string.";
    string comment2b = "Create a code point from a surrogate pair at a
certain position in a string.";
    string comment2c = "Create a code point from a high surrogate and a low
surrogate code point.";
```

```
//  Convert code point U+0041 to UTF-16. The UTF-16 equivalent of
//  U+0041 is a Char with hexadecimal value 0041.

    Console.WriteLine(comment);
    s1 = Char.ConvertFromUtf32(letterA);
    Console.Write("    1a) 0x{0:X} => ", letterA);
    Show(s1);
    Console.WriteLine();

//  Convert the lone UTF-16 character to a code point.

    Console.WriteLine(comment1b);
    letterA = Char.ConvertToUtf32(s1, 0);
    Console.Write("    1b) ");
    Show(s1);
    Console.WriteLine(" => 0x{0:X}", letterA);
    Console.WriteLine();

// ------------------------------------------------------------------

//  Convert the code point U+1D161 to UTF-16. The UTF-16 equivalent of
//  U+1D161 is a surrogate pair with hexadecimal values D834 and DD61.

    Console.WriteLine(comment);
    s1 = Char.ConvertFromUtf32(music);
    Console.Write("    2a) 0x{0:X} => ", music);
    Show(s1);
    Console.WriteLine();

//  Convert the surrogate pair in the string at index position
//  zero to a code point.

    Console.WriteLine(comment2b);
    music = Char.ConvertToUtf32(s1, 0);
    Console.Write("    2b) ");
    Show(s1);
    Console.WriteLine(" => 0x{0:X}", music);

//  Convert the high and low characters in the surrogate pair into a code
point.

    Console.WriteLine(comment2c);
    music = Char.ConvertToUtf32(s1[0], s1[1]);
    Console.Write("    2c) ");
    Show(s1);
    Console.WriteLine(" => 0x{0:X}", music);
    }

    private static void Show(string s)
    {
    for (int x = 0; x < s.Length; x++)
        {
        Console.Write("0x{0:X}{1}",
                      (int)s[x],
```

```
                        ((x == s.Length-1)? String.Empty : ", "));
        }
    }
}
/*
This example produces the following results:

Create a UTF-16 encoded string from a code point.
    1a) 0x41 => 0x41
Create a code point from a UTF-16 encoded string.
    1b) 0x41 => 0x41

Create a UTF-16 encoded string from a code point.
    2a) 0x1D161 => 0xD834, 0xDD61
Create a code point from a surrogate pair at a certain position in a string.
    2b) 0xD834, 0xDD61 => 0x1D161
Create a code point from a high surrogate and a low surrogate code point.
    2c) 0xD834, 0xDD61 => 0x1D161

*/
```

ConvertToUtf32(Char, Char)

Converts the value of a UTF-16 encoded surrogate pair into a Unicode code point.

```
C#

public static int ConvertToUtf32 (char highSurrogate, char lowSurrogate);
```

Parameters

`highSurrogate` Char

A high surrogate code unit (that is, a code unit ranging from U+D800 through U+DBFF).

`lowSurrogate` Char

A low surrogate code unit (that is, a code unit ranging from U+DC00 through U+DFFF).

Returns

Int32

The 21-bit Unicode code point represented by the `highSurrogate` and `lowSurrogate` parameters.

Exceptions

ArgumentOutOfRangeException

`highSurrogate` is not in the range U+D800 through U+DBFF, or `lowSurrogate` is not in the range U+DC00 through U+DFFF.

Remarks

Use this method to convert a surrogate pair into a 21-bit Unicode code point. To convert UTF-16 data into UTF-32 data, use the System.Text.UTF32Encoding class.

Ordinarily, UTF-16 encoding represents a single Unicode character as a 16-bit code unit. However, it also supports surrogate pairs, which allow a single abstract character to be represented as two 16-bit code units. These two Char objects must have code units that range from U+D800 to U+DBFF for the first (high) surrogate and from U+DC00 to U+DFFF for the second (low) surrogate. Surrogate pairs are supported only by UTF-16 encoding. This method allows a character represented by a UTF-16 surrogate pair to be converted to a character using UTF-32 encoding.

UWP	10.0

ConvertToUtf32(String, Int32)

Converts the value of a UTF-16 encoded character or surrogate pair at a specified position in a string into a Unicode code point.

```
C#

public static int ConvertToUtf32 (string s, int index);
```

Parameters

`s` String

A string that contains a character or surrogate pair.

`index` Int32

The index position of the character or surrogate pair in `s`.

Returns

Int32

The 21-bit Unicode code point represented by the character or surrogate pair at the position in the `s` parameter specified by the `index` parameter.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is not a position within `s`.

ArgumentException

The specified index position contains a surrogate pair, and either the first character in the pair is not a valid high surrogate or the second character in the pair is not a valid low surrogate.

Remarks

Use this method to convert a character or surrogate pair into a 21-bit Unicode code point. To convert UTF-16 data into UTF-32 data, use the System.Text.UTF32Encoding class.

Char.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether this instance is equal to a specified object or Char value.

Overloads

Expand table

Equals(Char)	Returns a value that indicates whether this instance is equal to the specified Char object.
Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object.

Equals(Char)

Returns a value that indicates whether this instance is equal to the specified Char object.

C#

```
public bool Equals (char obj);
```

Parameters

obj Char

An object to compare to this instance.

Returns

Boolean

`true` if the `obj` parameter equals the value of this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Char.Equals(Object) because it does not need to unbox the `obj` parameter.

See also

- Equals(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Returns a value that indicates whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

An object to compare with this instance or `null`.

Returns

Boolean

`true` if `obj` is an instance of Char and equals the value of this instance; otherwise, `false`.

Examples

The following code example demonstrates Equals.

C#

```
using System;

public class EqualsSample {
    public static void Main() {
        char chA = 'A';
        char chB = 'B';

        Console.WriteLine(chA.Equals('A'));     // Output: "True"
        Console.WriteLine('b'.Equals(chB));     // Output: "False"
    }
}
```

Remarks

The comparison performed by this method is based on the encoded values of this instance and `obj`, not necessarily their lexicographical characteristics.

Char.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.GetNumericValue Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified numeric Unicode character to a double-precision floating-point number.

Overloads

Expand table

GetNumericValue(Char)	Converts the specified numeric Unicode character to a double-precision floating point number.
GetNumericValue(String, Int32)	Converts the numeric Unicode character at the specified position in a specified string to a double-precision floating point number.

GetNumericValue(Char)

Converts the specified numeric Unicode character to a double-precision floating point number.

C#

```
public static double GetNumericValue (char c);
```

Parameters

c Char

The Unicode character to convert.

Returns

Double

The numeric value of `c` if that character represents a number; otherwise, -1.0.

Examples

The following example demonstrates GetNumericValue.

```
C#

using System;

public class GetNumericValueSample {
    public static void Main() {
        string str = "input: 1";

        Console.WriteLine(Char.GetNumericValue('8'));       // Output:
"8"
        Console.WriteLine(Char.GetNumericValue(str, 7));    // Output:
"1"
    }
}
```

Remarks

The `c` parameter must be the Char representation of a numeric value. For example, if `c` is "5", the return value is 5. However, if `c` is "z", the return value is -1.0.

A character has an associated numeric value if and only if it is a member of one of the following UnicodeCategory categories: `DecimalDigitNumber`, `LetterNumber`, or `OtherNumber`.

The GetNumericValue method assumes that `c` corresponds to a single linguistic character and checks whether that character can be converted to a decimal digit. However, some numbers in the Unicode standard are represented by two Char objects that form a surrogate pair. For example, the Aegean numbering system consists of code points U+10107 through U+10133. The following example uses the ConvertFromUtf32 method to instantiate a string that represents AEGEAN NUMBER ONE. As the output from the example shows, the GetNumericValue(Char) method returns -1 if it is passed either a high surrogate or a low surrogate of this character.

```
C#

int utf32 = 0x10107;        // AEGEAN NUMBER ONE
string surrogate = Char.ConvertFromUtf32(utf32);
foreach (var ch in surrogate)
   Console.WriteLine("U+{0:X4}: {1}    ", Convert.ToUInt16(ch),
```

```
                                                Char.GetNumericValue(ch));

// The example displays the following output:
//       U+D800: -1
//       U+DD07: -1
```

- GetNumericValue(Rune)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetNumericValue(String, Int32)

Converts the numeric Unicode character at the specified position in a specified string to a double-precision floating point number.

C#

```
public static double GetNumericValue (string s, int index);
```

Parameters

s String

A String.

index Int32

The character position in `s`.

Returns

Double

The numeric value of the character at position `index` in `s` if that character represents a number; otherwise, -1.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Examples

The following code example demonstrates GetNumericValue.

C#

```
using System;

public class GetNumericValueSample {
    public static void Main() {
        string str = "input: 1";

        Console.WriteLine(Char.GetNumericValue('8'));       // Output:
"8"
        Console.WriteLine(Char.GetNumericValue(str, 7));    // Output:
"1"
    }
}
```

Remarks

The `s` parameter must be the string representation of a numeric value. For example, if the character at position `index` in `s` is "5", the return value is 5. However, if the character at position `index` in `s` is "z", the return value is -1.

Character positions in a string are indexed starting from zero.

A character has an associated numeric value if and only if it is a member of one of the following UnicodeCategory categories: `DecimalDigitNumber`, `LetterNumber`, or `OtherNumber`.

If the Char object at position `index` is the first character of a valid surrogate pair, the GetNumericValue(String, Int32) method determines whether the surrogate pair forms a numeric digit. For example, the Aegean numbering system consists of code points U+10107 through U+10133. The following example uses the ConvertFromUtf32 method to instantiate a string that represents each Aegean number. As the output from the example shows, the GetNumericValue(String, Int32) method returns the correct numeric value if it is passed the high surrogate of an Aegean number. However, if it is passed the low surrogate, it considers only the low surrogate in isolation and returns -1.

C#

```
// Define a UTF32 value for each character in the
// Aegean numbering system.
for (int utf32 = 0x10107; utf32 <= 0x10133; utf32++) {
   string surrogate = Char.ConvertFromUtf32(utf32);
   for (int ctr = 0; ctr < surrogate.Length; ctr++)
      Console.Write("U+{0:X4} at position {1}: {2}     ",
                        Convert.ToUInt16(surrogate[ctr]), ctr,
                        Char.GetNumericValue(surrogate, ctr));

   Console.WriteLine();
}
// The example displays the following output:
//       U+D800 at position 0: 1     U+DD07 at position 1: -1
//       U+D800 at position 0: 2     U+DD08 at position 1: -1
//       U+D800 at position 0: 3     U+DD09 at position 1: -1
//       U+D800 at position 0: 4     U+DD0A at position 1: -1
//       U+D800 at position 0: 5     U+DD0B at position 1: -1
//       U+D800 at position 0: 6     U+DD0C at position 1: -1
//       U+D800 at position 0: 7     U+DD0D at position 1: -1
//       U+D800 at position 0: 8     U+DD0E at position 1: -1
//       U+D800 at position 0: 9     U+DD0F at position 1: -1
//       U+D800 at position 0: 10     U+DD10 at position 1: -1
//       U+D800 at position 0: 20     U+DD11 at position 1: -1
//       U+D800 at position 0: 30     U+DD12 at position 1: -1
//       U+D800 at position 0: 40     U+DD13 at position 1: -1
//       U+D800 at position 0: 50     U+DD14 at position 1: -1
//       U+D800 at position 0: 60     U+DD15 at position 1: -1
//       U+D800 at position 0: 70     U+DD16 at position 1: -1
//       U+D800 at position 0: 80     U+DD17 at position 1: -1
//       U+D800 at position 0: 90     U+DD18 at position 1: -1
//       U+D800 at position 0: 100     U+DD19 at position 1: -1
//       U+D800 at position 0: 200     U+DD1A at position 1: -1
//       U+D800 at position 0: 300     U+DD1B at position 1: -1
//       U+D800 at position 0: 400     U+DD1C at position 1: -1
//       U+D800 at position 0: 500     U+DD1D at position 1: -1
//       U+D800 at position 0: 600     U+DD1E at position 1: -1
//       U+D800 at position 0: 700     U+DD1F at position 1: -1
//       U+D800 at position 0: 800     U+DD20 at position 1: -1
//       U+D800 at position 0: 900     U+DD21 at position 1: -1
```

```
//       U+D800 at position 0: 1000     U+DD22 at position 1: -1
//       U+D800 at position 0: 2000     U+DD23 at position 1: -1
//       U+D800 at position 0: 3000     U+DD24 at position 1: -1
//       U+D800 at position 0: 4000     U+DD25 at position 1: -1
//       U+D800 at position 0: 5000     U+DD26 at position 1: -1
//       U+D800 at position 0: 6000     U+DD27 at position 1: -1
//       U+D800 at position 0: 7000     U+DD28 at position 1: -1
//       U+D800 at position 0: 8000     U+DD29 at position 1: -1
//       U+D800 at position 0: 9000     U+DD2A at position 1: -1
//       U+D800 at position 0: 10000     U+DD2B at position 1: -1
//       U+D800 at position 0: 20000     U+DD2C at position 1: -1
//       U+D800 at position 0: 30000     U+DD2D at position 1: -1
//       U+D800 at position 0: 40000     U+DD2E at position 1: -1
//       U+D800 at position 0: 50000     U+DD2F at position 1: -1
//       U+D800 at position 0: 60000     U+DD30 at position 1: -1

Char.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Char.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Char.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Char.GetUnicodeCategory Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Categorizes a Unicode character into a group identified by one of the UnicodeCategory values.

Overloads

Expand table

GetUnicodeCategory(Char)	Categorizes a specified Unicode character into a group identified by one of the UnicodeCategory values.
GetUnicodeCategory(String, Int32)	Categorizes the character at the specified position in a specified string into a group identified by one of the UnicodeCategory values.

Examples

The following code example demonstrates GetUnicodeCategory.

C#

```
using System;

public class GetUnicodeCategorySample {
    public static void Main() {
        char ch2 = '2';
        string str = "Upper Case";

        Console.WriteLine(Char.GetUnicodeCategory('a'));        // Output:
"LowercaseLetter"
        Console.WriteLine(Char.GetUnicodeCategory(ch2));        // Output:
"DecimalDigitNumber"
        Console.WriteLine(Char.GetUnicodeCategory(str, 6));     // Output:
"UppercaseLetter"
    }
}
```

GetUnicodeCategory(Char)

Categorizes a specified Unicode character into a group identified by one of the UnicodeCategory values.

```
C#

public static System.Globalization.UnicodeCategory GetUnicodeCategory
(char c);
```

Parameters

c Char

The Unicode character to categorize.

Returns

UnicodeCategory

A UnicodeCategory value that identifies the group that contains `c`.

Remarks

The Char.GetUnicodeCategory method does not always return the same UnicodeCategory value as the CharUnicodeInfo.GetUnicodeCategory(Char) method when it is passed a particular character as a parameter. The CharUnicodeInfo.GetUnicodeCategory(Char) method is designed to reflect the current version of the Unicode standard. In contrast, although the Char.GetUnicodeCategory method usually reflects the current version of the Unicode standard, it may return a character's category based on a previous version of the standard or it may return a category that differs from the current standard in order to preserve backward compatibility. As a result, we recommend that you use the CharUnicodeInfo.GetUnicodeCategory(Char) method instead of Char.GetUnicodeCategory(Char).

Starting with .NET Framework 4.6.2, Unicode characters are classified based on The Unicode Standard, Version 8.0.0. In versions of the .NET Framework from the .NET Framework 4 to the .NET Framework 4.6.1, they are classified based on The Unicode Standard, Version 6.3.0.

.NET Standard	2.0, 2.1

GetUnicodeCategory(String, Int32)

Categorizes the character at the specified position in a specified string into a group identified by one of the UnicodeCategory values.

C#

```
public static System.Globalization.UnicodeCategory GetUnicodeCategory
(string s, int index);
```

Parameters

s String

A String.

index Int32

The character position in `s`.

Returns

UnicodeCategory

A UnicodeCategory enumerated constant that identifies the group that contains the character at position `index` in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

The Char.GetUnicodeCategory method does not always return the same UnicodeCategory value as the CharUnicodeInfo.GetUnicodeCategory(String, Int32) method when it is passed a particular character as a parameter. The CharUnicodeInfo.GetUnicodeCategory(String, Int32) method is designed to reflect the current version of the Unicode standard. In contrast, although the Char.GetUnicodeCategory method usually reflects the current version of the Unicode standard, it may return a character's category based on a previous version of the standard or it may return a category that differs from the current standard in order to preserve backward compatibility. As a result, we recommend that you use the CharUnicodeInfo.GetUnicodeCategory(Char) method instead of Char.GetUnicodeCategory(String, Int32).

Starting with .NET Framework 4.6.2, Unicode characters are classified based on The Unicode Standard, Version 8.0.0. In versions of the .NET Framework from the .NET Framework 4 to the .NET Framework 4.6.1, they are classified based on The Unicode Standard, Version 6.3.0.

Char.IsAscii(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns `true` if `c` is an ASCII character ([U+0000..U+007F]).

C#

```
public static bool IsAscii (char c);
```

Parameters
