c Char

The character to analyze.

Returns

Boolean

`true` if `c` is an ASCII character; `false` otherwise.

Remarks

Per http://www.unicode.org/glossary/#ASCII, ASCII is only U+0000..U+007F.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Char.IsAsciiDigit(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an ASCII digit.

C#

```
public static bool IsAsciiDigit (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is an ASCII digit; otherwise, `false`.

Remarks

This method determines whether the character is in the range '0' through '9', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Char.IsAsciiHexDigit(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an ASCII hexademical digit.

C#

```
public static bool IsAsciiHexDigit (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is a hexademical digit; otherwise, `false`.

Remarks

This method determines whether the character is in the range '0' through '9', inclusive, 'A' through 'F', inclusive, or 'a' through 'f', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Char.IsAsciiHexDigitLower(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an ASCII lower-case hexademical digit.

C#

```
public static bool IsAsciiHexDigitLower (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is a lower-case hexademical digit; otherwise, `false`.

Remarks

This determines whether the character is in the range '0' through '9', inclusive, or 'a' through 'f', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Char.IsAsciiHexDigitUpper(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an ASCII upper-case hexademical digit.

C#

```
public static bool IsAsciiHexDigitUpper (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is a hexademical digit; otherwise, `false`.

Remarks

This determines whether the character is in the range '0' through '9', inclusive, or 'A' through 'F', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Char.IsAsciiLetter(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an ASCII letter.

C#

```
public static bool IsAsciiLetter (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is an ASCII letter; otherwise, `false`.

Remarks

This determines whether the character is in the range 'A' through 'Z', inclusive, or 'a' through 'z', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IsAsciiLetterLower(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as a lowercase ASCII letter.

C#

```
public static bool IsAsciiLetterLower (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is a lowercase ASCII letter; otherwise, `false`.

Remarks

This determines whether the character is in the range 'a' through 'z', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Char.IsAsciiLetterOrDigit(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an ASCII letter or digit.

C#

```
public static bool IsAsciiLetterOrDigit (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is an ASCII letter or digit; otherwise, `false`.

Remarks

This determines whether the character is in the range 'A' through 'Z', inclusive, 'a' through 'z', inclusive, or '0' through '9', inclusive.

Char.IsAsciiLetterUpper(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is categorized as an uppercase ASCII letter.

C#

```
public static bool IsAsciiLetterUpper (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if `c` is a lowercase ASCII letter; otherwise, `false`.

Remarks

This determines whether the character is in the range 'a' through 'z', inclusive.

Applies to

Product	Versions
.NET	7, 8, 9

Char.IsBetween(Char, Char, Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character is within the specified inclusive range.

C#

```
public static bool IsBetween (char c, char minInclusive, char maxInclusive);
```

Parameters

`c` Char

The character to evaluate.

`minInclusive` Char

The lower bound, inclusive.

`maxInclusive` Char

The upper bound, inclusive.

Returns

Boolean

`true` if `c` is within the specified range; otherwise, `false`.

Remarks

The method does not validate that `maxInclusive` is greater than or equal to `minInclusive`. If `maxInclusive` is less than `minInclusive`, the behavior is undefined.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IsControl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified Unicode character is categorized as a control character.

Overloads

Expand table

IsControl(Char)	Indicates whether the specified Unicode character is categorized as a control character.
IsControl(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a control character.

Remarks

Control characters are formatting and other non-printing characters, such as ACK, BEL, CR, FF, LF, and VT. The Unicode standard assigns code points from \U0000 to \U001F, \U007F, and from \U0080 to \U009F to control characters. According to the Unicode standard, these values are to be interpreted as control characters unless their use is otherwise defined by an application. Valid control characters are members of the UnicodeCategory.Control category.

IsControl(Char)

Indicates whether the specified Unicode character is categorized as a control character.

C#

```
public static bool IsControl (char c);
```

Parameters

`c` Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a control character; otherwise, `false`.

Examples

The following example lists the Unicode code point of each of the control characters.

C#

```
using System;

public class ControlChars
{
   public static void Main()
   {
      int charsWritten = 0;

      for (int ctr = 0x00; ctr <= 0xFFFF; ctr++)
      {
         char ch = Convert.ToChar(ctr);
         if (char.IsControl(ch))
         {
            Console.Write(@"\U{0:X4}    ", ctr);
            charsWritten++;
            if (charsWritten % 6 == 0)
               Console.WriteLine();
         }
      }
   }
}
// The example displays the following output to the console:
//       \U0000    \U0001    \U0002    \U0003    \U0004    \U0005
//       \U0006    \U0007    \U0008    \U0009    \U000A    \U000B
//       \U000C    \U000D    \U000E    \U000F    \U0010    \U0011
//       \U0012    \U0013    \U0014    \U0015    \U0016    \U0017
//       \U0018    \U0019    \U001A    \U001B    \U001C    \U001D
//       \U001E    \U001F    \U007F    \U0080    \U0081    \U0082
//       \U0083    \U0084    \U0085    \U0086    \U0087    \U0088
//       \U0089    \U008A    \U008B    \U008C    \U008D    \U008E
//       \U008F    \U0090    \U0091    \U0092    \U0093    \U0094
//       \U0095    \U0096    \U0097    \U0098    \U0099    \U009A
//       \U009B    \U009C    \U009D    \U009E    \U009F
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IsControl(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a control character.

C#

```
public static bool IsControl (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a control character; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Examples

The following example enumerates the characters in a string and determines whether any are control characters.

C#

```
using System;

public class ControlChar
{
   public static void Main()
   {
      string sentence = "This is a " + Environment.NewLine + "two-line
sentence.";
      for (int ctr = 0; ctr < sentence.Length; ctr++)
      {
         if (Char.IsControl(sentence, ctr))
           Console.WriteLine("Control character \\U{0} found in position
{1}.",
              Convert.ToInt32(sentence[ctr]).ToString("X4"), ctr);
      }
   }
}
// The example displays the following output to the console:
//       Control character \U000D found in position 10.
//       Control character \U000A found in position 11.
```

Applies to

Char.IsDigit Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a decimal digit.

Overloads

Expand table

IsDigit(Char)	Indicates whether the specified Unicode character is categorized as a decimal digit.
IsDigit(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a decimal digit.

Examples

The following code example demonstrates IsDigit.

C#

```
using System;

public class IsDigitSample {
    public static void Main() {
        char ch = '8';

        Console.WriteLine(Char.IsDigit(ch));                    // Output:
"True"
        Console.WriteLine(Char.IsDigit("sample string", 7));    // Output:
"False"
    }
}
```

Remarks

Valid digits are members of the UnicodeCategory.DecimalDigitNumber category.

IsDigit(Char)

Indicates whether the specified Unicode character is categorized as a decimal digit.

```
C#
public static bool IsDigit (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a decimal digit; otherwise, `false`.

Remarks

This method determines whether a Char is a radix-10 digit. This contrasts with IsNumber, which determines whether a `Char` is of any numeric Unicode category. Numbers include characters such as fractions, subscripts, superscripts, Roman numerals, currency numerators, encircled numbers, and script-specific digits.

Valid digits are members of the UnicodeCategory.DecimalDigitNumber category.

UWP	10.0

IsDigit(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a decimal digit.

C#

```
public static bool IsDigit (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a decimal digit; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

This method determines whether a Char is a radix-10 digit. This contrasts with IsNumber, which determines whether a Char is of any numeric Unicode category. Numbers include characters such as fractions, subscripts, superscripts, Roman numerals, currency numerators, encircled numbers, and script-specific digits.

Character positions in a string are indexed starting from zero.

Valid digits are members of the UnicodeCategory.DecimalDigitNumber category.

Char.IsHighSurrogate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the specified Char object is a high surrogate.

Overloads

Expand table

IsHighSurrogate(Char)	Indicates whether the specified Char object is a high surrogate.
IsHighSurrogate(String, Int32)	Indicates whether the Char object at the specified position in a string is a high surrogate.

Examples

The following code example demonstrates the IsHighSurrogate, IsLowSurrogate, and IsSurrogatePair methods.

C#

```
// This example demonstrates the Char.IsLowSurrogate() method
//                                     IsHighSurrogate() method
//                                     IsSurrogatePair() method
using System;

class Sample
{
    public static void Main()
    {
    char cHigh = '\uD800';
    char cLow  = '\uDC00';
    string s1  = new String(new char[] {'a', '\uD800', '\uDC00', 'z'});
    string divider = String.Concat( Environment.NewLine, new String('-',
70),
                                    Environment.NewLine);

    Console.WriteLine();
    Console.WriteLine("Hexadecimal code point of the character, cHigh:
```

```
{0:X4}", (int)cHigh);
    Console.WriteLine("Hexadecimal code point of the character, cLow:
{0:X4}", (int)cLow);
    Console.WriteLine();
    Console.WriteLine("Characters in string, s1: 'a', high surrogate, low
surrogate, 'z'");
    Console.WriteLine("Hexadecimal code points of the characters in string,
s1: ");
    for(int i = 0; i < s1.Length; i++)
        {
        Console.WriteLine("s1[{0}] = {1:X4} ", i, (int)s1[i]);
        }
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following characters a high
surrogate?");
    Console.WriteLine("A1) cLow?  - {0}", Char.IsHighSurrogate(cLow));
    Console.WriteLine("A2) cHigh? - {0}", Char.IsHighSurrogate(cHigh));
    Console.WriteLine("A3) s1[0]? - {0}", Char.IsHighSurrogate(s1, 0));
    Console.WriteLine("A4) s1[1]? - {0}", Char.IsHighSurrogate(s1, 1));
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following characters a low
surrogate?");
    Console.WriteLine("B1) cLow?  - {0}", Char.IsLowSurrogate(cLow));
    Console.WriteLine("B2) cHigh? - {0}", Char.IsLowSurrogate(cHigh));
    Console.WriteLine("B3) s1[0]? - {0}", Char.IsLowSurrogate(s1, 0));
    Console.WriteLine("B4) s1[2]? - {0}", Char.IsLowSurrogate(s1, 2));
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following pairs of characters a
surrogate pair?");
    Console.WriteLine("C1) cHigh and cLow?  - {0}",
Char.IsSurrogatePair(cHigh, cLow));
    Console.WriteLine("C2) s1[0] and s1[1]? - {0}", Char.IsSurrogatePair(s1,
0));
    Console.WriteLine("C3) s1[1] and s1[2]? - {0}", Char.IsSurrogatePair(s1,
1));
    Console.WriteLine("C4) s1[2] and s1[3]? - {0}", Char.IsSurrogatePair(s1,
2));
    Console.WriteLine(divider);
    }
}
/*
This example produces the following results:

Hexadecimal code point of the character, cHigh: D800
Hexadecimal code point of the character, cLow:  DC00

Characters in string, s1: 'a', high surrogate, low surrogate, 'z'
Hexadecimal code points of the characters in string, s1:
s1[0] = 0061
s1[1] = D800
s1[2] = DC00
s1[3] = 007A
```

```
-----------------------------------------------------------------------

Is each of the following characters a high surrogate?
A1) cLow?  - False
A2) cHigh? - True
A3) s1[0]? - False
A4) s1[1]? - True

-----------------------------------------------------------------------

Is each of the following characters a low surrogate?
B1) cLow?  - True
B2) cHigh? - False
B3) s1[0]? - False
B4) s1[2]? - True

-----------------------------------------------------------------------

Is each of the following pairs of characters a surrogate pair?
C1) cHigh and cLow?  - True
C2) s1[0] and s1[1]? - False
C3) s1[1] and s1[2]? - True
C4) s1[2] and s1[3]? - False

-----------------------------------------------------------------------

*/
```

IsHighSurrogate(Char)

Indicates whether the specified Char object is a high surrogate.

C#

```
public static bool IsHighSurrogate (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if the numeric value of the `c` parameter ranges from U+D800 through U+DBFF; otherwise, `false`.

Remarks

In addition to representing single characters using a 16-bit code point, UTF-16 encoding allows abstract characters to be represented using two 16-bit code points, which is known as a surrogate pair. The first element in this pair is the high surrogate. Its code point can range from U+D800 to U+DBFF. An individual surrogate has no interpretation of its own; it is meaningful only when used as part of a surrogate pair.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IsHighSurrogate(String, Int32)

Indicates whether the Char object at the specified position in a string is a high surrogate.

C#

```
public static bool IsHighSurrogate (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the numeric value of the specified character in the `s` parameter ranges from U+D800 through U+DBFF; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is not a position within `s`.

Remarks

The `index` parameter is zero-based.

In addition to representing single characters using a 16-bit code point, UTF-16 encoding allows abstract characters to be represented using two 16-bit code points, which is known as a surrogate pair. The first element in this pair is the high surrogate. Its code point can range from U+D800 to U+DBFF. An individual surrogate has no interpretation of its own; it is meaningful only when used as part of a surrogate pair.

Char.IsLetter Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a Unicode letter.

Overloads

Expand table

IsLetter(Char)	Indicates whether the specified Unicode character is categorized as a Unicode letter.
IsLetter(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a Unicode letter.

Examples

The following code example demonstrates IsLetter.

C#

```
using System;

public class IsLetterSample {
    public static void Main() {
        char ch = '8';

        Console.WriteLine(Char.IsLetter(ch));                    // False
        Console.WriteLine(Char.IsLetter("sample string", 7));    // True
    }
}
```

Remarks

This method determines whether a Char is a member of any category of Unicode letter. Unicode letters include the following:

- Uppercase letters, such as U+0041 (LATIN CAPITAL LETTER A) through U+005A (LATIN CAPITAL LETTER Z), or U+0400 (CYRILLIC CAPITAL LETTER IE WITH GRAVE) through U+042F (CYRILLIC CAPITAL LETTER YA). These characters are members of the UnicodeCategory.UppercaseLetter category.
- Lowercase letters, such as U+0061 (LATIN SMALL LETTER A) through U+007A (LATIN SMALL LETTER Z), or U+03AC (GREEK SMALL LETTER ALPHA WITH TONOS) through U+03CE (GREEK SMALL LETTER OMEGA WITH TONOS). These characters are members of the UnicodeCategory.LowercaseLetter category.
- Title case letters, such as U+01C5 (LATIN CAPITAL LETTER D WITH SMALL LETTER Z WITH CARON) or U+1FFC (GREEK CAPITAL LETTER OMEGA WITH PROSGEGRAMMENI). These characters are members of the UnicodeCategory.TitlecaseLetter category.
- Modifiers, such as U+02B0 (MODIFIER LETTER SMALL H) through U+02C1 (MODIFIER LETTER REVERSED GLOTTAL STOP), or U+1D2C (MODIFIER LETTER CAPITAL A) through U+1D61 (MODIFIER LETTER SMALL CHI). These characters are members of the UnicodeCategory.ModifierLetter category.
- Other letters, such as U+05D0 (HEBREW LETTER ALEF) through U+05EA (HEBREW LETTER TAV), U+0621 (ARABIC LETTER HAMZA) through U+063A (ARABIC LETTER GHAIN), or U+4E00 (<CJK Ideograph, First>) through U+9FC3 (<CJK Ideograph, Last>). These characters are members of the UnicodeCategory.OtherLetter category.

IsLetter(Char)

Indicates whether the specified Unicode character is categorized as a Unicode letter.

C#

```
public static bool IsLetter (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a letter; otherwise, `false`.

Remarks

This method determines whether a Char is a member of any category of Unicode letter. Unicode letters include the following:

- Uppercase letters, such as U+0041 (LATIN CAPITAL LETTER A) through U+005A (LATIN CAPITAL LETTER Z), or U+0400 (CYRILLIC CAPITAL LETTER IE WITH GRAVE) through U+042F (CYRILLIC CAPITAL LETTER YA). These characters are members of the UnicodeCategory.UppercaseLetter category.
- Lowercase letters, such as U+0061 (LATIN SMALL LETTER A) through U+007A (LATIN SMALL LETTER Z), or U+03AC (GREEK SMALL LETTER ALPHA WITH TONOS) through U+03CE (GREEK SMALL LETTER OMEGA WITH TONOS). These characters are members of the UnicodeCategory.LowercaseLetter category.
- Title case letters, such as U+01C5 (LATIN CAPITAL LETTER D WITH SMALL LETTER Z WITH CARON) or U+1FFC (GREEK CAPITAL LETTER OMEGA WITH PROSGEGRAMMENI). These characters are members of the UnicodeCategory.TitlecaseLetter category.
- Modifiers, such as U+02B0 (MODIFIER LETTER SMALL H) through U+02C1 (MODIFIER LETTER REVERSED GLOTTAL STOP), or U+1D2C (MODIFIER LETTER CAPITAL A) through U+1D61 (MODIFIER LETTER SMALL CHI). These characters are members of the UnicodeCategory.ModifierLetter category.
- Other letters, such as U+05D0 (HEBREW LETTER ALEF) through U+05EA (HEBREW LETTER TAV), U+0621 (ARABIC LETTER HAMZA) through U+063A (ARABIC LETTER GHAIN), or U+4E00 (<CJK Ideograph, First>) through U+9FC3 (<CJK Ideograph, Last>). These characters are members of the UnicodeCategory.OtherLetter category.

UWP	10.0

IsLetter(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a Unicode letter.

```
C#

public static bool IsLetter (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a letter; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

This method determines whether the character at a specified index position in a string is a member of any category of Unicode letter. Unicode letters include the following:

- Uppercase letters, such as U+0041 (LATIN CAPITAL LETTER A) through U+005A (LATIN CAPITAL LETTER Z), or U+0400 (CYRILLIC CAPITAL LETTER IE WITH GRAVE) through U+042F (CYRILLIC CAPITAL LETTER YA). These characters are members of the UnicodeCategory.UppercaseLetter category.
- Lowercase letters, such as U+0061 (LATIN SMALL LETTER A) through U+007A (LATIN SMALL LETTER Z), or U+03AC (GREEK SMALL LETTER ALPHA WITH TONOS) through U+03CE (GREEK SMALL LETTER OMEGA WITH TONOS). These characters are members of the UnicodeCategory.LowercaseLetter category.
- Title case letters, such as U+01C5 (LATIN CAPITAL LETTER D WITH SMALL LETTER Z WITH CARON) or U+1FFC (GREEK CAPITAL LETTER OMEGA WITH PROSGEGRAMMENI). These characters are members of the UnicodeCategory.TitlecaseLetter category.
- Modifiers, such as U+02B0 (MODIFIER LETTER SMALL H) through U+02C1 (MODIFIER LETTER REVERSED GLOTTAL STOP), or U+1D2C (MODIFIER LETTER CAPITAL A) through U+1D61 (MODIFIER LETTER SMALL CHI). These characters are members of the UnicodeCategory.ModifierLetter category.
- Other letters, such as U+05D0 (HEBREW LETTER ALEF) through U+05EA (HEBREW LETTER TAV), U+0621 (ARABIC LETTER HAMZA) through U+063A (ARABIC LETTER GHAIN), or U+4E00 (<CJK Ideograph, First>) through U+9FC3 (<CJK Ideograph, Last>). These characters are members of the UnicodeCategory.OtherLetter category.

Char.IsLetterOrDigit Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a letter or a decimal digit.

Overloads

Expand table

IsLetterOrDigit(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a letter or a decimal digit.
IsLetterOrDigit(Char)	Indicates whether the specified Unicode character is categorized as a letter or a decimal digit.

Examples

The following code example demonstrates IsLetterOrDigit.

C#

```
using System;

public class IsLetterOrDigitSample {
    public static void Main() {
        string str = "newline:\n";

        Console.WriteLine(Char.IsLetterOrDigit('8'));       // Output:
"True"
        Console.WriteLine(Char.IsLetterOrDigit(str, 8));    // Output:
"False", because it's a newline
    }
}
```

Remarks

Valid letters and decimal digits are members of the following categories in UnicodeCategory: `UppercaseLetter`, `LowercaseLetter`, `TitlecaseLetter`, `ModifierLetter`, `OtherLetter`, or `DecimalDigitNumber`.

IsLetterOrDigit(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a letter or a decimal digit.

```
C#
public static bool IsLetterOrDigit (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a letter or a decimal digit; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

Valid letters and decimal digits are members of the following categories in UnicodeCategory: `UppercaseLetter`, `LowercaseLetter`, `TitlecaseLetter`, `ModifierLetter`, `OtherLetter`, or `DecimalDigitNumber`.

IsLetterOrDigit(Char)

Indicates whether the specified Unicode character is categorized as a letter or a decimal digit.

C#

```
public static bool IsLetterOrDigit (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a letter or a decimal digit; otherwise, `false`.

Remarks

Valid letters and decimal digits are members of the following categories in UnicodeCategory: `UppercaseLetter`, `LowercaseLetter`, `TitlecaseLetter`, `ModifierLetter`, `OtherLetter`, or `DecimalDigitNumber`.

Char.IsLower Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a lowercase letter.

Overloads

Expand table

IsLower(Char)	Indicates whether the specified Unicode character is categorized as a lowercase letter.
IsLower(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a lowercase letter.

Examples

The following code example demonstrates IsLower.

C#

```
using System;

public class IsLowerSample {
    public static void Main() {
        char ch = 'a';

        Console.WriteLine(Char.IsLower(ch));                // Output:
"True"
        Console.WriteLine(Char.IsLower("upperCase", 5));    // Output:
"False"
    }
}
```

IsLower(Char)

Indicates whether the specified Unicode character is categorized as a lowercase letter.

```
C#

public static bool IsLower (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a lowercase letter; otherwise, `false`.

Remarks

Valid lowercase letters are members of the following category in UnicodeCategory: `LowercaseLetter`.

IsLower(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a lowercase letter.

```
C#
public static bool IsLower (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a lowercase letter; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

Valid lowercase letters are members of the following category in UnicodeCategory: `LowercaseLetter`.

Char.IsLowSurrogate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the specified Char object is a low surrogate.

Overloads

Expand table

IsLowSurrogate(Char)	Indicates whether the specified Char object is a low surrogate.
IsLowSurrogate(String, Int32)	Indicates whether the Char object at the specified position in a string is a low surrogate.

Examples

The following code example demonstrates the IsHighSurrogate, IsLowSurrogate, and IsSurrogatePair methods.

C#

```
// This example demonstrates the Char.IsLowSurrogate() method
//                                     IsHighSurrogate() method
//                                     IsSurrogatePair() method
using System;

class Sample
{
    public static void Main()
    {
    char cHigh = '\uD800';
    char cLow  = '\uDC00';
    string s1  = new String(new char[] {'a', '\uD800', '\uDC00', 'z'});
    string divider = String.Concat( Environment.NewLine, new String('-',
70),
                                    Environment.NewLine);

    Console.WriteLine();
    Console.WriteLine("Hexadecimal code point of the character, cHigh:
```

```
{0:X4}", (int)cHigh);
    Console.WriteLine("Hexadecimal code point of the character, cLow:
{0:X4}", (int)cLow);
    Console.WriteLine();
    Console.WriteLine("Characters in string, s1: 'a', high surrogate, low
surrogate, 'z'");
    Console.WriteLine("Hexadecimal code points of the characters in string,
s1: ");
    for(int i = 0; i < s1.Length; i++)
        {
        Console.WriteLine("s1[{0}] = {1:X4} ", i, (int)s1[i]);
        }
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following characters a high
surrogate?");
    Console.WriteLine("A1) cLow?  - {0}", Char.IsHighSurrogate(cLow));
    Console.WriteLine("A2) cHigh? - {0}", Char.IsHighSurrogate(cHigh));
    Console.WriteLine("A3) s1[0]? - {0}", Char.IsHighSurrogate(s1, 0));
    Console.WriteLine("A4) s1[1]? - {0}", Char.IsHighSurrogate(s1, 1));
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following characters a low
surrogate?");
    Console.WriteLine("B1) cLow?  - {0}", Char.IsLowSurrogate(cLow));
    Console.WriteLine("B2) cHigh? - {0}", Char.IsLowSurrogate(cHigh));
    Console.WriteLine("B3) s1[0]? - {0}", Char.IsLowSurrogate(s1, 0));
    Console.WriteLine("B4) s1[2]? - {0}", Char.IsLowSurrogate(s1, 2));
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following pairs of characters a
surrogate pair?");
    Console.WriteLine("C1) cHigh and cLow?  - {0}",
Char.IsSurrogatePair(cHigh, cLow));
    Console.WriteLine("C2) s1[0] and s1[1]? - {0}", Char.IsSurrogatePair(s1,
0));
    Console.WriteLine("C3) s1[1] and s1[2]? - {0}", Char.IsSurrogatePair(s1,
1));
    Console.WriteLine("C4) s1[2] and s1[3]? - {0}", Char.IsSurrogatePair(s1,
2));
    Console.WriteLine(divider);
    }
}
/*
This example produces the following results:

Hexadecimal code point of the character, cHigh: D800
Hexadecimal code point of the character, cLow:  DC00

Characters in string, s1: 'a', high surrogate, low surrogate, 'z'
Hexadecimal code points of the characters in string, s1:
s1[0] = 0061
s1[1] = D800
s1[2] = DC00
s1[3] = 007A
```

```
-----------------------------------------------------------------------

Is each of the following characters a high surrogate?
A1) cLow?  - False
A2) cHigh? - True
A3) s1[0]? - False
A4) s1[1]? - True

-----------------------------------------------------------------------

Is each of the following characters a low surrogate?
B1) cLow?  - True
B2) cHigh? - False
B3) s1[0]? - False
B4) s1[2]? - True

-----------------------------------------------------------------------

Is each of the following pairs of characters a surrogate pair?
C1) cHigh and cLow?  - True
C2) s1[0] and s1[1]? - False
C3) s1[1] and s1[2]? - True
C4) s1[2] and s1[3]? - False

-----------------------------------------------------------------------

*/
```

IsLowSurrogate(Char)

Indicates whether the specified Char object is a low surrogate.

C#

```
public static bool IsLowSurrogate (char c);
```

Parameters

c Char

The character to evaluate.

Returns

Boolean

`true` if the numeric value of the `c` parameter ranges from U+DC00 through U+DFFF; otherwise, `false`.

Remarks

In addition to representing single characters using a 16-bit code point, UTF-16 encoding allows abstract characters to be represented using two 16-bit code points, which is known as a surrogate pair. The second element in this pair is the low surrogate. Its code point can range from U+DC00 to U+DFFF. An individual surrogate has no interpretation of its own; it is meaningful only when used as part of a surrogate pair.

UWP	10.0

IsLowSurrogate(String, Int32)

Indicates whether the Char object at the specified position in a string is a low surrogate.

C#

```
public static bool IsLowSurrogate (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the numeric value of the specified character in the `s` parameter ranges from U+DC00 through U+DFFF; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is not a position within `s`.

Remarks

The `index` parameter is zero-based.

In addition to representing single characters using a 16-bit code point, UTF-16 encoding allows abstract characters to be represented using two 16-bit code points, which is known as a surrogate pair. The second element in this pair is the low surrogate. Its code point can range from U+DC00 to U+DFFF. An individual surrogate has no interpretation of its own; it is meaningful only when used as part of a surrogate pair.

Char.IsNumber Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a number.

Overloads

Expand table

IsNumber(Char)	Indicates whether the specified Unicode character is categorized as a number.
IsNumber(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a number.

IsNumber(Char)

Indicates whether the specified Unicode character is categorized as a number.

C#

```
public static bool IsNumber (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a number; otherwise, `false`.

Examples

The following example demonstrates IsNumber.

```C#
using System;

public class IsNumberSample {
    public static void Main() {
        string str = "non-numeric";

        Console.WriteLine(Char.IsNumber('8'));      // Output: "True"
        Console.WriteLine(Char.IsNumber(str, 3));   // Output: "False"
    }
}
```

Remarks

This method determines whether a Char is of any numeric Unicode category. In addition to including digits, numbers include characters, fractions, subscripts, superscripts, Roman numerals, currency numerators, and encircled numbers. This method contrasts with the IsDigit method, which determines whether a Char is a radix-10 digit.

> **Important**
>
> The **IsNumber(Char)** method is not intended to determine whether a string consists of numeric characters (for example, by calling the method for each character in a string). To determine whether a string consists of numeric characters, call one of the overloads of the `TryParse` method (such as **Int32.TryParse** or **Double.TryParse** of an integral or floating point type.

Valid numbers are members of the UnicodeCategory.DecimalDigitNumber, UnicodeCategory.LetterNumber, or UnicodeCategory.OtherNumber category.

The IsNumber(Char) method assumes that `c` corresponds to a single linguistic character and checks whether that character represents a number. However, some numbers in the Unicode standard are represented by two Char objects that form a surrogate pair. For example, the Aegean numbering system consists of code points U+10107 through U+10133. The following example uses the ConvertFromUtf32 method to instantiate a string that represents AEGEAN NUMBER ONE. As the output

from the example shows, the IsNumber(Char) method returns `false` if it is passed either a high surrogate or a low surrogate of this character.

C#

```
int utf32 = 0x10107;      // AEGEAN NUMBER ONE
string surrogate = Char.ConvertFromUtf32(utf32);
foreach (var ch in surrogate)
   Console.WriteLine("U+{0:X4}: {1}", Convert.ToUInt16(ch),
                                      Char.IsNumber(ch));

// The example displays the following output:
//       U+D800: False
//       U+DD07: False
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IsNumber(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a number.

C#

```
public static bool IsNumber (string s, int index);
```

Parameters

s String

A string.

index Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a number; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Examples

The following example demonstrates IsNumber.

C#

```
using System;

public class IsNumberSample {
    public static void Main() {
        string str = "non-numeric";

        Console.WriteLine(Char.IsNumber('8'));      // Output: "True"
        Console.WriteLine(Char.IsNumber(str, 3));   // Output: "False"
    }
}
```

Remarks

This method determines whether a Char is of any numeric Unicode category. In addition to including digits, numbers include characters, fractions, subscripts, superscripts, Roman numerals, currency numerators, and encircled numbers. This method contrasts with the IsDigit method, which determines whether a Char is a radix-10 digit.

Character positions in a string are indexed starting from zero.

> ⓘ **Important**
>
> The **IsNumber(String, Int32)** method is not intended to determine whether a string consists of numeric characters (for example, by calling the method for each character in a string). To determine whether a string consists of numeric characters, call one of the overloads of the `TryParse` method (such as **Int32.TryParse** or **Double.TryParse** of an integral or floating point type.

Valid numbers are members of the UnicodeCategory.DecimalDigitNumber, UnicodeCategory.LetterNumber, or UnicodeCategory.OtherNumber category.

If the Char object at position `index` is the first character of a valid surrogate pair, the IsNumber(String, Int32) method determines whether the surrogate pair forms a numeric digit. For example, the Aegean numbering system consists of code points U+10107 through U+10133. The following example uses the ConvertFromUtf32 method to instantiate a string that represents AEGEAN NUMBER ONE. As the output from the example shows, the IsNumber(String, Int32) method returns `true` if it is passed the high surrogate of AEGEAN NUMBER ONE. However, if it is passed the low surrogate, it considers only the category of the low surrogate and returns `false`.

C#

```
int utf32 = 0x10107;      // AEGEAN NUMBER ONE
string surrogate = Char.ConvertFromUtf32(utf32);
for (int ctr = 0; ctr < surrogate.Length; ctr++)
   Console.WriteLine("U+{0:X4} at position {1}: {2}",
                     Convert.ToUInt16(surrogate[ctr]), ctr,
                     Char.IsNumber(surrogate, ctr));
// The example displays the following output:
//       U+D800 at position 0: True
//       U+DD07 at position 1: False
```

Char.IsPunctuation Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a punctuation mark.

Overloads

Expand table

IsPunctuation(Char)	Indicates whether the specified Unicode character is categorized as a punctuation mark.
IsPunctuation(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a punctuation mark.

Examples

The following code example demonstrates IsPunctuation.

C#

```
using System;

public class IsPunctuationSample {
    public static void Main() {
        char ch = '.';

        Console.WriteLine(Char.IsPunctuation(ch));                    //
Output: "True"
        Console.WriteLine(Char.IsPunctuation("no punctuation", 3));     //
Output: "False"
    }
}
```

Remarks

Valid punctuation marks are members of the following categories in UnicodeCategory: `ConnectorPunctuation`, `DashPunctuation`, `OpenPunctuation`, `ClosePunctuation`, `InitialQuotePunctuation`, `FinalQuotePunctuation`, or `OtherPunctuation`. They include characters with the Unicode code points listed in the following table.

IsPunctuation(Char)

Indicates whether the specified Unicode character is categorized as a punctuation mark.

```
C#
public static bool IsPunctuation (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a punctuation mark; otherwise, `false`.

Remarks

Valid punctuation marks are members of the following categories in UnicodeCategory: `ConnectorPunctuation`, `DashPunctuation`, `OpenPunctuation`, `ClosePunctuation`, `InitialQuotePunctuation`, `FinalQuotePunctuation`, or `OtherPunctuation`. They include characters with the Unicode code points listed in the following table.

IsPunctuation(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a punctuation mark.

C#

```
public static bool IsPunctuation (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a punctuation mark; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

Valid punctuation marks are members of the following categories in UnicodeCategory: `ConnectorPunctuation`, `DashPunctuation`, `OpenPunctuation`, `ClosePunctuation`, `InitialQuotePunctuation`, `FinalQuotePunctuation`, or `OtherPunctuation`. Char.IsSeparator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a separator character.

Overloads

Expand table

IsSeparator(Char)	Indicates whether the specified Unicode character is categorized as a separator character.
IsSeparator(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a separator character.

Remarks

The Unicode standard recognizes three subcategories of separators:

- Space separators (the UnicodeCategory.SpaceSeparator category), which includes characters such as \u0020.
- Line separators (the UnicodeCategory.LineSeparator category), which includes \u2028.
- Paragraph separators (the UnicodeCategory.ParagraphSeparator category), which includes \u2029.

> **Note**
>
> The Unicode standard classifies the characters \u000A (LF), \u000C (FF), and \u000D (CR) as control characters (members of the **UnicodeCategory.Control** category), not as separator characters.

IsSeparator(Char)

Indicates whether the specified Unicode character is categorized as a separator character.

```
C#

public static bool IsSeparator (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is a separator character; otherwise, `false`.

Examples

The following example lists the Char objects that are classified as separator characters.

```
C#

using System;

public class Class1
{
   public static void Main()
   {
      for (int ctr = (int)(Char.MinValue); ctr <= (int)(Char.MaxValue);
ctr++)
      {
         char ch = (Char)ctr;
         if (Char.IsSeparator(ch))
            Console.WriteLine(@"\u{(int)ch:X4}
({Char.GetUnicodeCategory(ch)})");
      }
   }
}
// The example displays the following output:
//       \u0020 (SpaceSeparator)
//       \u00A0 (SpaceSeparator)
```

```
//       \u1680 (SpaceSeparator)
//       \u180E (SpaceSeparator)
//       \u2000 (SpaceSeparator)
//       \u2001 (SpaceSeparator)
//       \u2002 (SpaceSeparator)
//       \u2003 (SpaceSeparator)
//       \u2004 (SpaceSeparator)
//       \u2005 (SpaceSeparator)
//       \u2006 (SpaceSeparator)
//       \u2007 (SpaceSeparator)
//       \u2008 (SpaceSeparator)
//       \u2009 (SpaceSeparator)
//       \u200A (SpaceSeparator)
//       \u2028 (LineSeparator)
//       \u2029 (ParagraphSeparator)
//       \u202F (SpaceSeparator)
//       \u205F (SpaceSeparator)
//       \u3000 (SpaceSeparator)
```

Remarks

The Unicode standard recognizes three subcategories of separators:

- Space separators (the UnicodeCategory.SpaceSeparator category), which includes characters such as \u0020.
- Line separators (the UnicodeCategory.LineSeparator category), which includes \u2028.
- Paragraph separators (the UnicodeCategory.ParagraphSeparator category), which includes \u2029.

> **Note**
>
> The Unicode standard classifies the characters \u000A (LF), \u000C (FF), and \u000D (CR) as control characters (members of the **UnicodeCategory.Control** category), not as separator characters.

IsSeparator(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a separator character.

```
C#
public static bool IsSeparator (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a separator character; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Examples

The following example demonstrates IsSeparator.

C#

```
using System;

public class IsSeparatorSample {
    public static void Main() {
        string str = "twain1 twain2";

        Console.WriteLine(Char.IsSeparator('a'));       // Output:
"False"
        Console.WriteLine(Char.IsSeparator(str, 6));    // Output: "True"
    }
}
```

Remarks

Character positions in a string are indexed starting from zero.

The Unicode standard recognizes three subcategories of separators:

- Space separators (the UnicodeCategory.SpaceSeparator category), which includes characters such as \u0020.
- Line separators (the UnicodeCategory.LineSeparator category), which includes \u2028.
- Paragraph separators (the UnicodeCategory.ParagraphSeparator category), which includes \u2029.

> **Note**
>
> The Unicode standard classifies the characters \u000A (LF), \u000C (FF), and \u000D (CR) as control characters (members of the **UnicodeCategory.Control** category), not as separator characters.

Char.IsSurrogate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a character has a surrogate code unit.

Overloads

Expand table

IsSurrogate(String, Int32)	Indicates whether the character at the specified position in a specified string has a surrogate code unit.
IsSurrogate(Char)	Indicates whether the specified character has a surrogate code unit.

Examples

The following example demonstrates the IsSurrogate method.

C#

```
using System;

public class IsSurrogateSample {
    public static void Main() {
        string str = "\U00010F00"; // Unicode values between 0x10000 and
0x10FFF are represented by two 16-bit "surrogate" characters

        Console.WriteLine(Char.IsSurrogate('a'));       // Output: "False"
        Console.WriteLine(Char.IsSurrogate(str, 0));    // Output: "True"
    }
}
```

IsSurrogate(String, Int32)

Indicates whether the character at the specified position in a specified string has a surrogate code unit.

```C#
public static bool IsSurrogate (string s, int index);
```

Parameters

s String

A string.

index Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a either a high surrogate or a low surrogate; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

A surrogate is a Char object with a UTF-16 code unit in the range from U+D800 to U+DFFF. Each character with a code unit in this range belongs to the UnicodeCategory.Surrogate category. The individual surrogate code unit has no interpretation of its own, but has meaning only when used as part of a surrogate pair. For more information about surrogate pairs, see the Unicode Standard at the Unicode home page.

IsSurrogate(Char)

Indicates whether the specified character has a surrogate code unit.

C#

```
public static bool IsSurrogate (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is either a high surrogate or a low surrogate; otherwise, `false`.

Remarks

A surrogate is a Char object with a UTF-16 code unit in the range from U+D800 to U+DFFF. Each character with a code unit in this range belongs to the

UnicodeCategory.Surrogate category. The individual surrogate code unit has no interpretation of its own, but has meaning only when used as part of a surrogate pair. For more information about surrogate pairs, see the Unicode Standard at the Unicode home page.

Char.IsSurrogatePair Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two specified Char objects form a surrogate pair.

Overloads

Expand table

IsSurrogatePair(Char, Char)	Indicates whether the two specified Char objects form a surrogate pair.
IsSurrogatePair(String, Int32)	Indicates whether two adjacent Char objects at a specified position in a string form a surrogate pair.

Examples

The following code example demonstrates the IsHighSurrogate, IsLowSurrogate, and IsSurrogatePair methods.

C#

```
// This example demonstrates the Char.IsLowSurrogate() method
//                                IsHighSurrogate() method
//                                IsSurrogatePair() method
using System;

class Sample
{
    public static void Main()
    {
    char cHigh = '\uD800';
    char cLow  = '\uDC00';
    string s1  = new String(new char[] {'a', '\uD800', '\uDC00', 'z'});
    string divider = String.Concat( Environment.NewLine, new String('-',
70),
                                    Environment.NewLine);

    Console.WriteLine();
```

```
    Console.WriteLine("Hexadecimal code point of the character, cHigh:
{0:X4}", (int)cHigh);
    Console.WriteLine("Hexadecimal code point of the character, cLow:
{0:X4}", (int)cLow);
    Console.WriteLine();
    Console.WriteLine("Characters in string, s1: 'a', high surrogate, low
surrogate, 'z'");
    Console.WriteLine("Hexadecimal code points of the characters in string,
s1: ");
    for(int i = 0; i < s1.Length; i++)
        {
        Console.WriteLine("s1[{0}] = {1:X4} ", i, (int)s1[i]);
        }
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following characters a high
surrogate?");
    Console.WriteLine("A1) cLow?  - {0}", Char.IsHighSurrogate(cLow));
    Console.WriteLine("A2) cHigh? - {0}", Char.IsHighSurrogate(cHigh));
    Console.WriteLine("A3) s1[0]? - {0}", Char.IsHighSurrogate(s1, 0));
    Console.WriteLine("A4) s1[1]? - {0}", Char.IsHighSurrogate(s1, 1));
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following characters a low
surrogate?");
    Console.WriteLine("B1) cLow?  - {0}", Char.IsLowSurrogate(cLow));
    Console.WriteLine("B2) cHigh? - {0}", Char.IsLowSurrogate(cHigh));
    Console.WriteLine("B3) s1[0]? - {0}", Char.IsLowSurrogate(s1, 0));
    Console.WriteLine("B4) s1[2]? - {0}", Char.IsLowSurrogate(s1, 2));
    Console.WriteLine(divider);

    Console.WriteLine("Is each of the following pairs of characters a
surrogate pair?");
    Console.WriteLine("C1) cHigh and cLow?  - {0}",
Char.IsSurrogatePair(cHigh, cLow));
    Console.WriteLine("C2) s1[0] and s1[1]? - {0}", Char.IsSurrogatePair(s1,
0));
    Console.WriteLine("C3) s1[1] and s1[2]? - {0}", Char.IsSurrogatePair(s1,
1));
    Console.WriteLine("C4) s1[2] and s1[3]? - {0}", Char.IsSurrogatePair(s1,
2));
    Console.WriteLine(divider);
    }
}
/*
This example produces the following results:

Hexadecimal code point of the character, cHigh: D800
Hexadecimal code point of the character, cLow:  DC00

Characters in string, s1: 'a', high surrogate, low surrogate, 'z'
Hexadecimal code points of the characters in string, s1:
s1[0] = 0061
s1[1] = D800
s1[2] = DC00
```

```
s1[3] = 007A

----------------------------------------------------------------------

Is each of the following characters a high surrogate?
A1) cLow?  - False
A2) cHigh? - True
A3) s1[0]? - False
A4) s1[1]? - True

----------------------------------------------------------------------

Is each of the following characters a low surrogate?
B1) cLow?  - True
B2) cHigh? - False
B3) s1[0]? - False
B4) s1[2]? - True

----------------------------------------------------------------------

Is each of the following pairs of characters a surrogate pair?
C1) cHigh and cLow?  - True
C2) s1[0] and s1[1]? - False
C3) s1[1] and s1[2]? - True
C4) s1[2] and s1[3]? - False

----------------------------------------------------------------------

*/
```

IsSurrogatePair(Char, Char)

Indicates whether the two specified Char objects form a surrogate pair.

```
C#

public static bool IsSurrogatePair (char highSurrogate, char
lowSurrogate);
```

Parameters

highSurrogate Char

The character to evaluate as the high surrogate of a surrogate pair.

lowSurrogate Char

The character to evaluate as the low surrogate of a surrogate pair.

Returns

Boolean

`true` if the numeric value of the `highSurrogate` parameter ranges from U+D800 through U+DBFF, and the numeric value of the `lowSurrogate` parameter ranges from U+DC00 through U+DFFF; otherwise, `false`.

Remarks

Ordinarily, a single character is represented by a single 16-bit Unicode code unit. UTF-16 encoding also supports surrogate pairs, which allow a single abstract character to be represented by two 16-bit code units. The first code unit, whose value can range from U+D800 to U+DBFF, is the high surrogate. The second code unit, whose value can range from U+DC00 to U+DFFF, is the low surrogate. Individual surrogate code points have no interpretation of their own. For more information about surrogates and the Unicode Standard, see the Unicode home page.

UWP	10.0

IsSurrogatePair(String, Int32)

Indicates whether two adjacent Char objects at a specified position in a string form a surrogate pair.

```
C#

public static bool IsSurrogatePair (string s, int index);
```

Parameters

s String

A string.

index Int32

The starting position of the pair of characters to evaluate within `s`.

Returns

Boolean

`true` if the `s` parameter includes adjacent characters at positions `index` and `index` + 1, and the numeric value of the character at position `index` ranges from U+D800 through U+DBFF, and the numeric value of the character at position `index`+1 ranges from U+DC00 through U+DFFF; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is not a position within `s`.

Remarks

Ordinarily, a single character is represented by a single 16-bit Unicode code unit. UTF-16 encoding also supports surrogate pairs, which allow a single abstract character to be represented by two 16-bit code units. The first code unit, whose value can range from U+D800 to U+DBFF, is the high surrogate. The second code unit, whose value can range from U+DC00 to U+DFFF, is the low surrogate. Individual surrogate code points have no interpretation of their own. For more

Char.IsSymbol Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as a symbol character.

Overloads

Expand table

IsSymbol(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as a symbol character.
IsSymbol(Char)	Indicates whether the specified Unicode character is categorized as a symbol character.

Examples

The following code example demonstrates IsSymbol.

C#

```
using System;

public class IsSymbolSample {
    public static void Main() {
        string str = "non-symbolic characters";

        Console.WriteLine(Char.IsSymbol('+'));      // Output: "True"
        Console.WriteLine(Char.IsSymbol(str, 8));   // Output: "False"
    }
}
```

Remarks

Valid symbols are members of the following categories in UnicodeCategory: `MathSymbol`, `CurrencySymbol`, `ModifierSymbol`, and `OtherSymbol`.

Symbols in the Unicode standard are a loosely defined set of characters that include the following:

- Currency symbols.
- Letterlike symbols, which include a set of mathematical alphanumeric symbols as well as symbols such as ℅, №, and ™.
- Number forms, such as subscripts and superscripts.
- Mathematical operators and arrows.
- Geometric symbols.
- Technical symbols.
- Braille patterns.
- Dingbats.

IsSymbol(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as a symbol character.

```
C#
public static bool IsSymbol (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is a symbol character; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

Valid symbols are members of the following categories in System.Globalization.UnicodeCategory: `MathSymbol`, `CurrencySymbol`, `ModifierSymbol`, and `OtherSymbol`.

Symbols in the Unicode standard are a loosely defined set of characters that include the following:

- Currency symbols.
- Letterlike symbols, which include a set of mathematical alphanumeric symbols as well as symbols such as ℅, №, and ™.
- Number forms, such as subscripts and superscripts.
- Mathematical operators and arrows.
- Geometric symbols.
- Technical symbols.

Char.IsUpper Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as an uppercase letter.

Overloads

Expand table

IsUpper(Char)	Indicates whether the specified Unicode character is categorized as an uppercase letter.
IsUpper(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as an uppercase letter.

IsUpper(Char)

Indicates whether the specified Unicode character is categorized as an uppercase letter.

C#

```
public static bool IsUpper (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is an uppercase letter; otherwise, `false`.

Remarks

Valid uppercase letters are members of the following category in UnicodeCategory: `UppercaseLetter`.

IsUpper(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as an uppercase letter.

C#

```
public static bool IsUpper (string s, int index);
```

Parameters

s String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is an uppercase letter; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Char.IsWhiteSpace Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a Unicode character is categorized as white space.

Overloads

Expand table

IsWhiteSpace(Char)	Indicates whether the specified Unicode character is categorized as white space.
IsWhiteSpace(String, Int32)	Indicates whether the character at the specified position in a specified string is categorized as white space.

Examples

The following example demonstrates the IsWhiteSpace(Char) method.

C#

```
using System;

public class IsWhiteSpaceSample {
    public static void Main() {
        string str = "black matter";

        Console.WriteLine(Char.IsWhiteSpace('A'));      // Output: "False"
        Console.WriteLine(Char.IsWhiteSpace(str, 5));   // Output: "True"
    }
}
```

Remarks

White space characters are the following Unicode characters:

- Members of the UnicodeCategory.SpaceSeparator category, which includes the characters SPACE (U+0020), NO-BREAK SPACE (U+00A0), OGHAM SPACE MARK (U+1680), EN QUAD (U+2000), EM QUAD (U+2001), EN SPACE (U+2002), EM SPACE (U+2003), THREE-PER-EM SPACE (U+2004), FOUR-PER-EM SPACE (U+2005), SIX-PER-EM SPACE (U+2006), FIGURE SPACE (U+2007), PUNCTUATION SPACE (U+2008), THIN SPACE (U+2009), HAIR SPACE (U+200A), NARROW NO-BREAK SPACE (U+202F), MEDIUM MATHEMATICAL SPACE (U+205F), and IDEOGRAPHIC SPACE (U+3000).
- Members of the UnicodeCategory.LineSeparator category, which consists solely of the LINE SEPARATOR character (U+2028).
- Members of the UnicodeCategory.ParagraphSeparator category, which consists solely of the PARAGRAPH SEPARATOR character (U+2029).
- The characters CHARACTER TABULATION (U+0009), LINE FEED (U+000A), LINE TABULATION (U+000B), FORM FEED (U+000C), CARRIAGE RETURN (U+000D), and NEXT LINE (U+0085).

IsWhiteSpace(Char)

Indicates whether the specified Unicode character is categorized as white space.

```
C#
public static bool IsWhiteSpace (char c);
```

Parameters

c Char

The Unicode character to evaluate.

Returns

Boolean

`true` if `c` is white space; otherwise, `false`.

Remarks

White space characters are the following Unicode characters:

- Members of the UnicodeCategory.SpaceSeparator category, which includes the characters SPACE (U+0020), NO-BREAK SPACE (U+00A0), OGHAM SPACE MARK (U+1680), EN QUAD (U+2000), EM QUAD (U+2001), EN SPACE (U+2002), EM SPACE (U+2003), THREE-PER-EM SPACE (U+2004), FOUR-PER-EM SPACE (U+2005), SIX-PER-EM SPACE (U+2006), FIGURE SPACE (U+2007), PUNCTUATION SPACE (U+2008), THIN SPACE (U+2009), HAIR SPACE (U+200A), NARROW NO-BREAK SPACE (U+202F), MEDIUM MATHEMATICAL SPACE (U+205F), and IDEOGRAPHIC SPACE (U+3000).
- Members of the UnicodeCategory.LineSeparator category, which consists solely of the LINE SEPARATOR character (U+2028).
- Members of the UnicodeCategory.ParagraphSeparator category, which consists solely of the PARAGRAPH SEPARATOR character (U+2029).
- The characters CHARACTER TABULATION (U+0009), LINE FEED (U+000A), LINE TABULATION (U+000B), FORM FEED (U+000C), CARRIAGE RETURN (U+000D), and NEXT LINE (U+0085).

UWP	10.0

IsWhiteSpace(String, Int32)

Indicates whether the character at the specified position in a specified string is categorized as white space.

```
C#
public static bool IsWhiteSpace (string s, int index);
```

Parameters

`s` String

A string.

`index` Int32

The position of the character to evaluate in `s`.

Returns

Boolean

`true` if the character at position `index` in `s` is white space; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentOutOfRangeException

`index` is less than zero or greater than the last position in `s`.

Remarks

Character positions in a string are indexed starting from zero.

White space characters are the following Unicode characters:

- Members of the UnicodeCategory.SpaceSeparator category, which includes the characters SPACE (U+0020), NO-BREAK SPACE (U+00A0), OGHAM SPACE MARK (U+1680), EN QUAD (U+2000), EM QUAD (U+2001), EN SPACE (U+2002), EM SPACE (U+2003), THREE-PER-EM SPACE (U+2004), FOUR-PER-EM SPACE (U+2005), SIX-PER-EM SPACE (U+2006), FIGURE SPACE (U+2007), PUNCTUATION SPACE (U+2008), THIN SPACE (U+2009), HAIR SPACE (U+200A),

NARROW NO-BREAK SPACE (U+202F), MEDIUM MATHEMATICAL SPACE (U+205F), and IDEOGRAPHIC SPACE (U+3000).

- Members of the UnicodeCategory.LineSeparator category, which consists solely of the LINE SEPARATOR character (U+2028).
- Members of the UnicodeCategory.ParagraphSeparator category, which consists solely of the PARAGRAPH SEPARATOR character (U+2029).
- The characters CHARACTER TABULATION (U+0009), LINE FEED (U+000A), LINE TABULATION (U+000B), FORM FEED (U+000C), CARRIAGE RETURN (U+000D), and NEXT LINE (U+0085).

Char.Parse(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified string to its equivalent Unicode character.

C#

```
public static char Parse (string s);
```

Parameters

s String

A string that contains a single character, or `null`.

Returns

Char

A Unicode character equivalent to the sole character in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

The length of `s` is not 1.

Examples

The following code example demonstrates Parse.

C#

```
using System;

public class ParseSample {
    public static void Main() {
        Console.WriteLine(Char.Parse("A")); // Output: 'A'
    }
}
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.ToLower Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of a Unicode character to its lowercase equivalent.

Overloads

Expand table

ToLower(Char, CultureInfo)	Converts the value of a specified Unicode character to its lowercase equivalent using specified culture-specific formatting information.
ToLower(Char)	Converts the value of a Unicode character to its lowercase equivalent.

Examples

The following example demonstrates ToLower.

C#

```
using System;
using System.Globalization;

public class ToLowerSample {
    public static void Main() {
        Console.WriteLine(Char.ToLower('A'));              // Output: "a"
    }
}
```

ToLower(Char, CultureInfo)

Converts the value of a specified Unicode character to its lowercase equivalent using specified culture-specific formatting information.

C#

```
public static char ToLower (char c, System.Globalization.CultureInfo
culture);
```

Parameters

`c` Char

The Unicode character to convert.

`culture` CultureInfo

An object that supplies culture-specific casing rules.

Returns

Char

The lowercase equivalent of `c`, modified according to `culture`, or the unchanged value of `c`, if `c` is already lowercase or not alphabetic.

Exceptions

ArgumentNullException

`culture` is `null`.

Remarks

Use String.ToLower to convert a string to lowercase.

See also

- ToLower(Rune, CultureInfo)
- ToUpper(Rune, CultureInfo)
- CurrentCulture
- ToLower()
- ToUpper(Char, CultureInfo)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToLower(Char)

Converts the value of a Unicode character to its lowercase equivalent.

```
C#
public static char ToLower (char c);
```

Parameters

c Char

The Unicode character to convert.

Returns

Char

The lowercase equivalent of `c`, or the unchanged value of `c`, if `c` is already lowercase or not alphabetic.

Remarks

Casing rules are obtained from the current culture.

Use String.ToLower to convert a string to lowercase.

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling character-casing and string-casing methods that substitute default values. Instead, you should call methods that require parameters to be explicitly specified. To convert a character to lowercase by using the casing conventions of the current

culture, call the ToLower(Char, CultureInfo) method overload with a value of CurrentCulture for its `culture` parameter.

Char.ToLowerInvariant(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of a Unicode character to its lowercase equivalent using the casing rules of the invariant culture.

```
C#
public static char ToLowerInvariant (char c);
```

Parameters

c Char

The Unicode character to convert.

Returns

Char

The lowercase equivalent of the `c` parameter, or the unchanged value of `c`, if `c` is already lowercase or not alphabetic.

Remarks

If your application is unaffected by the current culture and depends on the case of a character changing in a predictable way, then use the ToLowerInvariant method. The ToLowerInvariant method is equivalent to `ToLower(Char, CultureInfo.InvariantCulture)`.

Use String.ToLowerInvariant to convert a string to lowercase.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to its equivalent string representation.

Overloads

Expand table

ToString(IFormatProvider)	Converts the value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(Char)	Converts the specified Unicode character to its equivalent string representation.
ToString()	Converts the value of this instance to its equivalent string representation.

Examples

The following code example demonstrates ToString.

C#

```
using System;

public class ToStringSample {
    public static void Main() {
        char ch = 'a';
        Console.WriteLine(ch.ToString());       // Output: "a"

        Console.WriteLine(Char.ToString('b'));  // Output: "b"
    }
}
```

ToString(IFormatProvider)

Converts the value of this instance to its equivalent string representation using the specified culture-specific format information.

```
C#

public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

(Reserved) An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Remarks

The `provider` parameter is ignored; it does not participate in this operation.

Char.ToUpper Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of a Unicode character to its uppercase equivalent.

Overloads

Expand table

ToUpper(Char, CultureInfo)	Converts the value of a specified Unicode character to its uppercase equivalent using specified culture-specific formatting information.
ToUpper(Char)	Converts the value of a Unicode character to its uppercase equivalent.

ToUpper(Char, CultureInfo)

Converts the value of a specified Unicode character to its uppercase equivalent using specified culture-specific formatting information.

C#

```
public static char ToUpper (char c, System.Globalization.CultureInfo
culture);
```

Parameters

`c` Char

The Unicode character to convert.

`culture` CultureInfo

An object that supplies culture-specific casing rules.

Returns

Char

The uppercase equivalent of `c`, modified according to `culture`, or the unchanged value of `c` if `c` is already uppercase, has no uppercase equivalent, or is not alphabetic.

Exceptions

ArgumentNullException

`culture` is `null`.

Examples

The following example converts each character in an array to its uppercase equivalent for the en-US culture, the invariant culture, and the tr-TR culture. In this example, the uppercase equivalent of each lowercase letter is identical for all cultures except for one case. The lowercase "i" character (U+0069) converts to "I" (U+0049) in the en-US and invariant cultures, but to "İ" (U+0130) in the tr-TR culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      CultureInfo[] cultures= { CultureInfo.CreateSpecificCulture("en-
US"),
                                CultureInfo.InvariantCulture,
                                CultureInfo.CreateSpecificCulture("tr-
TR") };
      Char[] chars = {'ä', 'e', 'E', 'i', 'I' };

      Console.WriteLine("Character     en-US     Invariant     tr-TR");
      foreach (var ch in chars) {
         Console.Write("    {0}", ch);
         foreach (var culture in cultures)
            Console.Write("{0,12}", Char.ToUpper(ch, culture));

         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       Character     en-US     Invariant     tr-TR
//           ä           Ä           Ä           Ä
```

```
//          e           E           E           E
//          E           E           E           E
//          i           I           I           İ
//          I           I           I           I
```

Remarks

Use String.ToUpper to convert a string to uppercase.

See also

- ToUpper(Rune, CultureInfo)
- ToLower(Rune, CultureInfo)
- CurrentCulture
- ToUpper()
- ToLower(Char, CultureInfo)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToUpper(Char)

Converts the value of a Unicode character to its uppercase equivalent.

C#

```
public static char ToUpper (char c);
```

Parameters

c Char

The Unicode character to convert.

Returns

Char

The uppercase equivalent of `c`, or the unchanged value of `c` if `c` is already uppercase, has no uppercase equivalent, or is not alphabetic.

Examples

The following example converts each character in an array to its uppercase equivalent.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      char[] chars = { 'e', 'E', '6', ',', 'ж', 'ä' };
      foreach (var ch in chars)
          Console.WriteLine("{0} --> {1} {2}", ch, Char.ToUpper(ch),
                                ch == Char.ToUpper(ch) ? "(Same Character)" :
"" );
   }
}
// The example displays the following output:
//       e --> E
//       E --> E (Same Character)
//       6 --> 6 (Same Character)
//       , --> , (Same Character)
//       ж --> Ж
//       ä --> Ä
```

Remarks

Casing rules are obtained from the current culture.

Use String.ToUpper to convert a string to uppercase.

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling character-casing and string-casing methods that substitute default values. Instead, you should call methods that require parameters to be explicitly specified. To convert a character to uppercase by using the casing conventions of the current

culture, call the ToUpper(Char, CultureInfo) method overload with a value of CurrentCulture for its `culture` parameter.

Char.ToUpperInvariant(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of a Unicode character to its uppercase equivalent using the casing rules of the invariant culture.

```
C#
public static char ToUpperInvariant (char c);
```

Parameters

c Char

The Unicode character to convert.

Returns

Char

The uppercase equivalent of the `c` parameter, or the unchanged value of `c`, if `c` is already uppercase or not alphabetic.

Remarks

If your application is unaffected by the current culture and depends on the case of a character changing in a predictable way, use the ToUpperInvariant method. The ToUpperInvariant method is equivalent to `ToUpper(Char, CultureInfo.InvariantCulture)`.

Use String.ToUpperInvariant to convert a string to uppercase.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.TryParse(String, Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified string to its equivalent Unicode character. A return code indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (string? s, out char result);
```

Parameters

s String

A string that contains a single character, or `null`.

result Char

When this method returns, contains a Unicode character equivalent to the sole character in `s`, if the conversion succeeded, or an undefined value if the conversion failed. The conversion fails if the `s` parameter is `null` or the length of `s` is not 1. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

Examples

The following code example demonstrates overloads of the TryParse method for several base types, and the TryParseExact method for the DateTime base type.

```
C#
```

```
// This example demonstrates overloads of the TryParse method for
// several base types, and the TryParseExact method for DateTime.

// In most cases, this example uses the most complex overload; that is, the
overload
// with the most parameters for a particular type. If a complex overload
specifies
// null (Nothing in Visual Basic) for the IFormatProvider parameter,
formatting
// information is obtained from the culture associated with the current
thread.
// If a complex overload specifies the style parameter, the parameter value
is
// the default value used by the equivalent simple overload.

using System;
using System.Globalization;

class Sample
{
    public static void Main()
    {
    bool     success;
    CultureInfo ci;
    string   nl = Environment.NewLine;
    string   msg1 =
             "This example demonstrates overloads of the TryParse method
for{0}" +
             "several base types, as well as the TryParseExact method for
DateTime.{0}";
    string   msg2 = "Non-numeric types:{0}";
    string   msg3 = "{0}Numeric types:{0}";
    string   msg4 = "{0}The following types are not CLS-compliant:{0}";

// Non-numeric types.
    Boolean  booleanVal;
    Char     charVal;
    DateTime datetimeVal;

// Numeric types.
    Byte     byteVal;
    Int16    int16Val;
    Int32    int32Val;
    Int64    int64Val;
    Decimal  decimalVal;
    Single   singleVal;
    Double   doubleVal;

// The following types are not CLS-compliant.
    SByte    sbyteVal;
    UInt16   uint16Val;
    UInt32   uint32Val;
    UInt64   uint64Val;
//
```

```
    Console.WriteLine(msg1, nl);

// Non-numeric types:
    Console.WriteLine(msg2, nl);
// DateTime
  // TryParse:
    // Assume current culture is en-US, and dates of the form: MMDDYYYY.
    success = DateTime.TryParse("7/4/2004 12:34:56", out datetimeVal);
    Show(success, "DateTime #1", datetimeVal.ToString());

    // Use fr-FR culture, and dates of the form: DDMMYYYY.
    ci = new CultureInfo("fr-FR");
    success = DateTime.TryParse("4/7/2004 12:34:56",
             ci, DateTimeStyles.None, out datetimeVal);
    Show(success, "DateTime #2", datetimeVal.ToString());

  // TryParseExact:
    // Use fr-FR culture. The format, "G", is short date and long time.
    success = DateTime.TryParseExact("04/07/2004 12:34:56", "G",
             ci, DateTimeStyles.None, out datetimeVal);
    Show(success, "DateTime #3", datetimeVal.ToString());

    // Assume en-US culture.
    string[] dateFormats = {"f", "F", "g", "G"};
    success = DateTime.TryParseExact("7/4/2004 12:34:56 PM",
             dateFormats, null, DateTimeStyles.None,

    Show(success, "DateTime #4", datetimeVal.ToString());

    Console.WriteLine();
// Boolean
    success = Boolean.TryParse("true", out booleanVal);
    Show(success, "Boolean", booleanVal.ToString());
// Char
    success = Char.TryParse("A", out charVal);
    Show(success, "Char", charVal.ToString());

// Numeric types:
    Console.WriteLine(msg3, nl);
// Byte
    success = Byte.TryParse("1", NumberStyles.Integer, null, out byteVal);
    Show(success, "Byte", byteVal.ToString());
// Int16
    success = Int16.TryParse("-2", NumberStyles.Integer, null, out
int16Val);
    Show(success, "Int16", int16Val.ToString());
// Int32
    success = Int32.TryParse("3", NumberStyles.Integer, null, out int32Val);
    Show(success, "Int32", int32Val.ToString());
// Int64
    success = Int64.TryParse("4", NumberStyles.Integer, null, out int64Val);
    Show(success, "Int64", int64Val.ToString());
// Decimal
    success = Decimal.TryParse("-5.5", NumberStyles.Number, null, out
decimalVal);
```

```
    Show(success, "Decimal", decimalVal.ToString());
// Single
    success = Single.TryParse("6.6",
             (NumberStyles.Float | NumberStyles.AllowThousands),
             null, out singleVal);
    Show(success, "Single", singleVal.ToString());
// Double
    success = Double.TryParse("-7",
             (NumberStyles.Float | NumberStyles.AllowThousands),
             null, out doubleVal);
    Show(success, "Double", doubleVal.ToString());

// Use the simple Double.TryParse overload, but specify an invalid value.

    success = Double.TryParse("abc", out doubleVal);
    Show(success, "Double #2", doubleVal.ToString());
//
    Console.WriteLine(msg4, nl);
// SByte
    success = SByte.TryParse("-8", NumberStyles.Integer, null, out
sbyteVal);
    Show(success, "SByte", sbyteVal.ToString());
// UInt16
    success = UInt16.TryParse("9", NumberStyles.Integer, null, out
uint16Val);
    Show(success, "UInt16", uint16Val.ToString());
// UInt32
    success = UInt32.TryParse("10", NumberStyles.Integer, null, out
uint32Val);
    Show(success, "UInt32", uint32Val.ToString());
// UInt64
    success = UInt64.TryParse("11", NumberStyles.Integer, null, out
uint64Val);
    Show(success, "UInt64", uint64Val.ToString());
    }

    protected static void Show(bool parseSuccess, string typeName,
                               string parseValue)
    {
    string msgSuccess = "Parse for {0} = {1}";
    string msgFailure = "** Parse for {0} failed. Invalid input.";
//
    if (parseSuccess == true)
        Console.WriteLine(msgSuccess, typeName, parseValue);
    else
        Console.WriteLine(msgFailure, typeName);
   }
}
/*
This example produces the following results:

This example demonstrates overloads of the TryParse method for
several base types, as well as the TryParseExact method for DateTime.

Non-numeric types:
```

```
Parse for DateTime #1 = 7/4/2004 12:34:56 PM
Parse for DateTime #2 = 7/4/2004 12:34:56 PM
Parse for DateTime #3 = 7/4/2004 12:34:56 PM
Parse for DateTime #4 = 7/4/2004 12:34:56 PM

Parse for Boolean = True
Parse for Char = A

Numeric types:

Parse for Byte = 1
Parse for Int16 = -2
Parse for Int32 = 3
Parse for Int64 = 4
Parse for Decimal = -5.5
Parse for Single = 6.6
Parse for Double = -7
** Parse for Double #2 failed. Invalid input.

The following types are not CLS-compliant:

Parse for SByte = -8
Parse for UInt16 = 9
Parse for UInt32 = 10
Parse for UInt64 = 11
*/
```

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails.

Char.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Note This conversion is not supported. Attempting to do so throws an InvalidCastException.

```
C#

bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

This conversion is not supported. No value is returned.

Implements

ToBoolean(IFormatProvider)

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The converted value of the current Char object.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(Char) method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Char.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

```
C#
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current Char object unchanged.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The converted value of the current Char object.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(Char) method instead.

Applies to

Product	Versions

Char.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

A Type object.

provider IFormatProvider

An IFormatProvider object.

Returns

Object

An object of the specified type.

Implements

ToType(Type, IFormatProvider)

Exceptions

ArgumentNullException

`type` is `null`.

InvalidCastException

The value of the current Char object cannot be converted to the type specified by the `type` parameter.

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface. The recommended alternative is to call the ChangeType(Object, Type, IFormatProvider) method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider object. (Specify `null` because the `provider` parameter is ignored.)

Returns

UInt16

The converted value of the current Char object.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt16(Char) method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Char.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider object. (Specify `null` because the `provider` parameter is ignored.)

Returns

UInt32

The converted value of the current Char object.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt32(Char) method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Char.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider object. (Specify `null` because the `provider` parameter is ignored.)

Returns

UInt64

The converted value of the current Char object.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Char instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt64(Char) method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Char.IFormattable.ToString(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Formats the value of the current instance using the specified format.

C#

```
string IFormattable.ToString (string format, IFormatProvider
formatProvider);
```

Parameters

`format` String

The format to use. -or- A `null` reference (`Nothing` in Visual Basic) to use the default format defined for the type of the IFormattable implementation.

`formatProvider` IFormatProvider

The provider to use to format the value. -or- A `null` reference (`Nothing` in Visual Basic) to obtain the numeric format information from the current locale setting of the operating system.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Char.IParsable<Char>.Parse(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a string into a value.

```
C#
static char IParsable<char>.Parse (string s, IFormatProvider provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Char

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.ISpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance into the provided span of characters.

C#

```
bool ISpanFormattable.TryFormat (Span<char> destination, out int
charsWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, the number of characters that were written in `destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Char.ISpanParsable<Char>.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a span of characters into a value.

C#

```
static char ISpanParsable<char>.Parse (ReadOnlySpan<char> s, IFormatProvider
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Char

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	7, 8, 9

Char.IUtf8SpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
bool IUtf8SpanFormattable.TryFormat (Span<byte> utf8Destination, out int
bytesWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Char.IAdditionOperators<Char,Char,Char>.Addition(Char, Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static char IAdditionOperators<char,char,char>.operator + (char left, char right);
```

Parameters

`left` Char

The value to which `right` is added.

`right` Char

The value that's added to `left`.

Returns

Char

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IAdditionOperators<Char,Char,Char>.CheckedAddition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static char IAdditionOperators<char,char,char>.op_CheckedAddition (char
left, char right);
```

Parameters

`left` Char

The value to which `right` is added.

`right` Char

The value that's added to `left`.

Returns

Char

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Char.IBinaryInteger<Char>.RotateLeft(Char, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
static char IBinaryInteger<char>.RotateLeft (char value, int rotateAmount);
```

Parameters

`value` Char

The value that's rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

Char

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IBinaryInteger<Char>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<char>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static char IBitwiseOperators<char,char,char>.operator ^ (char left, char
right);
```

Parameters

`left` Char

The value to xor with `right`.

`right` Char

The value to xor with `left`.

Returns

Char

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IComparisonOperators<Char,Char,Boolean>.GreaterThanOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<char,char,bool>.operator > (char left, char right);
```

Parameters

`left` Char

The value to compare with `right`.

`right` Char

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IComparisonOperators<Char,Char,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<char,char,bool>.operator >= (char left,
char right);
```

Parameters

`left` Char

The value to compare with `right`.

`right` Char

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Char.IComparisonOperators<Char,Char,Boolean>.Less Than Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<char,char,bool>.operator < (char left, char right);
```

Parameters

`left` Char

The value to compare with `right`.

`right` Char

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IComparisonOperators<Char,Char,Boolean>.LessThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<char,char,bool>.operator <= (char left,
char right);
```

Parameters

`left` Char

The value to compare with `right`.

`right` Char

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IDecrementOperators<Char>.CheckedDecrement(Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static char IDecrementOperators<char>.op_CheckedDecrement (char value);
```

Parameters

`value` Char

The value to decrement.

Returns

Char

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IDecrementOperators<Char>.Decrement(Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static char IDecrementOperators<char>.operator -- (char value);
```

Parameters

`value` Char

The value to decrement.

Returns

Char

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IDivisionOperators<Char,Char,Char>.Division(Char, Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static char IDivisionOperators<char,char,char>.operator / (char left, char
right);
```

Parameters

`left` Char

The value that `right` divides.

`right` Char

The value that divides `left`.

Returns

Char

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IEqualityOperators<Char,Char,Boolean>.Equality(Char, Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<char,char,bool>.operator == (char left, char right);
```

Parameters

`left` Char

The value to compare with `right`.

`right` Char

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IEqualityOperators<Char,Char,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<char,char,bool>.operator != (char left, char right);
```

Parameters

`left` Char

The value to compare with `right`.

`right` Char

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IIncrementOperators<Char>.CheckedIncrement(Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static char IIncrementOperators<char>.op_CheckedIncrement (char value);
```

Parameters

`value` Char

The value to increment.

Returns

Char

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IIncrementOperators<Char>.Increment(Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static char IIncrementOperators<char>.operator ++ (char value);
```

Parameters

`value` Char

The value to increment.

Returns

Char

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IMinMaxValue<Char>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static char System.Numerics.IMinMaxValue<System.Char>.MaxValue { get; }
```

Property Value

Char

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.IModulusOperators<Char,Char,Char>.Modulus(Char, Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static char IModulusOperators<char,char,char>.operator % (char left, char
right);
```

Parameters

`left` Char

The value that `right` divides.

`right` Char

The value that divides `left`.

Returns

Char

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IMultiplyOperators<Char,Char,Char>.CheckedMultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static char IMultiplyOperators<char,char,char>.op_CheckedMultiply (char
left, char right);
```

Parameters

left Char

The value that `right` multiplies.

right Char

The value that multiplies `left`.

Returns

Char

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.IMultiplyOperators<Char,Char,Char>.Multiply(Char, Char) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static char IMultiplyOperators<char,char,char>.operator * (char left, char
right);
```

Parameters

left Char

The value that `right` multiplies.

right Char

The value that multiplies `left`.

Returns

Char

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.Abs(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static char INumberBase<char>.Abs (char value);
```

Parameters

`value` Char

The value for which to get its absolute.

Returns

Char

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsCanonical(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<char>.IsCanonical (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsComplexNumber(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<char>.IsComplexNumber (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsEvenInteger(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
static bool INumberBase<char>.IsEvenInteger (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsFinite(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<char>.IsFinite (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsImaginaryNumber(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<char>.IsImaginaryNumber (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsInfinity(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<char>.IsInfinity (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.INumberBase<Char>.IsNaN(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<char>.IsNaN (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.IsNegative(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<char>.IsNegative (char value);
```

Parameters

`value` Char

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Char.INumberBase<Char>.MaxMagnitude(Char, Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static char INumberBase<char>.MaxMagnitude (char x, char y);
```

Parameters

x Char

The value to compare with `y`.

y Char

The value to compare with `x`.

Returns

Char

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.Max MagnitudeNumber(Char, Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

C#

```
static char INumberBase<char>.MaxMagnitudeNumber (char x, char y);
```

Parameters

x Char

The value to compare with `y`.

y Char

The value to compare with `x`.

Returns

Char

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Char.INumberBase<Char>.MinMagnitude(Char, Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
static char INumberBase<char>.MinMagnitude (char x, char y);
```

Parameters

x Char

The value to compare with `y`.

y Char

The value to compare with `x`.

Returns

Char

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Char.INumberBase<Char>.MinMagnitudeNumber(Char, Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

C#

```
static char INumberBase<char>.MinMagnitudeNumber (char x, char y);
```

Parameters

x Char

The value to compare with `y`.

y Char

The value to compare with `x`.

Returns

Char

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Char.INumberBase<Char>.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

INumberBase<Char>.Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Parses a span of characters into a value.
INumberBase<Char>.Parse(String, NumberStyles, IFormatProvider)	Parses a string into a value.

INumberBase<Char>.Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Parses a span of characters into a value.

C#

```
static char INumberBase<char>.Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Char

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

INumberBase<Char>.Parse(String, NumberStyles, IFormatProvider)

Parses a string into a value.

C#

```
static char INumberBase<char>.Parse (string s,
System.Globalization.NumberStyles style, IFormatProvider provider);
```

Parameters

`s` String

The string to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Char

The result of parsing `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Char.INumberBase<Char>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<char>.TryConvertToChecked<TOther> (char value, out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Char

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Char.INumberBase<Char>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<char>.TryConvertToSaturating<TOther> (char value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Char

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

Char.IShift Operators<Char,Int32,Char>.Left Shift(Char, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

C#

```
static char IShiftOperators<char,int,char>.operator << (char value, int
shiftAmount);
```

Parameters

`value` Char

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

Char

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Char.ISubtractionOperators<Char,Char,Char>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static char ISubtractionOperators<char,char,char>.op_CheckedSubtraction
(char left, char right);
```

Parameters

`left` Char

The value from which `right` is subtracted.

`right` Char

The value that's subtracted from `left`.

Returns

Char

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

CharEnumerator Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Supports iterating over a String object and reading its individual characters. This class cannot be inherited.

C#

```
public sealed class CharEnumerator : ICloneable,
System.Collections.Generic.IEnumerator<char>
```

Inheritance Object → CharEnumerator

Implements IEnumerator<Char> , IEnumerator , ICloneable , IDisposable

Examples

The following example uses the CharEnumerator class to enumerate the individual characters in a string. It instantiates a CharEnumerator object by calling the String.GetEnumerator method, moves from one character to the next by calling the MoveNext method, and displays the current character by retrieving the value of the Current property.

C#

```
string title = "A Tale of Two Cities";
CharEnumerator chEnum = title.GetEnumerator();
int ctr = 1;
string outputLine1 = null;
string outputLine2 = null;
string outputLine3 = null;

while (chEnum.MoveNext())
{
   outputLine1 += ctr < 10 || ctr % 10 != 0 ? "  " : (ctr / 10) + " ";
   outputLine2 += (ctr % 10) + " ";
   outputLine3 += chEnum.Current + " ";
   ctr++;
```

```
}

Console.WriteLine("The length of the string is {0} characters:",
                  title.Length);
Console.WriteLine(outputLine1);
Console.WriteLine(outputLine2);
Console.WriteLine(outputLine3);
// The example displays the following output to the console:
//       The length of the string is 20 characters:
//                           1                   2
//       1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0
//       A   T a l e   o f   T w o   C i t i e s
```

Note, however, that the same operation can be performed somewhat more intuitively by using `foreach` (in C#) or `For Each` (in Visual Basic), as the following example shows.

C#

```
string title = "A Tale of Two Cities";
int ctr = 1;
string outputLine1 = null;
string outputLine2 = null;
string outputLine3 = null;

foreach (char ch in title)
{
   outputLine1 += ctr < 10 || ctr % 10 != 0 ? "  " : (ctr / 10) + " ";
   outputLine2 += (ctr % 10) + " ";
   outputLine3 += ch + " ";
   ctr++;
}

Console.WriteLine("The length of the string is {0} characters:",
                  title.Length);
Console.WriteLine(outputLine1);
Console.WriteLine(outputLine2);
Console.WriteLine(outputLine3);
// The example displays the following output to the console:
//       The length of the string is 20 characters:
//                           1                   2
//       1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0
//       A   T a l e   o f   T w o   C i t i e s
```

Remarks

A CharEnumerator provides read-only access to the characters in a referenced String object. For example, the `foreach` statement of the Microsoft Visual Basic and C# programming languages, which iterates through the elements of a collection, retrieves a

CharEnumerator from a String object in order to iterate through the characters in that object.

> **Important**
>
> The `CharEnumerator` class enumerates individual 16-bit **Char** instances. It does not consider graphemes (that is, a character followed by one or more combiding characters) or surrogate pairs (that is, characters outside the Unicode Basic Multilingual Plane) as single characters. For an enumerator that handles these types of characters as a single unit, use the **StringInfo** class.

There is no public constructor for CharEnumerator. Instead, call a String object's GetEnumerator method to obtain a CharEnumerator that is initialized to reference the string.

A CharEnumerator maintains an internal index to the characters in the string the CharEnumerator references. The state of the index is invalid when it references a character position logically before the first character or after the last character in the string, and valid when it references a character within the string. The index is initialized to a position logically before the first character, and is set to a position after the last character when the iteration is complete. An exception is thrown if you attempt to access a character while the index is invalid.

The MoveNext method increments the index by one, so the first and subsequent characters are accessed in turn. The Reset method sets the index to a position logically before the first character. The Current property retrieves the character currently referenced by index. The Clone method creates a copy of the CharEnumerator.

> **Note**
>
> Several independent instances of **CharEnumerator** across one or more threads can have access to a single instance of **String**. This class is implemented to support the **IEnumerator** interface. For more information regarding the use of an enumerator, see the **IEnumerator** topic.

Properties

Expand table

Current	Gets the currently referenced character in the string enumerated by this CharEnumerator object.

Methods

Expand table

Clone()	Creates a copy of the current CharEnumerator object.
Dispose()	Releases all resources used by the current instance of the CharEnumerator class.
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
MoveNext()	Increments the internal index of the current CharEnumerator object to the next character of the enumerated string.
Reset()	Initializes the index to a position logically before the first character of the enumerated string.
ToString()	Returns a string that represents the current object. (Inherited from Object)

Explicit Interface Implementations

Expand table

IEnumerator.Current	Gets the currently referenced character in the string enumerated by this CharEnumerator object. For a description of this member, see Current.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CharEnumerator.Current Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the currently referenced character in the string enumerated by this CharEnumerator object.

```
C#
public char Current { get; }
```

Property Value

Char

The Unicode character currently referenced by this CharEnumerator object.

Implements

Current

Exceptions

InvalidOperationException

The index is invalid; that is, it is before the first or after the last character of the enumerated string.

Examples

The following example uses the CharEnumerator class to enumerate the individual characters in a string. It instantiates a CharEnumerator object by calling the String.GetEnumerator method, moves from one character to the next by calling the MoveNext method, and displays the current character by retrieving the value of the Current property.

```
C#
```

```
string title = "A Tale of Two Cities";
CharEnumerator chEnum = title.GetEnumerator();
int ctr = 1;
string outputLine1 = null;
string outputLine2 = null;
string outputLine3 = null;

while (chEnum.MoveNext())
{
   outputLine1 += ctr < 10 || ctr % 10 != 0 ? "  " : (ctr / 10) + " ";
   outputLine2 += (ctr % 10) + " ";
   outputLine3 += chEnum.Current + " ";
   ctr++;
}

Console.WriteLine("The length of the string is {0} characters:",
                  title.Length);
Console.WriteLine(outputLine1);
Console.WriteLine(outputLine2);
Console.WriteLine(outputLine3);
// The example displays the following output to the console:
//       The length of the string is 20 characters:
//                           1                   2
//       1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0
//       A   T a l e   o f   T w o   C i t i e s
```

Note, however, that the same operation can be performed somewhat more intuitively by using `foreach` (in C#) or `For Each` (in Visual Basic), as the following example shows.

C#

```
string title = "A Tale of Two Cities";
int ctr = 1;
string outputLine1 = null;
string outputLine2 = null;
string outputLine3 = null;

foreach (char ch in title)
{
   outputLine1 += ctr < 10 || ctr % 10 != 0 ? "  " : (ctr / 10) + " ";
   outputLine2 += (ctr % 10) + " ";
   outputLine3 += ch + " ";
   ctr++;
}

Console.WriteLine("The length of the string is {0} characters:",
                  title.Length);
Console.WriteLine(outputLine1);
Console.WriteLine(outputLine2);
Console.WriteLine(outputLine3);
// The example displays the following output to the console:
//       The length of the string is 20 characters:
```

```
//                        1                   2
//      1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0
//      A   T a l e   o f   T w o   C i t i e s
```

Remarks

The CharEnumerator class maintains an internal index to the enumerated string, and the Current property returns the character that is currently referenced by the index. This property should be invoked only when the index is valid; otherwise, an exception is thrown.

The index is always invalid for an empty string ("""). The index is also invalid after the String.GetEnumerator or Reset method is called. After either of these methods is called, invoke the MoveNext method to adjust the index to the first character in the enumerated string. The index is valid whenever the MoveNext method returns `true`.

Current does not move the index, and consecutive calls to Current return the same character until MoveNext, Reset, or String.GetEnumerator is called.

Applies to

CharEnumerator.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a copy of the current CharEnumerator object.

C#

```
public object Clone ();
```

Returns

Object

An Object that is a copy of the current CharEnumerator object.

Implements

Clone()

Remarks

The return value is a copy of this instance of CharEnumerator and its current state. This is useful for saving your state while iterating through a String object.

For example, suppose your application uses an original instance of CharEnumerator to iterate through each character in a String. When some unique character is encountered, your application pauses processing and invokes the Clone method. In effect, this saves the CharEnumerator object's index in the String.

Your application uses the clone to navigate to another part of the `String` to perform some auxiliary processing. The side-effect of this navigation is the clone loses track of the position where processing stopped. However, when the auxiliary processing is complete, your application discards the clone and uses the original CharEnumerator instance to resume working on the String where the original processing stopped.

> **Note**
>
> This method is implemented to support the **ICloneable** interface.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

CharEnumerator.Dispose Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Releases all resources used by the current instance of the CharEnumerator class.

C#

```
public void Dispose ();
```

Implements

Dispose()

Remarks

Call Dispose when you are finished using the CharEnumerator. The Dispose method leaves the CharEnumerator in an unusable state. After calling Dispose, you must release all references to the CharEnumerator so the garbage collector can reclaim the memory that the CharEnumerator was occupying.

For more information, see Cleaning Up Unmanaged Resources and Implementing a Dispose Method.

> ⓘ **Note**
>
> Always call **Dispose** before you release your last reference to the **CharEnumerator**. Otherwise, the resources it is using will not be freed until the garbage collector calls the **CharEnumerator** object's `Finalize` method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

CharEnumerator.MoveNext Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments the internal index of the current CharEnumerator object to the next character of the enumerated string.

```
C#

public bool MoveNext ();
```

Returns

Boolean

`true` if the index is successfully incremented and within the enumerated string; otherwise, `false`.

Implements

MoveNext()

Examples

The following example uses the CharEnumerator class to enumerate the individual characters in a string. It instantiates a CharEnumerator object by calling the String.GetEnumerator method, moves from one character to the next by calling the MoveNext method, and displays the current character by retrieving the value of the Current property.

```
C#

string title = "A Tale of Two Cities";
CharEnumerator chEnum = title.GetEnumerator();
int ctr = 1;
string outputLine1 = null;
string outputLine2 = null;
```

```
string outputLine3 = null;

while (chEnum.MoveNext())
{
   outputLine1 += ctr < 10 || ctr % 10 != 0 ? "  " : (ctr / 10) + " ";
   outputLine2 += (ctr % 10) + " ";
   outputLine3 += chEnum.Current + " ";
   ctr++;
}

Console.WriteLine("The length of the string is {0} characters:",
                  title.Length);
Console.WriteLine(outputLine1);
Console.WriteLine(outputLine2);
Console.WriteLine(outputLine3);
// The example displays the following output to the console:
//       The length of the string is 20 characters:
//                           1                   2
//       1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0
//       A   T a l e   o f   T w o   C i t i e s
```

Note, however, that the same operation can be performed somewhat more intuitively by using `foreach` (in C#) or `For Each` (in Visual Basic), as the following example shows.

C#

```
string title = "A Tale of Two Cities";
int ctr = 1;
string outputLine1 = null;
string outputLine2 = null;
string outputLine3 = null;

foreach (char ch in title)
{
   outputLine1 += ctr < 10 || ctr % 10 != 0 ? "  " : (ctr / 10) + " ";
   outputLine2 += (ctr % 10) + " ";
   outputLine3 += ch + " ";
   ctr++;
}

Console.WriteLine("The length of the string is {0} characters:",
                  title.Length);
Console.WriteLine(outputLine1);
Console.WriteLine(outputLine2);
Console.WriteLine(outputLine3);
// The example displays the following output to the console:
//       The length of the string is 20 characters:
//                           1                   2
//       1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0
//       A   T a l e   o f   T w o   C i t i e s
```

Remarks

The CharEnumerator class maintains an internal index to the enumerated string, and the MoveNext method increments the index by one. Call MoveNext after calling GetEnumerator or Reset to increment the current character position to the first character in the enumerated string. Check that the return value is `true` to determine that the current character position is valid.

If the index is already beyond the last character of the enumerated string, the index is not changed and `false` is returned.

Notice that if the enumerated string is empty ("""), the state of the CharEnumerator is always invalid. This is because the internal index for the CharEnumerator is initially before the first character of the enumerated string and is therefore invalid. MoveNext logically sets the index after the last (nonexistent) character of the enumerated string which is also invalid.

Applies to

CharEnumerator.Reset Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes the index to a position logically before the first character of the enumerated string.

C#

```
public void Reset ();
```

Implements

Reset()

Remarks

The CharEnumerator class maintains an internal index to the enumerated string, and the Reset method sets the index to the invalid state.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

CharEnumerator.IEnumerator.Current Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the currently referenced character in the string enumerated by this CharEnumerator object. For a description of this member, see Current.

C#

```
object? System.Collections.IEnumerator.Current { get; }
```

Property Value

Object

The boxed Unicode character currently referenced by this CharEnumerator object.

Implements

Current

Exceptions

InvalidOperationException

Enumeration has not started.

-or-

Enumeration has ended.

Remarks

This member is an explicit interface member implementation. It can be used only when the CharEnumerator instance is cast to an IEnumerator interface.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

CLSCompliantAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a program element is compliant with the Common Language Specification (CLS). This class cannot be inherited.

C#

```
[System.AttributeUsage(System.AttributeTargets.All, AllowMultiple=false,
Inherited=true)]
public sealed class CLSCompliantAttribute : Attribute
```

Inheritance Object → Attribute → CLSCompliantAttribute

Attributes AttributeUsageAttribute

Examples

The following example applies a CLSCompliantAttribute to the entire assembly.

C#

```
using System;
    [assembly: CLSCompliant(true)]
```

The following declaration generates a CLS-compliance warning because the type `UInt32` is not specified in the CLS.

C#

```
public int SetValue(UInt32 value);
```

If the declaration is marked with a CLSCompliantAttribute, no compiler warning or error is generated.

C#

```
[CLSCompliant(false)]
 public int SetValue(UInt32 value);
```

Remarks

The CLSCompliantAttribute attribute is used to indicate whether a particular program element complies with the Common Language Specification (CLS), which defines the features that any language that targets .NET must support. CLS compliance is primarily of concern to library developers who want to ensure that their libraries are accessible in any language that targets .NET. For more information, See Language Independence and Language-Independent Components.

You can apply the CLSCompliantAttribute attribute to the following program elements: assembly, module, class, struct, enum, constructor, method, property, field, event, interface, delegate, parameter, and return value. However, the notion of CLS compliance is only meaningful for assemblies, modules, types, and members of types, not parts of a member signature. Consequently, CLSCompliantAttribute is ignored when applied to parameter or return value program elements.

If no CLSCompliantAttribute is applied to a program element, then by default:

- The assembly is not CLS-compliant.
- The type is CLS-compliant only if its enclosing type or assembly is CLS-compliant.
- The member of a type is CLS-compliant only if the type is CLS-compliant.

If an assembly is marked as CLS-compliant, any publicly exposed type in the assembly that is not CLS-compliant must be marked with CLSCompliantAttribute using a `false` argument. Similarly, if a class is marked as CLS-compliant, you must individually mark all members that are not CLS-compliant. All non-compliant members must provide corresponding CLS-compliant alternatives.

Attributes that are applied to assemblies or modules must occur after the C# `using` (`Imports` in Visual Basic) clauses and before the code.

For more information about using attributes, see Attributes.

ⓘ **Note**

The current Microsoft Visual Basic compiler intentionally does not generate a CLS-compliance warning, however, a future release of the compiler will issue that warning.

Constructors

Expand table

CLSCompliant Attribute(Boolean)	Initializes an instance of the CLSCompliantAttribute class with a Boolean value indicating whether the indicated program element is CLS-compliant.

Properties

Expand table

Is Compliant	Gets the Boolean value indicating whether the indicated program element is CLS-compliant.
TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefault Attribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object.

	(Inherited from Attribute)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Comparison<T> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the method that compares two objects of the same type.

```
C#
public delegate int Comparison<in T>(T x, T y);
```

Type Parameters

T

The type of the objects to compare.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

x T

The first object to compare.

y T

The second object to compare.

Return Value

Int32

A signed integer that indicates the relative values of `x` and `y`, as shown in the following table.

Expand table

Value	Meaning
Less than 0	`x` is less than `y`.
0	`x` equals `y`.
Greater than 0	`x` is greater than `y`.

Examples

The following code example demonstrates the use of the Comparison<T> delegate with the Sort(Comparison<T>) method overload.

The code example defines an alternative comparison method for strings, named `CompareDinosByLength`. This method works as follows: First, the comparands are tested for `null`, and a null reference is treated as less than a non-null. Second, the string lengths are compared, and the longer string is deemed to be greater. Third, if the lengths are equal, ordinary string comparison is used.

A List<T> of strings is created and populated with four strings, in no particular order. The list also includes an empty string and a null reference. The list is displayed, sorted using a Comparison<T> generic delegate representing the `CompareDinosByLength` method, and displayed again.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
    private static int CompareDinosByLength(string x, string y)
    {
        if (x == null)
        {
            if (y == null)
            {
                // If x is null and y is null, they're
                // equal.
                return 0;
            }
            else
            {
                // If x is null and y is not null, y
                // is greater.
                return -1;
            }
        }
```

```
        else
        {
            // If x is not null...
            //
            if (y == null)
                // ...and y is null, x is greater.
            {
                return 1;
            }
            else
            {
                // ...and y is not null, compare the
                // lengths of the two strings.
                //
                int retval = x.Length.CompareTo(y.Length);

                if (retval != 0)
                {
                    // If the strings are not of equal length,
                    // the longer string is greater.
                    //
                    return retval;
                }
                else
                {
                    // If the strings are of equal length,
                    // sort them with ordinary string comparison.
                    //
                    return x.CompareTo(y);
                }
            }
        }
    }

    public static void Main()
    {
        List<string> dinosaurs = new List<string>();
        dinosaurs.Add("Pachycephalosaurus");
        dinosaurs.Add("Amargasaurus");
        dinosaurs.Add("");
        dinosaurs.Add(null);
        dinosaurs.Add("Mamenchisaurus");
        dinosaurs.Add("Deinonychus");
        Display(dinosaurs);

        Console.WriteLine("\nSort with generic Comparison<string>
delegate:");
        dinosaurs.Sort(CompareDinosByLength);
        Display(dinosaurs);
    }

    private static void Display(List<string> list)
    {
        Console.WriteLine();
        foreach( string s in list )
```

```
        {
            if (s == null)
                Console.WriteLine("(null)");
            else
                Console.WriteLine("\"{0}\"", s);
        }
    }
}

/* This code example produces the following output:

"Pachycephalosaurus"
"Amargasaurus"
""
(null)
"Mamenchisaurus"
"Deinonychus"

Sort with generic Comparison<string> delegate:

(null)
""
"Deinonychus"
"Amargasaurus"
"Mamenchisaurus"
"Pachycephalosaurus"
 */
```

The following example uses the Comparison<T> delegate to sort the elements of a collection of `CityInfo` objects. `CityInfo` is an application-defined class that contains information about a city and its population. The example defines three methods, `CompareByName`, `CompareByPopulation`, and `CompareByNames`, that offer three different ways of ordering the `CityInfo` objects. Each method is assigned to the `comparison` argument of the Array.Sort<T>(T[], Comparison<T>) method.

C#

```
using System;

public class CityInfo
{
   string cityName;
   string countryName;
   int pop2010;

   public CityInfo(string name, string country, int pop2010)
   {
      this.cityName = name;
      this.countryName = country;
      this.pop2010 = pop2010;
   }
```

```
   public string City
   { get { return this.cityName; } }

   public string Country
   { get { return this.countryName; } }

   public int Population
   { get { return this.pop2010; } }

   public static int CompareByName(CityInfo city1, CityInfo city2)
   {
      return String.Compare(city1.City, city2.City);
   }

   public static int CompareByPopulation(CityInfo city1, CityInfo city2)
   {
      return city1.Population.CompareTo(city2.Population);
   }

   public static int CompareByNames(CityInfo city1, CityInfo city2)
   {
      return String.Compare(city1.Country + city1.City, city2.Country +
city2.City);
   }
}

public class Example
{
   public static void Main()
   {
      CityInfo NYC = new CityInfo("New York City", "United States of
America", 8175133 );
      CityInfo Det = new CityInfo("Detroit", "United States of America",
713777);
      CityInfo Paris = new CityInfo("Paris", "France",  2193031);
      CityInfo[] cities = { NYC, Det, Paris };
      // Display ordered array.
      DisplayArray(cities);

      // Sort array by city name.
      Array.Sort(cities, CityInfo.CompareByName);
      DisplayArray(cities);

      // Sort array by population.
      Array.Sort(cities, CityInfo.CompareByPopulation);
      DisplayArray(cities);

      // Sort array by country + city name.
      Array.Sort(cities, CityInfo.CompareByNames);
      DisplayArray(cities);
   }

   private static void DisplayArray(CityInfo[] cities)
   {
```

```
      Console.WriteLine("{0,-20} {1,-25} {2,10}", "City", "Country",
"Population");
      foreach (var city in cities)
         Console.WriteLine("{0,-20} {1,-25} {2,10:N0}", city.City,
                           city.Country, city.Population);

      Console.WriteLine();
   }
}
// The example displays the following output:
//     City                 Country                   Population
//     New York City        United States of America   8,175,133
//     Detroit              United States of America     713,777
//     Paris                France                    2,193,031
//
//     City                 Country                   Population
//     Detroit              United States of America     713,777
//     New York City        United States of America   8,175,133
//     Paris                France                    2,193,031
//
//     City                 Country                   Population
//     Detroit              United States of America     713,777
//     Paris                France                    2,193,031
//     New York City        United States of America   8,175,133
//
//     City                 Country                   Population
//     Paris                France                    2,193,031
//     Detroit              United States of America     713,777
//     New York City        United States of America   8,175,133
```

Remarks

This delegate is used by the Sort<T>(T[], Comparison<T>) method overload of the Array class and the Sort(Comparison<T>) method overload of the List<T> class to sort the elements of an array or list.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Console Class

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Represents the standard input, output, and error streams for console applications. This class cannot be inherited.

C#

```
public static class Console
```

Inheritance Object → Console

Remarks

For more information about this API, see Supplemental API remarks for Console.

Properties

Expand table

BackgroundColor	Gets or sets the background color of the console.
BufferHeight	Gets or sets the height of the buffer area.
BufferWidth	Gets or sets the width of the buffer area.
CapsLock	Gets a value indicating whether the CAPS LOCK keyboard toggle is turned on or turned off.
CursorLeft	Gets or sets the column position of the cursor within the buffer area.
CursorSize	Gets or sets the height of the cursor within a character cell.
CursorTop	Gets or sets the row position of the cursor within the buffer area.
CursorVisible	Gets or sets a value indicating whether the cursor is visible.

Error	Gets the standard error output stream.
Foreground Color	Gets or sets the foreground color of the console.
In	Gets the standard input stream.
InputEncoding	Gets or sets the encoding the console uses to read input.
IsError Redirected	Gets a value that indicates whether the error output stream has been redirected from the standard error stream.
IsInput Redirected	Gets a value that indicates whether input has been redirected from the standard input stream.
IsOutput Redirected	Gets a value that indicates whether output has been redirected from the standard output stream.
KeyAvailable	Gets a value indicating whether a key press is available in the input stream.
LargestWindow Height	Gets the largest possible number of console window rows, based on the current font and screen resolution.
LargestWindow Width	Gets the largest possible number of console window columns, based on the current font and screen resolution.
NumberLock	Gets a value indicating whether the NUM LOCK keyboard toggle is turned on or turned off.
Out	Gets the standard output stream.
Output Encoding	Gets or sets the encoding the console uses to write output.
Title	Gets or sets the title to display in the console title bar.
TreatControl CAsInput	Gets or sets a value indicating whether the combination of the Control modifier key and C console key (Ctrl+C) is treated as ordinary input or as an interruption that is handled by the operating system.
WindowHeight	Gets or sets the height of the console window area.
WindowLeft	Gets or sets the leftmost position of the console window area relative to the screen buffer.
WindowTop	Gets or sets the top position of the console window area relative to the screen buffer.
WindowWidth	Gets or sets the width of the console window.

Methods

Expand table

Beep()	Plays the sound of a beep through the console speaker.
Beep(Int32, Int32)	Plays the sound of a beep of a specified frequency and duration through the console speaker.
Clear()	Clears the console buffer and corresponding console window of display information.
GetCursorPosition()	Gets the position of the cursor.
MoveBufferArea(Int32, Int32, Int32, Int32, Int32, Int32)	Copies a specified source area of the screen buffer to a specified destination area.
MoveBufferArea(Int32, Int32, Int32, Int32, Int32, Int32, Char, ConsoleColor, ConsoleColor)	Copies a specified source area of the screen buffer to a specified destination area.
OpenStandardError()	Acquires the standard error stream.
OpenStandardError(Int32)	Acquires the standard error stream, which is set to a specified buffer size.
OpenStandardInput()	Acquires the standard input stream.
OpenStandardInput(Int32)	Acquires the standard input stream, which is set to a specified buffer size.
OpenStandardOutput()	Acquires the standard output stream.
OpenStandardOutput(Int32)	Acquires the standard output stream, which is set to a specified buffer size.
Read()	Reads the next character from the standard input stream.
ReadKey()	Obtains the next character or function key pressed by the user. The pressed key is displayed in the console window.
ReadKey(Boolean)	Obtains the next character or function key pressed by the user. The pressed key is optionally displayed in the console window.
ReadLine()	Reads the next line of characters from the standard input stream.
ResetColor()	Sets the foreground and background console colors to their defaults.

SetBufferSize(Int32, Int32)	Sets the height and width of the screen buffer area to the specified values.
SetCursorPosition(Int32, Int32)	Sets the position of the cursor.
SetError(TextWriter)	Sets the Error property to the specified TextWriter object.
SetIn(TextReader)	Sets the In property to the specified TextReader object.
SetOut(TextWriter)	Sets the Out property to target the TextWriter object.
SetWindowPosition(Int32, Int32)	Sets the position of the console window relative to the screen buffer.
SetWindowSize(Int32, Int32)	Sets the height and width of the console window to the specified values.
Write(Boolean)	Writes the text representation of the specified Boolean value to the standard output stream.
Write(Char)	Writes the specified Unicode character value to the standard output stream.
Write(Char[])	Writes the specified array of Unicode characters to the standard output stream.
Write(Char[], Int32, Int32)	Writes the specified subarray of Unicode characters to the standard output stream.
Write(Decimal)	Writes the text representation of the specified Decimal value to the standard output stream.
Write(Double)	Writes the text representation of the specified double-precision floating-point value to the standard output stream.
Write(Int32)	Writes the text representation of the specified 32-bit signed integer value to the standard output stream.
Write(Int64)	Writes the text representation of the specified 64-bit signed integer value to the standard output stream.
Write(Object)	Writes the text representation of the specified object to the standard output stream.
Write(Single)	Writes the text representation of the specified single-precision floating-point value to the standard output stream.
Write(String)	Writes the specified string value to the standard output stream.

Write(String, Object)	Writes the text representation of the specified object to the standard output stream using the specified format information.
Write(String, Object, Object)	Writes the text representation of the specified objects to the standard output stream using the specified format information.
Write(String, Object, Object, Object)	Writes the text representation of the specified objects to the standard output stream using the specified format information.
Write(String, Object[])	Writes the text representation of the specified array of objects to the standard output stream using the specified format information.
Write(UInt32)	Writes the text representation of the specified 32-bit unsigned integer value to the standard output stream.
Write(UInt64)	Writes the text representation of the specified 64-bit unsigned integer value to the standard output stream.
WriteLine()	Writes the current line terminator to the standard output stream.
WriteLine(Boolean)	Writes the text representation of the specified Boolean value, followed by the current line terminator, to the standard output stream.
WriteLine(Char)	Writes the specified Unicode character, followed by the current line terminator, value to the standard output stream.
WriteLine(Char[])	Writes the specified array of Unicode characters, followed by the current line terminator, to the standard output stream.
WriteLine(Char[], Int32, Int32)	Writes the specified subarray of Unicode characters, followed by the current line terminator, to the standard output stream.
WriteLine(Decimal)	Writes the text representation of the specified Decimal value, followed by the current line terminator, to the standard output stream.
WriteLine(Double)	Writes the text representation of the specified double-precision floating-point value, followed by the current line terminator, to the standard output stream.
WriteLine(Int32)	Writes the text representation of the specified 32-bit signed integer value, followed by the current line

	terminator, to the standard output stream.
WriteLine(Int64)	Writes the text representation of the specified 64-bit signed integer value, followed by the current line terminator, to the standard output stream.
WriteLine(Object)	Writes the text representation of the specified object, followed by the current line terminator, to the standard output stream.
WriteLine(Single)	Writes the text representation of the specified single-precision floating-point value, followed by the current line terminator, to the standard output stream.
WriteLine(String)	Writes the specified string value, followed by the current line terminator, to the standard output stream.
WriteLine(String, Object)	Writes the text representation of the specified object, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(String, Object, Object)	Writes the text representation of the specified objects, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(String, Object, Object, Object)	Writes the text representation of the specified objects, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(String, Object[])	Writes the text representation of the specified array of objects, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(UInt32)	Writes the text representation of the specified 32-bit unsigned integer value, followed by the current line terminator, to the standard output stream.
WriteLine(UInt64)	Writes the text representation of the specified 64-bit unsigned integer value, followed by the current line terminator, to the standard output stream.

Events

Expand table

CancelKeyPress	Occurs when the Control modifier key (Ctrl) and either the C console key (C) or the Break key are pressed simultaneously (Ctrl+C or Ctrl+Break).

Console.BackgroundColor Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the background color of the console.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static ConsoleColor BackgroundColor { get; set; }
```

Property Value

ConsoleColor

A value that specifies the background color of the console; that is, the color that appears behind each character. The default is black.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentException

The color specified in a set operation is not a valid member of ConsoleColor.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

Examples

The following example saves the values of the ConsoleColor enumeration to an array and stores the current values of the BackgroundColor and ForegroundColor properties to variables. It then changes the foreground color to each color in the ConsoleColor enumeration except to the color that matches the current background, and it changes the background color to each color in the ConsoleColor enumeration except to the color that matches the current foreground. (If the foreground color is the same as the background color, the text isn't visible.) Finally, it calls the ResetColor method to restore the original console colors.

C#

```
using System;

class Example
{
   public static void Main()
   {
      // Get an array with the values of ConsoleColor enumeration members.
      ConsoleColor[] colors = (ConsoleColor[])
ConsoleColor.GetValues(typeof(ConsoleColor));
      // Save the current background and foreground colors.
      ConsoleColor currentBackground = Console.BackgroundColor;
      ConsoleColor currentForeground = Console.ForegroundColor;

      // Display all foreground colors except the one that matches the
background.
      Console.WriteLine("All the foreground colors except {0}, the
background color:",
                        currentBackground);
      foreach (var color in colors) {
         if (color == currentBackground) continue;

         Console.ForegroundColor = color;
         Console.WriteLine("   The foreground color is {0}.", color);
      }
      Console.WriteLine();
      // Restore the foreground color.
      Console.ForegroundColor = currentForeground;

      // Display each background color except the one that matches the
current foreground color.
      Console.WriteLine("All the background colors except {0}, the
foreground color:",
                        currentForeground);
      foreach (var color in colors) {
         if (color == currentForeground) continue;

         Console.BackgroundColor = color;
         Console.WriteLine("   The background color is {0}.", color);
      }

      // Restore the original console colors.
```

```
        Console.ResetColor();
        Console.WriteLine("\nOriginal colors restored...");
    }
}
//The example displays output like the following:
//    All the foreground colors except DarkCyan, the background color:
//       The foreground color is Black.
//       The foreground color is DarkBlue.
//       The foreground color is DarkGreen.
//       The foreground color is DarkRed.
//       The foreground color is DarkMagenta.
//       The foreground color is DarkYellow.
//       The foreground color is Gray.
//       The foreground color is DarkGray.
//       The foreground color is Blue.
//       The foreground color is Green.
//       The foreground color is Cyan.
//       The foreground color is Red.
//       The foreground color is Magenta.
//       The foreground color is Yellow.
//       The foreground color is White.
//
//    All the background colors except White, the foreground color:
//       The background color is Black.
//       The background color is DarkBlue.
//       The background color is DarkGreen.
//       The background color is DarkCyan.
//       The background color is DarkRed.
//       The background color is DarkMagenta.
//       The background color is DarkYellow.
//       The background color is Gray.
//       The background color is DarkGray.
//       The background color is Blue.
//       The background color is Green.
//       The background color is Cyan.
//       The background color is Red.
//       The background color is Magenta.
//       The background color is Yellow.
//
//    Original colors restored...
```

Remarks

A change to the BackgroundColor property affects only output that is written to individual character cells after the background color is changed. To change the background color of the console window as a whole, set the BackgroundColor property and call the Clear method. The following example provides an illustration.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      WriteCharacterStrings(1, 26, true);
      Console.MoveBufferArea(0, Console.CursorTop - 10, 30, 1,
                             Console.CursorLeft, Console.CursorTop + 1);
      Console.CursorTop = Console.CursorTop + 3;
      Console.WriteLine("Press any key...");
      Console.ReadKey();

      Console.Clear();
      WriteCharacterStrings(1, 26, false);
   }

   private static void WriteCharacterStrings(int start, int end,
                                             bool changeColor)
   {
      for (int ctr = start; ctr <= end; ctr++) {
         if (changeColor)
            Console.BackgroundColor = (ConsoleColor) ((ctr - 1) % 16);

         Console.WriteLine(new String((char)(ctr + 64), 30));
      }
   }
}
```

A get operation for a Windows-based application, in which a console does not exist, returns ConsoleColor.Black. Unix systems don't provide any general mechanism to fetch the current console colors. Because of that, BackgroundColor returns `(ConsoleColor)-1` until it is set in explicit way (using the setter).

Console.BufferHeight Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the height of the buffer area.

C#

```
public static int BufferHeight {
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")] get;
[System.Runtime.Versioning.SupportedOSPlatform("windows")] set; }
```

Property Value

Int32

The current height, in rows, of the buffer area.

Attributes UnsupportedOSPlatformAttribute, SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value in a set operation is less than or equal to zero.

-or-

The value in a set operation is greater than or equal to Int16.MaxValue.

-or-

The value in a set operation is less than WindowTop + WindowHeight.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the BufferHeight and BufferWidth properties. The example reports the dimensions of an operating system window set to a buffer size of 300 rows and 85 columns.

C#

```
// This example demonstrates the Console.BufferHeight and
//                               Console.BufferWidth properties.
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine("The current buffer height is {0} rows.",
                      Console.BufferHeight);
    Console.WriteLine("The current buffer width is {0} columns.",
                      Console.BufferWidth);
    }
}
/*
This example produces the following results:

The current buffer height is 300 rows.
The current buffer width is 85 columns.
*/
```

Remarks

This property defines the number of rows (or lines) stored in the buffer that is accessed by a console mode window. In contrast, the WindowHeight property defines the number of rows that are actually displayed in the console window at any particular time. If the number of rows actually written to the buffer exceeds the number of rows defined by the WindowHeight property, the window can be scrolled vertically so that it displays a contiguous number of rows that are equal to the WindowHeight property and are located anywhere in the buffer.

If a set operation decreases the value of the BufferHeight property, the uppermost lines are removed. For example, if the number of lines is reduced from 300 to 250, lines 0 through 49 are removed, and the existing lines 50 through 299 become lines 0 through 249.

Console.BufferWidth Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the width of the buffer area.

C#

```
public static int BufferWidth {
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")] get;
[System.Runtime.Versioning.SupportedOSPlatform("windows")] set; }
```

Property Value

Int32

The current width, in columns, of the buffer area.

Attributes UnsupportedOSPlatformAttribute, SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value in a set operation is less than or equal to zero.

-or-

The value in a set operation is greater than or equal to Int16.MaxValue.

-or-

The value in a set operation is less than WindowLeft + WindowWidth.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the BufferHeight and BufferWidth properties. The example reports the dimensions of an operating system window set to a buffer size of 300 rows and 85 columns.

C#

```
// This example demonstrates the Console.BufferHeight and
//                                Console.BufferWidth properties.
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine("The current buffer height is {0} rows.",
                      Console.BufferHeight);
    Console.WriteLine("The current buffer width is {0} columns.",
                      Console.BufferWidth);
    }
}
/*
This example produces the following results:

The current buffer height is 300 rows.
The current buffer width is 85 columns.
*/
```

Remarks

If a set operation decreases the value of the BufferWidth property, the rightmost columns are removed. For example, if the number of columns is reduced from 80 to 60, columns 60 through 79 of each row are removed.

Console.CapsLock Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value indicating whether the CAPS LOCK keyboard toggle is turned on or turned off.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static bool CapsLock { get; }
```

Property Value

Boolean

`true` if CAPS LOCK is turned on; `false` if CAPS LOCK is turned off.

Attributes SupportedOSPlatformAttribute

Exceptions

PlatformNotSupportedException

The get operation is invoked on an operating system other than Windows.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.CursorLeft Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the column position of the cursor within the buffer area.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static int CursorLeft { get; set; }
```

Property Value

Int32

The current position, in columns, of the cursor.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value in a set operation is less than zero.

-or-

The value in a set operation is greater than or equal to BufferWidth.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

Examples

This example demonstrates the CursorLeft and CursorTop properties, and the SetCursorPosition and Clear methods. The example positions the cursor, which determines where the next write will occur, to draw a 5 character by 5 character rectangle using a combination of "+", "|", and "-" strings. Note that the rectangle could be drawn with fewer steps using a combination of other strings.

C#

```
// This example demonstrates the
//     Console.CursorLeft and
//     Console.CursorTop properties, and the
//     Console.SetCursorPosition and
//     Console.Clear methods.
using System;

class Sample
{
    protected static int origRow;
    protected static int origCol;

    protected static void WriteAt(string s, int x, int y)
    {
    try
        {
        Console.SetCursorPosition(origCol+x, origRow+y);
        Console.Write(s);
        }
    catch (ArgumentOutOfRangeException e)
        {
        Console.Clear();
        Console.WriteLine(e.Message);
        }
    }

    public static void Main()
    {
// Clear the screen, then save the top and left coordinates.
    Console.Clear();
    origRow = Console.CursorTop;
    origCol = Console.CursorLeft;

// Draw the left side of a 5x5 rectangle, from top to bottom.
    WriteAt("+", 0, 0);
    WriteAt("|", 0, 1);
    WriteAt("|", 0, 2);
    WriteAt("|", 0, 3);
    WriteAt("+", 0, 4);

// Draw the bottom side, from left to right.
    WriteAt("-", 1, 4); // shortcut: WriteAt("---", 1, 4)
```

```
    WriteAt("-", 2, 4); // ...
    WriteAt("-", 3, 4); // ...
    WriteAt("+", 4, 4);

// Draw the right side, from bottom to top.
    WriteAt("|", 4, 3);
    WriteAt("|", 4, 2);
    WriteAt("|", 4, 1);
    WriteAt("+", 4, 0);

// Draw the top side, from right to left.
    WriteAt("-", 3, 0); // shortcut: WriteAt("---", 1, 0)
    WriteAt("-", 2, 0); // ...
    WriteAt("-", 1, 0); // ...
//
    WriteAt("All done!", 0, 6);
    Console.WriteLine();
    }
}
/*
This example produces the following results:

+---+
|   |
|   |
|   |
+---+

All done!

*/
```

Console.CursorSize Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the height of the cursor within a character cell.

C#

```
public static int CursorSize {
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")] get;
[System.Runtime.Versioning.SupportedOSPlatform("windows")] set; }
```

Property Value

Int32

The size of the cursor expressed as a percentage of the height of a character cell. The property value ranges from 1 to 100.

Attributes UnsupportedOSPlatformAttribute, SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value specified in a set operation is less than 1 or greater than 100.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the CursorSize property. The example increases the size of the cursor each time any console key is pressed, then restores the cursor to its original size before terminating.

C#

```
// This example demonstrates the Console.CursorSize property.
using System;

class Sample
{
    public static void Main()
    {
    string m0 = "This example increments the cursor size from 1% to
100%:\n";
    string m1 = "Cursor size = {0}%. (Press any key to continue...)";
    int[] sizes = {1, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100};
    int saveCursorSize;
//
    saveCursorSize = Console.CursorSize;
    Console.WriteLine(m0);
    foreach (int size in sizes)
        {
        Console.CursorSize = size;
        Console.WriteLine(m1, size);
        Console.ReadKey();
        }
    Console.CursorSize = saveCursorSize;
    }
}
/*
This example produces the following results:

This example increments the cursor size from 1% to 100%:

Cursor size = 1%. (Press any key to continue...)
Cursor size = 10%. (Press any key to continue...)
Cursor size = 20%. (Press any key to continue...)
Cursor size = 30%. (Press any key to continue...)
Cursor size = 40%. (Press any key to continue...)
Cursor size = 50%. (Press any key to continue...)
Cursor size = 60%. (Press any key to continue...)
Cursor size = 70%. (Press any key to continue...)
Cursor size = 80%. (Press any key to continue...)
Cursor size = 90%. (Press any key to continue...)
Cursor size = 100%. (Press any key to continue...)

*/
```

Remarks

The cursor appearance varies, ranging from a horizontal line at the bottom of the cell when the property value is 1, to completely filling the cell when the property value is 100.

Console.CursorTop Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the row position of the cursor within the buffer area.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static int CursorTop { get; set; }
```

Property Value

Int32

The current position, in rows, of the cursor.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value in a set operation is less than zero.

-or-

The value in a set operation is greater than or equal to BufferHeight.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

Examples

This example demonstrates the CursorLeft and CursorTop properties, and the SetCursorPosition and Clear methods. The example positions the cursor, which determines where the next write will occur, to draw a 5 character by 5 character rectangle using a combination of "+", "|", and "-" strings. Console.CursorVisible Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets a value indicating whether the cursor is visible.

C#

```
public static bool CursorVisible {
[System.Runtime.Versioning.SupportedOSPlatform("windows")] get;
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")] set; }
```

Property Value

Boolean

`true` if the cursor is visible; otherwise, `false`.

Attributes SupportedOSPlatformAttribute, UnsupportedOSPlatformAttribute

Exceptions

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The get operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the CursorVisible property. The example makes the cursor visible if the first column of input is a '+' character or invisible if the input is a '-' character.

C#

```
// This example demonstrates the Console.CursorVisible property.

using System;

class Sample
{
    public static void Main()
    {
    string m1 = "\nThe cursor is {0}.\nType any text then press Enter. " +
                "Type '+' in the first column to show \n" +
                "the cursor, '-' to hide the cursor, " +
                "or lowercase 'x' to quit:";
    string s;
    bool saveCursorVisibile;
    int  saveCursorSize;
//
    Console.CursorVisible = true; // Initialize the cursor to visible.
    saveCursorVisibile = Console.CursorVisible;
    saveCursorSize  = Console.CursorSize;
    Console.CursorSize = 100;     // Emphasize the cursor.

    while(true)
        {
        Console.WriteLine(m1,
                         ((Console.CursorVisible == true) ?
                           "VISIBLE" : "HIDDEN"));
        s = Console.ReadLine();
        if (String.IsNullOrEmpty(s) == false)
            if (s[0] == '+')
                Console.CursorVisible = true;
            else if (s[0] == '-')
                Console.CursorVisible = false;
            else if (s[0] == 'x')
                break;
        }
    Console.CursorVisible = saveCursorVisibile;
    Console.CursorSize    = saveCursorSize;
    }
}
/*
This example produces the following results. Note that these results
cannot depict cursor visibility. You must run the example to see the
cursor behavior:

The cursor is VISIBLE.
Type any text then press Enter. Type '+' in the first column to show
the cursor, '-' to hide the cursor, or lowercase 'x' to quit:
```

```
The quick brown fox

The cursor is VISIBLE.
Type any text then press Enter. Type '+' in the first column to show
the cursor, '-' to hide the cursor, or lowercase 'x' to quit:
-

The cursor is HIDDEN.
Type any text then press Enter. Type '+' in the first column to show
the cursor, '-' to hide the cursor, or lowercase 'x' to quit:
jumps over

The cursor is HIDDEN.
Type any text then press Enter. Type '+' in the first column to show
the cursor, '-' to hide the cursor, or lowercase 'x' to quit:
+

The cursor is VISIBLE.
Type any text then press Enter. Type '+' in the first column to show
the cursor, '-' to hide the cursor, or lowercase 'x' to quit:
the lazy dog.

The cursor is VISIBLE.
Type any text then press Enter. Type '+' in the first column to show
the cursor, '-' to hide the cursor, or lowercase 'x' to quit:
x

Console.Error Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the standard error output stream.

C#

```
public static System.IO.TextWriter Error { get; }
```

Property Value

TextWriter

A TextWriter that represents the standard error output stream.

Examples

The following example is a command line utility named ExpandTabs that replaces tab characters in a text file with four spaces, the value defined by the `tabSize` variable. It redirects the standard input and output streams to files, but uses the Error property to write the standard error stream to the console. It can be launched from the command line by supplying the name of the file that contains tab characters and the name of the output file.

C#

```
using System;
using System.IO;

public class ExpandTabs
{
    private const int tabSize = 4;
    private const string usageText = "Usage: EXPANDTABSEX inputfile.txt
outputfile.txt";

    public static void Main(string[] args)
    {
        StreamWriter writer = null;
```

```
        if (args.Length < 2) {
            Console.WriteLine(usageText);
            return;
        }

        try {
            writer = new StreamWriter(args[1]);
            Console.SetOut(writer);
            Console.SetIn(new StreamReader(args[0]));
        }
        catch(IOException e) {
            TextWriter errorWriter = Console.Error;
            errorWriter.WriteLine(e.Message);
            errorWriter.WriteLine(usageText);
            return;
        }
        int i;
        while ((i = Console.Read()) != -1) {
            char c = (char)i;
            if (c == '\t')
                Console.Write("").PadRight(tabSize, ' '));
            else
                Console.Write(c);
        }
        writer.Close();
        // Recover the standard output stream so that a
        // completion message can be displayed.
        StreamWriter standardOutput = new
StreamWriter(Console.OpenStandardOutput());
        standardOutput.AutoFlush = true;
        Console.SetOut(standardOutput);
        Console.WriteLine("EXPANDTABSEX has completed the processing of
{0}.", args[0]);
        return;
    }
}
```

The following example is a simple text file viewer that displays the contents of one or more text files to the console. If there are no command line arguments, or if any files passed as command line arguments do not exist, the example calls the SetError method to redirect error information to a file, calls the OpenStandardError method in the process of reacquiring the standard error stream, and indicates that error information was written to a file.

C#

```
using System;
using System.IO;

public class ViewTextFile
```

```
{
   public static void Main()
   {
      String[] args = Environment.GetCommandLineArgs();
      String errorOutput = "";
      // Make sure that there is at least one command line argument.
      if (args.Length <= 1)
         errorOutput += "You must include a filename on the command
line.\n";

      for (int ctr = 1; ctr <= args.GetUpperBound(0); ctr++)  {
         // Check whether the file exists.
         if (! File.Exists(args[ctr])) {
            errorOutput += String.Format("'{0}' does not exist.\n",
args[ctr]);
         }
         else {
            // Display the contents of the file.
            StreamReader sr = new StreamReader(args[ctr]);
            String contents = sr.ReadToEnd();
            sr.Close();
            Console.WriteLine("*****Contents of file '{0}':\n\n",
                              args[ctr]);
            Console.WriteLine(contents);
            Console.WriteLine("*****\n");
         }
      }

      // Check for error conditions.
      if (! String.IsNullOrEmpty(errorOutput)) {
         // Write error information to a file.
         Console.SetError(new StreamWriter(@".\ViewTextFile.Err.txt"));
         Console.Error.WriteLine(errorOutput);
         Console.Error.Close();
         // Reacquire the standard error stream.
         var standardError = new StreamWriter(Console.OpenStandardError());
         standardError.AutoFlush = true;
         Console.SetError(standardError);
         Console.Error.WriteLine("\nError information written to
ViewTextFile.Err.txt");
      }
   }
}
// If the example is compiled and run with the following command line:
//     ViewTextFile file1.txt file2.txt
// and neither file1.txt nor file2.txt exist, it displays the
// following output:
//     Error information written to ViewTextFile.Err.txt
// and writes the following text to ViewTextFile.Err.txt:
//     'file1.txt' does not exist.
//     'file2.txt' does not exist.
```

Note that the StreamWriter.AutoFlush property is set to `true` before reacquiring the error stream. This ensures that output will be sent to the console immediately rather than buffered.

Remarks

This standard error stream is set to the console by default. It can be set to another stream with the SetError method. After the standard error stream is redirected, it can be reacquired by calling the OpenStandardError method.

In console applications whose informational output is often redirected to a file, the standard error stream available through the Error property can be used to display information to the console even if output is redirected. The following example displays product tables for 10 numbers at a time starting with 1. After every set of 10 numbers, the Error property is used to ask the user whether to display the next set. If the standard output is redirected to a file, the user is still asked whether the routine should generate the next set of products.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int increment = 0;
      bool exitFlag = false;

      while (! exitFlag) {
         if (Console.IsOutputRedirected)
            Console.Error.WriteLine("Generating multiples of numbers from
{0} to {1}",
                                    increment + 1, increment + 10);

         Console.WriteLine("Generating multiples of numbers from {0} to
{1}",
                           increment + 1, increment + 10);
         for (int ctr = increment + 1; ctr <= increment + 10; ctr++) {
            Console.Write("Multiples of {0}: ", ctr);
            for (int ctr2 = 1; ctr2 <= 10; ctr2++)
               Console.Write("{0}{1}", ctr * ctr2, ctr2 == 10 ? "" : ", ");

            Console.WriteLine();
         }
         Console.WriteLine();

         increment += 10;
```

```
            Console.Error.Write("Display multiples of {0} through {1} (y/n)? ",
                                increment + 1, increment + 10);
            Char response = Console.ReadKey(true).KeyChar;
            Console.Error.WriteLine(response);
            if (! Console.IsOutputRedirected)
               Console.CursorTop--;

            if (Char.ToUpperInvariant(response) == 'N')
               exitFlag = true;
         }
      }
   }
```

Console.ForegroundColor Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the foreground color of the console.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static ConsoleColor ForegroundColor { get; set; }
```

Property Value

ConsoleColor

A ConsoleColor that specifies the foreground color of the console; that is, the color of each character that is displayed. The default is gray.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentException

The color specified in a set operation is not a valid member of ConsoleColor.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

Examples

The following example checks whether the console's background color is black and, if it is, it changes the background color to red and the foreground color to black.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      if (Console.BackgroundColor == ConsoleColor.Black) {
         Console.BackgroundColor = ConsoleColor.Red;
         Console.ForegroundColor = ConsoleColor.Black;
         Console.Clear();
      }
   }
}
```

The following example saves the values of the ConsoleColor enumeration to an array and stores the current values of the BackgroundColor and ForegroundColor properties to variables. It then changes the foreground color to each color in the ConsoleColor enumeration except to the color that matches the current background, and it changes the background color to each color in the ConsoleColor enumeration except to the color that matches the current foreground. (If the foreground color is the same as the background color, the text isn't visible.) Finally, it calls the ResetColor method to restore the original console colors.

C#

```
using System;

class Example
{
   public static void Main()
   {
      // Get an array with the values of ConsoleColor enumeration members.
      ConsoleColor[] colors = (ConsoleColor[])
ConsoleColor.GetValues(typeof(ConsoleColor));
      // Save the current background and foreground colors.
      ConsoleColor currentBackground = Console.BackgroundColor;
      ConsoleColor currentForeground = Console.ForegroundColor;

      // Display all foreground colors except the one that matches the
background.
      Console.WriteLine("All the foreground colors except {0}, the
background color:",
                        currentBackground);
      foreach (var color in colors) {
         if (color == currentBackground) continue;
```

```
         Console.ForegroundColor = color;
         Console.WriteLine("   The foreground color is {0}.", color);
      }
      Console.WriteLine();
      // Restore the foreground color.
      Console.ForegroundColor = currentForeground;

      // Display each background color except the one that matches the
current foreground color.
      Console.WriteLine("All the background colors except {0}, the
foreground color:",
                        currentForeground);
      foreach (var color in colors) {
         if (color == currentForeground) continue;

         Console.BackgroundColor = color;
         Console.WriteLine("   The background color is {0}.", color);
      }

      // Restore the original console colors.
      Console.ResetColor();
      Console.WriteLine("\nOriginal colors restored...");
   }
}
//The example displays output like the following:
//    All the foreground colors except DarkCyan, the background color:
//       The foreground color is Black.
//       The foreground color is DarkBlue.
//       The foreground color is DarkGreen.
//       The foreground color is DarkRed.
//       The foreground color is DarkMagenta.
//       The foreground color is DarkYellow.
//       The foreground color is Gray.
//       The foreground color is DarkGray.
//       The foreground color is Blue.
//       The foreground color is Green.
//       The foreground color is Cyan.
//       The foreground color is Red.
//       The foreground color is Magenta.
//       The foreground color is Yellow.
//       The foreground color is White.
//
//    All the background colors except White, the foreground color:
//       The background color is Black.
//       The background color is DarkBlue.
//       The background color is DarkGreen.
//       The background color is DarkCyan.
//       The background color is DarkRed.
//       The background color is DarkMagenta.
//       The background color is DarkYellow.
//       The background color is Gray.
//       The background color is DarkGray.
//       The background color is Blue.
//       The background color is Green.
```

```
//       The background color is Cyan.
//       The background color is Red.
//       The background color is Magenta.
//       The background color is Yellow.
//
//    Original colors restored...
```

Remarks

A get operation for a Windows-based application, in which a console does not exist, returns Gray. Unix systems don't provide any general mechanism to fetch the current console colors. Because of that, ForegroundColor returns `(ConsoleColor)-1` until it is set in explicit way (using the setter).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.In Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the standard input stream.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static System.IO.TextReader In { get; }
```

Property Value

TextReader

A TextReader that represents the standard input stream.

Attributes UnsupportedOSPlatformAttribute

Examples

The following sample illustrates the use of the `In` property.

C#

```
using System;
using System.IO;

class InTest {
    public static void Main() {

        TextReader tIn = Console.In;
        TextWriter tOut = Console.Out;

        tOut.WriteLine("Hola Mundo!");
        tOut.Write("What is your name: ");
        String name = tIn.ReadLine();
```

```
        tOut.WriteLine("Buenos Dias, {0}!", name);
    }
}
```

Remarks

This property is set to the standard input stream by default. This property can be set to another stream with the SetIn method.

Read operations on the standard input stream execute synchronously. That is, they block until the specified read operation has completed. This is true even if an asynchronous method, such as ReadLineAsync, is called on the TextReader object returned by the In property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Console.InputEncoding Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the encoding the console uses to read input.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static System.Text.Encoding InputEncoding { get; set; }
```

Property Value

Encoding

The encoding used to read console input.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentNullException

The property value in a set operation is `null`.

IOException

An error occurred during the execution of this operation.

SecurityException

Your application does not have permission to perform this operation.

Remarks

The console uses the input encoding to translate keyboard input into a corresponding character. The input encoding incorporates a code page that maps 256 keyboard character codes to individual characters. Different code pages include different special characters, typically customized for a language or a group of languages.

Starting with the .NET Framework 4, a property get operation may return a cached value instead of the console's current input encoding. This can occur if the value of the InputEncoding property is modified by some means other than an assignment to the InputEncoding property, such as calling the Windows `SetConsoleCP` function or using the `chcp` command from a PowerShell script.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.IsErrorRedirected Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value that indicates whether the error output stream has been redirected from the standard error stream.

```
C#
public static bool IsErrorRedirected { get; }
```

Property Value

Boolean

`true` if error output is redirected; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Console.IsInputRedirected Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value that indicates whether input has been redirected from the standard input stream.

```
C#
public static bool IsInputRedirected { get; }
```

Property Value

Boolean

`true` if input is redirected; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Console.IsOutputRedirected Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value that indicates whether output has been redirected from the standard output stream.

```
C#
public static bool IsOutputRedirected { get; }
```

Property Value

Boolean

`true` if output is redirected; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Console.KeyAvailable Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value indicating whether a key press is available in the input stream.

C#

```
public static bool KeyAvailable { get; }
```

Property Value

Boolean

`true` if a key press is available; otherwise, `false`.

Exceptions

IOException

An I/O error occurred.

InvalidOperationException

Standard input is redirected to a file instead of the keyboard.

Examples

The following example demonstrates how to use the KeyAvailable property to create a loop that runs until a key is pressed.

C#

```
using System;
using System.Threading;

class Sample
{
    public static void Main()
    {
```

```
        ConsoleKeyInfo cki;

        do {
            Console.WriteLine("\nPress a key to display; press the 'x' key to
quit.");

            // Your code could perform some useful task in the following
loop. However,
            // for the sake of this example we'll merely pause for a quarter
second.

            while (Console.KeyAvailable == false)
                Thread.Sleep(250); // Loop until input is entered.

            cki = Console.ReadKey(true);
            Console.WriteLine("You pressed the '{0}' key.", cki.Key);
        } while(cki.Key != ConsoleKey.X);
    }
}
/*
This example produces results similar to the following:

Press a key to display; press the 'x' key to quit.
You pressed the 'H' key.

Press a key to display; press the 'x' key to quit.
You pressed the 'E' key.

Press a key to display; press the 'x' key to quit.
You pressed the 'PageUp' key.

Press a key to display; press the 'x' key to quit.
You pressed the 'DownArrow' key.

Press a key to display; press the 'x' key to quit.
You pressed the 'X' key.
*/
```

Remarks

The property value is returned immediately; that is, the KeyAvailable property does not block input until a key press is available.

Use the KeyAvailable property in conjunction with only the ReadKey method, not the Read or ReadLine methods.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.LargestWindowHeight Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the largest possible number of console window rows, based on the current font and screen resolution.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static int LargestWindowHeight { get; }
```

Property Value

Int32

The height of the largest possible console window measured in rows.

Attributes UnsupportedOSPlatformAttribute

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.LargestWindowWidth Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the largest possible number of console window columns, based on the current font and screen resolution.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static int LargestWindowWidth { get; }
```

Property Value

Int32

The width of the largest possible console window measured in columns.

Attributes UnsupportedOSPlatformAttribute

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.NumberLock Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value indicating whether the NUM LOCK keyboard toggle is turned on or turned off.

```C#
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static bool NumberLock { get; }
```

Property Value

Boolean

`true` if NUM LOCK is turned on; `false` if NUM LOCK is turned off.

Attributes SupportedOSPlatformAttribute

Exceptions

PlatformNotSupportedException

The get operation is invoked on an operating system other than Windows.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Console.Out Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the standard output stream.

C#

```
public static System.IO.TextWriter Out { get; }
```

Property Value

TextWriter

A TextWriter that represents the standard output stream.

Examples

The following example uses the Out property to display an array containing the names of files in the application's current directory to the standard output device. It then sets the standard output to a file named Files.txt and lists the array elements to the file. Finally, it sets the output to the standard output stream and again displays the array elements to the standard output device.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      // Get all files in the current directory.
      string[] files = Directory.GetFiles(".");
      Array.Sort(files);

      // Display the files to the current output source to the console.
      Console.Out.WriteLine("First display of filenames to the console:");
```

```
        Array.ForEach(files, s => Console.Out.WriteLine(s));
        Console.Out.WriteLine();

        // Redirect output to a file named Files.txt and write file list.
        StreamWriter sw = new StreamWriter(@".\Files.txt");
        sw.AutoFlush = true;
        Console.SetOut(sw);
        Console.Out.WriteLine("Display filenames to a file:");
        Array.ForEach(files, s => Console.Out.WriteLine(s));
        Console.Out.WriteLine();

        // Close previous output stream and redirect output to standard
output.
        Console.Out.Close();
        sw = new StreamWriter(Console.OpenStandardOutput());
        sw.AutoFlush = true;
        Console.SetOut(sw);

        // Display the files to the current output source to the console.
        Console.Out.WriteLine("Second display of filenames to the console:");
        Array.ForEach(files, s => Console.Out.WriteLine(s));
    }
}
```

Remarks

This property is set to the standard output stream by default. This property can be set to another stream with the SetOut method.

Note that calls to `Console.Out.WriteLine` methods are equivalent to calls to the corresponding WriteLine methods.

Console.OutputEncoding Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the encoding the console uses to write output.

C#

```
public static System.Text.Encoding OutputEncoding { get;
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")] set; }
```

Property Value

Encoding

The encoding used to write console output.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentNullException

The property value in a set operation is `null`.

IOException

An error occurred during the execution of this operation.

SecurityException

Your application does not have permission to perform this operation.

Remarks

The console uses the output encoding to translate characters written by an application into corresponding console display characters. The default code page that the console

uses is determined by the system locale.

Starting with the .NET Framework 4, a property get operation may return a cached value instead of the console's current output encoding. This can occur if the value of the OutputEncoding property is modified by some means other than an assignment to the OutputEncoding property, such as calling the Windows `SetConsoleOutputCP` function.

Notes to Callers

Of the Unicode encodings, the Console class supports UTF-8 encoding with the UTF8Encoding class and, starting with the .NET Framework 4.5, it supports UTF-16 encoding with the UnicodeEncoding class. UTF-32 encoding with the UTF32Encoding class is not supported. Attempting to set the output encoding to UTF-32 throws an IOException.

Note that successfully displaying Unicode characters to the console requires the following:

- The console must use a TrueType font, such as Lucida Console or Consolas, to display characters.
- A font used by the console must define the particular glyph or glyphs to be displayed. The console can take advantage of font linking to display glyphs from linked fonts if the base font does not contain a definition for that glyph.

For more information about support for Unicode encoding by the console, see the "Unicode Support for the Console" section in the Console class.

Console.Title Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the title to display in the console title bar.

C#

```
public static string Title {
[System.Runtime.Versioning.SupportedOSPlatform("windows")] get;
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")] set; }
```

Property Value

String

The string to be displayed in the title bar of the console. The maximum length of the title string is 24500 characters.

Attributes SupportedOSPlatformAttribute, UnsupportedOSPlatformAttribute

Exceptions

InvalidOperationException

In a get operation, the retrieved title is longer than 24500 characters.

ArgumentOutOfRangeException

In a set operation, the specified title is longer than 24500 characters.

ArgumentNullException

In a set operation, the specified title is `null`.

IOException

An I/O error occurred.

PlatformNotSupportedException

The get operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the Title property. The example displays the current title of the operating system window, waits for a key press, then displays a new title.

C#

```
// This example demonstrates the Console.Title property.
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine("The current console title is: \"{0}\"",
                      Console.Title);
    Console.WriteLine("  (Press any key to change the console title.)");
    Console.ReadKey(true);
    Console.Title = "The title has changed!";
    Console.WriteLine("Note that the new console title is \"{0}\"\n" +
                      "  (Press any key to quit.)", Console.Title);
    Console.ReadKey(true);
    }
}
/*
This example produces the following results:

>myTitle
The current console title is: "Command Prompt - myTitle"
  (Press any key to change the console title.)
Note that the new console title is "The title has changed!"
  (Press any key to quit.)

*/
```

Console.TreatControlCAsInput Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets a value indicating whether the combination of the Control modifier key and C console key (Ctrl+C) is treated as ordinary input or as an interruption that is handled by the operating system.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static bool TreatControlCAsInput { get; set; }
```

Property Value

Boolean

`true` if Ctrl+C is treated as ordinary input; otherwise, `false`.

Attributes UnsupportedOSPlatformAttribute

Exceptions

IOException

Unable to get or set the input mode of the console input buffer.

Examples

The following example demonstrates the TreatControlCAsInput property.

C#

```
using System;

class Example
```

```
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT, and a
console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do
      {
         cki = Console.ReadKey();
         Console.Write(" --- You pressed ");
         if((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
         if((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
         if((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
         Console.WriteLine(cki.Key.ToString());
       } while (cki.Key != ConsoleKey.Escape);
    }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       a --- You pressed A
//       k --- You pressed ALT+K
//       ► --- You pressed CTL+P
//         --- You pressed RightArrow
//       R --- You pressed SHIFT+R
//                --- You pressed CTL+I
//       j --- You pressed ALT+J
//       O --- You pressed SHIFT+O
//       § --- You pressed CTL+U
```

Remarks

If the value of the TreatControlCAsInput property is `false` and Ctrl+C is pressed, the pressed keys are not stored in the input buffer and the operating system terminates the currently executing process. This is the default value.

> ⊗ **Caution**
>
> Use this property judiciously because setting it to `true` has such a dramatic effect. Most users expect Ctrl+C to terminate a console application. If you disable the

effect of Ctrl+C, the user must remember to use Ctrl+Break to terminate the application, which is a less familiar key combination.

Applies to

Console.WindowHeight Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the height of the console window area.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static int WindowHeight { get; set; }
```

Property Value

Int32

The height of the console window measured in rows.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value of the WindowWidth property or the value of the WindowHeight property is less than or equal to 0.

-or-

The value of the WindowHeight property plus the value of the WindowTop property is greater than or equal to Int16.MaxValue.

-or-

The value of the WindowWidth property or the value of the WindowHeight property is greater than the largest possible window width or height for the current screen resolution and console font.

IOException

Error reading or writing information.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the SetWindowSize method, and the WindowWidth and WindowHeight properties. You must run the example to see the full effect of changing the console window size.

The example reports the dimensions of a console window set to 85 columns and 43 rows, then waits for a key press. When any key is pressed, the dimensions of the console window are halved, the new dimensions are reported, and the example waits for another key press. Finally, when any key is pressed the console window is restored to its original dimensions and the example terminates.

C#

```
// This example demonstrates the Console.SetWindowSize method,
//                            the Console.WindowWidth property,
//                        and the Console.WindowHeight property.
using System;

class Sample
{
    public static void Main()
    {
    int origWidth, width;
    int origHeight, height;
    string m1 = "The current window width is {0}, and the " +
                "current window height is {1}.";
    string m2 = "The new window width is {0}, and the new " +
                "window height is {1}.";
    string m4 = "  (Press any key to continue...)";
//
// Step 1: Get the current window dimensions.
//
    origWidth  = Console.WindowWidth;
    origHeight = Console.WindowHeight;
    Console.WriteLine(m1, Console.WindowWidth,
                          Console.WindowHeight);
    Console.WriteLine(m4);
    Console.ReadKey(true);
//
// Step 2: Cut the window to 1/4 its original size.
//
```

```
    width  = origWidth/2;
    height = origHeight/2;
    Console.SetWindowSize(width, height);
    Console.WriteLine(m2, Console.WindowWidth,
                          Console.WindowHeight);
    Console.WriteLine(m4);
    Console.ReadKey(true);
//
// Step 3: Restore the window to its original size.
//
    Console.SetWindowSize(origWidth, origHeight);
    Console.WriteLine(m1, Console.WindowWidth,
                          Console.WindowHeight);
    }
}
/*
This example produces the following results:

The current window width is 85, and the current window height is 43.
  (Press any key to continue...)
The new window width is 42, and the new window height is 21.
  (Press any key to continue...)
The current window width is 85, and the current window height is 43.

*/
```

Remarks

Attempting to set the value of the WindowHeight property when output is redirected throws either an ArgumentOutOfRangeException or an IOException exception. To prevent an exception, you can set the value of this property only if the IsOutputRedirected property returns `false`.

Console.WindowLeft Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the leftmost position of the console window area relative to the screen buffer.

C#

```
public static int WindowLeft { get;
[System.Runtime.Versioning.SupportedOSPlatform("windows")] set; }
```

Property Value

Int32

The leftmost console window position measured in columns.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

In a set operation, the value to be assigned is less than zero.

-or-

As a result of the assignment, WindowLeft plus WindowWidth would exceed BufferWidth.

IOException

Error reading or writing information.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

The following example opens an 80-column console window and defines a buffer area that is 120 columns wide. It displays information on window and buffer size, and then waits for the user to press either the LEFT ARROW key or the RIGHT ARROW key. In the former case, it decrements the value of the WindowLeft property by one if the result is a legal value. In the latter case, it increases the value of the WindowLeft property by one if the result would be legal. Note that the example does not have to handle an ArgumentOutOfRangeException, because it checks that the value to be assigned to the WindowLeft property is not negative and does not cause the sum of the WindowLeft and WindowWidth properties to exceed the BufferWidth property value.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      ConsoleKeyInfo key;
      bool moved = false;

      Console.BufferWidth += 4;
      Console.Clear();

      ShowConsoleStatistics();
      do
      {
         key = Console.ReadKey(true);
         if (key.Key == ConsoleKey.LeftArrow)
         {
            int pos = Console.WindowLeft - 1;
            if (pos >= 0 && pos + Console.WindowWidth <=
Console.BufferWidth)
            {
               Console.WindowLeft = pos;
               moved = true;
            }
         }
         else if (key.Key == ConsoleKey.RightArrow)
         {
            int pos = Console.WindowLeft + 1;
            if (pos + Console.WindowWidth <= Console.BufferWidth)
            {
               Console.WindowLeft = pos;
               moved = true;
            }
         }
         if (moved)
```

```
            {
               ShowConsoleStatistics();
               moved = false;
            }
            Console.WriteLine();
         } while (true);
      }

      private static void ShowConsoleStatistics()
      {
         Console.WriteLine("Console statistics:");
         Console.WriteLine("   Buffer: {0} x {1}", Console.BufferHeight,
Console.BufferWidth);
         Console.WriteLine("   Window: {0} x {1}", Console.WindowHeight,
Console.WindowWidth);
         Console.WriteLine("   Window starts at {0}.", Console.WindowLeft);
         Console.WriteLine("Press <- or -> to move window, Ctrl+C to exit.");
      }
   }
```

Remarks

The console represents a rectangular window into a larger rectangular buffer area. Both the window and the buffer are measured vertically by their number of rows and horizontally by their number of columns. The dimensions of the buffer area are defined by the BufferHeight and BufferWidth properties. The dimensions of the console area are defined by the WindowHeight and WindowWidth properties. The WindowLeft property determines which column of the buffer area is displayed in the first column of the console window. The value of the WindowLeft property can range from 0 to BufferWidth - WindowWidth. Attempting to set it to a value outside that range throws an ArgumentOutOfRangeException.

When a console window first opens, the default value of the WindowLeft property is zero, which indicates that the first column shown by the console corresponds to the first column (the column at position zero) in the buffer area. The default width of both the console window and the buffer area is 80 columns. This means that the WindowLeft property can be modified only if the console window is made narrower or the buffer area is made wider.

Note that if the width of the buffer area exceeds the width of the console window, the value of the WindowLeft property is automatically adjusted when the user uses the horizontal scroll bar to define the window's relationship to the buffer area.

Attempting to set the value of the WindowLeft property when output is redirected throws an IOException exception. To prevent the exception, you can set the value of this

property only if the IsOutputRedirected property returns `false`.

Console.WindowTop Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the top position of the console window area relative to the screen buffer.

C#

```
public static int WindowTop { get;
[System.Runtime.Versioning.SupportedOSPlatform("windows")] set; }
```

Property Value

Int32

The uppermost console window position measured in rows.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

In a set operation, the value to be assigned is less than zero.

-or-

As a result of the assignment, WindowTop plus WindowHeight would exceed BufferHeight.

IOException

Error reading or writing information.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

The following example demonstrates the WindowLeft, WindowTop, WindowWidth, WindowHeight, BufferWidth, BufferHeight, and CursorVisible properties; and the SetWindowPosition, SetBufferSize, and ReadKey methods. The example draws a grid pattern in the screen buffer based on the screen buffer width. Then the example moves the console window in response to which of the UP ARROW, DOWN ARROW, LEFT ARROW, or RIGHT ARROW console keys is pressed. The grid pattern helps you see the movement of the console window relative to the screen buffer.

C#

```
// This example demonstrates the Console.WindowLeft and
//                               Console.WindowTop properties.
using System;
using System.Text;
using System.IO;
//
class Sample
{
    public static int saveBufferWidth;
    public static int saveBufferHeight;
    public static int saveWindowHeight;
    public static int saveWindowWidth;
    public static bool saveCursorVisible;
//
    public static void Main()
    {
    string m1 = "1) Press the cursor keys to move the console window.\n" +
                "2) Press any key to begin. When you're finished...\n" +
                "3) Press the Escape key to quit.";
    string g1 = "+----";
    string g2 = "|    ";
    string grid1;
    string grid2;
    StringBuilder sbG1 = new StringBuilder();
    StringBuilder sbG2 = new StringBuilder();
    ConsoleKeyInfo cki;
    int y;
//
    try
    {
    saveBufferWidth  = Console.BufferWidth;
    saveBufferHeight = Console.BufferHeight;
    saveWindowHeight = Console.WindowHeight;
    saveWindowWidth  = Console.WindowWidth;
    saveCursorVisible = Console.CursorVisible;
//
    Console.Clear();
    Console.WriteLine(m1);
    Console.ReadKey(true);

// Set the smallest possible window size before setting the buffer size.
    Console.SetWindowSize(1, 1);
```

```
    Console.SetBufferSize(80, 80);
    Console.SetWindowSize(40, 20);

// Create grid lines to fit the buffer. (The buffer width is 80, but
// this same technique could be used with an arbitrary buffer width.)
    for (y = 0; y < Console.BufferWidth/g1.Length; y++)
        {
        sbG1.Append(g1);
        sbG2.Append(g2);
        }
    sbG1.Append(g1, 0, Console.BufferWidth%g1.Length);
    sbG2.Append(g2, 0, Console.BufferWidth%g2.Length);
    grid1 = sbG1.ToString();
    grid2 = sbG2.ToString();

    Console.CursorVisible = false;
    Console.Clear();
    for (y = 0; y < Console.BufferHeight-1; y++)
        {
        if (y%3 == 0)
            Console.Write(grid1);
        else
            Console.Write(grid2);
        }

    Console.SetWindowPosition(0, 0);
    do
        {
        cki = Console.ReadKey(true);
        switch (cki.Key)
            {
            case ConsoleKey.LeftArrow:
                if (Console.WindowLeft > 0)
                    Console.SetWindowPosition(
                            Console.WindowLeft-1, Console.WindowTop);
                break;
            case ConsoleKey.UpArrow:
                if (Console.WindowTop > 0)
                    Console.SetWindowPosition(
                            Console.WindowLeft, Console.WindowTop-1);
                break;
            case ConsoleKey.RightArrow:
                if (Console.WindowLeft < (Console.BufferWidth-
Console.WindowWidth))
                    Console.SetWindowPosition(
                            Console.WindowLeft+1, Console.WindowTop);
                break;
            case ConsoleKey.DownArrow:
                if (Console.WindowTop < (Console.BufferHeight-
Console.WindowHeight))
                    Console.SetWindowPosition(
                            Console.WindowLeft, Console.WindowTop+1);
                break;
            }
        }
```

```
    while (cki.Key != ConsoleKey.Escape);  // end do-while
    } // end try
    catch (IOException e)
        {
        Console.WriteLine(e.Message);
        }
    finally
        {
        Console.Clear();
        Console.SetWindowSize(1, 1);
        Console.SetBufferSize(saveBufferWidth, saveBufferHeight);
        Console.SetWindowSize(saveWindowWidth, saveWindowHeight);
        Console.CursorVisible = saveCursorVisible;
        }
    } // end Main
} // end Sample
/*
This example produces results similar to the following:

1) Press the cursor keys to move the console window.
2) Press any key to begin. When you're finished...
3) Press the Escape key to quit.

...

+----+----+----+-
|    |    |    |
|    |    |    |
+----+----+----+-
|    |    |    |
|    |    |    |
+----+----+----+-

*/
```

Remarks

The console represents a rectangular window into a larger rectangular buffer area. Both the window and the buffer are measured vertically by their number of rows and horizontally by their number of columns. The dimensions of the buffer area are defined by the BufferHeight and BufferWidth properties. The dimensions of the console area are defined by the WindowHeight and WindowWidth properties. The WindowTop property determines which row of the buffer area is displayed in the first column of the console window. The value of the WindowTop property can range from 0 to BufferHeight - WindowHeight. Attempting to set it to a value outside that range throws an ArgumentOutOfRangeException.

Attempting to set the value of the WindowTop property when output is redirected throws an IOException exception. To prevent the exception, you can set the value of this

property only if the IsOutputRedirected property returns `false`.

Console.WindowWidth Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets the width of the console window.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static int WindowWidth { get; set; }
```

Property Value

Int32

The width of the console window measured in columns.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

The value of the WindowWidth property or the value of the WindowHeight property is less than or equal to 0.

-or-

The value of the WindowHeight property plus the value of the WindowTop property is greater than or equal to Int16.MaxValue.

-or-

The value of the WindowWidth property or the value of the WindowHeight property is greater than the largest possible window width or height for the current screen resolution and console font.

IOException

Error reading or writing information.

PlatformNotSupportedException

The set operation is invoked on an operating system other than Windows.

Examples

This example demonstrates the SetWindowSize method, and the WindowWidth and WindowHeight properties. You must run the example to see the full effect of changing the console window size.

The example reports the dimensions of a console window set to 85 columns and 43 rows, then waits for a key press. When any key is pressed, the dimensions of the console window are halved, the new dimensions are reported, and the example waits for another key press. Finally, when any key is pressed the console window is restored to its original dimensions and the example terminates.

C#

```
// This example demonstrates the Console.SetWindowSize method,
//                            the Console.WindowWidth property,
//                        and the Console.WindowHeight property.
using System;

class Sample
{
    public static void Main()
    {
    int origWidth, width;
    int origHeight, height;
    string m1 = "The current window width is {0}, and the " +
                "current window height is {1}.";
    string m2 = "The new window width is {0}, and the new " +
                "window height is {1}.";
    string m4 = "  (Press any key to continue...)";
//
// Step 1: Get the current window dimensions.
//
    origWidth  = Console.WindowWidth;
    origHeight = Console.WindowHeight;
    Console.WriteLine(m1, Console.WindowWidth,
                          Console.WindowHeight);
    Console.WriteLine(m4);
    Console.ReadKey(true);
//
// Step 2: Cut the window to 1/4 its original size.
//
```

```
    width  = origWidth/2;
    height = origHeight/2;
    Console.SetWindowSize(width, height);
    Console.WriteLine(m2, Console.WindowWidth,
                          Console.WindowHeight);
    Console.WriteLine(m4);
    Console.ReadKey(true);
//
// Step 3: Restore the window to its original size.
//
    Console.SetWindowSize(origWidth, origHeight);
    Console.WriteLine(m1, Console.WindowWidth,
                          Console.WindowHeight);
    }
}
/*
This example produces the following results:

The current window width is 85, and the current window height is 43.
  (Press any key to continue...)
The new window width is 42, and the new window height is 21.
  (Press any key to continue...)
The current window width is 85, and the current window height is 43.

*/
```

Remarks

Attempting to set the value of the WindowWidth property when output is redirected throws either an ArgumentOutOfRangeException or an IOException exception. To prevent an exception, you can set the value of this property only if the IsOutputRedirected property returns `false`.

Console.Beep Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Plays the sound of a beep through the console speaker.

Overloads

Expand table

Beep()	Plays the sound of a beep through the console speaker.
Beep(Int32, Int32)	Plays the sound of a beep of a specified frequency and duration through the console speaker.

Beep()

Plays the sound of a beep through the console speaker.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static void Beep ();
```

Attributes UnsupportedOSPlatformAttribute

Exceptions

HostProtectionException

This method was executed on a server, such as SQL Server, that does not permit access to a user interface.

Examples

The following example demonstrates the Beep method. The example accepts a number from 1 through 9 as a command line argument, and plays the beep that number of times.

C#

```
// This example demonstrates the Console.Beep() method.
using System;

class Sample
{
    public static void Main(String[] args)
    {
    int x = 0;
//
    if ((args.Length == 1) &&
        (Int32.TryParse(args[0], out x) == true) &&
        ((x >= 1) && (x <= 9)))
        {
        for (int i = 1; i <= x; i++)
            {
            Console.WriteLine("Beep number {0}.", i);
            Console.Beep();
            }
        }
    else
        {
            Console.WriteLine("Usage: Enter the number of times (between
1 and 9) to beep.");
        }
    }
}
/*
This example produces the following results:

>beep
Usage: Enter the number of times (between 1 and 9) to beep

>beep 9
Beep number 1.
Beep number 2.
Beep number 3.
Beep number 4.
Beep number 5.
Beep number 6.
Beep number 7.
Beep number 8.
Beep number 9.

*/
```

Remarks

By default, the beep plays at a frequency of 800 hertz for a duration of 200 milliseconds.

Beep wraps a call to the Windows Beep function. Whether Beep produces a sound on versions of Windows before Windows 7 depends on the presence of a 8254 programmable interval timer chip. Starting with Windows 7, it depends on the default sound device.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Beep(Int32, Int32)

Plays the sound of a beep of a specified frequency and duration through the console speaker.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static void Beep (int frequency, int duration);
```

Parameters

`frequency` Int32

The frequency of the beep, ranging from 37 to 32767 hertz.

`duration` Int32

The duration of the beep measured in milliseconds.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

`frequency` is less than 37 or more than 32767 hertz.

-or-

`duration` is less than or equal to zero.

HostProtectionException

This method was executed on a server, such as SQL Server, that does not permit access to the console.

PlatformNotSupportedException

The current operating system is not Windows.

Examples

This example demonstrates the Beep method by playing the first few notes of a song through the console speaker.

C#

```
// This example demonstrates the Console.Beep(Int32, Int32) method
using System;
using System.Threading;

class Sample
{
    public static void Main()
    {
// Declare the first few notes of the song, "Mary Had A Little Lamb".
    Note[] Mary =
        {
        new Note(Tone.B, Duration.QUARTER),
        new Note(Tone.A, Duration.QUARTER),

Console.Clear Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Clears the console buffer and corresponding console window of display information.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static void Clear ();
```

Attributes UnsupportedOSPlatformAttribute

Exceptions

IOException

An I/O error occurred.

Examples

The following example uses the Clear method to clear the console before it executes a loop, prompts the user to select a foreground and background color and to enter a string to display. If the user chooses not to exit the program, the console's original foreground and background colors are restored and the Clear method is called again before re-executing the loop.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Save colors so they can be restored when use finishes input.
      ConsoleColor dftForeColor = Console.ForegroundColor;
```

```
      ConsoleColor dftBackColor = Console.BackgroundColor;
      bool continueFlag = true;
      Console.Clear();

      do {
         ConsoleColor newForeColor = ConsoleColor.White;
         ConsoleColor newBackColor = ConsoleColor.Black;

         Char foreColorSelection = GetKeyPress("Select Text Color (B for
Blue, R for Red, Y for Yellow): ",
                                               new Char[] { 'B', 'R', 'Y' }
);
         switch (foreColorSelection) {
            case 'B':
            case 'b':
               newForeColor = ConsoleColor.DarkBlue;
               break;
            case 'R':
            case 'r':
               newForeColor = ConsoleColor.DarkRed;
               break;
            case 'Y':
            case 'y':
               newForeColor = ConsoleColor.DarkYellow;
               break;
         }
         Char backColorSelection = GetKeyPress("Select Background Color (W
for White, G for Green, M for Magenta): ",
                                               new Char[] { 'W', 'G', 'M' });
         switch (backColorSelection) {
            case 'W':
            case 'w':
               newBackColor = ConsoleColor.White;
               break;
            case 'G':
            case 'g':
               newBackColor = ConsoleColor.Green;
               break;
            case 'M':
            case 'm':
               newBackColor = ConsoleColor.Magenta;
               break;
         }

         Console.WriteLine();
         Console.Write("Enter a message to display: ");
         String textToDisplay = Console.ReadLine();
         Console.WriteLine();
         Console.ForegroundColor = newForeColor;
         Console.BackgroundColor = newBackColor;
         Console.WriteLine(textToDisplay);
         Console.WriteLine();
         if (Char.ToUpper(GetKeyPress("Display another message (Y/N): ", new
Char[] { 'Y', 'N' } )) == 'N')
            continueFlag = false;
```

```
         // Restore the default settings and clear the screen.
         Console.ForegroundColor = dftForeColor;
         Console.BackgroundColor = dftBackColor;
         Console.Clear();
      } while (continueFlag);
   }

   private static Char GetKeyPress(String msg, Char[] validChars)
   {
      ConsoleKeyInfo keyPressed;
      bool valid = false;

      Console.WriteLine();
      do {
         Console.Write(msg);
         keyPressed = Console.ReadKey();
         Console.WriteLine();
         if (Array.Exists(validChars, ch =>
ch.Equals(Char.ToUpper(keyPressed.KeyChar))))
            valid = true;
      } while (! valid);
      return keyPressed.KeyChar;
   }
}
```

The example relies on a `GetKeyPress` method to validate the user's selection of a foreground and background color.

This example demonstrates the CursorLeft and CursorTop properties, and the SetCursorPosition and Clear methods. The example positions the cursor, which determines where the next write will occur, to draw a 5 character by 5 character rectangle using a combination of "+", "|", and "-" strings. Note that the rectangle could be drawn with fewer steps using a combination of other strings.

C#

```
// This example demonstrates the
//     Console.CursorLeft and
//     Console.CursorTop properties, and the
//     Console.SetCursorPosition and
//     Console.Clear methods.
using System;

class Sample
{
    protected static int origRow;
    protected static int origCol;

    protected static void WriteAt(string s, int x, int y)
    {
```

```
    try
        {
        Console.SetCursorPosition(origCol+x, origRow+y);
        Console.Write(s);
        }
    catch (ArgumentOutOfRangeException e)
        {
        Console.Clear();
        Console.WriteLine(e.Message);
        }
    }

    public static void Main()
    {
// Clear the screen, then save the top and left coordinates.
    Console.Clear();
    origRow = Console.CursorTop;
    origCol = Console.CursorLeft;

// Draw the left side of a 5x5 rectangle, from top to bottom.
    WriteAt("+", 0, 0);
    WriteAt("|", 0, 1);
    WriteAt("|", 0, 2);
    WriteAt("|", 0, 3);
    WriteAt("+", 0, 4);

// Draw the bottom side, from left to right.
    WriteAt("-", 1, 4); // shortcut: WriteAt("---", 1, 4)
    WriteAt("-", 2, 4); // ...
    WriteAt("-", 3, 4); // ...
    WriteAt("+", 4, 4);

// Draw the right side, from bottom to top.
    WriteAt("|", 4, 3);
    WriteAt("|", 4, 2);
    WriteAt("|", 4, 1);
    WriteAt("+", 4, 0);

// Draw the top side, from right to left.
    WriteAt("-", 3, 0); // shortcut: WriteAt("---", 1, 0)
    WriteAt("-", 2, 0); // ...
    WriteAt("-", 1, 0); // ...
//
    WriteAt("All done!", 0, 6);
    Console.WriteLine();
    }
}
/*
This example produces the following results:

+---+
|   |
|   |
|   |
+---+
```

```
All done!

*/
```

Remarks

Using the Clear method is equivalent invoking the MS-DOS `cls` command in the command prompt window. When the Clear method is called, the cursor automatically scrolls to the top-left corner of the window and the contents of the screen buffer are set to blanks using the current foreground background colors.

> **Note**
>
> Attempting to call the **Clear** method when a console application's output is redirected to a file throws a **IOException**. To prevent this, always wrap a call to the **Clear** method in a `try`...`catch` block.

Console.GetCursorPosition Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the position of the cursor.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static (int Left, int Top) GetCursorPosition ();
```

Returns

ValueTuple<Int32,Int32>

The column and row position of the cursor.

Attributes UnsupportedOSPlatformAttribute

Remarks

Columns are numbered from left to right starting at 0. Rows are numbered from top to bottom starting at 0.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Console.MoveBufferArea Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Copies a specified source area of the screen buffer to a specified destination area.

Overloads

Expand table

MoveBufferArea(Int32, Int32, Int32, Int32, Int32, Int32)	Copies a specified source area of the screen buffer to a specified destination area.
MoveBufferArea(Int32, Int32, Int32, Int32, Int32, Int32, Char, ConsoleColor, ConsoleColor)	Copies a specified source area of the screen buffer to a specified destination area.

MoveBufferArea(Int32, Int32, Int32, Int32, Int32, Int32)

Copies a specified source area of the screen buffer to a specified destination area.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static void MoveBufferArea (int sourceLeft, int sourceTop, int
sourceWidth, int sourceHeight, int targetLeft, int targetTop);
```

Parameters

`sourceLeft` Int32

The leftmost column of the source area.

`sourceTop` Int32

The topmost row of the source area.

`sourceWidth` Int32

The number of columns in the source area.

`sourceHeight` Int32

The number of rows in the source area.

`targetLeft` Int32

The leftmost column of the destination area.

`targetTop` Int32

The topmost row of the destination area.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

One or more of the parameters is less than zero.

-or-

`sourceLeft` or `targetLeft` is greater than or equal to BufferWidth.

-or-

`sourceTop` or `targetTop` is greater than or equal to BufferHeight.

-or-

`sourceTop` + `sourceHeight` is greater than or equal to BufferHeight.

-or-

`sourceLeft` + `sourceWidth` is greater than or equal to BufferWidth.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The current operating system is not Windows.

Remarks

If the destination and source parameters specify a position located outside the boundaries of the current screen buffer, only the portion of the source area that fits within the destination area is copied. That is, the source area is clipped to fit the current screen buffer.

The MoveBufferArea method copies the source area to the destination area. If the destination area does not intersect the source area, the source area is filled with blanks using the current foreground and background colors. Otherwise, the intersected portion of the source area is not filled.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

MoveBufferArea(Int32, Int32, Int32, Int32, Int32, Int32, Char, ConsoleColor, ConsoleColor)

Copies a specified source area of the screen buffer to a specified destination area.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static void MoveBufferArea (int sourceLeft, int sourceTop, int
sourceWidth, int sourceHeight, int targetLeft, int targetTop, char
sourceChar, ConsoleColor sourceForeColor, ConsoleColor sourceBackColor);
```

Parameters

`sourceLeft` Int32

The leftmost column of the source area.

`sourceTop` Int32

The topmost row of the source area.

`sourceWidth` Int32

The number of columns in the source area.

`sourceHeight` Int32

The number of rows in the source area.

`targetLeft` Int32

The leftmost column of the destination area.

`targetTop` Int32

The topmost row of the destination area.

`sourceChar` Char

The character used to fill the source area.

`sourceForeColor` ConsoleColor

The foreground color used to fill the source area.

`sourceBackColor` ConsoleColor

The background color used to fill the source area.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

One or more of the parameters is less than zero.

-or-

`sourceLeft` or `targetLeft` is greater than or equal to BufferWidth.

-or-

`sourceTop` or `targetTop` is greater than or equal to BufferHeight.

-or-

`sourceTop` + `sourceHeight` is greater than or equal to BufferHeight.

-or-

`sourceLeft` + `sourceWidth` is greater than or equal to BufferWidth.

ArgumentException

One or both of the color parameters is not a member of the ConsoleColor enumeration.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The current operating system is not Windows.

Remarks

If the destination and source parameters specify a position located beyond the boundaries of the current screen buffer, only the portion of the source area that fits within the destination area is copied. That is, the source area is clipped to fit the current screen buffer.

The MoveBufferArea method copies the source area to the destination area. If the destination area does not intersect the source area, the source area is filled with the character specified by `sourceChar`, using the colors specified by `sourceForeColor` and `sourceBackColor`. Otherwise, the intersected portion of the source area is not filled.

The MoveBufferArea method performs no operation if `sourceWidth` or `sourceHeight` is zero.

Console.OpenStandardError Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Acquires the standard error stream.

Overloads

Expand table

OpenStandardError()	Acquires the standard error stream.
OpenStandardError(Int32)	Acquires the standard error stream, which is set to a specified buffer size.

OpenStandardError()

Acquires the standard error stream.

C#

```
public static System.IO.Stream OpenStandardError ();
```

Returns

Stream

The standard error stream.

Examples

The following example is a simple text file viewer that displays the contents of one or more text files to the console. If there are no command line arguments, or if any files passed as command line arguments do not exist, the example calls the SetError method to redirect error information to a file, calls the OpenStandardError method in

the process of reacquiring the standard error stream, and indicates that error information was written to a file.

C#

```
using System;
using System.IO;

public class ViewTextFile
{
   public static void Main()
   {
      String[] args = Environment.GetCommandLineArgs();
      String errorOutput = "";
      // Make sure that there is at least one command line argument.
      if (args.Length <= 1)
         errorOutput += "You must include a filename on the command
line.\n";

      for (int ctr = 1; ctr <= args.GetUpperBound(0); ctr++)  {
         // Check whether the file exists.
         if (! File.Exists(args[ctr])) {
            errorOutput += String.Format("'{0}' does not exist.\n",
args[ctr]);
         }
         else {
            // Display the contents of the file.
            StreamReader sr = new StreamReader(args[ctr]);
            String contents = sr.ReadToEnd();
            sr.Close();
            Console.WriteLine("*****Contents of file '{0}':\n\n",
                              args[ctr]);
            Console.WriteLine(contents);
            Console.WriteLine("*****\n");
         }
      }

      // Check for error conditions.
      if (! String.IsNullOrEmpty(errorOutput)) {
         // Write error information to a file.
         Console.SetError(new StreamWriter(@".\ViewTextFile.Err.txt"));
         Console.Error.WriteLine(errorOutput);
         Console.Error.Close();
         // Reacquire the standard error stream.
         var standardError = new
StreamWriter(Console.OpenStandardError());
         standardError.AutoFlush = true;
         Console.SetError(standardError);
         Console.Error.WriteLine("\nError information written to
ViewTextFile.Err.txt");
      }
   }
}
// If the example is compiled and run with the following command line:
```

```
//     ViewTextFile file1.txt file2.txt
// and neither file1.txt nor file2.txt exist, it displays the
// following output:
//     Error information written to ViewTextFile.Err.txt
// and writes the following text to ViewTextFile.Err.txt:
//     'file1.txt' does not exist.
//     'file2.txt' does not exist.
```

Note that the StreamWriter.AutoFlush property is set to `true` before reacquiring the error stream. This ensures that output will be sent to the console immediately rather than buffered.

Remarks

This method can be used to reacquire the standard error stream after it has been changed by the SetError method.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

OpenStandardError(Int32)

Acquires the standard error stream, which is set to a specified buffer size.

```
C#
```

```
public static System.IO.Stream OpenStandardError (int bufferSize);
```

Parameters

`bufferSize` Int32

This parameter has no effect, but its value must be greater than or equal to zero.

Returns

Stream

The standard error stream.

Exceptions

ArgumentOutOfRangeException

`bufferSize` is less than or equal to zero.

Remarks

This method can be used to reacquire the standard error stream after it has been changed by the SetError method.

Console.OpenStandardInput Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Acquires the standard input stream.

Overloads

Expand table

OpenStandardInput()	Acquires the standard input stream.
OpenStandardInput(Int32)	Acquires the standard input stream, which is set to a specified buffer size.

OpenStandardInput()

Acquires the standard input stream.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static System.IO.Stream OpenStandardInput ();
```

Returns

Stream

The standard input stream.

Attributes UnsupportedOSPlatformAttribute

Examples

The following example illustrates the use of the `OpenStandardInput` method.

C#

```
using System;
using System.Text;
using System.IO;

public class Decoder {
    public static void Main() {
        Stream inputStream = Console.OpenStandardInput();
        byte[] bytes = new byte[100];
        Console.WriteLine("To decode, type or paste the UTF7 encoded
string and press enter:");
        Console.WriteLine("(Example: \"M+APw-nchen ist wundervoll\")");
        int outputLength = inputStream.Read(bytes, 0, 100);
        char[] chars = Encoding.UTF7.GetChars(bytes, 0, outputLength);
        Console.WriteLine("Decoded string:");
        Console.WriteLine(new string(chars));
    }
}
```

Remarks

This method can be used to reacquire the standard input stream after it has been changed by the SetIn method.

Console.OpenStandardOutput Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Acquires the standard output stream.

Overloads

Expand table

OpenStandardOutput()	Acquires the standard output stream.
OpenStandardOutput(Int32)	Acquires the standard output stream, which is set to a specified buffer size.

OpenStandardOutput()

Acquires the standard output stream.

C#

```
public static System.IO.Stream OpenStandardOutput ();
```

Returns

Stream

The standard output stream.

Examples

The following example illustrates the use of the OpenStandardOutput method. It replaces four consecutive space characters in a string with a tab character. To run it, you must supply two command-line arguments. The first is the name of an existing text file to redirect the standard input stream to. The second is the name of a file to

redirect the standard output stream to. This file need not exist. If it does, its contents will be overwritten.

C#

```
using System;
using System.IO;

public class InsertTabs
{
    private const int tabSize = 4;
    private const string usageText = "Usage: INSERTTABS inputfile.txt
outputfile.txt";
    public static int Main(string[] args)
    {
        if (args.Length < 2)
        {
            Console.WriteLine(usageText);
            return 1;
        }

        try
        {
            // Attempt to open output file.
            using (var writer = new StreamWriter(args[1]))
            {
                using (var reader = new StreamReader(args[0]))
                {
                    // Redirect standard output from the console to the
output file.
                    Console.SetOut(writer);
                    // Redirect standard input from the console to the
input file.
                    Console.SetIn(reader);
                    string line;
                    while ((line = Console.ReadLine()) != null)
                    {
                        string newLine =
line.Replace(("").PadRight(tabSize, ' '), "\t");
                        Console.WriteLine(newLine);
                    }
                }
            }
        }
        catch(IOException e)
        {
            TextWriter errorWriter = Console.Error;
            errorWriter.WriteLine(e.Message);
            errorWriter.WriteLine(usageText);
            return 1;
        }

        // Recover the standard output stream so that a
        // completion message can be displayed.
```

```
        var standardOutput = new
StreamWriter(Console.OpenStandardOutput());
        standardOutput.AutoFlush = true;
        Console.SetOut(standardOutput);
        Console.WriteLine($"INSERTTABS has completed the processing of
{args[0]}.");
        return 0;
    }
}
```

Remarks

This method can be used to reacquire the standard output stream after it has been changed by the SetOut method.

Console.Read Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Reads the next character from the standard input stream.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
public static int Read ();
```

Returns

Int32

The next character from the input stream, or negative one (-1) if there are currently no more characters to be read.

Attributes UnsupportedOSPlatformAttribute

Exceptions

IOException

An I/O error occurred.

Examples

The following example demonstrates the Read method.

C#

```
// This example demonstrates the Console.Read() method.
using System;

class Sample
{
    public static void Main()
```

```
    {
    string m1 = "\nType a string of text then press Enter. " +
                "Type '+' anywhere in the text to quit:\n";
    string m2 = "Character '{0}' is hexadecimal 0x{1:x4}.";
    string m3 = "Character     is hexadecimal 0x{0:x4}.";
    char ch;
    int x;
//
    Console.WriteLine(m1);
    do
        {
        x = Console.Read();
        try
            {
            ch = Convert.ToChar(x);
            if (Char.IsWhiteSpace(ch))
               {
               Console.WriteLine(m3, x);
               if (ch == 0x0a)
                   Console.WriteLine(m1);
               }
            else
                {
                    Console.WriteLine(m2, ch, x);
                }
            }
        catch (OverflowException e)
            {
            Console.WriteLine("{0} Value read = {1}.", e.Message, x);
            ch = Char.MinValue;
            Console.WriteLine(m1);
            }
        } while (ch != '+');
    }
}
/*
This example produces the following results:

Type a string of text then press Enter. Type '+' anywhere in the text to
quit:

The quick brown fox.
Character 'T' is hexadecimal 0x0054.
Character 'h' is hexadecimal 0x0068.
Character 'e' is hexadecimal 0x0065.
Character     is hexadecimal 0x0020.
Character 'q' is hexadecimal 0x0071.
Character 'u' is hexadecimal 0x0075.
Character 'i' is hexadecimal 0x0069.
Character 'c' is hexadecimal 0x0063.
Character 'k' is hexadecimal 0x006b.
Character     is hexadecimal 0x0020.
Character 'b' is hexadecimal 0x0062.
Character 'r' is hexadecimal 0x0072.
Character 'o' is hexadecimal 0x006f.
```

```
Character 'w' is hexadecimal 0x0077.
Character 'n' is hexadecimal 0x006e.
Character     is hexadecimal 0x0020.
Character 'f' is hexadecimal 0x0066.
Character 'o' is hexadecimal 0x006f.
Character 'x' is hexadecimal 0x0078.
Character '.' is hexadecimal 0x002e.
Character     is hexadecimal 0x000d.
Character     is hexadecimal 0x000a.

Type a string of text then press Enter. Type '+' anywhere in the text to
quit:

^Z
Value was either too large or too small for a character. Value read = -1.

Type a string of text then press Enter. Type '+' anywhere in the text to
quit:

+
Character '+' is hexadecimal 0x002b.

*/
```

Remarks

The Read method blocks its return while you type input characters; it terminates when you press the Enter key. Pressing Enter appends a platform-dependent line termination sequence to your input (for example, Windows appends a carriage return-linefeed sequence). Subsequent calls to the Read method retrieve your input one character at a time. After the final character is retrieved, Read blocks its return again and the cycle repeats.

> ⓘ **Important**
>
> The **ReadLine** method, or the **KeyAvailable** property and **ReadKey** method are preferable to using the **Read** method.

Note that the method does not return -1 unless you perform one of the following actions:

- Simultaneously press the Control modifier key and Z console key (Ctrl+Z), which signals the end-of-file condition. If you're on Windows, you must also press the Enter console key.

- Press an equivalent key that signals the end-of-file condition, such as the F6 function key in Windows.
- Redirect the input stream to a source, such as a text file, that has an actual end-of-file character.

Console.ReadKey Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Obtains the next character or function key pressed by the user.

Overloads

Expand table

ReadKey()	Obtains the next character or function key pressed by the user. The pressed key is displayed in the console window.
ReadKey(Boolean)	Obtains the next character or function key pressed by the user. The pressed key is optionally displayed in the console window.

ReadKey()

Obtains the next character or function key pressed by the user. The pressed key is displayed in the console window.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static ConsoleKeyInfo ReadKey ();
```

Returns

ConsoleKeyInfo

An object that describes the ConsoleKey constant and Unicode character, if any, that correspond to the pressed console key. The ConsoleKeyInfo object also describes, in

a bitwise combination of ConsoleModifiers values, whether one or more Shift, Alt, or Ctrl modifier keys was pressed simultaneously with the console key.

Attributes UnsupportedOSPlatformAttribute

Exceptions

InvalidOperationException

The In property is redirected from some stream other than the console.

Examples

One of the most common uses of the ReadKey() method is to halt program execution until the user presses a key and the app either terminates or displays an additional window of information. The following example uses the ReadKey() method to wait for the user to press the Enter key before terminating the app.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime dat = DateTime.Now;
      Console.WriteLine("The time: {0:d} at {0:t}", dat);
      TimeZoneInfo tz = TimeZoneInfo.Local;
      Console.WriteLine("The time zone: {0}\n",
                        tz.IsDaylightSavingTime(dat) ?
                           tz.DaylightName : tz.StandardName);
      Console.Write("Press <Enter> to exit... ");
      while (Console.ReadKey().Key != ConsoleKey.Enter) {}
   }
}
// The example displays output like the following:
//     The time: 11/11/2015 at 4:02 PM:
//     The time zone: Pacific Standard Time
```

Note that this overload of the ReadKey method by default echoes any displayable keys that the user presses to the console. To suppress them, call the ReadKey method with an `intercept` argument of `true`.

The following example uses the ReadKey() method to display information about which key the user pressed.

C#

```
using System;

class Example
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT,
and a console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do
      {
         cki = Console.ReadKey();
         Console.Write(" --- You pressed ");
         if((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
         if((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
         if((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
         Console.WriteLine(cki.Key.ToString());
       } while (cki.Key != ConsoleKey.Escape);
    }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       a --- You pressed A
//       k --- You pressed ALT+K
//       ► --- You pressed CTL+P
//         --- You pressed RightArrow
//       R --- You pressed SHIFT+R
//                --- You pressed CTL+I
//       j --- You pressed ALT+J
//       O --- You pressed SHIFT+O
//       § --- You pressed CTL+U
```

Remarks

The ReadKey method waits, that is, blocks on the thread issuing the ReadKey method, until a character or function key is pressed. A character or function key can be pressed in combination with one or more Alt, Ctrl, or Shift modifier keys. However, pressing a modifier key by itself will not cause the ReadKey method to return.

Depending on your application, you might want to use the ReadKey method in conjunction with the KeyAvailable property.

The ReadKey method reads from the keyboard even if the standard input is redirected to a file with the SetIn method.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

ReadKey(Boolean)

Obtains the next character or function key pressed by the user. The pressed key is optionally displayed in the console window.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static ConsoleKeyInfo ReadKey (bool intercept);
```

Parameters

`intercept` Boolean

Determines whether to display the pressed key in the console window. `true` to not display the pressed key; otherwise, `false`.

Returns

ConsoleKeyInfo

An object that describes the ConsoleKey constant and Unicode character, if any, that correspond to the pressed console key. The ConsoleKeyInfo object also describes, in a bitwise combination of ConsoleModifiers values, whether one or more Shift, Alt, or Ctrl modifier keys was pressed simultaneously with the console key.

Attributes UnsupportedOSPlatformAttribute

Exceptions

InvalidOperationException

The In property is redirected from some stream other than the console.

Examples

One of the most common uses of the ReadKey method is to halt program execution until the user presses a key and the app either terminates or displays an additional window of information. The following example uses the ReadKey(Boolean) method to wait for the user to press the Enter key before terminating the app. Note that, if the user presses any other key, it is not echoed to the console.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime dat = DateTime.Now;
      Console.WriteLine("The time: {0:d} at {0:t}", dat);
      TimeZoneInfo tz = TimeZoneInfo.Local;
      Console.WriteLine("The time zone: {0}\n",
                        tz.IsDaylightSavingTime(dat) ?
                           tz.DaylightName : tz.StandardName);
      Console.Write("Press <Enter> to exit... ");
      while (Console.ReadKey(true).Key != ConsoleKey.Enter) {}
   }
}
// The example displays output like the following:
```

```
//      The time: 11/11/2015 at 4:02 PM:
//      The time zone: Pacific Standard Time
```

The following example uses the ReadKey(Boolean) method to display information about the key pressed by a user without echoing that key to the console.

```C#
using System;

class Example
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT,
and a console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do {
         cki = Console.ReadKey(true);
         Console.Write("You pressed ");
         if ((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
         if ((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
         if ((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
         Console.WriteLine("{0} (character '{1}')", cki.Key,
cki.KeyChar);
      } while (cki.Key != ConsoleKey.Escape);
   }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       You pressed CTL+A (character '☺')
//       You pressed C (character 'c')
//       You pressed CTL+C (character '♥')
//       You pressed K (character 'k')
//       You pressed ALT+I (character 'i')
//       You pressed ALT+U (character 'u')
//       You pressed ALT+SHIFT+H (character 'H')
//       You pressed Escape (character '←')
```

Remarks

The ReadKey method waits, that is, blocks on the thread issuing the ReadKey method, until a character or function key is pressed. A character or function key can be pressed in combination with one or more Alt, Ctrl, or Shift modifier keys. However, pressing a modifier key by itself will not cause the ReadKey method to return.

If the `intercept` parameter is `true`, the pressed key is intercepted and not displayed in the console window; otherwise, the pressed key is displayed.

Depending on your application, you might want to use the ReadKey method in conjunction with the KeyAvailable property.

The ReadKey method reads from the keyboard even if the standard input is redirected to a file with the SetIn method.

Console.ReadLine Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Reads the next line of characters from the standard input stream.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
public static string? ReadLine ();
```

Returns

String

The next line of characters from the input stream, or `null` if no more lines are available.

Attributes UnsupportedOSPlatformAttribute

Exceptions

IOException

An I/O error occurred.

OutOfMemoryException

There is insufficient memory to allocate a buffer for the returned string.

ArgumentOutOfRangeException

The number of characters in the next line of characters is greater than Int32.MaxValue.

Examples

The following example requires two command line arguments: the name of an existing text file, and the name of a file to write the output to. It opens the existing text file and redirects the standard input from the keyboard to that file. It also redirects the standard

output from the console to the output file. It then uses the Console.ReadLine method to read each line in the file, replaces every sequence of four spaces with a tab character, and uses the Console.WriteLine method to write the result to the output file.

C#

```
using System;
using System.IO;

public class InsertTabs
{
    private const int tabSize = 4;
    private const string usageText = "Usage: INSERTTABS inputfile.txt
outputfile.txt";
    public static int Main(string[] args)
    {
        if (args.Length < 2)
        {
            Console.WriteLine(usageText);
            return 1;
        }

        try
        {
            // Attempt to open output file.
            using (var writer = new StreamWriter(args[1]))
            {
                using (var reader = new StreamReader(args[0]))
                {
                    // Redirect standard output from the console to the
output file.
                    Console.SetOut(writer);
                    // Redirect standard input from the console to the input
file.
                    Console.SetIn(reader);
                    string line;
                    while ((line = Console.ReadLine()) != null)
                    {
                        string newLine = line.Replace(("").PadRight(tabSize,
' '), "\t");
                        Console.WriteLine(newLine);
                    }
                }
            }
        }
        catch(IOException e)
        {
            TextWriter errorWriter = Console.Error;
            errorWriter.WriteLine(e.Message);
            errorWriter.WriteLine(usageText);
            return 1;
        }
```

```
        // Recover the standard output stream so that a
        // completion message can be displayed.
        var standardOutput = new StreamWriter(Console.OpenStandardOutput());
        standardOutput.AutoFlush = true;
        Console.SetOut(standardOutput);
        Console.WriteLine($"INSERTTABS has completed the processing of
{args[0]}.");
        return 0;
    }
}
```

Remarks

The ReadLine method reads a line from the standard input stream. (For the definition of a line, see the paragraph after the following list.) This means that:

- If the standard input device is the keyboard, the ReadLine method blocks until the user presses the **Enter** key.

  One of the most common uses of the ReadLine method is to pause program execution before clearing the console and displaying new information to it, or to prompt the user to press the Enter key before terminating the application. The following example illustrates this.

  C#

  ```
  using System;

  public class Example
  {
     public static void Main()
     {
        Console.Clear();

        DateTime dat = DateTime.Now;

        Console.WriteLine("\nToday is {0:d} at {0:T}.", dat);
        Console.Write("\nPress any key to continue... ");
        Console.ReadLine();
     }
  }
  // The example displays output like the following:
  //     Today is 10/26/2015 at 12:22:22 PM.
  //
  //     Press any key to continue...
  ```

- If standard input is redirected to a file, the ReadLine method reads a line of text from a file. For example, the following is a text file named ReadLine1.txt:

```
This is the first line.
This is the second line.
This is the third line.
This is the fourth line.
```

The following example uses the ReadLine method to read input that is redirected from a file. The read operation terminates when the method returns `null`, which indicates that no lines remain to be read.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      if (! Console.IsInputRedirected) {
         Console.WriteLine("This example requires that input be
redirected from a file.");
         return;
      }

      Console.WriteLine("About to call Console.ReadLine in a loop.");
      Console.WriteLine("----");
      String s;
      int ctr = 0;
      do {
         ctr++;
         s = Console.ReadLine();
         Console.WriteLine("Line {0}: {1}", ctr, s);
      } while (s != null);
      Console.WriteLine("---");
   }
}
// The example displays the following output:
//       About to call Console.ReadLine in a loop.
//       ----
//       Line 1: This is the first line.
//       Line 2: This is the second line.
//       Line 3: This is the third line.
//       Line 4: This is the fourth line.
//       Line 5:
//       ---
```

After compiling the example to an executable named ReadLine1.exe, you can run it from the command line to read the contents of the file and display them to the console. The syntax is:

```
ReadLine1 < ReadLine1.txt
```

A line is defined as a sequence of characters followed by a carriage return (hexadecimal 0x000d), a line feed (hexadecimal 0x000a), or the value of the Environment.NewLine property. The returned string does not contain the terminating character(s). By default, the method reads input from a 256-character input buffer. Because this includes the Environment.NewLine character(s), the method can read lines that contain up to 254 characters. To read longer lines, call the OpenStandardInput(Int32) method.

The ReadLine method executes synchronously. That is, it blocks until a line is read or the `Ctrl+Z` keyboard combination (followed by `Enter` on Windows), is pressed. The In property returns a TextReader object that represents the standard input stream and that has both a synchronous TextReader.ReadLine method and an asynchronous TextReader.ReadLineAsync method. However, when used as the console's standard input stream, the TextReader.ReadLineAsync executes synchronously rather than asynchronously and returns a `Task<String>` only after the read operation has completed.

If this method throws an OutOfMemoryException exception, the reader's position in the underlying Stream object is advanced by the number of characters the method was able to read, but the characters already read into the internal ReadLine buffer are discarded. Since the position of the reader in the stream cannot be changed, the characters already read are unrecoverable, and can be accessed only by reinitializing the TextReader. If the initial position within the stream is unknown or the stream does not support seeking, the underlying Stream also needs to be reinitialized. To avoid such a situation and to produce robust code, you should use the KeyAvailable property and ReadKey method and store the read characters in a pre-allocated buffer.

If the `Ctrl+Z` key combination (followed by `Enter` on Windows) is pressed when the method is reading input from the console, the method returns `null`. This enables the user to prevent further keyboard input when the ReadLine method is called in a loop. The following example illustrates this scenario.

```C#
using System;
```

```
public class Example
{
   public static void Main()
   {
      string line;
      Console.WriteLine("Enter one or more lines of text (press CTRL+Z to
exit):");
      Console.WriteLine();
      do {
         Console.Write("   ");
         line = Console.ReadLine();
         if (line != null)
            Console.WriteLine("      " + line);
      } while (line != null);
   }
}
// The following displays possible output from this example:
//       Enter one or more lines of text (press CTRL+Z to exit):
//
//          This is line #1.
//             This is line #1.
//          This is line #2
//             This is line #2
//          ^Z
//
//       >
```

Console.ResetColor Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the foreground and background console colors to their defaults.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static void ResetColor ();
```

Attributes UnsupportedOSPlatformAttribute

Exceptions

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

Examples

The following example saves the values of the ConsoleColor enumeration to an array and stores the current values of the BackgroundColor and ForegroundColor properties to variables. It then changes the foreground color to each color in the ConsoleColor enumeration except to the color that matches the current background, and it changes the background color to each color in the ConsoleColor enumeration except to the color that matches the current foreground. (If the foreground color is the same as the background color, the text isn't visible.) Finally, it calls the ResetColor method to restore the original console colors.

C#

```
using System;

class Example
{
   public static void Main()
   {
      // Get an array with the values of ConsoleColor enumeration members.
      ConsoleColor[] colors = (ConsoleColor[])
ConsoleColor.GetValues(typeof(ConsoleColor));
      // Save the current background and foreground colors.
      ConsoleColor currentBackground = Console.BackgroundColor;
      ConsoleColor currentForeground = Console.ForegroundColor;

      // Display all foreground colors except the one that matches the
background.
      Console.WriteLine("All the foreground colors except {0}, the
background color:",
                        currentBackground);
      foreach (var color in colors) {
         if (color == currentBackground) continue;

         Console.ForegroundColor = color;
         Console.WriteLine("   The foreground color is {0}.", color);
      }
      Console.WriteLine();
      // Restore the foreground color.
      Console.ForegroundColor = currentForeground;

      // Display each background color except the one that matches the
current foreground color.
      Console.WriteLine("All the background colors except {0}, the
foreground color:",
                        currentForeground);
      foreach (var color in colors) {
         if (color == currentForeground) continue;

         Console.BackgroundColor = color;
         Console.WriteLine("   The background color is {0}.", color);
      }

      // Restore the original console colors.
      Console.ResetColor();
      Console.WriteLine("\nOriginal colors restored...");
   }
}
//The example displays output like the following:
//    All the foreground colors except DarkCyan, the background color:
//       The foreground color is Black.
//       The foreground color is DarkBlue.
//       The foreground color is DarkGreen.
//       The foreground color is DarkRed.
//       The foreground color is DarkMagenta.
//       The foreground color is DarkYellow.
//       The foreground color is Gray.
```

```
//       The foreground color is DarkGray.
//       The foreground color is Blue.
//       The foreground color is Green.
//       The foreground color is Cyan.
//       The foreground color is Red.
//       The foreground color is Magenta.
//       The foreground color is Yellow.
//       The foreground color is White.
//
//    All the background colors except White, the foreground color:
//       The background color is Black.
//       The background color is DarkBlue.
//       The background color is DarkGreen.
//       The background color is DarkCyan.
//       The background color is DarkRed.
//       The background color is DarkMagenta.
//       The background color is DarkYellow.
//       The background color is Gray.
//       The background color is DarkGray.
//       The background color is Blue.
//       The background color is Green.
//       The background color is Cyan.
//       The background color is Red.
//       The background color is Magenta.
//       The background color is Yellow.
//
//    Original colors restored...
```

Remarks

The foreground and background colors are restored to the colors that existed when the current process began. For more information, see the ForegroundColor and BackgroundColor properties.

Console.SetBufferSize(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the height and width of the screen buffer area to the specified values.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static void SetBufferSize (int width, int height);
```

Parameters

width Int32

The width of the buffer area measured in columns.

height Int32

The height of the buffer area measured in rows.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

`height` or `width` is less than or equal to zero.

-or-

`height` or `width` is greater than or equal to Int16.MaxValue.

-or-

`width` is less than WindowLeft + WindowWidth.

-or-

`height` is less than WindowTop + WindowHeight.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The current operating system is not Windows.

Examples

The following example demonstrates the WindowLeft, WindowTop, WindowWidth, WindowHeight, BufferWidth, BufferHeight, and CursorVisible properties; and the SetWindowPosition, SetBufferSize, and ReadKey methods. The example draws a grid pattern in the screen buffer based on the screen buffer width. Then the example moves the console window in response to which of the UP ARROW, DOWN ARROW, LEFT ARROW, or RIGHT ARROW console keys is pressed. The grid pattern helps you see the movement of the console window relative to the screen buffer.

C#

```
// This example demonstrates the Console.WindowLeft and
//                               Console.WindowTop properties.
using System;
using System.Text;
using System.IO;
//
class Sample
{
    public static int saveBufferWidth;
    public static int saveBufferHeight;
    public static int saveWindowHeight;
    public static int saveWindowWidth;
    public static bool saveCursorVisible;
//
    public static void Main()
    {
    string m1 = "1) Press the cursor keys to move the console window.\n" +
                "2) Press any key to begin. When you're finished...\n" +
                "3) Press the Escape key to quit.";
    string g1 = "+----";
    string g2 = "|    ";
    string grid1;
    string grid2;
    StringBuilder sbG1 = new StringBuilder();
```

```
    StringBuilder sbG2 = new StringBuilder();
    ConsoleKeyInfo cki;
    int y;
//
    try
    {
    saveBufferWidth  = Console.BufferWidth;
    saveBufferHeight = Console.BufferHeight;
    saveWindowHeight = Console.WindowHeight;
    saveWindowWidth  = Console.WindowWidth;
    saveCursorVisible = Console.CursorVisible;
//
    Console.Clear();
    Console.WriteLine(m1);
    Console.ReadKey(true);

// Set the smallest possible window size before setting the buffer size.
    Console.SetWindowSize(1, 1);
    Console.SetBufferSize(80, 80);
    Console.SetWindowSize(40, 20);

// Create grid lines to fit the buffer. (The buffer width is 80, but
// this same technique could be used with an arbitrary buffer width.)
    for (y = 0; y < Console.BufferWidth/g1.Length; y++)
        {
        sbG1.Append(g1);
        sbG2.Append(g2);
        }
    sbG1.Append(g1, 0, Console.BufferWidth%g1.Length);
    sbG2.Append(g2, 0, Console.BufferWidth%g2.Length);
    grid1 = sbG1.ToString();
    grid2 = sbG2.ToString();

    Console.CursorVisible = false;
    Console.Clear();
    for (y = 0; y < Console.BufferHeight-1; y++)
        {
        if (y%3 == 0)
            Console.Write(grid1);
        else
            Console.Write(grid2);
        }

    Console.SetWindowPosition(0, 0);
    do
        {
        cki = Console.ReadKey(true);
        switch (cki.Key)
            {
            case ConsoleKey.LeftArrow:
                if (Console.WindowLeft > 0)
                    Console.SetWindowPosition(
                            Console.WindowLeft-1, Console.WindowTop);
                break;
            case ConsoleKey.UpArrow:
```

```
                if (Console.WindowTop > 0)
                    Console.SetWindowPosition(
                            Console.WindowLeft, Console.WindowTop-1);
                break;
            case ConsoleKey.RightArrow:
                if (Console.WindowLeft < (Console.BufferWidth-
Console.WindowWidth))
                    Console.SetWindowPosition(
                            Console.WindowLeft+1, Console.WindowTop);
                break;
            case ConsoleKey.DownArrow:
                if (Console.WindowTop < (Console.BufferHeight-
Console.WindowHeight))
                    Console.SetWindowPosition(
                            Console.WindowLeft, Console.WindowTop+1);
                break;
            }
        }
    while (cki.Key != ConsoleKey.Escape);  // end do-while
    } // end try
    catch (IOException e)
        {
        Console.WriteLine(e.Message);
        }
    finally
        {
        Console.Clear();
        Console.SetWindowSize(1, 1);
        Console.SetBufferSize(saveBufferWidth, saveBufferHeight);
        Console.SetWindowSize(saveWindowWidth, saveWindowHeight);
        Console.CursorVisible = saveCursorVisible;
        }
    } // end Main
} // end Sample
/*
This example produces results similar to the following:

1) Press the cursor keys to move the console window.
2) Press any key to begin. When you're finished...
3) Press the Escape key to quit.

Console.SetCursorPosition(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the position of the cursor.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static void SetCursorPosition (int left, int top);
```

Parameters

left Int32

The column position of the cursor. Columns are numbered from left to right starting at 0.

top Int32

The row position of the cursor. Rows are numbered from top to bottom starting at 0.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

`left` or `top` is less than zero.

-or-

`left` is greater than or equal to BufferWidth.

-or-

`top` is greater than or equal to BufferHeight.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

Examples

This example demonstrates the CursorLeft and CursorTop properties, and the SetCursorPosition and Clear methods. The example positions the cursor, which determines where the next write will occur, to draw a 5 character by 5 character rectangle using a combination of "+", "|", and "-" strings. Note that the rectangle could be drawn with fewer steps using a combination of other strings.

C#

```
// This example demonstrates the
//     Console.CursorLeft and
//     Console.CursorTop properties, and the
//     Console.SetCursorPosition and
//     Console.Clear methods.
using System;

class Sample
{
    protected static int origRow;
    protected static int origCol;

    protected static void WriteAt(string s, int x, int y)
    {
    try
        {
        Console.SetCursorPosition(origCol+x, origRow+y);
        Console.Write(s);
        }
    catch (ArgumentOutOfRangeException e)
        {
        Console.Clear();
        Console.WriteLine(e.Message);
        }
    }

    public static void Main()
    {
// Clear the screen, then save the top and left coordinates.
    Console.Clear();
    origRow = Console.CursorTop;
```

```
    origCol = Console.CursorLeft;

// Draw the left side of a 5x5 rectangle, from top to bottom.
    WriteAt("+", 0, 0);
    WriteAt("|", 0, 1);
    WriteAt("|", 0, 2);
    WriteAt("|", 0, 3);
    WriteAt("+", 0, 4);

// Draw the bottom side, from left to right.
    WriteAt("-", 1, 4); // shortcut: WriteAt("---", 1, 4)
    WriteAt("-", 2, 4); // ...
    WriteAt("-", 3, 4); // ...
    WriteAt("+", 4, 4);

// Draw the right side, from bottom to top.
    WriteAt("|", 4, 3);
    WriteAt("|", 4, 2);
    WriteAt("|", 4, 1);
    WriteAt("+", 4, 0);

// Draw the top side, from right to left.
    WriteAt("-", 3, 0); // shortcut: WriteAt("---", 1, 0)
    WriteAt("-", 2, 0); // ...
    WriteAt("-", 1, 0); // ...
//
    WriteAt("All done!", 0, 6);
    Console.WriteLine();
    }
}
/*
This example produces the following results:

+---+
|   |
|   |
|   |
+---+

All done!

*/
```

Remarks

Use the SetCursorPosition method to specify where the next write operation in the console window is to begin. If the specified cursor position is outside the area that is currently visible in the console window, the window origin changes automatically to make the cursor visible.

The cursor automatically moves to the next character position each time a character is written to the console window. If the cursor is at the bottom right character position of the console window, the next write operation causes the console window to scroll so the cursor remains visible. If you want to write a character to the bottom right character position without causing the console window to scroll, use the MoveBufferArea method to move a character to that position.

Console.SetError(TextWriter) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the Error property to the specified TextWriter object.

C#

```
public static void SetError (System.IO.TextWriter newError);
```

Parameters

`newError` TextWriter

A stream that is the new standard error output.

Exceptions

ArgumentNullException

`newError` is `null`.

SecurityException

The caller does not have the required permission.

Examples

The following example shows how to redirect the standard error stream to a file.

C#

```
using System;
using System.IO;
using System.Reflection;

public class RedirectStdErr
{
   public static void Main()
   {
      // Define file to receive error stream.
```

```
        DateTime appStart = DateTime.Now;
        string fn = @"c:\temp\errlog" + appStart.ToString("yyyyMMddHHmm") +
".log";
        TextWriter errStream = new StreamWriter(fn);
        string appName = typeof(RedirectStdErr).Assembly.Location;
        appName = appName.Substring(appName.LastIndexOf('\\') + 1);
        // Redirect standard error stream to file.
        Console.SetError(errStream);
        // Write file header.
        Console.Error.WriteLine("Error Log for Application {0}", appName);
        Console.Error.WriteLine();
        Console.Error.WriteLine("Application started at {0}.", appStart);
        Console.Error.WriteLine();
        //
        // Application code along with error output
        //
        // Close redirected error stream.
        Console.Error.Close();
    }
}
```

Remarks

By default, the Error property is set to the standard error output stream.

A StreamWriter that encapsulates a FileStream can be used to send error messages to a file.

Console.SetIn(TextReader) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the In property to the specified TextReader object.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static void SetIn (System.IO.TextReader newIn);
```

Parameters

newIn TextReader

A stream that is the new standard input.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentNullException

`newIn` is `null`.

SecurityException

The caller does not have the required permission.

Examples

The following example illustrates the use of the SetIn method. It replaces four consecutive space characters in a string with a tab character. To run it, you must supply two command line arguments. The first is the name of an existing text file to redirect the standard input stream to. The second is the name of a file to redirect the standard output stream to. This file need not exist. If it does, its contents will be overwritten.

C#

```
using System;
using System.IO;

public class InsertTabs
{
    private const int tabSize = 4;
    private const string usageText = "Usage: INSERTTABS inputfile.txt
outputfile.txt";
    public static int Main(string[] args)
    {
        if (args.Length < 2)
        {
            Console.WriteLine(usageText);
            return 1;
        }

        try
        {
            // Attempt to open output file.
            using (var writer = new StreamWriter(args[1]))
            {
                using (var reader = new StreamReader(args[0]))
                {
                    // Redirect standard output from the console to the
output file.
                    Console.SetOut(writer);
                    // Redirect standard input from the console to the input
file.
                    Console.SetIn(reader);
                    string line;
                    while ((line = Console.ReadLine()) != null)
                    {
                        string newLine = line.Replace(("").PadRight(tabSize,
' '), "\t");
                        Console.WriteLine(newLine);
                    }
                }
            }
        }
        catch(IOException e)
        {
            TextWriter errorWriter = Console.Error;
            errorWriter.WriteLine(e.Message);
            errorWriter.WriteLine(usageText);
            return 1;
        }

        // Recover the standard output stream so that a
        // completion message can be displayed.
        var standardOutput = new StreamWriter(Console.OpenStandardOutput());
        standardOutput.AutoFlush = true;
        Console.SetOut(standardOutput);
```

```
        Console.WriteLine($"INSERTTABS has completed the processing of
{args[0]}.");
        return 0;
    }
}
```

Remarks

By default, the In property is set to the standard input stream.

A StreamReader that encapsulates a FileStream can be used to receive input from a file.

Console.SetOut(TextWriter) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the Out property to target the TextWriter object.

```
C#

public static void SetOut (System.IO.TextWriter newOut);
```

Parameters

newOut TextWriter

A text writer to be used as the new standard output.

Exceptions

ArgumentNullException

`newOut` is `null`.

SecurityException

The caller does not have the required permission.

Examples

The following example illustrates the use of the SetOut method. It replaces four consecutive space characters in a string with a tab character. To run it, you must supply two command line arguments. The first is the name of an existing text file to redirect the standard input stream to. The second is the name of a file to redirect the standard output stream to. This file need not exist. If it does, its contents will be overwritten.

```
C#

using System;
using System.IO;

public class InsertTabs
```

```
{
    private const int tabSize = 4;
    private const string usageText = "Usage: INSERTTABS inputfile.txt
outputfile.txt";
    public static int Main(string[] args)
    {
        if (args.Length < 2)
        {
            Console.WriteLine(usageText);
            return 1;
        }

        try
        {
            // Attempt to open output file.
            using (var writer = new StreamWriter(args[1]))
            {
                using (var reader = new StreamReader(args[0]))
                {
                    // Redirect standard output from the console to the
output file.
                    Console.SetOut(writer);
                    // Redirect standard input from the console to the input
file.
                    Console.SetIn(reader);
                    string line;
                    while ((line = Console.ReadLine()) != null)
                    {
                        string newLine = line.Replace(("").PadRight(tabSize,
' '), "\t");
                        Console.WriteLine(newLine);
                    }
                }
            }
        }
        catch(IOException e)
        {
            TextWriter errorWriter = Console.Error;
            errorWriter.WriteLine(e.Message);
            errorWriter.WriteLine(usageText);
            return 1;
        }

        // Recover the standard output stream so that a
        // completion message can be displayed.
        var standardOutput = new StreamWriter(Console.OpenStandardOutput());
        standardOutput.AutoFlush = true;
        Console.SetOut(standardOutput);
        Console.WriteLine($"INSERTTABS has completed the processing of
{args[0]}.");
        return 0;
    }
}
```

Remarks

By default, the Out property is set to the standard output stream.

A StreamWriter that encapsulates a FileStream can be used to send output to a file. For example:

```C#
Console.WriteLine("Hello World");
FileStream fs = new FileStream("Test.txt", FileMode.Create);
// First, save the standard output.
TextWriter tmp = Console.Out;
StreamWriter sw = new StreamWriter(fs);
Console.SetOut(sw);
Console.WriteLine("Hello file");
Console.SetOut(tmp);
Console.WriteLine("Hello World");
sw.Close();
```

The actual object returned by Out may be a synchronized wrapper around the provided text writer.

Console.SetWindowPosition(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the position of the console window relative to the screen buffer.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static void SetWindowPosition (int left, int top);
```

Parameters

left Int32

The column position of the upper left corner of the console window.

top Int32

The row position of the upper left corner of the console window.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

`left` or `top` is less than zero.

-or-

`left` + WindowWidth is greater than BufferWidth.

-or-

`top` + WindowHeight is greater than BufferHeight.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The current operating system is not Windows.

Examples

The following example demonstrates the WindowLeft, WindowTop, WindowWidth, WindowHeight, BufferWidth, BufferHeight, and CursorVisible properties; and the SetWindowPosition, SetBufferSize, and ReadKey methods. The example draws a grid pattern in the screen buffer based on the screen buffer width. Then the example moves the console window in response to which of the UP ARROW, DOWN ARROW, LEFT ARROW, or RIGHT ARROW console keys is pressed. The grid pattern helps you see the movement of the console window relative to the screen buffer.

C#

```
// This example demonstrates the Console.WindowLeft and
//                               Console.WindowTop properties.
using System;
using System.Text;
using System.IO;
//
class Sample
{
    public static int saveBufferWidth;
    public static int saveBufferHeight;
    public static int saveWindowHeight;
    public static int saveWindowWidth;
    public static bool saveCursorVisible;
//
    public static void Main()
    {
    string m1 = "1) Press the cursor keys to move the console window.\n" +
                "2) Press any key to begin. When you're finished...\n" +
                "3) Press the Escape key to quit.";
    string g1 = "+----";
    string g2 = "|    ";
    string grid1;
    string grid2;
    StringBuilder sbG1 = new StringBuilder();
    StringBuilder sbG2 = new StringBuilder();
    ConsoleKeyInfo cki;
    int y;
//
```

```
    try
    {
    saveBufferWidth  = Console.BufferWidth;
    saveBufferHeight = Console.BufferHeight;
    saveWindowHeight = Console.WindowHeight;
    saveWindowWidth  = Console.WindowWidth;
    saveCursorVisible = Console.CursorVisible;
//
    Console.Clear();
    Console.WriteLine(m1);
    Console.ReadKey(true);

// Set the smallest possible window size before setting the buffer size.
    Console.SetWindowSize(1, 1);
    Console.SetBufferSize(80, 80);
    Console.SetWindowSize(40, 20);

// Create grid lines to fit the buffer. (The buffer width is 80, but
// this same technique could be used with an arbitrary buffer width.)
    for (y = 0; y < Console.BufferWidth/g1.Length; y++)
        {
        sbG1.Append(g1);
        sbG2.Append(g2);
        }
    sbG1.Append(g1, 0, Console.BufferWidth%g1.Length);
    sbG2.Append(g2, 0, Console.BufferWidth%g2.Length);
    grid1 = sbG1.ToString();
    grid2 = sbG2.ToString();

    Console.CursorVisible = false;
    Console.Clear();
    for (y = 0; y < Console.BufferHeight-1; y++)
        {
        if (y%3 == 0)
            Console.Write(grid1);
        else
            Console.Write(grid2);
        }

    Console.SetWindowPosition(0, 0);
    do
        {
        cki = Console.ReadKey(true);
        switch (cki.Key)
            {
            case ConsoleKey.LeftArrow:
                if (Console.WindowLeft > 0)
                    Console.SetWindowPosition(
                            Console.WindowLeft-1, Console.WindowTop);
                break;
            case ConsoleKey.UpArrow:
                if (Console.WindowTop > 0)
                    Console.SetWindowPosition(
                            Console.WindowLeft, Console.WindowTop-1);
                break;
```

```
            case ConsoleKey.RightArrow:
                if (Console.WindowLeft < (Console.BufferWidth-
Console.WindowWidth))
                    Console.SetWindowPosition(
                            Console.WindowLeft+1, Console.WindowTop);
                break;
            case ConsoleKey.DownArrow:
                if (Console.WindowTop < (Console.BufferHeight-
Console.WindowHeight))
                    Console.SetWindowPosition(
                            Console.WindowLeft, Console.WindowTop+1);
                break;
            }
        }
    while (cki.Key != ConsoleKey.Escape);  // end do-while
    } // end try
    catch (IOException e)
        {
        Console.WriteLine(e.Message);
        }
    finally
        {
        Console.Clear();
        Console.SetWindowSize(1, 1);
        Console.SetBufferSize(saveBufferWidth, saveBufferHeight);
        Console.SetWindowSize(saveWindowWidth, saveWindowHeight);
        Console.CursorVisible = saveCursorVisible;
        }
    } // end Main
} // end Sample
/*
This example produces results similar to the following:

1) Press the cursor keys to move the console window.
2) Press any key to begin. When you're finished...
3) Press the Escape key to quit.

...

+----+----+----+-
|    |    |    |
|    |    |    |
+----+----+----+-
|    |    |    |
|    |    |    |
+----+----+----+-

*/
```

Remarks

The operating system window displays the console window, and the console window displays a portion of the screen buffer. The SetWindowPosition method affects the position of the console window relative to the screen buffer, but does not affect the position of the operating system window relative to the desktop.

The console and operating system windows generally do not affect each other. However, if the screen buffer cannot be displayed in the current boundaries of the console window, the operating system automatically appends scroll bars to the operating system window. In that case, moving the operating system window scroll bars affects the position of the console window, and moving the console window with the SetWindowPosition method affects the position of the operating system window scroll bars.

Console.SetWindowSize(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Sets the height and width of the console window to the specified values.

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static void SetWindowSize (int width, int height);
```

Parameters

width Int32

The width of the console window measured in columns.

height Int32

The height of the console window measured in rows.

Attributes UnsupportedOSPlatformAttribute

Exceptions

ArgumentOutOfRangeException

`width` or `height` is less than or equal to zero.

-or-

`width` plus WindowLeft or `height` plus WindowTop is greater than or equal to Int16.MaxValue.

-or-

`width` or `height` is greater than the largest possible window width or height for the current screen resolution and console font.

SecurityException

The user does not have permission to perform this action.

IOException

An I/O error occurred.

PlatformNotSupportedException

The current operating system is not Windows.

Examples

This example demonstrates the SetWindowSize method, and the WindowWidth and WindowHeight properties. You must run the example to see the full effect of changing the console window size.

The example reports the dimensions of a console window set to 85 columns and 43 rows, then waits for a key to be pressed. When any key is pressed, the dimensions of the console window are halved, the new dimensions are reported, and the example waits for another key press. Finally, when any key is pressed, the console window is restored to its original dimensions and the example terminates.

C#

```
// This example demonstrates the Console.SetWindowSize method,
//                            the Console.WindowWidth property,
//                        and the Console.WindowHeight property.
using System;

class Sample
{
    public static void Main()
    {
    int origWidth, width;
    int origHeight, height;
    string m1 = "The current window width is {0}, and the " +
                "current window height is {1}.";
    string m2 = "The new window width is {0}, and the new " +
                "window height is {1}.";
    string m4 = "  (Press any key to continue...)";
//
// Step 1: Get the current window dimensions.
//
    origWidth  = Console.WindowWidth;
```

```
    origHeight = Console.WindowHeight;
    Console.WriteLine(m1, Console.WindowWidth,
                          Console.WindowHeight);
    Console.WriteLine(m4);
    Console.ReadKey(true);
//
// Step 2: Cut the window to 1/4 its original size.
//
    width  = origWidth/2;
    height = origHeight/2;
    Console.SetWindowSize(width, height);
    Console.WriteLine(m2, Console.WindowWidth,
                          Console.WindowHeight);
    Console.WriteLine(m4);
    Console.ReadKey(true);
//
// Step 3: Restore the window to its original size.
//
    Console.SetWindowSize(origWidth, origHeight);
    Console.WriteLine(m1, Console.WindowWidth,
                          Console.WindowHeight);
    }
}
/*
This example produces the following results:

The current window width is 85, and the current window height is 43.
  (Press any key to continue...)
The new window width is 42, and the new window height is 21.
  (Press any key to continue...)
The current window width is 85, and the current window height is 43.

*/
```

Console.Write Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Writes the text representation of the specified value or values to the standard output stream.

Overloads

Expand table

Write(String, Object, Object, Object)	Writes the text representation of the specified objects to the standard output stream using the specified format information.
Write(String, Object, Object)	Writes the text representation of the specified objects to the standard output stream using the specified format information.
Write(String, Object[])	Writes the text representation of the specified array of objects to the standard output stream using the specified format information.
Write(String, Object)	Writes the text representation of the specified object to the standard output stream using the specified format information.
Write(UInt64)	Writes the text representation of the specified 64-bit unsigned integer value to the standard output stream.
Write(UInt32)	Writes the text representation of the specified 32-bit unsigned integer value to the standard output stream.
Write(String)	Writes the specified string value to the standard output stream.
Write(Char[], Int32, Int32)	Writes the specified subarray of Unicode characters to the standard output stream.
Write(Object)	Writes the text representation of the specified object to the standard output stream.
Write(Single)	Writes the text representation of the specified single-precision floating-point value to the standard output stream.
Write(Char)	Writes the specified Unicode character value to the standard output

	stream.
Write(Char[])	Writes the specified array of Unicode characters to the standard output stream.
Write(Boolean)	Writes the text representation of the specified Boolean value to the standard output stream.
Write(Double)	Writes the text representation of the specified double-precision floating-point value to the standard output stream.
Write(Int32)	Writes the text representation of the specified 32-bit signed integer value to the standard output stream.
Write(Int64)	Writes the text representation of the specified 64-bit signed integer value to the standard output stream.
Write(Decimal)	Writes the text representation of the specified Decimal value to the standard output stream.

Write(String, Object, Object, Object)

Writes the text representation of the specified objects to the standard output stream using the specified format information.

C#

```
public static void Write (string format, object? arg0, object? arg1,
object? arg2);
```

Parameters

`format` String

A composite format string.

`arg0` Object

The first object to write using `format`.

`arg1` Object

The second object to write using `format`.

`arg2` Object

The third object to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example uses the `WriteLine` method to demonstrate the standard formatting specifiers for numbers, dates, and enumerations.

C#

```
// This code example demonstrates the Console.WriteLine() method.
// Formatting for this example uses the "en-US" culture.

using System;
class Sample
{
    enum Color {Yellow = 1, Blue, Green};
    static DateTime thisDate = DateTime.Now;

    public static void Main()
    {
        Console.Clear();

        // Format a negative integer or floating-point number in various
ways.
        Console.WriteLine("Standard Numeric Format Specifiers");
        Console.WriteLine(
            "(C) Currency: . . . . . . . . {0:C}\n" +
            "(D) Decimal:. . . . . . . . . {0:D}\n" +
            "(E) Scientific: . . . . . . . {1:E}\n" +
            "(F) Fixed point:. . . . . . . {1:F}\n" +
            "(G) General:. . . . . . . . . {0:G}\n" +
            "    (default):. . . . . . . . {0} (default = 'G')\n" +
            "(N) Number: . . . . . . . . . {0:N}\n" +
            "(P) Percent:. . . . . . . . . {1:P}\n" +
            "(R) Round-trip: . . . . . . . {1:R}\n" +
            "(X) Hexadecimal:. . . . . . . {0:X}\n",
            -123, -123.45f);

        // Format the current date in various ways.
        Console.WriteLine("Standard DateTime Format Specifiers");
        Console.WriteLine(
```

```
            "(d) Short date: . . . . . {0:d}\n" +
            "(D) Long date:. . . . . {0:D}\n" +
            "(t) Short time: . . . . . {0:t}\n" +
            "(T) Long time:. . . . . {0:T}\n" +
            "(f) Full date/short time: . . {0:f}\n" +
            "(F) Full date/long time:. . . {0:F}\n" +
            "(g) General date/short time:. {0:g}\n" +
            "(G) General date/long time: . {0:G}\n" +
            "    (default):. . . . . {0} (default = 'G')\n" +
            "(M) Month:. . . . . {0:M}\n" +
            "(R) RFC1123:. . . . . {0:R}\n" +
            "(s) Sortable: . . . . . {0:s}\n" +
            "(u) Universal sortable: . . . {0:u} (invariant)\n" +
            "(U) Universal full date/time: {0:U}\n" +
            "(Y) Year: . . . . . {0:Y}\n",
            thisDate);

        // Format a Color enumeration value in various ways.
        Console.WriteLine("Standard Enumeration Format Specifiers");
        Console.WriteLine(
            "(G) General:. . . . . {0:G}\n" +
            "    (default):. . . . . {0} (default = 'G')\n" +
            "(F) Flags:. . . . . {0:F} (flags or integer)\n" +
            "(D) Decimal number: . . . . . {0:D}\n" +
            "(X) Hexadecimal:. . . . . {0:X}\n",
            Color.Green);
    }
}
/*
This code example produces the following results:

Standard Numeric Format Specifiers
(C) Currency: . . . . . ($123.00)
(D) Decimal:. . . . . -123
(E) Scientific: . . . . . -1.234500E+002
(F) Fixed point:. . . . . -123.45

*/
```

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{`*index*[`,`*alignment*][`:`*formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.
- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about date and time format specifiers, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.
- For more information about enumeration format specifiers, see Enumeration Format Strings.
- For more information about formatting, see Formatting Types.

Write(String, Object, Object)

Writes the text representation of the specified objects to the standard output stream using the specified format information.

C#

```
public static void Write (string format, object? arg0, object? arg1);
```

Parameters

`format` String

A composite format string.

`arg0` Object

The first object to write using `format`.

`arg1` Object

The second object to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example uses the `WriteLine` method to demonstrate the standard formatting specifiers for numbers, dates, and enumerations.

C#

```
// This code example demonstrates the Console.WriteLine() method.
// Formatting for this example uses the "en-US" culture.

using System;
class Sample
{
    enum Color {Yellow = 1, Blue, Green};
    static DateTime thisDate = DateTime.Now;

    public static void Main()
    {
        Console.Clear();

        // Format a negative integer or floating-point number in various
ways.
        Console.WriteLine("Standard Numeric Format Specifiers");
        Console.WriteLine(
            "(C) Currency: . . . . . . . . {0:C}\n" +
            "(D) Decimal:. . . . . . . . . {0:D}\n" +
            "(E) Scientific: . . . . . . . {1:E}\n" +
            "(F) Fixed point:. . . . . . . {1:F}\n" +
            "(G) General:. . . . . . . . . {0:G}\n" +

*/
```

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{`*index*[`,`*alignment*][`:`*formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(String, Object[])

Writes the text representation of the specified array of objects to the standard output stream using the specified format information.

```
C#

public static void Write (string format, params object?[]? arg);
```

Parameters

format String

A composite format string.

arg Object[]

An array of objects to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` or `arg` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example defines a `Person` class with a number of properties that provide information about a person. Its `GetDescription` method returns an array that contains all of the property values except one. The example then uses the array returned by the `GetDescription` method to display the values of the Person object.

```
C#

using System;

public class Person
{
   public String Name { get; set; }
   public DateTime BirthDate  { get; set; }
   public Double Height { get; set; }
   public Double Weight { get; set; }
```

```
   public Char Gender { get; set; }
   public String Remarks { get; set; }

   public object[] GetDescription()
   {
      return new object[] { Name, Gender, Height, Weight, BirthDate};
   }
}

public class Example
{
   public static void Main()
   {
      var p1 = new Person() { Name = "John", Gender = 'M',
                              BirthDate = new DateTime(1992, 5, 10),
                              Height = 73.5, Weight = 207 };
      p1.Remarks = "Client since 1/3/2012";
      Console.Write("{0}: {1}, born {4:d}  Height {2} inches, Weight {3}
lbs  ",
                    p1.GetDescription());
      if (String.IsNullOrEmpty(p1.Remarks))
         Console.WriteLine();
      else
         Console.WriteLine("{1}Remarks: {0}", p1.Remarks,
                           Console.CursorLeft + p1.Remarks.Length + 10 >
Console.WindowWidth ?
                              "\n   " : "");
   }
}
// The example displays the following output:
//    John: M, born 5/10/1992  Height 73.5 inches, Weight 207 lbs
Remarks: Client since 1/3/2012
```

Note that the example calls the Write(String, Object[]) method rather than the WriteLine(String, Object[]) method because it attempts to display the value of the `Person.Remarks` property on the same line. To do this, it examines the value of the CursorLeft and WindowWidth properties to determine whether there is enough space for the remark to fit. If there is, it displays the line. If not, it writes a line, indents three spaces, and displays the remark.

The following example is identical to the first, except that it supplies a five-item list as the `arg` argument instead of a parameter array.

C#

```
using System;

public class Person
{
   public String Name { get; set; }
   public DateTime BirthDate  { get; set; }
```

```
    public Double Height { get; set; }
    public Double Weight { get; set; }
    public Char Gender { get; set; }
    public String Remarks { get; set; }

    public object[] GetDescription()
    {
       return new object[] { Name, Gender, Height, Weight, BirthDate};
    }
 }

 public class Example
 {
    public static void Main()
    {
       var p1 = new Person() { Name = "John", Gender = 'M',
                               BirthDate = new DateTime(1992, 5, 10),
                               Height = 73.5, Weight = 207 };
       p1.Remarks = "Client since 1/3/2012";
       Console.Write("{0}: {1}, born {2:d}  Height {3} inches, Weight {4}
 lbs  ",
                      p1.Name, p1.Gender, p1.BirthDate, p1.Height,
 p1.Weight);
       if (String.IsNullOrEmpty(p1.Remarks))
          Console.WriteLine();
       else
          Console.WriteLine("{1}Remarks: {0}", p1.Remarks,
                            Console.CursorLeft + p1.Remarks.Length + 10 >
 Console.WindowWidth ?
                               "\n    " : "");
    }
 }
 // The example displays the following output:
 //    John: M, born 5/10/1992  Height 73.5 inches, Weight 207 lbs
 Remarks: Client since 1/3/2012
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{`*index*[`,`*alignment*][`:`*formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an

optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.
- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about date and time format specifiers, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.
- For more information about enumeration format specifiers, see Enumeration Format Strings.
- For more information about formatting, see Formatting Types.

The `arg` parameter is a parameter array. Arguments can be passed to the method either as an array or as list of five or more items. The examples illustrate both forms of method call.

Notes to Callers

This method is not called by C++ code. The C++ compiler resolves calls to System.Console.Write that include a string and a list of four or more object parameters as a call to Write(String, Object, Object, Object, Object). It resolves calls to System.Console.Write that include a string and an object array as a call to Write(String, Object).

Write(String, Object)

Writes the text representation of the specified object to the standard output stream using the specified format information.

C#

```
public static void Write (string format, object? arg0);
```

Parameters

`format` String

A composite format string.

`arg0` Object

An object to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` is `null`.

FormatException

The format specification in `format` is invalid.

*/
```

The following example illustrates the use of the Write method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

This method uses the composite formatting feature of the .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{` *index*[`,` *alignment*][`:` *formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.
- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about date and time format specifiers, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.
- For more information about enumeration format specifiers, see Enumeration Format Strings.
- For more information about formatting, see Formatting Types.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(UInt64)

Important

This API is not CLS-compliant.

Writes the text representation of the specified 64-bit unsigned integer value to the standard output stream.

C#

```
[System.CLSCompliant(false)]
public static void Write (ulong value);
```

Parameters

value UInt64

The value to write.

Attributes CLSCompliantAttribute

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
```

```
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling the UInt64.ToString method.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(UInt32)

> Important
>
> This API is not CLS-compliant.

Writes the text representation of the specified 32-bit unsigned integer value to the standard output stream.

C#

```
[System.CLSCompliant(false)]
public static void Write (uint value);
```

Parameters

`value` UInt32

The value to write.

Attributes CLSCompliantAttribute

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
```

```
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling the UInt32.ToString method.

Write(String)

Writes the specified string value to the standard output stream.

C#

```
public static void Write (string? value);
```

Parameters

`value` String

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

If value is `null`, nothing is written to the standard output stream.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(Char[], Int32, Int32)

Writes the specified subarray of Unicode characters to the standard output stream.

C#

```
public static void Write (char[] buffer, int index, int count);
```

Parameters

`buffer` Char[]

An array of Unicode characters.

`index` Int32

The starting position in `buffer`.

`count` Int32

The number of characters to write.

Exceptions

ArgumentNullException

`buffer` is `null`.

ArgumentOutOfRangeException

`index` or `count` is less than zero.

ArgumentException

`index` plus `count` specify a position that is not within `buffer`.

IOException

An I/O error occurred.

Remarks

This method writes `count` characters starting at position `index` of `buffer` to the standard output stream.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(Object)

Writes the text representation of the specified object to the standard output stream.

C#

```
public static void Write (object? value);
```

Parameters

`value` Object

The value to write, or `null`.

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

If `value` is `null`, nothing is written and no exception is thrown. Otherwise, the `ToString` method of `value` is called to produce its string representation, and the resulting string is written to the standard output stream.

Write(Single)

Writes the text representation of the specified single-precision floating-point value to the standard output stream.

C#

```
public static void Write (float value);
```

Parameters

`value` Single

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling the Single.ToString method.

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(Boolean)

Writes the text representation of the specified Boolean value to the standard output stream.

C#

```
public static void Write (bool value);
```

Parameters

`value` Boolean

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling Boolean.ToString, which outputs either Boolean.TrueString or Boolean.FalseString.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Write(Double)

Writes the text representation of the specified double-precision floating-point value to the standard output stream.

C#

```
public static void Write (double value);
```

Parameters

`value` Double

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)
        {
            string[] fields = lineInput.Split(new char[] {'\t'});
            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling the Double.ToString method.

Write(Int32)

Writes the text representation of the specified 32-bit signed integer value to the standard output stream.

C#

```
public static void Write (int value);
```

Parameters

`value` Int32

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example illustrates the use of the `Write` method.

C#

```
public class FormatConverter
{
    public static void Main(string[] args)
    {
        string lineInput;
        while ((lineInput = Console.ReadLine()) != null)

            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling the Int32.ToString method.

            bool isFirstField = true;
            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
```

```
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling the Int64.ToString method.

            foreach (var item in fields)
            {
                if (isFirstField)
                    isFirstField = false;
                else
                    Console.Write(',');

                // If the field represents a boolean, replace with a
numeric representation.
                bool itemBool;
                if (Boolean.TryParse(item, out itemBool))
                    Console.Write(Convert.ToByte(itemBool));
                else
                    Console.Write(item);
            }
            Console.WriteLine();
        }
    }
}
```

Remarks

The text representation of `value` is produced by calling Decimal.ToString.

Console.WriteLine Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Writes the specified data, followed by the current line terminator, to the standard output stream.

Overloads

Expand table

WriteLine(String, Object, Object)	Writes the text representation of the specified objects, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(String)	Writes the specified string value, followed by the current line terminator, to the standard output stream.
WriteLine(Char[], Int32, Int32)	Writes the specified subarray of Unicode characters, followed by the current line terminator, to the standard output stream.
WriteLine(String, Object[])	Writes the text representation of the specified array of objects, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(String, Object)	Writes the text representation of the specified object, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(UInt64)	Writes the text representation of the specified 64-bit unsigned integer value, followed by the current line terminator, to the standard output stream.
WriteLine(UInt32)	Writes the text representation of the specified 32-bit unsigned integer value, followed by the current line terminator, to the standard output stream.
WriteLine(Single)	Writes the text representation of the specified single-precision floating-point value, followed by the current line terminator, to the standard output stream.

WriteLine(Decimal)	Writes the text representation of the specified Decimal value, followed by the current line terminator, to the standard output stream.
WriteLine(Int64)	Writes the text representation of the specified 64-bit signed integer value, followed by the current line terminator, to the standard output stream.
WriteLine(Int32)	Writes the text representation of the specified 32-bit signed integer value, followed by the current line terminator, to the standard output stream.
WriteLine(Double)	Writes the text representation of the specified double-precision floating-point value, followed by the current line terminator, to the standard output stream.
WriteLine(Char[])	Writes the specified array of Unicode characters, followed by the current line terminator, to the standard output stream.
WriteLine(Char)	Writes the specified Unicode character, followed by the current line terminator, value to the standard output stream.
WriteLine(Boolean)	Writes the text representation of the specified Boolean value, followed by the current line terminator, to the standard output stream.
WriteLine()	Writes the current line terminator to the standard output stream.
WriteLine(String, Object, Object, Object)	Writes the text representation of the specified objects, followed by the current line terminator, to the standard output stream using the specified format information.
WriteLine(Object)	Writes the text representation of the specified object, followed by the current line terminator, to the standard output stream.

Remarks

The default line terminator is a string whose value is a carriage return followed by a line feed ("\r\n" in C#, or `vbCrLf` in Visual Basic). You can change the line terminator by setting the TextWriter.NewLine property of the Out property to another string.

WriteLine(String, Object, Object)

Writes the text representation of the specified objects, followed by the current line terminator, to the standard output stream using the specified format information.

```
C#

public static void WriteLine (string format, object? arg0, object? arg1);
```

Parameters

`format` String

A composite format string.

`arg0` Object

The first object to write using `format`.

`arg1` Object

The second object to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example demonstrates the standard formatting specifiers for numbers, dates, and enumerations.

```
C#

// This code example demonstrates the Console.WriteLine() method.
// Formatting for this example uses the "en-US" culture.

using System;
class Sample
{
    enum Color {Yellow = 1, Blue, Green};
    static DateTime thisDate = DateTime.Now;

    public static void Main()
```

```
    {
        Console.Clear();

        // Format a negative integer or floating-point number in various
ways.
        Console.WriteLine("Standard Numeric Format Specifiers");
        Console.WriteLine(
            "(C) Currency: . . . . . . . . {0:C}\n" +
            "(D) Decimal:. . . . . . . . . {0:D}\n" +
            "(E) Scientific: . . . . . . . {1:E}\n" +
            "(F) Fixed point:. . . . . . . {1:F}\n" +
            "(G) General:. . . . . . . . . {0:G}\n" +
            "    (default):. . . . . . . . {0} (default = 'G')\n" +
            "(N) Number: . . . . . . . . . {0:N}\n" +
            "(P) Percent:. . . . . . . . . {1:P}\n" +
            "(R) Round-trip: . . . . . . . {1:R}\n" +
            "(X) Hexadecimal:. . . . . . . {0:X}\n",
            -123, -123.45f);

        // Format the current date in various ways.
        Console.WriteLine("Standard DateTime Format Specifiers");
        Console.WriteLine(
            "(d) Short date: . . . . . . . {0:d}\n" +
            "(D) Long date:. . . . . . . . {0:D}\n" +
            "(t) Short time: . . . . . . . {0:t}\n" +
            "(T) Long time:. . . . . . . . {0:T}\n" +
            "(f) Full date/short time: . . {0:f}\n" +
            "(F) Full date/long time:. . . {0:F}\n" +
            "(g) General date/short time:. {0:g}\n" +
            "(G) General date/long time: . {0:G}\n" +
            "    (default):. . . . . . . . {0} (default = 'G')\n" +
            "(M) Month:. . . . . . . . . . {0:M}\n" +
            "(R) RFC1123:. . . . . . . . . {0:R}\n" +
            "(s) Sortable: . . . . . . . . {0:s}\n" +
            "(u) Universal sortable: . . . {0:u} (invariant)\n" +
            "(U) Universal full date/time: {0:U}\n" +
            "(Y) Year: . . . . . . . . . . {0:Y}\n",
            thisDate);

        // Format a Color enumeration value in various ways.
        Console.WriteLine("Standard Enumeration Format Specifiers");
        Console.WriteLine(
            "(G) General:. . . . . . . . . {0:G}\n" +
            "    (default):. . . . . . . . {0} (default = 'G')\n" +
            "(F) Flags:. . . . . . . . . . {0:F} (flags or integer)\n" +
            "(D) Decimal number: . . . . . {0:D}\n" +
            "(X) Hexadecimal:. . . . . . . {0:X}\n",
            Color.Green);
    }
}
/*

*/
```

The following example is a tip calculator that calculates an 18% tip and uses the WriteLine method to display the amount of the original charge, the amount of the tip, and the total amount. The example is a console application that requires the user to supply the amount of the original charge as a command-line parameter.

C#

```
using System;

public class TipCalculator
{
    private const double tipRate = 0.18;
    public static void Main(string[] args)
    {
        double billTotal;
        if (args.Length == 0 || ! Double.TryParse(args[0], out
```

```
billTotal))
        {
            Console.WriteLine("usage: TIPCALC total");
            return;
        }
        double tip = billTotal * tipRate;
        Console.WriteLine();
        Console.WriteLine($"Bill total:\t{billTotal,8:c}");
        Console.WriteLine($"Tip total/rate:\t{tip,8:c} ({tipRate:p1})");
        Console.WriteLine(("").PadRight(24, '-'));
        Console.WriteLine($"Grand total:\t{billTotal + tip,8:c}");
    }
}

/*
>tipcalc 52.23

Bill total:       $52.23
Tip total/rate:    $9.40 (18.0 %)
------------------------
Grand total:      $61.63
*/
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{` *index*[`,` *alignment*][`:` *formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about date and time format specifiers, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.
- For more information about enumeration format specifiers, see Enumeration Format Strings.
- For more information about formatting, see Formatting Types.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(String)

Writes the specified string value, followed by the current line terminator, to the standard output stream.

```
C#
```

```
public static void WriteLine (string? value);
```

Parameters

`value` String

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The example changes the line terminator from its default value of "\r\n" or `vbCrLf` to "\r\n\r\n" or `vbCrLf` + `vbCrLf`. It then calls the WriteLine() and WriteLine(String) methods to display output to the console.

C#

```
string[] lines = { "This is the first line.",
                   "This is the second line." };
// Output the lines using the default newline sequence.
Console.WriteLine("With the default new line characters:");
Console.WriteLine();
foreach (string line in lines)
   Console.WriteLine(line);

Console.WriteLine();

// Redefine the newline characters to double space.
Console.Out.NewLine = "\r\n\r\n";
// Output the lines using the new newline sequence.
Console.WriteLine("With redefined new line characters:");
Console.WriteLine();
foreach (string line in lines)
   Console.WriteLine(line);

// The example displays the following output:
//       With the default new line characters:
//
//       This is the first line.
//       This is the second line.
//
//       With redefined new line characters:
//
//
```

```
//
//       This is the first line.
//
//       This is the second line.
```

Remarks

If value is `null`, only the line terminator is written to the standard output stream.

For more information about the line terminator, see the Remarks section of the WriteLine() method.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(Char[], Int32, Int32)

Writes the specified subarray of Unicode characters, followed by the current line terminator, to the standard output stream.

C#

```
public static void WriteLine (char[] buffer, int index, int count);
```

Parameters

`buffer` Char[]

An array of Unicode characters.

`index` Int32

The starting position in `buffer`.

`count` Int32

The number of characters to write.

Exceptions

ArgumentNullException

`buffer` is `null`.

ArgumentOutOfRangeException

`index` or `count` is less than zero.

ArgumentException

`index` plus `count` specify a position that is not within `buffer`.

IOException

An I/O error occurred.

Remarks

This method writes `count` characters starting at position `index` of `buffer` to the standard output stream.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(String, Object[])

Writes the text representation of the specified array of objects, followed by the current line terminator, to the standard output stream using the specified format information.

C#

```
public static void WriteLine (string format, params object?[]? arg);
```

Parameters

`format` String

A composite format string.

`arg` Object[]

An array of objects to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` or `arg` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example demonstrates the standard formatting specifiers for numbers, dates, and enumerations.

C#

```
// This code example demonstrates the Console.WriteLine() method.
// Formatting for this example uses the "en-US" culture.

using System;
class Sample
{
    enum Color {Yellow = 1, Blue, Green};
    static DateTime thisDate = DateTime.Now;

    public static void Main()
    {
        Console.Clear();

        // Format a negative integer or floating-point number in various
ways.
        Console.WriteLine("Standard Numeric Format Specifiers");
        Console.WriteLine(
            "(C) Currency: . . . . . . . . {0:C}\n" +
            "(D) Decimal:. . . . . . . . . {0:D}\n" +
            "(E) Scientific: . . . . . . . {1:E}\n" +
            "(F) Fixed point:. . . . . . . {1:F}\n" +
            "(G) General:. . . . . . . . . {0:G}\n" +
            "    (default):. . . . . . . . {0} (default = 'G')\n" +

*/
```

The following example is a tip calculator that calculates an 18% tip and uses the WriteLine method to display the amount of the original charge, the amount of the tip, and the total amount. The example is a console application that requires the user to supply the amount of the original charge as a command-line parameter.

C#

```
using System;

public class TipCalculator
{
    private const double tipRate = 0.18;
    public static void Main(string[] args)
    {
        double billTotal;
        if (args.Length == 0 || ! Double.TryParse(args[0], out
billTotal))
        {
            Console.WriteLine("usage: TIPCALC total");
            return;
        }
        double tip = billTotal * tipRate;
        Console.WriteLine();
        Console.WriteLine($"Bill total:\t{billTotal,8:c}");
        Console.WriteLine($"Tip total/rate:\t{tip,8:c} ({tipRate:p1})");
        Console.WriteLine(("").PadRight(24, '-'));
        Console.WriteLine($"Grand total:\t{billTotal + tip,8:c}");
    }
}

/*
>tipcalc 52.23

Bill total:       $52.23
Tip total/rate:    $9.40 (18.0 %)
------------------------
Grand total:      $61.63
*/
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the

parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{` *index*[`,` *alignment*][`:` *formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.
- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about date and time format specifiers, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.
- For more information about enumeration format specifiers, see Enumeration Format Strings.
- For more information about formatting, see Formatting Types.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

Notes to Callers

This method is not called by C++ code. The C++ compiler resolves calls to System.Console.WriteLine that include a string and a list of four or more object parameters as a call to WriteLine(String, Object, Object, Object, Object). It resolves calls to System.Console.WriteLine that include a string and an object array as a call to WriteLine(String, Object).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(String, Object)

Writes the text representation of the specified object, followed by the current line terminator, to the standard output stream using the specified format information.

C#

```
public static void WriteLine (string format, object? arg0);
```

Parameters

`format` String

A composite format string.

`arg0` Object

An object to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example calls the WriteLine(String, Object) method to display five randomly generated Boolean values.

C#

```
Random rnd = new Random();
// Generate five random Boolean values.
for (int ctr = 1; ctr <= 5; ctr++) {
   bool bln = rnd.Next(0, 2) == 1;
   Console.WriteLine($"True or False: {bln}");
}

// The example displays an output similar to the following:
//       True or False: False
//       True or False: True
//       True or False: False
//       True or False: False
//       True or False: True
```

The following example calls the WriteLine(String, Object) method to display the current date. Note that the format item in the `format` argument uses the "D" standard date and time format string to display the date in the long date format of the current culture.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("Today's date: {0:D}", DateTime.Now);
   }
}
// The example displays output like the following:
//       Today's date: Monday, April 1, 2019
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The

resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{` *index*[`,` *alignment*][`:` *formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.

WriteLine(UInt64)

> Important
>
> This API is not CLS-compliant.

Writes the text representation of the specified 64-bit unsigned integer value, followed by the current line terminator, to the standard output stream.

C#

```
[System.CLSCompliant(false)]
public static void WriteLine (ulong value);
```

Parameters

`value` UInt64

The value to write.

Attributes CLSCompliantAttribute

Exceptions

IOException

An I/O error occurred.

Examples

The following example is a tip calculator that calculates an 18% tip and uses the WriteLine method to display the amount of the original charge, the amount of the

tip, and the total amount. The example is a console application that requires the user to supply the amount of the original charge as a command-line parameter.

C#

```
using System;

public class TipCalculator
{
    private const double tipRate = 0.18;
    public static void Main(string[] args)
    {
        double billTotal;
        if (args.Length == 0 || ! Double.TryParse(args[0], out
billTotal))
        {
            Console.WriteLine("usage: TIPCALC total");
            return;
        }
        double tip = billTotal * tipRate;
        Console.WriteLine();
        Console.WriteLine($"Bill total:\t{billTotal,8:c}");
        Console.WriteLine($"Tip total/rate:\t{tip,8:c} ({tipRate:p1})");
        Console.WriteLine("").PadRight(24, '-'));
        Console.WriteLine($"Grand total:\t{billTotal + tip,8:c}");
    }
}

/*
>tipcalc 52.23

Bill total:       $52.23
Tip total/rate:    $9.40 (18.0 %)
------------------------
Grand total:      $61.63
*/
```

Remarks

The text representation of `value` is produced by calling the UInt64.ToString method.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

            return;
        }
        double tip = billTotal * tipRate;
        Console.WriteLine();
        Console.WriteLine($"Bill total:\t{billTotal,8:c}");
        Console.WriteLine($"Tip total/rate:\t{tip,8:c} ({tipRate:p1})");
        Console.WriteLine(("").PadRight(24, '-'));
        Console.WriteLine($"Grand total:\t{billTotal + tip,8:c}");
    }
}

/*
>tipcalc 52.23

Bill total:       $52.23
Tip total/rate:    $9.40 (18.0 %)
------------------------
Grand total:      $61.63
*/
```

Remarks

The text representation of `value` is produced by calling the Single.ToString method.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(Decimal)

Writes the text representation of the specified Decimal value, followed by the current line terminator, to the standard output stream.

C#

```
public static void WriteLine (decimal value);
```

Parameters

`value` Decimal

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example is a tip calculator that calculates an 18% tip and uses the WriteLine method to display the amount of the original charge, the amount of the

tip, and the total amount. The example is a console application that requires the user to supply the amount of the original charge as a command-line parameter.

C#

```
using System;

public class TipCalculator
{
    private const double tipRate = 0.18;
    public static void Main(string[] args)
    {
        double billTotal;
        if (args.Length == 0 || ! Double.TryParse(args[0], out
billTotal))
        {
            Console.WriteLine("usage: TIPCALC total");
            return;
        }
        double tip = billTotal * tipRate;
        Console.WriteLine();
        Console.WriteLine($"Bill total:\t{billTotal,8:c}");
        Console.WriteLine($"Tip total/rate:\t{tip,8:c} ({tipRate:p1})");
        Console.WriteLine("").PadRight(24, '-'));
        Console.WriteLine($"Grand total:\t{billTotal + tip,8:c}");
    }
}

/*
>tipcalc 52.23

Bill total:       $52.23
Tip total/rate:    $9.40 (18.0 %)
------------------------
Grand total:      $61.63
*/
```

Remarks

The text representation of `value` is produced by calling the Decimal.ToString method.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

WriteLine(Int64)

Writes the text representation of the specified 64-bit signed integer value, followed by the current line terminator, to the standard output stream.

C#

```
public static void WriteLine (long value);
```

Parameters

`value` Int64

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example is a tip calculator that calculates an 18% tip and uses the WriteLine method to display the amount of the original charge, the amount of the tip, and the total amount. The example is a console application that requires the user to supply the amount of the original charge as a command-line parameter.

C#

WriteLine(Char[])

Writes the specified array of Unicode characters, followed by the current line terminator, to the standard output stream.

C#

```
public static void WriteLine (char[]? buffer);
```

Parameters

`buffer` Char[]

A Unicode character array.

Exceptions

IOException

An I/O error occurred.

Remarks

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

WriteLine(Boolean)

Writes the text representation of the specified Boolean value, followed by the current line terminator, to the standard output stream.

C#

```
public static void WriteLine (bool value);
```

Parameters

`value` Boolean

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example generates ten random integers and uses the Console.WriteLine(Boolean) method to indicate whether they are even.

C#

```
// Assign 10 random integers to an array.
Random rnd = new Random();
int[] numbers = new int[10];
for (int ctr = 0; ctr <= numbers.GetUpperBound(0); ctr++)
   numbers[ctr] = rnd.Next();

// Determine whether the numbers are even or odd.
foreach (var number in numbers) {
   bool even = (number % 2 == 0);
   Console.WriteLine("Is {0} even:", number);
   Console.WriteLine(even);
```

```
    Console.WriteLine();
}
```

Remarks

The text representation of `value` is produced by calling the Boolean.ToString method.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

- Read()
- ReadLine()
- Write(String, Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine()

Writes the current line terminator to the standard output stream.

C#

```
public static void WriteLine ();
```

Exceptions

IOException

An I/O error occurred.

Examples

The example changes the line terminator from its default value of "\r\n" or `vbCrLf` to "\r\n\r\n" or `vbCrLf` + `vbCrLf`. It then calls the WriteLine() and WriteLine(String) methods to display output to the console.

C#

```
string[] lines = { "This is the first line.",
                   "This is the second line." };
// Output the lines using the default newline sequence.
Console.WriteLine("With the default new line characters:");
Console.WriteLine();
foreach (string line in lines)
   Console.WriteLine(line);

Console.WriteLine();

// Redefine the newline characters to double space.
Console.Out.NewLine = "\r\n\r\n";
// Output the lines using the new newline sequence.
Console.WriteLine("With redefined new line characters:");
Console.WriteLine();
foreach (string line in lines)
   Console.WriteLine(line);

// The example displays the following output:
//       With the default new line characters:
//
//       This is the first line.
//       This is the second line.
//
//       With redefined new line characters:
//
//
//
//       This is the first line.
//
//       This is the second line.
```

Remarks

The default line terminator is a string whose value is a carriage return followed by a line feed ("\r\n" in C#, or `vbCrLf` in Visual Basic). You can change the line terminator by setting the TextWriter.NewLine property of the Out property to another string. The example provides an illustration.

.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(String, Object, Object, Object)

Writes the text representation of the specified objects, followed by the current line terminator, to the standard output stream using the specified format information.

C#

```
public static void WriteLine (string format, object? arg0, object? arg1,
object? arg2);
```

Parameters

`format` String

A composite format string.

`arg0` Object

The first object to write using `format`.

`arg1` Object

The second object to write using `format`.

`arg2` Object

The third object to write using `format`.

Exceptions

IOException

An I/O error occurred.

ArgumentNullException

`format` is `null`.

FormatException

The format specification in `format` is invalid.

Examples

The following example demonstrates the standard formatting specifiers for numbers, dates, and enumerations.

C#

```
// This code example demonstrates the Console.WriteLine() method.
// Formatting for this example uses the "en-US" culture.

using System;
class Sample
{
    enum Color {Yellow = 1, Blue, Green};
    static DateTime thisDate = DateTime.Now;

    public static void Main()
    {
        Console.Clear();

        // Format a negative integer or floating-point number in various
ways.
        Console.WriteLine("Standard Numeric Format Specifiers");
        Console.WriteLine(
            "(C) Currency: . . . . . . . . {0:C}\n" +

*/
```

The following example is a tip calculator that calculates an 18% tip and uses the WriteLine method to display the amount of the original charge, the amount of the tip, and the total amount. The example is a console application that requires the user to supply the amount of the original charge as a command-line parameter.

C#

```
using System;

public class TipCalculator
{
    private const double tipRate = 0.18;
    public static void Main(string[] args)
    {
        double billTotal;
        if (args.Length == 0 || ! Double.TryParse(args[0], out
billTotal))
        {
            Console.WriteLine("usage: TIPCALC total");
            return;
        }
        double tip = billTotal * tipRate;
        Console.WriteLine();
        Console.WriteLine($"Bill total:\t{billTotal,8:c}");
        Console.WriteLine($"Tip total/rate:\t{tip,8:c} ({tipRate:p1})");
        Console.WriteLine("").PadRight(24, '-'));
        Console.WriteLine($"Grand total:\t{billTotal + tip,8:c}");
    }
}

/*
>tipcalc 52.23
```

```
Bill total:       $52.23
Tip total/rate:    $9.40 (18.0 %)
------------------------
Grand total:      $61.63
*/
```

Remarks

This method uses the composite formatting feature of .NET to convert the value of an object to its text representation and embed that representation in a string. The resulting string is written to the output stream.

The `format` parameter consists of zero or more runs of text intermixed with zero or more indexed placeholders, called format items, that correspond to an object in the parameter list of this method. The formatting process replaces each format item with the text representation of the value of the corresponding object.

The syntax of a format item is `{` *index*[`,` *alignment*][`:` *formatString*]`}`, which specifies a mandatory index, the optional length and alignment of the formatted text, and an optional string of format specifier characters that govern how the value of the corresponding object is formatted.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics.

- For more information about the composite formatting feature supported by methods such as Format, AppendFormat, and some overloads of WriteLine, see Composite Formatting.
- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about date and time format specifiers, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.
- For more information about enumeration format specifiers, see Enumeration Format Strings.
- For more information about formatting, see Formatting Types.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

WriteLine(Object)

Writes the text representation of the specified object, followed by the current line terminator, to the standard output stream.

C#

```
public static void WriteLine (object? value);
```

Parameters

`value` Object

The value to write.

Exceptions

IOException

An I/O error occurred.

Examples

The following example uses the WriteLine(Object) method to display each value in an object array to the console.

```
C#

Object[] values = { true, 12.632, 17908, "stringValue",
                            'a', 16907.32m };
foreach (var value in values)
   Console.WriteLine(value);

// The example displays the following output:
//    True
//    12.632
//    17908
//    stringValue
//    a
//    16907.32
```

Remarks

If `value` is `null`, only the line terminator is written. Otherwise, the `ToString` method of `value` is called to produce its string representation, and the resulting string is written to the standard output stream.

For more information about the line terminator, see the Remarks section of the WriteLine method that takes no parameters.

Console.CancelKeyPress Event

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Occurs when the Control modifier key (Ctrl) and either the C console key (C) or the Break key are pressed simultaneously (Ctrl+C or Ctrl+Break).

C#

```
[System.Runtime.Versioning.UnsupportedOSPlatform("browser")]
[System.Runtime.Versioning.UnsupportedOSPlatform("android")]
[System.Runtime.Versioning.UnsupportedOSPlatform("ios")]
[System.Runtime.Versioning.UnsupportedOSPlatform("tvos")]
public static event ConsoleCancelEventHandler? CancelKeyPress;
```

Event Type

ConsoleCancelEventHandler

Attributes UnsupportedOSPlatformAttribute

Examples

The following example demonstrates how the CancelKeyPress event is used. When you press Ctrl+C, the read operation is interrupted and the `myHandler` event handler is invoked. Upon entry to the event handler, the ConsoleCancelEventArgs.Cancel property is `false`, which means that the current process will terminate when the event handler terminates. However, the event handler sets the ConsoleCancelEventArgs.Cancel property to `true`, which means that the process will not terminate and the read operation will resume.

C#

```
using System;

class Sample
{
```

```
    public static void Main()
    {
        ConsoleKeyInfo cki;

        Console.Clear();

        // Establish an event handler to process key press events.
        Console.CancelKeyPress += new ConsoleCancelEventHandler(myHandler);
        while (true)
        {
            Console.Write("Press any key, or 'X' to quit, or ");
            Console.WriteLine("CTRL+C to interrupt the read operation:");

            // Start a console read operation. Do not display the input.
            cki = Console.ReadKey(true);

            // Announce the name of the key that was pressed .
            Console.WriteLine($"  Key pressed: {cki.Key}\n");

            // Exit if the user pressed the 'X' key.
            if (cki.Key == ConsoleKey.X) break;
        }
    }

    protected static void myHandler(object sender, ConsoleCancelEventArgs
args)
    {
        Console.WriteLine("\nThe read operation has been interrupted.");

        Console.WriteLine($"  Key pressed: {args.SpecialKey}");

        Console.WriteLine($"  Cancel property: {args.Cancel}");

        // Set the Cancel property to true to prevent the process from
terminating.
        Console.WriteLine("Setting the Cancel property to true...");
        args.Cancel = true;

        // Announce the new value of the Cancel property.
        Console.WriteLine($"  Cancel property: {args.Cancel}");
        Console.WriteLine("The read operation will resume...\n");
    }
}
// The example displays output similar to the following:
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: J
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: Enter
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//
```

```
//    The read operation has been interrupted.
//      Key pressed: ControlC
//      Cancel property: False
//    Setting the Cancel property to true...
//      Cancel property: True
//    The read operation will resume...
//
//      Key pressed: Q
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: X
```

Remarks

This event is used in conjunction with System.ConsoleCancelEventHandler and System.ConsoleCancelEventArgs. The CancelKeyPress event enables a console application to intercept the Ctrl+C signal so the event handler can decide whether to continue executing or terminate. For more information about handling events, see Handling and Raising Events.

When the user presses either Ctrl+C or Ctrl+Break, the CancelKeyPress event is fired and the application's ConsoleCancelEventHandler event handler is executed. The event handler is passed a ConsoleCancelEventArgs object that has two useful properties:

- SpecialKey, which allows you to determine whether the handler was invoked as a result of the user pressing Ctrl+C (the property value is ConsoleSpecialKey.ControlC) or Ctrl+Break (the property value is ConsoleSpecialKey.ControlBreak).
- Cancel, which allows you to determine how your application should respond to the user pressing Ctrl+C or Ctrl+Break. By default, the Cancel property is `false`, which causes program execution to terminate when the event handler exits. Changing its property to `true` specifies that the application should continue to execute.

> **Tip**
>
> If your application has simple requirements, you can use the **TreatControlCAsInput** property instead of this event. By setting this property to `false`, you can ensure that your application always exits if the user presses Ctrl+C. By setting it to `true`, you can ensure that pressing Ctrl+C will not terminate the application.

The event handler for this event is executed on a thread pool thread.

ConsoleCancelEventArgs Class

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Provides data for the CancelKeyPress event. This class cannot be inherited.

C#

```
public sealed class ConsoleCancelEventArgs : EventArgs
```

Inheritance Object → EventArgs → ConsoleCancelEventArgs

Examples

The following example demonstrates how to use the ConsoleCancelEventArgs class to handle an event.

C#

```
using System;

class Sample
{
    public static void Main()
    {
        ConsoleKeyInfo cki;

        Console.Clear();

        // Establish an event handler to process key press events.
        Console.CancelKeyPress += new ConsoleCancelEventHandler(myHandler);
        while (true)
        {
            Console.Write("Press any key, or 'X' to quit, or ");
            Console.WriteLine("CTRL+C to interrupt the read operation:");

            // Start a console read operation. Do not display the input.
            cki = Console.ReadKey(true);

            // Announce the name of the key that was pressed .
            Console.WriteLine($"  Key pressed: {cki.Key}\n");
```

```
            // Exit if the user pressed the 'X' key.
            if (cki.Key == ConsoleKey.X) break;
        }
    }

    protected static void myHandler(object sender, ConsoleCancelEventArgs
args)
    {
        Console.WriteLine("\nThe read operation has been interrupted.");

        Console.WriteLine($"  Key pressed: {args.SpecialKey}");

        Console.WriteLine($"  Cancel property: {args.Cancel}");

        // Set the Cancel property to true to prevent the process from
terminating.
        Console.WriteLine("Setting the Cancel property to true...");
        args.Cancel = true;

        // Announce the new value of the Cancel property.
        Console.WriteLine($"  Cancel property: {args.Cancel}");
        Console.WriteLine("The read operation will resume...\n");
    }
}
// The example displays output similar to the following:
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: J
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: Enter
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//
//    The read operation has been interrupted.
//      Key pressed: ControlC
//      Cancel property: False
//    Setting the Cancel property to true...
//      Cancel property: True
//    The read operation will resume...
//
//      Key pressed: Q
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: X
```

Remarks

A user can interrupt a console application process by simultaneously pressing the Control modifier key and the C console key (Ctrl+C), or the Control modifier key and the Break console key (Ctrl+Break). Consequently, .NET provides a ConsoleCancelEventArgs object to the event handler for the Console.CancelKeyPress event to specify whether the process should be cancelled.

If the Cancel property is set to `true` in the event handler, the process is resumed; otherwise, the process is terminated. By default, the value of the ConsoleCancelEventArgs property is `false`, and the process terminates.

Properties

Expand table

Cancel	Gets or sets a value that indicates whether simultaneously pressing the Control modifier key and the C console key (Ctrl+C) or the Ctrl+Break keys terminates the current process. The default is `false`, which terminates the current process.
Special Key	Gets the combination of modifier and console keys that interrupted the current process.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

ConsoleCancelEventArgs.Cancel Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets or sets a value that indicates whether simultaneously pressing the Control modifier key and the C console key (Ctrl+C) or the Ctrl+Break keys terminates the current process. The default is `false`, which terminates the current process.

```
C#

public bool Cancel { get; set; }
```

Property Value

Boolean

`true` if the current process should resume when the event handler concludes; `false` if the current process should terminate. The default value is `false`; the current process terminates when the event handler returns. If `true`, the current process continues.

Examples

The following example demonstrates how to use the Cancel property to handle an event.

```
C#

using System;

class Sample
{
    public static void Main()
    {
        ConsoleKeyInfo cki;

        Console.Clear();
```

```
        // Establish an event handler to process key press events.
        Console.CancelKeyPress += new ConsoleCancelEventHandler(myHandler);
        while (true)
        {
            Console.Write("Press any key, or 'X' to quit, or ");
            Console.WriteLine("CTRL+C to interrupt the read operation:");

            // Start a console read operation. Do not display the input.
            cki = Console.ReadKey(true);

            // Announce the name of the key that was pressed .
            Console.WriteLine($"  Key pressed: {cki.Key}\n");

            // Exit if the user pressed the 'X' key.
            if (cki.Key == ConsoleKey.X) break;
        }
    }

    protected static void myHandler(object sender, ConsoleCancelEventArgs
args)
    {
        Console.WriteLine("\nThe read operation has been interrupted.");

        Console.WriteLine($"  Key pressed: {args.SpecialKey}");

        Console.WriteLine($"  Cancel property: {args.Cancel}");

        // Set the Cancel property to true to prevent the process from
terminating.
        Console.WriteLine("Setting the Cancel property to true...");
        args.Cancel = true;

        // Announce the new value of the Cancel property.
        Console.WriteLine($"  Cancel property: {args.Cancel}");
        Console.WriteLine("The read operation will resume...\n");
    }
}
// The example displays output similar to the following:
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: J
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: Enter
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//
//    The read operation has been interrupted.
//      Key pressed: ControlC
//      Cancel property: False
//    Setting the Cancel property to true...
//      Cancel property: True
```

```
//    The read operation will resume...
//
//      Key pressed: Q
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: X
```

Remarks

The Cancel property is automatically initialized to `false` when the handler for the CancelKeyPress event is invoked. The value of the Cancel property when the event handler finishes determines whether the current process resumes or terminates.

In a set operation after Ctrl+C is pressed, specify `true` to indicate that the current process should resume when the event handler concludes, or `false` to indicate that the current process should terminate.

Notes to Callers

In the .NET Framework 3.5 and .NET Framework 4, attempting to set the Cancel property to `true` if the CancelKeyPress event was invoked by the user pressing Ctrl+Break threw an InvalidOperationException exception. In the .NET Framework 4.5, you can set the Cancel property to `true` after the user presses Ctrl+Break and cancel the termination of the application.

ConsoleCancelEventArgs.SpecialKey Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the combination of modifier and console keys that interrupted the current process.

C#

```
public ConsoleSpecialKey SpecialKey { get; }
```

Property Value

ConsoleSpecialKey

One of the enumeration values that specifies the key combination that interrupted the current process. There is no default value.

Examples

The following example demonstrates how to use the SpecialKey property to handle an event.

C#

```
using System;

class Sample
{
    public static void Main()
    {
        ConsoleKeyInfo cki;

        Console.Clear();

        // Establish an event handler to process key press events.
        Console.CancelKeyPress += new ConsoleCancelEventHandler(myHandler);
        while (true)
        {
```

```
            Console.Write("Press any key, or 'X' to quit, or ");
            Console.WriteLine("CTRL+C to interrupt the read operation:");

            // Start a console read operation. Do not display the input.
            cki = Console.ReadKey(true);

            // Announce the name of the key that was pressed .
            Console.WriteLine($"  Key pressed: {cki.Key}\n");

            // Exit if the user pressed the 'X' key.
            if (cki.Key == ConsoleKey.X) break;
        }
    }

    protected static void myHandler(object sender, ConsoleCancelEventArgs
args)
    {
        Console.WriteLine("\nThe read operation has been interrupted.");

        Console.WriteLine($"  Key pressed: {args.SpecialKey}");

        Console.WriteLine($"  Cancel property: {args.Cancel}");

        // Set the Cancel property to true to prevent the process from
terminating.
        Console.WriteLine("Setting the Cancel property to true...");
        args.Cancel = true;

        // Announce the new value of the Cancel property.
        Console.WriteLine($"  Cancel property: {args.Cancel}");
        Console.WriteLine("The read operation will resume...\n");
    }
}
// The example displays output similar to the following:
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: J
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: Enter
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//
//    The read operation has been interrupted.
//      Key pressed: ControlC
//      Cancel property: False
//    Setting the Cancel property to true...
//      Cancel property: True
//    The read operation will resume...
//
//      Key pressed: Q
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
```

```
operation:
//      Key pressed: X
```

ConsoleCancelEventHandler Delegate

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Represents the method that will handle the CancelKeyPress event of a Console.

C#

```
public delegate void ConsoleCancelEventHandler(object? sender,
ConsoleCancelEventArgs e);
```

Parameters

sender Object

The source of the event.

e ConsoleCancelEventArgs

A ConsoleCancelEventArgs object that contains the event data.

Examples

The following code example demonstrates how to use the ConsoleCancelEventHandler class to handle an event.

C#

```
using System;

class Sample
{
    public static void Main()
    {
        ConsoleKeyInfo cki;

        Console.Clear();

        // Establish an event handler to process key press events.
        Console.CancelKeyPress += new ConsoleCancelEventHandler(myHandler);
        while (true)
```

```
        {
            Console.Write("Press any key, or 'X' to quit, or ");
            Console.WriteLine("CTRL+C to interrupt the read operation:");

            // Start a console read operation. Do not display the input.
            cki = Console.ReadKey(true);

            // Announce the name of the key that was pressed .
            Console.WriteLine($"  Key pressed: {cki.Key}\n");

            // Exit if the user pressed the 'X' key.
            if (cki.Key == ConsoleKey.X) break;
        }
    }

    protected static void myHandler(object sender, ConsoleCancelEventArgs
args)
    {
        Console.WriteLine("\nThe read operation has been interrupted.");

        Console.WriteLine($"  Key pressed: {args.SpecialKey}");

        Console.WriteLine($"  Cancel property: {args.Cancel}");

        // Set the Cancel property to true to prevent the process from
terminating.
        Console.WriteLine("Setting the Cancel property to true...");
        args.Cancel = true;

        // Announce the new value of the Cancel property.
        Console.WriteLine($"  Cancel property: {args.Cancel}");
        Console.WriteLine("The read operation will resume...\n");
    }
}
// The example displays output similar to the following:
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: J
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: Enter
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//
//    The read operation has been interrupted.
//      Key pressed: ControlC
//      Cancel property: False
//    Setting the Cancel property to true...
//      Cancel property: True
//    The read operation will resume...
//
//      Key pressed: Q
//
```

```
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: X
```

Remarks

When you create a ConsoleCancelEventHandler delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate. For more information about event-handler delegates, see Handling and Raising Events.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

ConsoleColor Enum

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Specifies constants that define foreground and background colors for the console.

C#

```
public enum ConsoleColor
```

Inheritance Object → ValueType → Enum → ConsoleColor

Fields

Expand table

Black	0	The color black.
Blue	9	The color blue.
Cyan	11	The color cyan (blue-green).
DarkBlue	1	The color dark blue.
DarkCyan	3	The color dark cyan (dark blue-green).
DarkGray	8	The color dark gray.
DarkGreen	2	The color dark green.
DarkMagenta	5	The color dark magenta (dark purplish-red).
DarkRed	4	The color dark red.
DarkYellow	6	The color dark yellow (ochre).
Gray	7	The color gray.
Green	10	The color green.
Magenta	13	The color magenta (purplish-red).

Red	12	The color red.
White	15	The color white.
Yellow	14	The color yellow.

Examples

The following example saves the values of the ConsoleColor enumeration to an array and stores the current values of the BackgroundColor and ForegroundColor properties to variables. It then changes the foreground color to each color in the ConsoleColor enumeration except to the color that matches the current background, and it changes the background color to each color in the ConsoleColor enumeration except to the color that matches the current foreground. (If the foreground color is the same as the background color, the text isn't visible.) Finally, it calls the ResetColor method to restore the original console colors.

C#

```
using System;

class Example
{
   public static void Main()
   {
      // Get an array with the values of ConsoleColor enumeration members.
      ConsoleColor[] colors = (ConsoleColor[])
ConsoleColor.GetValues(typeof(ConsoleColor));
      // Save the current background and foreground colors.
      ConsoleColor currentBackground = Console.BackgroundColor;
      ConsoleColor currentForeground = Console.ForegroundColor;

      // Display all foreground colors except the one that matches the
background.
      Console.WriteLine("All the foreground colors except {0}, the
background color:",
                        currentBackground);
      foreach (var color in colors) {
         if (color == currentBackground) continue;

         Console.ForegroundColor = color;
         Console.WriteLine("   The foreground color is {0}.", color);
      }
      Console.WriteLine();
      // Restore the foreground color.
      Console.ForegroundColor = currentForeground;

      // Display each background color except the one that matches the
current foreground color.
```

```
      Console.WriteLine("All the background colors except {0}, the
foreground color:",
                        currentForeground);
      foreach (var color in colors) {
         if (color == currentForeground) continue;

         Console.BackgroundColor = color;
         Console.WriteLine("   The background color is {0}.", color);
      }

      // Restore the original console colors.
      Console.ResetColor();
      Console.WriteLine("\nOriginal colors restored...");
   }
}
//The example displays output like the following:
//    All the foreground colors except DarkCyan, the background color:
//       The foreground color is Black.
//       The foreground color is DarkBlue.
//       The foreground color is DarkGreen.
//       The foreground color is DarkRed.
//       The foreground color is DarkMagenta.
//       The foreground color is DarkYellow.
//       The foreground color is Gray.
//       The foreground color is DarkGray.
//       The foreground color is Blue.
//       The foreground color is Green.
//       The foreground color is Cyan.
//       The foreground color is Red.
//       The foreground color is Magenta.
//       The foreground color is Yellow.
//       The foreground color is White.
//
//    All the background colors except White, the foreground color:
//       The background color is Black.
//       The background color is DarkBlue.
//       The background color is DarkGreen.
//       The background color is DarkCyan.
//       The background color is DarkRed.
//       The background color is DarkMagenta.
//       The background color is DarkYellow.
//       The background color is Gray.
//       The background color is DarkGray.
//       The background color is Blue.
//       The background color is Green.
//       The background color is Cyan.
//       The background color is Red.
//       The background color is Magenta.
//       The background color is Yellow.
//
//    Original colors restored...
```

ConsoleKey Enum

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Specifies the standard keys on a console.

C#

```
public enum ConsoleKey
```

Inheritance Object → ValueType → Enum → ConsoleKey

Fields

Expand table

A	65	The A key.
Add	107	The Add key (the addition key on the numeric keypad).
Applications	93	The Application key (Microsoft Natural Keyboard).
Attention	246	The ATTN key.
B	66	The B key.
Backspace	8	The BACKSPACE key.
BrowserBack	166	The Browser Back key.
BrowserFavorites	171	The Browser Favorites key.
BrowserForward	167	The Browser Forward key.
BrowserHome	172	The Browser Home key.
BrowserRefresh	168	The Browser Refresh key.
BrowserSearch	170	The Browser Search key.
BrowserStop	169	The Browser Stop key.

C	67	The C key.
Clear	12	The CLEAR key.
CrSel	247	The CRSEL (CURSOR SELECT) key.
D	68	The D key.
D0	48	The 0 key.
D1	49	The 1 key.
D2	50	The 2 key.
D3	51	The 3 key.
D4	52	The 4 key.
D5	53	The 5 key.
D6	54	The 6 key.
D7	55	The 7 key.
D8	56	The 8 key.
D9	57	The 9 key.
Decimal	110	The Decimal key (the decimal key on the numeric keypad).
Delete	46	The DEL (DELETE) key.
Divide	111	The Divide key (the division key on the numeric keypad).
DownArrow	40	The DOWN ARROW key.
E	69	The E key.
End	35	The END key.
Enter	13	The ENTER key.
EraseEndOfFile	249	The ERASE EOF key.
Escape	27	The ESC (ESCAPE) key.
Execute	43	The EXECUTE key.
ExSel	248	The EXSEL (EXTEND SELECTION) key.
F	70	The F key.
F1	112	The F1 key.

F10	121	The F10 key.
F11	122	The F11 key.
F12	123	The F12 key.
F13	124	The F13 key.
F14	125	The F14 key.
F15	126	The F15 key.
F16	127	The F16 key.
F17	128	The F17 key.
F18	129	The F18 key.
F19	130	The F19 key.
F2	113	The F2 key.
F20	131	The F20 key.
F21	132	The F21 key.
F22	133	The F22 key.
F23	134	The F23 key.
F24	135	The F24 key.
F3	114	The F3 key.
F4	115	The F4 key.
F5	116	The F5 key.
F6	117	The F6 key.
F7	118	The F7 key.
F8	119	The F8 key.
F9	120	The F9 key.
G	71	The G key.
H	72	The H key.
Help	47	The HELP key.
Home	36	The HOME key.

I	73	The I key.
Insert	45	The INS (INSERT) key.
J	74	The J key.
K	75	The K key.
L	76	The L key.
LaunchApp1	182	The Start Application 1 key (Microsoft Natural Keyboard).
LaunchApp2	183	The Start Application 2 key (Microsoft Natural Keyboard).
LaunchMail	180	The Start Mail key (Microsoft Natural Keyboard).
LaunchMediaSelect	181	The Select Media key (Microsoft Natural Keyboard).
LeftArrow	37	The LEFT ARROW key.
LeftWindows	91	The left Windows logo key (Microsoft Natural Keyboard).
M	77	The M key.
MediaNext	176	The Media Next Track key.
MediaPlay	179	The Media Play/Pause key.
MediaPrevious	177	The Media Previous Track key.
MediaStop	178	The Media Stop key.
Multiply	106	The Multiply key (the multiplication key on the numeric keypad).
N	78	The N key.
NoName	252	A constant reserved for future use.
None	0	
NumPad0	96	The 0 key on the numeric keypad.
NumPad1	97	The 1 key on the numeric keypad.
NumPad2	98	The 2 key on the numeric keypad.
NumPad3	99	The 3 key on the numeric keypad.
NumPad4	100	The 4 key on the numeric keypad.
NumPad5	101	The 5 key on the numeric keypad.
NumPad6	102	The 6 key on the numeric keypad.

NumPad7	103	The 7 key on the numeric keypad.
NumPad8	104	The 8 key on the numeric keypad.
NumPad9	105	The 9 key on the numeric keypad.
O	79	The O key.
Oem1	186	The OEM 1 key (OEM specific).
Oem102	226	The OEM 102 key (OEM specific).
Oem2	191	The OEM 2 key (OEM specific).
Oem3	192	The OEM 3 key (OEM specific).
Oem4	219	The OEM 4 key (OEM specific).
Oem5	220	The OEM 5 (OEM specific).
Oem6	221	The OEM 6 key (OEM specific).
Oem7	222	The OEM 7 key (OEM specific).
Oem8	223	The OEM 8 key (OEM specific).
OemClear	254	The CLEAR key (OEM specific).
OemComma	188	The OEM Comma key on any country/region keyboard.
OemMinus	189	The OEM Minus key on any country/region keyboard.
OemPeriod	190	The OEM Period key on any country/region keyboard.
OemPlus	187	The OEM Plus key on any country/region keyboard.
P	80	The P key.
Pa1	253	The PA1 key.
Packet	231	The PACKET key (used to pass Unicode characters with keystrokes).
PageDown	34	The PAGE DOWN key.
PageUp	33	The PAGE UP key.
Pause	19	The PAUSE key.
Play	250	The PLAY key.
Print	42	The PRINT key.
PrintScreen	44	The PRINT SCREEN key.

Process	229	The IME PROCESS key.
Q	81	The Q key.
R	82	The R key.
RightArrow	39	The RIGHT ARROW key.
RightWindows	92	The right Windows logo key (Microsoft Natural Keyboard).
S	83	The S key.
Select	41	The SELECT key.
Separator	108	The Separator key.
Sleep	95	The Computer Sleep key.
Spacebar	32	The SPACEBAR key.
Subtract	109	The Subtract key (the subtraction key on the numeric keypad).
T	84	The T key.
Tab	9	The TAB key.
U	85	The U key.
UpArrow	38	The UP ARROW key.
V	86	The V key.
VolumeDown	174	The Volume Down key (Microsoft Natural Keyboard).
VolumeMute	173	The Volume Mute key (Microsoft Natural Keyboard).
VolumeUp	175	The Volume Up key (Microsoft Natural Keyboard).
W	87	The W key.
X	88	The X key.
Y	89	The Y key.
Z	90	The Z key.
Zoom	251	The ZOOM key.

Examples

The following example uses the ConsoleKey enumeration to indicate to the user which key the user had pressed.

C#

```
using System;
using System.Text;

public class ConsoleKeyExample
{
   public static void Main()
   {
      ConsoleKeyInfo input;
      do {
         Console.WriteLine("Press a key, together with Alt, Ctrl, or
Shift.");
         Console.WriteLine("Press Esc to exit.");
         input = Console.ReadKey(true);

         StringBuilder output = new StringBuilder(
                        String.Format("You pressed {0}",
input.Key.ToString()));
         bool modifiers = false;

         if (input.Modifiers.HasFlag(ConsoleModifiers.Alt)) {
            output.Append(", together with " +
ConsoleModifiers.Alt.ToString());
            modifiers = true;
         }
         if (input.Modifiers.HasFlag(ConsoleModifiers.Control))
         {
            if (modifiers) {
               output.Append(" and ");
            }
            else {
               output.Append(", together with ");
               modifiers = true;
            }
            output.Append(ConsoleModifiers.Control.ToString());
         }
         if (input.Modifiers.HasFlag(ConsoleModifiers.Shift))
         {
            if (modifiers) {
               output.Append(" and ");
            }
            else {
               output.Append(", together with ");
               modifiers = true;
            }
            output.Append(ConsoleModifiers.Shift.ToString());
         }
         output.Append(".");
         Console.WriteLine(output.ToString());
         Console.WriteLine();
```

```
        } while (input.Key != ConsoleKey.Escape);
    }
}
// The output from a sample console session might appear as follows:
//       Press a key, together with Alt, Ctrl, or Shift.
//       Press Esc to exit.
//       You pressed D.
//
//       Press a key, together with Alt, Ctrl, or Shift.
//       Press Esc to exit.
//       You pressed X, together with Shift.
//
//       Press a key, together with Alt, Ctrl, or Shift.
//       Press Esc to exit.
//       You pressed L, together with Control and Shift.
//
//       Press a key, together with Alt, Ctrl, or Shift.
//       Press Esc to exit.
//       You pressed P, together with Alt and Control and Shift.
//
//       Press a key, together with Alt, Ctrl, or Shift.
//       Press Esc to exit.
//       You pressed Escape.
```

Remarks

The ConsoleKey enumeration is typically used in the nfo structure, which is returned by the Console.ReadKey method to indicate which key on the console has been pressed.

ConsoleKeyInfo Struct

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Describes the console key that was pressed, including the character represented by the console key and the state of the SHIFT, ALT, and CTRL modifier keys.

C#

```
public readonly struct ConsoleKeyInfo : IEquatable<ConsoleKeyInfo>
```

Inheritance Object → ValueType → ConsoleKeyInfo

Implements IEquatable<ConsoleKeyInfo>

Examples

The following example demonstrates using a ConsoleKeyInfo object in a read operation.

C#

```
using System;

class Example
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT, and a
console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do
      {
         cki = Console.ReadKey();
         Console.Write(" --- You pressed ");
         if((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
```

```
            if((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
            if((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
            Console.WriteLine(cki.Key.ToString());
        } while (cki.Key != ConsoleKey.Escape);
    }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       a --- You pressed A
//       k --- You pressed ALT+K
//       ► --- You pressed CTL+P
//         --- You pressed RightArrow
//       R --- You pressed SHIFT+R
//                --- You pressed CTL+I
//       j --- You pressed ALT+J
//       O --- You pressed SHIFT+O
//       § --- You pressed CTL+U
```

Remarks

The ConsoleKeyInfo type is not intended to be created by users. Instead, it is returned to the user in response to calling the Console.ReadKey method.

The ConsoleKeyInfo object describes the ConsoleKey constant and Unicode character, if any, that correspond to the pressed console key. The ConsoleKeyInfo object also describes, in a bitwise combination of ConsoleModifiers values, whether one or more SHIFT, ALT, or CTRL modifier keys was pressed simultaneously with the console key.

Constructors

Expand table

ConsoleKeyInfo(Char, ConsoleKey, Boolean, Boolean, Boolean)	Initializes a new instance of the ConsoleKeyInfo structure using the specified character, console key, and modifier keys.

Properties

Expand table

Key	Gets the console key represented by the current ConsoleKeyInfo object.

KeyChar	Gets the Unicode character represented by the current ConsoleKeyInfo object.
Modifiers	Gets a bitwise combination of ConsoleModifiers values that specifies one or more modifier keys pressed simultaneously with the console key.

Methods

Expand table

Equals(ConsoleKeyInfo)	Gets a value indicating whether the specified ConsoleKeyInfo object is equal to the current ConsoleKeyInfo object.
Equals(Object)	Gets a value indicating whether the specified object is equal to the current ConsoleKeyInfo object.
GetHashCode()	Returns the hash code for the current ConsoleKeyInfo object.

Operators

Expand table

Equality(ConsoleKeyInfo, ConsoleKeyInfo)	Indicates whether the specified ConsoleKeyInfo objects are equal.
Inequality(ConsoleKeyInfo, ConsoleKeyInfo)	Indicates whether the specified ConsoleKeyInfo objects are not equal.

Applies to

Product	Versions

ConsoleKeyInfo(Char, ConsoleKey, Boolean, Boolean, Boolean) Constructor

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Initializes a new instance of the ConsoleKeyInfo structure using the specified character, console key, and modifier keys.

C#

```
public ConsoleKeyInfo (char keyChar, ConsoleKey key, bool shift, bool alt,
bool control);
```

Parameters

keyChar Char

The Unicode character that corresponds to the `key` parameter.

key ConsoleKey

The console key that corresponds to the `keyChar` parameter.

shift Boolean

`true` to indicate that a SHIFT key was pressed; otherwise, `false`.

alt Boolean

`true` to indicate that an ALT key was pressed; otherwise, `false`.

control Boolean

`true` to indicate that a CTRL key was pressed; otherwise, `false`.

Exceptions

ArgumentOutOfRangeException

The numeric value of the `key` parameter is less than 0 or greater than 255.

Remarks

This type is not intended to be created by users. Instead, it is returned to the user in response to calling the Console.ReadKey method.

The ConsoleKeyInfo type does not specify whether the left or right SHIFT, ALT, or CTRL modifier key was pressed.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

ConsoleKeyInfo.Key Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the console key represented by the current ConsoleKeyInfo object.

C#

```
public ConsoleKey Key { get; }
```

Property Value

ConsoleKey

A value that identifies the console key that was pressed.

Examples

The following example demonstrates using a Key property in a read operation.

C#

```
using System;

class Example
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT, and a
console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do
      {
         cki = Console.ReadKey();
         Console.Write(" --- You pressed ");
         if((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
```

```
            if((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
            if((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
            Console.WriteLine(cki.Key.ToString());
        } while (cki.Key != ConsoleKey.Escape);
    }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       a --- You pressed A
//       k --- You pressed ALT+K
//       ► --- You pressed CTL+P
//         --- You pressed RightArrow
//       R --- You pressed SHIFT+R
//                --- You pressed CTL+I
//       j --- You pressed ALT+J
//       O --- You pressed SHIFT+O
//       § --- You pressed CTL+U
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ConsoleKeyInfo.KeyChar Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets the Unicode character represented by the current ConsoleKeyInfo object.

C#

```
public char KeyChar { get; }
```

Property Value

Char

An object that corresponds to the console key represented by the current ConsoleKeyInfo object.

Examples

The following example uses the KeyChar property to add the characters input by the user into a string. The example ignores special keys other than **ENTER**, **ESC**, and **BACKSPACE**.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Configure console.
      Console.BufferWidth = 80;
      Console.WindowWidth = Console.BufferWidth;
      Console.TreatControlCAsInput = true;

      string inputString = String.Empty;
      ConsoleKeyInfo keyInfo;

      Console.WriteLine("Enter a string. Press <Enter> or Esc to exit.");
```

```
      do {
         keyInfo = Console.ReadKey(true);
         // Ignore if Alt or Ctrl is pressed.
         if ((keyInfo.Modifiers & ConsoleModifiers.Alt) ==
ConsoleModifiers.Alt)
            continue;
         if ((keyInfo.Modifiers & ConsoleModifiers.Control) ==
ConsoleModifiers.Control)
            continue;
         // Ignore if KeyChar value is \u0000.
         if (keyInfo.KeyChar == '\u0000') continue;
         // Ignore tab key.
         if (keyInfo.Key == ConsoleKey.Tab) continue;
         // Handle backspace.
         if (keyInfo.Key == ConsoleKey.Backspace) {
            // Are there any characters to erase?
            if (inputString.Length >= 1) {
               // Determine where we are in the console buffer.
               int cursorCol = Console.CursorLeft - 1;
               int oldLength = inputString.Length;
               int extraRows = oldLength / 80;

               inputString = inputString.Substring(0, oldLength - 1);
               Console.CursorLeft = 0;
               Console.CursorTop = Console.CursorTop - extraRows;
               Console.Write(inputString + new String(' ', oldLength -
inputString.Length));
               Console.CursorLeft = cursorCol;
            }
            continue;
         }
         // Handle Escape key.
         if (keyInfo.Key == ConsoleKey.Escape) break;
         // Handle key by adding it to input string.
         Console.Write(keyInfo.KeyChar);
         inputString += keyInfo.KeyChar;
      } while (keyInfo.Key != ConsoleKey.Enter);
      Console.WriteLine("\n\nYou entered:\n    {0}",
                        String.IsNullOrEmpty(inputString) ? "<nothing>" :
inputString);
   }
}
```

Remarks

If the key pressed does not map to a Unicode character (for example, if the user presses the **F1** key or the **Home** key), the value of the KeyChar property is \U0000.

Applies to

ConsoleKeyInfo.Modifiers Property

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a bitwise combination of ConsoleModifiers values that specifies one or more modifier keys pressed simultaneously with the console key.

C#

```
public ConsoleModifiers Modifiers { get; }
```

Property Value

ConsoleModifiers

A bitwise combination of the enumeration values. There is no default value.

Examples

The following example demonstrates using a Modifiers property in a read operation.

C#

```
using System;

class Example
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT, and a
console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do
      {
         cki = Console.ReadKey();
         Console.Write(" --- You pressed ");
```

```
            if((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
            if((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
            if((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
            Console.WriteLine(cki.Key.ToString());
        } while (cki.Key != ConsoleKey.Escape);
    }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       a --- You pressed A
//       k --- You pressed ALT+K
//       ► --- You pressed CTL+P
//         --- You pressed RightArrow
//       R --- You pressed SHIFT+R
//                --- You pressed CTL+I
//       j --- You pressed ALT+J
//       O --- You pressed SHIFT+O
//       § --- You pressed CTL+U
```

ConsoleKeyInfo.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Gets a value indicating whether an object or specified ConsoleKeyInfo object is equal to the current ConsoleKeyInfo object.

Overloads

Expand table

Equals(ConsoleKeyInfo)	Gets a value indicating whether the specified ConsoleKeyInfo object is equal to the current ConsoleKeyInfo object.
Equals(Object)	Gets a value indicating whether the specified object is equal to the current ConsoleKeyInfo object.

Equals(ConsoleKeyInfo)

Gets a value indicating whether the specified ConsoleKeyInfo object is equal to the current ConsoleKeyInfo object.

C#

```
public bool Equals (ConsoleKeyInfo obj);
```

Parameters

obj ConsoleKeyInfo

An object to compare to the current ConsoleKeyInfo object.

Returns

Boolean

`true` if `obj` is equal to the current ConsoleKeyInfo object; otherwise, `false`.

Implements

Equals(T)

Remarks

Two ConsoleKeyInfo objects are equal if their corresponding KeyChar, Key, and Modifiers properties are equal.

The Equals method performs slightly better than the ConsoleKeyInfo.Equals(Object) method because it does not have to convert `obj` to an object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

Equals(Object)

Gets a value indicating whether the specified object is equal to the current ConsoleKeyInfo object.

C#

```
public override bool Equals (object? value);
```

Parameters

`value` Object

An object to compare to the current ConsoleKeyInfo object.

Returns

Boolean

`true` if `value` is a ConsoleKeyInfo object and is equal to the current ConsoleKeyInfo object; otherwise, `false`.

Examples

The following example demonstrates the Equals method.

C#

```
// This example demonstrates the ConsoleKeyInfo.Equals() method.

using System;
using System.Text;

class Sample
{
    public static void Main()
    {
    string k1 = "\nEnter a key ......... ";
    string k2 = "\nEnter another key ... ";
    string key1 = "";
    string key2 = "";
    string areKeysEqual = "The {0} and {1} keys are {2}equal.";
    string equalValue = "";
    string prompt = "Press the escape key (ESC) to quit, " +
                    "or any other key to continue.";
    ConsoleKeyInfo cki1;
    ConsoleKeyInfo cki2;

//
// The Console.TreatControlCAsInput property prevents this example from
// ending if you press CTL+C, however all other operating system keys and
// shortcuts, such as ALT+TAB or the Windows Logo key, are still in
effect.
//
    Console.TreatControlCAsInput = true;

// Request that the user enter two key presses. A key press and any
// combination shift, CTRL, and ALT modifier keys is permitted.
    do
    {
        Console.Write(k1);
        cki1 = Console.ReadKey(false);
        Console.Write(k2);
        cki2 = Console.ReadKey(false);
        Console.WriteLine();
//
        key1 = KeyCombination(cki1);
```

```
        key2 = KeyCombination(cki2);
        if (cki1.Equals(cki2))
            equalValue = "";
        else
            equalValue = "not ";
        Console.WriteLine(areKeysEqual, key1, key2, equalValue);
//
        Console.WriteLine(prompt);
        cki1 = Console.ReadKey(true);
    } while (cki1.Key != ConsoleKey.Escape);
// Note: This example requires the Escape (Esc) key.
    }

// The KeyCombination() method creates a string that specifies what
// key and what combination of shift, CTRL, and ALT modifier keys
// were pressed simultaneously.

    protected static string KeyCombination(ConsoleKeyInfo sourceCki)
    {
    StringBuilder sb = new StringBuilder();
    sb.Length = 0;
    string keyCombo;
    if (sourceCki.Modifiers != 0)
        {
        if ((sourceCki.Modifiers & ConsoleModifiers.Alt) != 0)
            sb.Append("ALT+");
        if ((sourceCki.Modifiers & ConsoleModifiers.Shift) != 0)
            sb.Append("SHIFT+");
        if ((sourceCki.Modifiers & ConsoleModifiers.Control) != 0)
            sb.Append("CTL+");
        }
    sb.Append(sourceCki.Key.ToString());
    keyCombo = sb.ToString();
    return keyCombo;
    }
}

/*
This example produces results similar to the following output:

Enter a key ......... a
Enter another key ... a
The A and A keys are equal.
Press the escape key (ESC) to quit, or any other key to continue.

Enter a key ......... a
Enter another key ... A
The A and SHIFT+A keys are not equal.
Press the escape key (ESC) to quit, or any other key to continue.

Enter a key ......... S
Enter another key ...
The ALT+SHIFT+S and ALT+CTL+F keys are not equal.
Press the escape key (ESC) to quit, or any other key to continue.
```

```
Enter a key .........
Enter another key ...
The UpArrow and UpArrow keys are equal.
Press the escape key (ESC) to quit, or any other key to continue.

*/
```

Remarks

Two ConsoleKeyInfo objects are equal if their corresponding KeyChar, Key, and Modifiers properties are equal.

Applies to

ConsoleKeyInfo.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Returns the hash code for the current ConsoleKeyInfo object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Examples

The following example demonstrates the GetHashCode method.

C#

```
// This example demonstrates the ConsoleKeyInfo.GetHashCode() method.

using System;
using System.Text;

class Sample
{
    public static void Main()
    {
    string k1 = "\nEnter a key ......... ";
    string key1 = "";
    string hashCodeFmt = "The hash code for the {0} key is {1}.";
    string prompt = "Press the escape key (ESC) to quit, " +
                    "or any other key to continue.";
    ConsoleKeyInfo cki1;
    int hashCode = 0;

//
// The Console.TreatControlCAsInput property prevents this example from
```

```
// ending if you press CTL+C, however all other operating system keys and
// shortcuts, such as ALT+TAB or the Windows Logo key, are still in effect.
//
    Console.TreatControlCAsInput = true;

// Request that the user enter two key presses. A key press and any
// combination shift, CTRL, and ALT modifier keys is permitted.
    do
    {
        Console.Write(k1);
        cki1 = Console.ReadKey(false);
        Console.WriteLine();
//
        key1 = KeyCombination(cki1);
        hashCode = cki1.GetHashCode();
        Console.WriteLine(hashCodeFmt, key1, hashCode);
//
        Console.WriteLine(prompt);
        cki1 = Console.ReadKey(true);
    } while (cki1.Key != ConsoleKey.Escape);
// Note: This example requires the Escape (Esc) key.
    }

// The KeyCombination() method creates a string that specifies what
// key and what combination of shift, CTRL, and ALT modifier keys
// were pressed simultaneously.

    protected static string KeyCombination(ConsoleKeyInfo sourceCki)
    {
    StringBuilder sb = new StringBuilder();
    sb.Length = 0;
    string keyCombo;
    if (sourceCki.Modifiers != 0)
        {
        if ((sourceCki.Modifiers & ConsoleModifiers.Alt) != 0)
            sb.Append("ALT+");
        if ((sourceCki.Modifiers & ConsoleModifiers.Shift) != 0)
            sb.Append("SHIFT+");
        if ((sourceCki.Modifiers & ConsoleModifiers.Control) != 0)
            sb.Append("CTL+");
        }
    sb.Append(sourceCki.Key.ToString());
    keyCombo = sb.ToString();
    return keyCombo;
    }
}

/*
This example produces results similar to the following output:

Enter a key ......... a
The hash code for the A key is 97.
Press the escape key (ESC) to quit, or any other key to continue.

Enter a key ......... S
```

```
The hash code for the SHIFT+S key is 83.
Press the escape key (ESC) to quit, or any other key to continue.

Enter a key .........
The hash code for the ALT+SHIFT+CTL+J key is 7.
Press the escape key (ESC) to quit, or any other key to continue.

*/
```

Remarks

The value returned by the GetHashCode method is not suitable for distinguishing one ConsoleKeyInfo object from another. If your application needs a unique hash code, override the GetHashCode method with your own method.

Applies to

ConsoleKeyInfo.Equality(ConsoleKeyInfo, ConsoleKeyInfo) Operator

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Indicates whether the specified ConsoleKeyInfo objects are equal.

C#

```
public static bool operator == (ConsoleKeyInfo a, ConsoleKeyInfo b);
```

Parameters

a ConsoleKeyInfo

The first object to compare.

b ConsoleKeyInfo

The second object to compare.

Returns

Boolean

`true` if `a` is equal to `b`; otherwise, `false`.

Remarks

Two ConsoleKeyInfo objects are equal if their corresponding KeyChar, Key, and Modifiers properties are equal.

The equivalent method for this operator is ConsoleKeyInfo.Equals(ConsoleKeyInfo).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

ConsoleKeyInfo.Inequality(ConsoleKeyInfo, ConsoleKeyInfo) Operator

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Indicates whether the specified ConsoleKeyInfo objects are not equal.

```
C#
public static bool operator != (ConsoleKeyInfo a, ConsoleKeyInfo b);
```

Parameters

a ConsoleKeyInfo

The first object to compare.

b ConsoleKeyInfo

The second object to compare.

Returns

Boolean

`true` if `a` is not equal to `b`; otherwise, `false`.

Remarks

Two ConsoleKeyInfo objects are equal if their corresponding KeyChar, Key, and Modifiers properties are equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.6, 2.0, 2.1

ConsoleModifiers Enum

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Represents the SHIFT, ALT, and CTRL modifier keys on a keyboard.

This enumeration supports a bitwise combination of its member values.

C#

```
[System.Flags]
public enum ConsoleModifiers
```

Inheritance Object → ValueType → Enum → ConsoleModifiers

Attributes FlagsAttribute

Fields

Expand table

Alt	1	The left or right ALT modifier key.
Control	4	The left or right CTRL modifier key.
None	0	
Shift	2	The left or right SHIFT modifier key.

Examples

The following code example reads a key and determines whether one or more modifier keys was pressed.

C#

```
using System;

class Example
{
   public static void Main()
   {
      ConsoleKeyInfo cki;
      // Prevent example from ending if CTL+C is pressed.
      Console.TreatControlCAsInput = true;

      Console.WriteLine("Press any combination of CTL, ALT, and SHIFT, and a
console key.");
      Console.WriteLine("Press the Escape (Esc) key to quit: \n");
      do
      {
         cki = Console.ReadKey();
         Console.Write(" --- You pressed ");
         if((cki.Modifiers & ConsoleModifiers.Alt) != 0)
Console.Write("ALT+");
         if((cki.Modifiers & ConsoleModifiers.Shift) != 0)
Console.Write("SHIFT+");
         if((cki.Modifiers & ConsoleModifiers.Control) != 0)
Console.Write("CTL+");
         Console.WriteLine(cki.Key.ToString());
       } while (cki.Key != ConsoleKey.Escape);
    }
}
// This example displays output similar to the following:
//       Press any combination of CTL, ALT, and SHIFT, and a console key.
//       Press the Escape (Esc) key to quit:
//
//       a --- You pressed A
//       k --- You pressed ALT+K
//       ► --- You pressed CTL+P
//         --- You pressed RightArrow
//       R --- You pressed SHIFT+R
//                --- You pressed CTL+I
//       j --- You pressed ALT+J
//       O --- You pressed SHIFT+O
//       § --- You pressed CTL+U
```

Remarks

No distinction is made between the left or right SHIFT, ALT, and CTRL keys.

The ConsoleModifiers enumeration is used in conjunction with the ConsoleKeyInfo type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ConsoleSpecialKey Enum

Reference

Definition

Namespace: System

Assembly: System.Console.dll

Specifies combinations of modifier and console keys that can interrupt the current process.

C#

```
public enum ConsoleSpecialKey
```

Inheritance Object → ValueType → Enum → ConsoleSpecialKey

Fields

Expand table

ControlBreak	1	The Control modifier key plus the BREAK console key.
ControlC	0	The Control modifier key plus the C console key.

Examples

The following code example displays the ConsoleSpecialKey value that invokes the associated event handler.

C#

```
using System;

class Sample
{
    public static void Main()
    {
        ConsoleKeyInfo cki;

        Console.Clear();
```

```
        // Establish an event handler to process key press events.
        Console.CancelKeyPress += new ConsoleCancelEventHandler(myHandler);
        while (true)
        {
            Console.Write("Press any key, or 'X' to quit, or ");
            Console.WriteLine("CTRL+C to interrupt the read operation:");

            // Start a console read operation. Do not display the input.
            cki = Console.ReadKey(true);

            // Announce the name of the key that was pressed .
            Console.WriteLine($"  Key pressed: {cki.Key}\n");

            // Exit if the user pressed the 'X' key.
            if (cki.Key == ConsoleKey.X) break;
        }
    }

    protected static void myHandler(object sender, ConsoleCancelEventArgs
args)
    {
        Console.WriteLine("\nThe read operation has been interrupted.");

        Console.WriteLine($"  Key pressed: {args.SpecialKey}");

        Console.WriteLine($"  Cancel property: {args.Cancel}");

        // Set the Cancel property to true to prevent the process from
terminating.
        Console.WriteLine("Setting the Cancel property to true...");
        args.Cancel = true;

        // Announce the new value of the Cancel property.
        Console.WriteLine($"  Cancel property: {args.Cancel}");
        Console.WriteLine("The read operation will resume...\n");
    }
}
// The example displays output similar to the following:
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: J
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: Enter
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//
//    The read operation has been interrupted.
//      Key pressed: ControlC
//      Cancel property: False
//    Setting the Cancel property to true...
//      Cancel property: True
//    The read operation will resume...
```

```
//
//      Key pressed: Q
//
//    Press any key, or 'X' to quit, or CTRL+C to interrupt the read
operation:
//      Key pressed: X
```

Remarks

The ConsoleCancelEventArgs.SpecialKey property returns the ConsoleSpecialKey enumeration type.

Simultaneously pressing certain key combinations signals the operating system to interrupt the currently running process. The two valid key combinations are ConsoleModifiers.Control plus BREAK (CTRL+BREAK) and ConsoleModifiers.Control plus ConsoleKey.C (CTRL+C).

Applies to

Product	Versions

ContextBoundObject Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines the base class for all context-bound classes.

C#

```
public abstract class ContextBoundObject : MarshalByRefObject
```

Inheritance Object → MarshalByRefObject → ContextBoundObject

Derived System.EnterpriseServices.ServicedComponent
System.ServiceModel.ComIntegration.ServiceMoniker

Remarks

Objects that reside in a context and are bound to the context rules are called context-bound objects. A context is a set of properties or usage rules that define an environment where a collection of objects resides. The rules are enforced when the objects are entering or leaving a context. Objects that are not context-bound are called agile objects.

Contexts are created during object activation. A new object is placed into an existing context or into a new context created using the attributes included in the metadata of the type. Context-bound classes are marked with a ContextAttribute that provides the usage rules. The context properties that can be added include policies regarding synchronization and transactions.

Notes to Implementers

The current version of the common language runtime does not support generic ContextBoundObject types or nongeneric ContextBoundObject types that have generic methods. Attempting to create an instance of such a type causes a TypeLoadException.

Constructors

Expand table

ContextBoundObject()	Instantiates an instance of the ContextBoundObject class.

Methods

Expand table

CreateObjRef(Type)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. (Inherited from MarshalByRefObject)
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetLifetimeService()	**Obsolete.** Retrieves the current lifetime service object that controls the lifetime policy for this instance. (Inherited from MarshalByRefObject)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeLifetime Service()	**Obsolete.** Obtains a lifetime service object to control the lifetime policy for this instance. (Inherited from MarshalByRefObject)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Memberwise Clone(Boolean)	Creates a shallow copy of the current MarshalByRefObject object. (Inherited from MarshalByRefObject)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ContextMarshalException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt to marshal an object across a context boundary fails.

C#

```
public class ContextMarshalException : SystemException
```

Inheritance Object → Exception → SystemException → ContextMarshalException

Remarks

Objects can marshal by value or by reference. Any attempt to pass a type that cannot be marshaled through a context boundary will result in a ContextMarshalException.

ContextMarshalException uses the HRESULT COR_E_CONTEXTMARSHAL which has the value 0x80131504L.

ContextMarshalException uses the default Equals implementation, which supports reference equality.

For a list of initial property values for an instance of ContextMarshalException, see the ContextMarshalException constructors.

Constructors

Expand table

ContextMarshalException()	Initializes a new instance of the ContextMarshalException class with default properties.
ContextMarshalException(SerializationInfo, StreamingContext)	**Obsolete.**

	Initializes a new instance of the ContextMarshalException class with serialized data.
ContextMarshalException(String)	Initializes a new instance of the ContextMarshalException class with a specified error message.
ContextMarshalException(String, Exception)	Initializes a new instance of the ContextMarshalException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object.

	(Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1 *(2.0, 3.0, 3.5)*
.NET Standard	2.0, 2.1

ContextMarshalException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ContextMarshalException class.

Overloads

Expand table

ContextMarshalException()	Initializes a new instance of the ContextMarshalException class with default properties.
ContextMarshalException(String)	Initializes a new instance of the ContextMarshalException class with a specified error message.
ContextMarshalException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ContextMarshalException class with serialized data.
ContextMarshalException(String, Exception)	Initializes a new instance of the ContextMarshalException class with a specified error message and a reference to the inner exception that is the cause of this exception.

ContextMarshalException()

Initializes a new instance of the ContextMarshalException class with default properties.

C#

```
public ContextMarshalException ();
```

Remarks

The following table shows the initial property values for an instance of ContextMarshalException.

Expand table

Property	Value
InnerException	`null`.
Message	The empty string ("").

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ContextMarshalException(String)

Initializes a new instance of the ContextMarshalException class with a specified error message.

C#

```
public ContextMarshalException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Remarks

The following table shows the initial property values for an instance of ContextMarshalException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ContextMarshalException(SerializationInfo, StreamingContext)

Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ContextMarshalException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ContextMarshalException
```

```
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ContextMarshalException(String, Exception)

Initializes a new instance of the ContextMarshalException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public ContextMarshalException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of ContextMarshalException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ContextStaticAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that the value of a static field is unique for a particular context.

C#

```
[System.AttributeUsage(System.AttributeTargets.Field, Inherited=false)]
public class ContextStaticAttribute : Attribute
```

Inheritance Object → Attribute → ContextStaticAttribute

Attributes AttributeUsageAttribute

Remarks

A static field marked with `ContextStaticAttribute` is not shared between contexts. If the indicated static field is accessed on a different context, it will contain a different value. Use this attribute as it is, and do not derive from it.

The following example shows the syntax of this attribute:

[ContextStatic]

static int f=7;

For more information about using attributes, see Attributes.

Constructors

Expand table

ContextStaticAttribute()	Initializes a new instance of the ContextStaticAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Convert Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a base data type to another base data type.

C#

```
public static class Convert
```

Inheritance Object → Convert

Remarks

For more information about this API, see Supplemental API remarks for Convert.

Fields

Expand table

DBNull	A constant that represents a database column that is absent of data; that is, database null.

Methods

Expand table

ChangeType(Object, Type)	Returns an object of the specified type and whose value is equivalent to the specified object.
ChangeType(Object, Type, IFormatProvider)	Returns an object of the specified type whose value is equivalent to the specified object. A parameter supplies culture-specific formatting information.
ChangeType(Object, TypeCode)	Returns an object of the specified type whose value is

	equivalent to the specified object.
ChangeType(Object, TypeCode, IFormatProvider)	Returns an object of the specified type whose value is equivalent to the specified object. A parameter supplies culture-specific formatting information.
FromBase64CharArray(Char[], Int32, Int32)	Converts a subset of a Unicode character array, which encodes binary data as base-64 digits, to an equivalent 8-bit unsigned integer array. Parameters specify the subset in the input array and the number of elements to convert.
FromBase64String(String)	Converts the specified string, which encodes binary data as base-64 digits, to an equivalent 8-bit unsigned integer array.
FromHexString(ReadOnlySpan<Char>)	Converts the span, which encodes binary data as hex characters, to an equivalent 8-bit unsigned integer array.
FromHexString(String)	Converts the specified string, which encodes binary data as hex characters, to an equivalent 8-bit unsigned integer array.
GetTypeCode(Object)	Returns the TypeCode for the specified object.
IsDBNull(Object)	Returns an indication whether the specified object is of type DBNull.
ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32)	Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits. Parameters specify the subsets as offsets in the input and output arrays, and the number of elements in the input array to convert.
ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32, Base64FormattingOptions)	Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits. Parameters specify the subsets as offsets in the input and output arrays, the number of elements in the input array to convert, and whether line breaks are inserted in the output array.
ToBase64String(Byte[])	Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits.
ToBase64String(Byte[], Base64FormattingOptions)	Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. You can specify whether to insert line breaks in the return value.
ToBase64String(Byte[], Int32, Int32)	Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. Parameters specify the subset as an offset in the input array, and the number of elements in the array to convert.
ToBase64String(Byte[], Int32, Int32, Base64FormattingOptions)	Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64

	digits. Parameters specify the subset as an offset in the input array, the number of elements in the array to convert, and whether to insert line breaks in the return value.
ToBase64String(ReadOnlySpan<Byte>, Base64FormattingOptions)	Converts the 8-bit unsigned integers inside the specified read-only span into their equivalent string representation that is encoded with base-64 digits. You can optionally specify whether to insert line breaks in the return value.
ToBoolean(Boolean)	Returns the specified Boolean value; no actual conversion is performed.
ToBoolean(Byte)	Converts the value of the specified 8-bit unsigned integer to an equivalent Boolean value.
ToBoolean(Char)	Calling this method always throws InvalidCastException.
ToBoolean(DateTime)	Calling this method always throws InvalidCastException.
ToBoolean(Decimal)	Converts the value of the specified decimal number to an equivalent Boolean value.
ToBoolean(Double)	Converts the value of the specified double-precision floating-point number to an equivalent Boolean value.
ToBoolean(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent Boolean value.
ToBoolean(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent Boolean value.
ToBoolean(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent Boolean value.
ToBoolean(Object)	Converts the value of a specified object to an equivalent Boolean value.
ToBoolean(Object, IFormatProvider)	Converts the value of the specified object to an equivalent Boolean value, using the specified culture-specific formatting information.
ToBoolean(SByte)	Converts the value of the specified 8-bit signed integer to an equivalent Boolean value.
ToBoolean(Single)	Converts the value of the specified single-precision floating-point number to an equivalent Boolean value.
ToBoolean(String)	Converts the specified string representation of a logical value to its Boolean equivalent.
ToBoolean(String, IFormatProvider)	Converts the specified string representation of a logical value to its Boolean equivalent, using the specified culture-specific

	formatting information.
ToBoolean(UInt16)	Converts the value of the specified 16-bit unsigned integer to an equivalent Boolean value.
ToBoolean(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent Boolean value.
ToBoolean(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent Boolean value.
ToByte(Boolean)	Converts the specified Boolean value to the equivalent 8-bit unsigned integer.
ToByte(Byte)	Returns the specified 8-bit unsigned integer; no actual conversion is performed.
ToByte(Char)	Converts the value of the specified Unicode character to the equivalent 8-bit unsigned integer.
ToByte(DateTime)	Calling this method always throws InvalidCastException.
ToByte(Decimal)	Converts the value of the specified decimal number to an equivalent 8-bit unsigned integer.
ToByte(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 8-bit unsigned integer.
ToByte(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(Object)	Converts the value of the specified object to an 8-bit unsigned integer.
ToByte(Object, IFormatProvider)	Converts the value of the specified object to an 8-bit unsigned integer, using the specified culture-specific formatting information.
ToByte(SByte)	Converts the value of the specified 8-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 8-bit unsigned integer.
ToByte(String)	Converts the specified string representation of a number to an equivalent 8-bit unsigned integer.

ToByte(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 8-bit unsigned integer, using specified culture-specific formatting information.
ToByte(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 8-bit unsigned integer.
ToByte(UInt16)	Converts the value of the specified 16-bit unsigned integer to an equivalent 8-bit unsigned integer.
ToByte(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 8-bit unsigned integer.
ToByte(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 8-bit unsigned integer.
ToChar(Boolean)	Calling this method always throws InvalidCastException.
ToChar(Byte)	Converts the value of the specified 8-bit unsigned integer to its equivalent Unicode character.
ToChar(Char)	Returns the specified Unicode character value; no actual conversion is performed.
ToChar(DateTime)	Calling this method always throws InvalidCastException.
ToChar(Decimal)	Calling this method always throws InvalidCastException.
ToChar(Double)	Calling this method always throws InvalidCastException.
ToChar(Int16)	Converts the value of the specified 16-bit signed integer to its equivalent Unicode character.
ToChar(Int32)	Converts the value of the specified 32-bit signed integer to its equivalent Unicode character.
ToChar(Int64)	Converts the value of the specified 64-bit signed integer to its equivalent Unicode character.
ToChar(Object)	Converts the value of the specified object to a Unicode character.
ToChar(Object, IFormatProvider)	Converts the value of the specified object to its equivalent Unicode character, using the specified culture-specific formatting information.
ToChar(SByte)	Converts the value of the specified 8-bit signed integer to its equivalent Unicode character.
ToChar(Single)	Calling this method always throws InvalidCastException.

ToChar(String)	Converts the first character of a specified string to a Unicode character.
ToChar(String, IFormatProvider)	Converts the first character of a specified string to a Unicode character, using specified culture-specific formatting information.
ToChar(UInt16)	Converts the value of the specified 16-bit unsigned integer to its equivalent Unicode character.
ToChar(UInt32)	Converts the value of the specified 32-bit unsigned integer to its equivalent Unicode character.
ToChar(UInt64)	Converts the value of the specified 64-bit unsigned integer to its equivalent Unicode character.
ToDateTime(Boolean)	Calling this method always throws InvalidCastException.
ToDateTime(Byte)	Calling this method always throws InvalidCastException.
ToDateTime(Char)	Calling this method always throws InvalidCastException.
ToDateTime(DateTime)	Returns the specified DateTime object; no actual conversion is performed.
ToDateTime(Decimal)	Calling this method always throws InvalidCastException.
ToDateTime(Double)	Calling this method always throws InvalidCastException.
ToDateTime(Int16)	Calling this method always throws InvalidCastException.
ToDateTime(Int32)	Calling this method always throws InvalidCastException.
ToDateTime(Int64)	Calling this method always throws InvalidCastException.
ToDateTime(Object)	Converts the value of the specified object to a DateTime object.
ToDateTime(Object, IFormat Provider)	Converts the value of the specified object to a DateTime object, using the specified culture-specific formatting information.
ToDateTime(SByte)	Calling this method always throws InvalidCastException.
ToDateTime(Single)	Calling this method always throws InvalidCastException.
ToDateTime(String)	Converts the specified string representation of a date and time to an equivalent date and time value.
ToDateTime(String, IFormat Provider)	Converts the specified string representation of a number to an equivalent date and time, using the specified culture-specific formatting information.

ToDateTime(UInt16)	Calling this method always throws InvalidCastException.
ToDateTime(UInt32)	Calling this method always throws InvalidCastException.
ToDateTime(UInt64)	Calling this method always throws InvalidCastException.
ToDecimal(Boolean)	Converts the specified Boolean value to the equivalent decimal number.
ToDecimal(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent decimal number.
ToDecimal(Char)	Calling this method always throws InvalidCastException.
ToDecimal(DateTime)	Calling this method always throws InvalidCastException.
ToDecimal(Decimal)	Returns the specified decimal number; no actual conversion is performed.
ToDecimal(Double)	Converts the value of the specified double-precision floating-point number to an equivalent decimal number.
ToDecimal(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent decimal number.
ToDecimal(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent decimal number.
ToDecimal(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent decimal number.
ToDecimal(Object)	Converts the value of the specified object to an equivalent decimal number.
ToDecimal(Object, IFormat Provider)	Converts the value of the specified object to an equivalent decimal number, using the specified culture-specific formatting information.
ToDecimal(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent decimal number.
ToDecimal(Single)	Converts the value of the specified single-precision floating-point number to the equivalent decimal number.
ToDecimal(String)	Converts the specified string representation of a number to an equivalent decimal number.
ToDecimal(String, IFormat Provider)	Converts the specified string representation of a number to an equivalent decimal number, using the specified culture-specific formatting information.

ToDecimal(UInt16)	Converts the value of the specified 16-bit unsigned integer to an equivalent decimal number.
ToDecimal(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent decimal number.
ToDecimal(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent decimal number.
ToDouble(Boolean)	Converts the specified Boolean value to the equivalent double-precision floating-point number.
ToDouble(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent double-precision floating-point number.
ToDouble(Char)	Calling this method always throws InvalidCastException.
ToDouble(DateTime)	Calling this method always throws InvalidCastException.
ToDouble(Decimal)	Converts the value of the specified decimal number to an equivalent double-precision floating-point number.
ToDouble(Double)	Returns the specified double-precision floating-point number; no actual conversion is performed.
ToDouble(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent double-precision floating-point number.
ToDouble(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent double-precision floating-point number.
ToDouble(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent double-precision floating-point number.
ToDouble(Object)	Converts the value of the specified object to a double-precision floating-point number.
ToDouble(Object, IFormat Provider)	Converts the value of the specified object to an double-precision floating-point number, using the specified culture-specific formatting information.
ToDouble(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent double-precision floating-point number.
ToDouble(Single)	Converts the value of the specified single-precision floating-point number to an equivalent double-precision floating-point number.
ToDouble(String)	Converts the specified string representation of a number to an equivalent double-precision floating-point number.

ToDouble(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent double-precision floating-point number, using the specified culture-specific formatting information.
ToDouble(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent double-precision floating-point number.
ToDouble(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent double-precision floating-point number.
ToDouble(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent double-precision floating-point number.
ToHexString(Byte[])	Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters.
ToHexString(Byte[], Int32, Int32)	Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters. Parameters specify the subset as an offset in the input array and the number of elements in the array to convert.
ToHexString(ReadOnlySpan<Byte>)	Converts a span of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters.
ToInt16(Boolean)	Converts the specified Boolean value to the equivalent 16-bit signed integer.
ToInt16(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 16-bit signed integer.
ToInt16(Char)	Converts the value of the specified Unicode character to the equivalent 16-bit signed integer.
ToInt16(DateTime)	Calling this method always throws InvalidCastException.
ToInt16(Decimal)	Converts the value of the specified decimal number to an equivalent 16-bit signed integer.
ToInt16(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 16-bit signed integer.
ToInt16(Int16)	Returns the specified 16-bit signed integer; no actual conversion is performed.
ToInt16(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 16-bit signed integer.
ToInt16(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 16-bit signed integer.

ToInt16(Object)	Converts the value of the specified object to a 16-bit signed integer.
ToInt16(Object, IFormatProvider)	Converts the value of the specified object to a 16-bit signed integer, using the specified culture-specific formatting information.
ToInt16(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 16-bit signed integer.
ToInt16(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 16-bit signed integer.
ToInt16(String)	Converts the specified string representation of a number to an equivalent 16-bit signed integer.
ToInt16(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 16-bit signed integer, using the specified culture-specific formatting information.
ToInt16(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 16-bit signed integer.
ToInt16(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 16-bit signed integer.
ToInt16(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 16-bit signed integer.
ToInt16(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 16-bit signed integer.
ToInt32(Boolean)	Converts the specified Boolean value to the equivalent 32-bit signed integer.
ToInt32(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 32-bit signed integer.
ToInt32(Char)	Converts the value of the specified Unicode character to the equivalent 32-bit signed integer.
ToInt32(DateTime)	Calling this method always throws InvalidCastException.
ToInt32(Decimal)	Converts the value of the specified decimal number to an equivalent 32-bit signed integer.
ToInt32(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 32-bit signed integer.
ToInt32(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent 32-bit signed integer.

ToInt32(Int32)	Returns the specified 32-bit signed integer; no actual conversion is performed.
ToInt32(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 32-bit signed integer.
ToInt32(Object)	Converts the value of the specified object to a 32-bit signed integer.
ToInt32(Object, IFormatProvider)	Converts the value of the specified object to a 32-bit signed integer, using the specified culture-specific formatting information.
ToInt32(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 32-bit signed integer.
ToInt32(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 32-bit signed integer.
ToInt32(String)	Converts the specified string representation of a number to an equivalent 32-bit signed integer.
ToInt32(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 32-bit signed integer, using the specified culture-specific formatting information.
ToInt32(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 32-bit signed integer.
ToInt32(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 32-bit signed integer.
ToInt32(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 32-bit signed integer.
ToInt32(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 32-bit signed integer.
ToInt64(Boolean)	Converts the specified Boolean value to the equivalent 64-bit signed integer.
ToInt64(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 64-bit signed integer.
ToInt64(Char)	Converts the value of the specified Unicode character to the equivalent 64-bit signed integer.
ToInt64(DateTime)	Calling this method always throws InvalidCastException.
ToInt64(Decimal)	Converts the value of the specified decimal number to an equivalent 64-bit signed integer.

ToInt64(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 64-bit signed integer.
ToInt64(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent 64-bit signed integer.
ToInt64(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 64-bit signed integer.
ToInt64(Int64)	Returns the specified 64-bit signed integer; no actual conversion is performed.
ToInt64(Object)	Converts the value of the specified object to a 64-bit signed integer.
ToInt64(Object, IFormatProvider)	Converts the value of the specified object to a 64-bit signed integer, using the specified culture-specific formatting information.
ToInt64(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 64-bit signed integer.
ToInt64(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 64-bit signed integer.
ToInt64(String)	Converts the specified string representation of a number to an equivalent 64-bit signed integer.
ToInt64(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 64-bit signed integer, using the specified culture-specific formatting information.
ToInt64(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 64-bit signed integer.
ToInt64(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 64-bit signed integer.
ToInt64(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 64-bit signed integer.
ToInt64(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 64-bit signed integer.
ToSByte(Boolean)	Converts the specified Boolean value to the equivalent 8-bit signed integer.
ToSByte(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 8-bit signed integer.
ToSByte(Char)	Converts the value of the specified Unicode character to the equivalent 8-bit signed integer.

ToSByte(DateTime)	Calling this method always throws InvalidCastException.
ToSByte(Decimal)	Converts the value of the specified decimal number to an equivalent 8-bit signed integer.
ToSByte(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 8-bit signed integer.
ToSByte(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 8-bit signed integer.
ToSByte(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 8-bit signed integer.
ToSByte(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 8-bit signed integer.
ToSByte(Object)	Converts the value of the specified object to an 8-bit signed integer.
ToSByte(Object, IFormatProvider)	Converts the value of the specified object to an 8-bit signed integer, using the specified culture-specific formatting information.
ToSByte(SByte)	Returns the specified 8-bit signed integer; no actual conversion is performed.
ToSByte(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 8-bit signed integer.
ToSByte(String)	Converts the specified string representation of a number to an equivalent 8-bit signed integer.
ToSByte(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 8-bit signed integer, using the specified culture-specific formatting information.
ToSByte(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 8-bit signed integer.
ToSByte(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 8-bit signed integer.
ToSByte(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 8-bit signed integer.
ToSByte(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 8-bit signed integer.
ToSingle(Boolean)	Converts the specified Boolean value to the equivalent single-precision floating-point number.

ToSingle(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent single-precision floating-point number.
ToSingle(Char)	Calling this method always throws InvalidCastException.
ToSingle(DateTime)	Calling this method always throws InvalidCastException.
ToSingle(Decimal)	Converts the value of the specified decimal number to an equivalent single-precision floating-point number.
ToSingle(Double)	Converts the value of the specified double-precision floating-point number to an equivalent single-precision floating-point number.
ToSingle(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent single-precision floating-point number.
ToSingle(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent single-precision floating-point number.
ToSingle(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent single-precision floating-point number.
ToSingle(Object)	Converts the value of the specified object to a single-precision floating-point number.
ToSingle(Object, IFormatProvider)	Converts the value of the specified object to an single-precision floating-point number, using the specified culture-specific formatting information.
ToSingle(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent single-precision floating-point number.
ToSingle(Single)	Returns the specified single-precision floating-point number; no actual conversion is performed.
ToSingle(String)	Converts the specified string representation of a number to an equivalent single-precision floating-point number.
ToSingle(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent single-precision floating-point number, using the specified culture-specific formatting information.
ToSingle(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent single-precision floating-point number.
ToSingle(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent single-precision floating-point number.
ToSingle(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent single-precision floating-point number.

ToString(Boolean)	Converts the specified Boolean value to its equivalent string representation.
ToString(Boolean, IFormat Provider)	Converts the specified Boolean value to its equivalent string representation.
ToString(Byte)	Converts the value of the specified 8-bit unsigned integer to its equivalent string representation.
ToString(Byte, IFormatProvider)	Converts the value of the specified 8-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Byte, Int32)	Converts the value of an 8-bit unsigned integer to its equivalent string representation in a specified base.
ToString(Char)	Converts the value of the specified Unicode character to its equivalent string representation.
ToString(Char, IFormatProvider)	Converts the value of the specified Unicode character to its equivalent string representation, using the specified culture-specific formatting information.
ToString(DateTime)	Converts the value of the specified DateTime to its equivalent string representation.
ToString(DateTime, IFormat Provider)	Converts the value of the specified DateTime to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Decimal)	Converts the value of the specified decimal number to its equivalent string representation.
ToString(Decimal, IFormat Provider)	Converts the value of the specified decimal number to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Double)	Converts the value of the specified double-precision floating-point number to its equivalent string representation.
ToString(Double, IFormat Provider)	Converts the value of the specified double-precision floating-point number to its equivalent string representation.
ToString(Int16)	Converts the value of the specified 16-bit signed integer to its equivalent string representation.
ToString(Int16, IFormatProvider)	Converts the value of the specified 16-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int16, Int32)	Converts the value of a 16-bit signed integer to its equivalent string representation in a specified base.

ToString(Int32)	Converts the value of the specified 32-bit signed integer to its equivalent string representation.
ToString(Int32, IFormatProvider)	Converts the value of the specified 32-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int32, Int32)	Converts the value of a 32-bit signed integer to its equivalent string representation in a specified base.
ToString(Int64)	Converts the value of the specified 64-bit signed integer to its equivalent string representation.
ToString(Int64, IFormatProvider)	Converts the value of the specified 64-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int64, Int32)	Converts the value of a 64-bit signed integer to its equivalent string representation in a specified base.
ToString(Object)	Converts the value of the specified object to its equivalent string representation.
ToString(Object, IFormatProvider)	Converts the value of the specified object to its equivalent string representation using the specified culture-specific formatting information.
ToString(SByte)	Converts the value of the specified 8-bit signed integer to its equivalent string representation.
ToString(SByte, IFormatProvider)	Converts the value of the specified 8-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Single)	Converts the value of the specified single-precision floating-point number to its equivalent string representation.
ToString(Single, IFormatProvider)	Converts the value of the specified single-precision floating-point number to its equivalent string representation, using the specified culture-specific formatting information.
ToString(String)	Returns the specified string instance; no actual conversion is performed.
ToString(String, IFormatProvider)	Returns the specified string instance; no actual conversion is performed.
ToString(UInt16)	Converts the value of the specified 16-bit unsigned integer to its equivalent string representation.
ToString(UInt16, IFormatProvider)	Converts the value of the specified 16-bit unsigned integer to its equivalent string representation, using the specified

	culture-specific formatting information.
ToString(UInt32)	Converts the value of the specified 32-bit unsigned integer to its equivalent string representation.
ToString(UInt32, IFormatProvider)	Converts the value of the specified 32-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(UInt64)	Converts the value of the specified 64-bit unsigned integer to its equivalent string representation.
ToString(UInt64, IFormatProvider)	Converts the value of the specified 64-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToUInt16(Boolean)	Converts the specified Boolean value to the equivalent 16-bit unsigned integer.
ToUInt16(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 16-bit unsigned integer.
ToUInt16(Char)	Converts the value of the specified Unicode character to the equivalent 16-bit unsigned integer.
ToUInt16(DateTime)	Calling this method always throws InvalidCastException.
ToUInt16(Decimal)	Converts the value of the specified decimal number to an equivalent 16-bit unsigned integer.
ToUInt16(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 16-bit unsigned integer.
ToUInt16(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 16-bit unsigned integer.
ToUInt16(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 16-bit unsigned integer.
ToUInt16(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 16-bit unsigned integer.
ToUInt16(Object)	Converts the value of the specified object to a 16-bit unsigned integer.
ToUInt16(Object, IFormat Provider)	Converts the value of the specified object to a 16-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt16(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 16-bit unsigned integer.

ToUInt16(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 16-bit unsigned integer.
ToUInt16(String)	Converts the specified string representation of a number to an equivalent 16-bit unsigned integer.
ToUInt16(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 16-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt16(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 16-bit unsigned integer.
ToUInt16(UInt16)	Returns the specified 16-bit unsigned integer; no actual conversion is performed.
ToUInt16(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 16-bit unsigned integer.
ToUInt16(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 16-bit unsigned integer.
ToUInt32(Boolean)	Converts the specified Boolean value to the equivalent 32-bit unsigned integer.
ToUInt32(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 32-bit unsigned integer.
ToUInt32(Char)	Converts the value of the specified Unicode character to the equivalent 32-bit unsigned integer.
ToUInt32(DateTime)	Calling this method always throws InvalidCastException.
ToUInt32(Decimal)	Converts the value of the specified decimal number to an equivalent 32-bit unsigned integer.
ToUInt32(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 32-bit unsigned integer.
ToUInt32(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 32-bit unsigned integer.
ToUInt32(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 32-bit unsigned integer.
ToUInt32(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 32-bit unsigned integer.
ToUInt32(Object)	Converts the value of the specified object to a 32-bit unsigned integer.

ToUInt32(Object, IFormat Provider)	Converts the value of the specified object to a 32-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt32(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 32-bit unsigned integer.
ToUInt32(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 32-bit unsigned integer.
ToUInt32(String)	Converts the specified string representation of a number to an equivalent 32-bit unsigned integer.
ToUInt32(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 32-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt32(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 32-bit unsigned integer.
ToUInt32(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 32-bit unsigned integer.
ToUInt32(UInt32)	Returns the specified 32-bit unsigned integer; no actual conversion is performed.
ToUInt32(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 32-bit unsigned integer.
ToUInt64(Boolean)	Converts the specified Boolean value to the equivalent 64-bit unsigned integer.
ToUInt64(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 64-bit unsigned integer.
ToUInt64(Char)	Converts the value of the specified Unicode character to the equivalent 64-bit unsigned integer.
ToUInt64(DateTime)	Calling this method always throws InvalidCastException.
ToUInt64(Decimal)	Converts the value of the specified decimal number to an equivalent 64-bit unsigned integer.
ToUInt64(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 64-bit unsigned integer.
ToUInt64(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 64-bit unsigned integer.
ToUInt64(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 64-bit unsigned integer.

ToUInt64(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 64-bit unsigned integer.
ToUInt64(Object)	Converts the value of the specified object to a 64-bit unsigned integer.
ToUInt64(Object, IFormat Provider)	Converts the value of the specified object to a 64-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt64(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 64-bit unsigned integer.
ToUInt64(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 64-bit unsigned integer.
ToUInt64(String)	Converts the specified string representation of a number to an equivalent 64-bit unsigned integer.
ToUInt64(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 64-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt64(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 64-bit unsigned integer.
ToUInt64(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 64-bit unsigned integer.
ToUInt64(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 64-bit unsigned integer.
ToUInt64(UInt64)	Returns the specified 64-bit unsigned integer; no actual conversion is performed.
TryFromBase64Chars(ReadOnly Span<Char>, Span<Byte>, Int32)	Tries to convert the specified span containing a string representation that is encoded with base-64 digits into a span of 8-bit unsigned integers.
TryFromBase64String(String, Span<Byte>, Int32)	Tries to convert the specified string representation that is encoded with base-64 digits into a span of 8-bit unsigned integers.
TryToBase64Chars(ReadOnly Span<Byte>, Span<Char>, Int32, Base64FormattingOptions)	Tries to convert the 8-bit unsigned integers inside the specified read-only span into their equivalent string representation that is encoded with base-64 digits. You can optionally specify whether to insert line breaks in the return value.

Convert.DBNull Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A constant that represents a database column that is absent of data; that is, database null.

```
C#

public static readonly object DBNull;
```

Field Value

Object

Remarks

The DBNull field is equivalent to DBNull.Value, as the following example shows.

```
C#

Console.WriteLine(Convert.DBNull.Equals(DBNull.Value));
// Displays True.
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Convert.ChangeType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an object of a specified type whose value is equivalent to a specified object.

Overloads

Expand table

ChangeType(Object, Type)	Returns an object of the specified type and whose value is equivalent to the specified object.
ChangeType(Object, TypeCode)	Returns an object of the specified type whose value is equivalent to the specified object.
ChangeType(Object, Type, IFormatProvider)	Returns an object of the specified type whose value is equivalent to the specified object. A parameter supplies culture-specific formatting information.
ChangeType(Object, TypeCode, IFormatProvider)	Returns an object of the specified type whose value is equivalent to the specified object. A parameter supplies culture-specific formatting information.

ChangeType(Object, Type)

Returns an object of the specified type and whose value is equivalent to the specified object.

C#

```
public static object? ChangeType (object? value, Type conversionType);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`conversionType` Type

The type of object to return.

Returns

Object

An object whose type is `conversionType` and whose value is equivalent to `value`.

-or-

A null reference (`Nothing` in Visual Basic), if `value` is `null` and `conversionType` is not a value type.

Exceptions

InvalidCastException

This conversion is not supported.

-or-

`value` is `null` and `conversionType` is a value type.

-or-

`value` does not implement the IConvertible interface.

FormatException

`value` is not in a format recognized by `conversionType`.

OverflowException

`value` represents a number that is out of the range of `conversionType`.

ArgumentNullException

`conversionType` is `null`.

Examples

The following example illustrates the use of the ChangeType method.

```
C#
```

```
using System;

public class ChangeTypeTest {
    public static void Main() {

        Double d = -2.345;
        int i = (int)Convert.ChangeType(d, typeof(int));

        Console.WriteLine("The double value {0} when converted to an int
becomes {1}", d, i);

        string s = "12/12/98";
        DateTime dt = (DateTime)Convert.ChangeType(s, typeof(DateTime));

        Console.WriteLine("The string value {0} when converted to a Date
becomes {1}", s, dt);
    }
}
```

Remarks

ChangeType is a general-purpose conversion method that converts the object specified by `value` to `conversionType`. The `value` parameter can be an object of any type, and `conversionType` can also be a Type object that represents any base or custom type. For the conversion to succeed, `value` must implement the IConvertible interface, because the method simply wraps a call to an appropriate IConvertible method. The method requires that conversion of `value` to `conversionType` be supported.

This method uses the current thread's culture for the conversion.

Notes to Callers

The ChangeType(Object, Type) method can convert an enumeration value to another type. However, it cannot convert another type to an enumeration value, even if the source type is the underlying type of the enumeration. To convert a type to an enumeration value, use a casting operator (in C#) or a conversion function (in Visual Basic). The following example illustrates the conversion to and from a `Continent` enumeration value.

C#

```
using System;

public enum Continent
```

```
{
   Africa, Antarctica, Asia, Australia, Europe,
   NorthAmerica, SouthAmerica
};

public class Example
{
   public static void Main()
   {
      // Convert a Continent to a Double.
      Continent cont = Continent.NorthAmerica;
      Console.WriteLine("{0:N2}",
                        Convert.ChangeType(cont, typeof(Double)));

      // Convert a Double to a Continent.
      Double number = 6.0;
      try {
         Console.WriteLine("{0}",
                           Convert.ChangeType(number,
typeof(Continent)));
      }
      catch (InvalidCastException) {
         Console.WriteLine("Cannot convert a Double to a Continent");
      }

      Console.WriteLine("{0}", (Continent) number);
   }
}
// The example displays the following output:
//       5.00
//       Cannot convert a Double to a Continent
//       SouthAmerica
```

The ChangeType(Object, Type) method can convert a nullable type to another type. However, it cannot convert another type to a value of a nullable type, even if `conversionType` is the underlying type of the Nullable<T>.To perform the conversion, you can use a casting operator (in C#) or a conversion function (in Visual Basic). The following example illustrates the conversion to and from a nullable type.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int? intValue1 = 12893;
      double dValue1 = (double) Convert.ChangeType(intValue1,
typeof(Double));
      Console.WriteLine("{0} ({1})--> {2} ({3})", intValue1,
intValue1.GetType().Name,
```

```
                        dValue1, dValue1.GetType().Name);

        float fValue1 = 16.3478f;
        int? intValue2 = (int) fValue1;
        Console.WriteLine("{0} ({1})--> {2} ({3})", fValue1,
fValue1.GetType().Name,
                        intValue2, intValue2.GetType().Name);
    }
}
// The example displays the following output:
//    12893 (Int32)--> 12893 (Double)
//    16.3478 (Single)--> 16 (Int32)
```

UWP	10.0

ChangeType(Object, TypeCode)

Returns an object of the specified type whose value is equivalent to the specified object.

C#

```
public static object? ChangeType (object? value, TypeCode typeCode);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`typeCode` TypeCode

The type of object to return.

Returns

Object

An object whose underlying type is `typeCode` and whose value is equivalent to `value`.

-or-

A null reference (`Nothing` in Visual Basic), if `value` is `null` and `typeCode` is Empty, String, or Object.

Exceptions

InvalidCastException

This conversion is not supported.

-or-

`value` is `null` and `typeCode` specifies a value type.

-or-

`value` does not implement the IConvertible interface.

FormatException

`value` is not in a format recognized by the `typeCode` type.

OverflowException

`value` represents a number that is out of the range of the `typeCode` type.

ArgumentException

`typeCode` is invalid.

Examples

The following example illustrates how to use the ChangeType(Object, TypeCode) method to change an Object to the type specified by the TypeCode parameter, if possible.

```
C#

using System;

public class ChangeTypeTest {
```

```
    public static void Main() {

        Double d = -2.345;
        int i = (int)Convert.ChangeType(d, TypeCode.Int32);

        Console.WriteLine("The Double {0} when converted to an Int32 is
{1}", d, i);

        string s = "12/12/2009";
        DateTime dt = (DateTime)Convert.ChangeType(s, typeof(DateTime));

        Console.WriteLine("The String {0} when converted to a Date is
{1}", s, dt);
    }
}
// The example displays the following output:
//    The Double -2.345 when converted to an Int32 is -2
//    The String 12/12/2009 when converted to a Date is 12/12/2009
12:00:00 AM
```

Remarks

ChangeType(Object, TypeCode) is a general-purpose conversion method that converts the object specified by `value` to a predefined type specified by `typeCode`. The `value` parameter can be an object of any type. For the conversion to succeed, `value` must implement the IConvertible interface, because the method simply wraps a call to an appropriate IConvertible method. The method also requires that conversion of `value` to `typeCode` be supported.

The ChangeType(Object, TypeCode) method does not support the conversion of `value` to a custom type. To perform such a conversion, call the ChangeType(Object, Type) method.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	2.0, 2.1

ChangeType(Object, Type, IFormatProvider)

Returns an object of the specified type whose value is equivalent to the specified object. A parameter supplies culture-specific formatting information.

```
C#

public static object? ChangeType (object? value, Type conversionType,
IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`conversionType` Type

The type of object to return.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Object

An object whose type is `conversionType` and whose value is equivalent to `value`.

-or-

`value`, if the Type of `value` and `conversionType` are equal.

-or-

A null reference (`Nothing` in Visual Basic), if `value` is `null` and `conversionType` is not a value type.

Exceptions

InvalidCastException

This conversion is not supported.

-or-

`value` is `null` and `conversionType` is a value type.

-or-

`value` does not implement the IConvertible interface.

FormatException

`value` is not in a format for `conversionType` recognized by `provider`.

OverflowException

`value` represents a number that is out of the range of `conversionType`.

ArgumentNullException

`conversionType` is `null`.

Examples

The following example defines a `Temperature` class that implements the IConvertible interface.

C#

```
using System;
using System.Globalization;

public class Temperature : IConvertible
{
   private decimal m_Temp;

   public Temperature(decimal temperature)
   {
      this.m_Temp = temperature;
   }

   public decimal Celsius
   {
      get { return this.m_Temp; }
   }

   public decimal Kelvin
   {
      get { return this.m_Temp + 273.15m; }
   }

   public decimal Fahrenheit
   {
      get { return Math.Round((decimal) (this.m_Temp * 9 / 5 + 32), 2); }
   }
```

```
    public override string ToString()
    {
        return m_Temp.ToString("N2") + "°C";
    }

    // IConvertible implementations.
    public TypeCode GetTypeCode()
    {
        return TypeCode.Object;
    }

    public bool ToBoolean(IFormatProvider provider)
    {
        if (m_Temp == 0)
            return false;
        else
            return true;
    }

    public byte ToByte(IFormatProvider provider)
    {
        if (m_Temp < Byte.MinValue || m_Temp > Byte.MaxValue)
            throw new OverflowException(String.Format("{0} is out of range
of the Byte type.",
                                                      this.m_Temp));
        else
            return Decimal.ToByte(this.m_Temp);
    }

    public char ToChar(IFormatProvider provider)
    {
        throw new InvalidCastException("Temperature to Char conversion is
not supported.");
    }

    public DateTime ToDateTime(IFormatProvider provider)
    {
        throw new InvalidCastException("Temperature to DateTime conversion

         default:
            throw new InvalidCastException(String.Format("Conversion to
{0} is not supported.", conversionType.Name));
      }
   }

   public ushort ToUInt16(IFormatProvider provider)
   {
      if (this.m_Temp < UInt16.MinValue || this.m_Temp > UInt16.MaxValue)
         throw new OverflowException(String.Format("{0} is out of range
of the UInt16 type.",
                                                     this.m_Temp));
      else
         return Decimal.ToUInt16(this.m_Temp);
   }

   public uint ToUInt32(IFormatProvider provider)
   {
      if (this.m_Temp < UInt32.MinValue || this.m_Temp > UInt32.MaxValue)
         throw new OverflowException(String.Format("{0} is out of range
of the UInt32 type.",
```

```
                                                        this.m_Temp));
      else
         return Decimal.ToUInt32(this.m_Temp);
   }

   public ulong ToUInt64(IFormatProvider provider)
   {
      if (this.m_Temp < UInt64.MinValue || this.m_Temp > UInt64.MaxValue)
         throw new OverflowException(String.Format("{0} is out of range
of the UInt64 type.",
                                                        this.m_Temp));
      else
         return Decimal.ToUInt64(this.m_Temp);
   }
}
```

The following example creates an instance of the `Temperature` class and calls the ChangeType(Object, Type, IFormatProvider) method to convert it to the basic numeric types supported by .NET and to a String. It illustrates that the ChangeType method wraps a call to the source type's IConvertible implementation.

C#

```
public class Example
{
   public static void Main()
   {
      Temperature cool = new Temperature(5);
      Type[] targetTypes = { typeof(SByte), typeof(Int16), typeof(Int32),
                             typeof(Int64), typeof(Byte), typeof(UInt16),
                             typeof(UInt32), typeof(UInt64),
typeof(Decimal),
                             typeof(Single), typeof(Double),
typeof(String) };
      CultureInfo provider = new CultureInfo("fr-FR");

      foreach (Type targetType in targetTypes)
      {
         try {
            object value = Convert.ChangeType(cool, targetType,
provider);
            Console.WriteLine("Converted {0} {1} to {2} {3}.",
                              cool.GetType().Name, cool.ToString(),
                              targetType.Name, value);
         }
         catch (InvalidCastException) {
            Console.WriteLine("Unsupported {0} --> {1} conversion.",
                              cool.GetType().Name, targetType.Name);
         }
         catch (OverflowException) {
            Console.WriteLine("{0} is out of range of the {1} type.",
                              cool, targetType.Name);
```

```
            }
        }
    }
}
// The example dosplays the following output:
//       Converted Temperature 5.00°C to SByte 5.
//       Converted Temperature 5.00°C to Int16 5.
//       Converted Temperature 5.00°C to Int32 5.
//       Converted Temperature 5.00°C to Int64 5.
//       Converted Temperature 5.00°C to Byte 5.
//       Converted Temperature 5.00°C to UInt16 5.
//       Converted Temperature 5.00°C to UInt32 5.
//       Converted Temperature 5.00°C to UInt64 5.
//       Converted Temperature 5.00°C to Decimal 5.
//       Converted Temperature 5.00°C to Single 5.
//       Converted Temperature 5.00°C to Double 5.
//       Converted Temperature 5.00°C to String 5,00°C.
```

Remarks

ChangeType is a general-purpose conversion method that converts the object specified by `value` to `conversionType`. The `value` parameter can be an object of any type, and `conversionType` can also be a Type object that represents any base or custom type. For the conversion to succeed, `value` must implement the IConvertible interface, because the method simply wraps a call to an appropriate IConvertible method. The method requires that conversion of `value` to `conversionType` be supported.

The `provider` parameter is an IFormatProvider implementation that supplies formatting information for the conversion. Whether and how this parameter is used depends on the underlying IConvertible implementation. If `value` is a base data type, `provider` is used only for the following conversions:

- Conversion from a number to a string, or from a string to a number. `provider` must be a CultureInfo object, a NumberFormatInfo object, or a custom IFormatProvider implementation that returns a NumberFormatInfo object. However, because the ChangeType(Object, TypeCode, IFormatProvider) method performs the conversion using the default "G" format specifier, the `provider` parameter has no effect if `value` or the target type is an unsigned integer. If `provider` is `null`, the CultureInfo object that represents the current culture is used.

- Conversion from a DateTime value to a string, or from a string to a DateTime value. `provider` must be a CultureInfo or DateTimeFormatInfo object. If

`provider` is `null`, the CultureInfo object that represents the current culture is used.

If `value` is an application-defined type, its IConvertible implementation may use the `provider` parameter.

Notes to Callers

The ChangeType(Object, Type, IFormatProvider) method can convert an enumeration value to another type. However, it cannot convert another type to an enumeration value, even if the source type is the underlying type of the enumeration. To convert a type to an enumeration value, use a casting operator (in C#) or a conversion function (in Visual Basic). The following example illustrates the conversion to and from a `Continent` enumeration value.

C#

```
using System;

public enum Continent
{
   Africa, Antarctica, Asia, Australia, Europe,
   NorthAmerica, SouthAmerica
};

public class Example
{
   public static void Main()
   {
      // Convert a Continent to a Double.
      Continent cont = Continent.NorthAmerica;
      Console.WriteLine("{0:N2}",
                        Convert.ChangeType(cont, typeof(Double)));

      // Convert a Double to a Continent.
      Double number = 6.0;
      try {
         Console.WriteLine("{0}",
                           Convert.ChangeType(number,
typeof(Continent)));
      }
      catch (InvalidCastException) {
         Console.WriteLine("Cannot convert a Double to a Continent");
      }

      Console.WriteLine("{0}", (Continent) number);
   }
}
// The example displays the following output:
```

```
//       5.00
//       Cannot convert a Double to a Continent
//       SouthAmerica
```

The ChangeType(Object, Type, IFormatProvider) method can convert a nullable type to another type. However, it cannot convert another type to a value of a nullable type, even if `conversionType` is the underlying type of the Nullable<T>. To perform the conversion, you can use a casting operator (in C#) or a conversion function (in Visual Basic). The following example illustrates the conversion to and from a nullable type.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int? intValue1 = 12893;
      double dValue1 = (double) Convert.ChangeType(intValue1,
typeof(Double), null);
      Console.WriteLine("{0} ({1})--> {2} ({3})", intValue1,
intValue1.GetType().Name,
                        dValue1, dValue1.GetType().Name);

      float fValue1 = 16.3478f;
      int? intValue2 = (int) fValue1;
      Console.WriteLine("{0} ({1})--> {2} ({3})", fValue1,
fValue1.GetType().Name,
                        intValue2, intValue2.GetType().Name);
   }
}
// The example displays the following output:
//    12893 (Int32)--> 12893 (Double)
//    16.3478 (Single)--> 16 (Int32)
```

ChangeType(Object, TypeCode, IFormatProvider)

Returns an object of the specified type whose value is equivalent to the specified object. A parameter supplies culture-specific formatting information.

C#

```
public static object? ChangeType (object? value, TypeCode typeCode,
IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`typeCode` TypeCode

The type of object to return.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Object

An object whose underlying type is `typeCode` and whose value is equivalent to `value`.

-or-

A null reference (`Nothing` in Visual Basic), if `value` is `null` and `typeCode` is Empty, String, or Object.

Exceptions

InvalidCastException

This conversion is not supported.

-or-

`value` is `null` and `typeCode` specifies a value type.

-or-

`value` does not implement the IConvertible interface.

FormatException

`value` is not in a format for the `typeCode` type recognized by `provider`.

OverflowException

`value` represents a number that is out of the range of the `typeCode` type.

ArgumentException

`typeCode` is invalid.

Examples

The following example defines a custom format provider named `InterceptProvider` that indicates when its GetFormat method is called and returns a NumberFormatInfo for the fr-FR culture and a DateTimeFormatInfo object for the en-US culture. This format provider is used in all calls to the ChangeType(Object, TypeCode, IFormatProvider) method. The example then creates an array with a Double and a DateTime value and makes repeated calls to ChangeType(Object, TypeCode, IFormatProvider) with each value and each member of the TypeCode enumeration. The example illustrates when the method uses the IFormatProvider parameter and also illustrates the use of the `provider` parameter to perform culture-sensitive formatting.

C#

```
using System;
using System.Globalization;

public class InterceptProvider : IFormatProvider
{
   public object GetFormat(Type formatType)
   {
      if (formatType == typeof(NumberFormatInfo)) {
         Console.WriteLine("   Returning a fr-FR numeric format
```

```
provider.");
         return new System.Globalization.CultureInfo("fr-
FR").NumberFormat;
      }
      else if (formatType == typeof(DateTimeFormatInfo)) {
         Console.WriteLine("   Returning an en-US date/time format
provider.");
         return new System.Globalization.CultureInfo("en-
US").DateTimeFormat;
      }
      else {
         Console.WriteLine("   Requesting a format provider of {0}.",
formatType.Name);
         return null;
      }
   }
}

public class Example
{
   public static void Main()
   {
      object[] values = { 103.5d, new DateTime(2010, 12, 26, 14, 34, 0)
};
      IFormatProvider provider = new InterceptProvider();

      // Convert value to each of the types represented in TypeCode enum.
      foreach (object value in values)
      {
         // Iterate types in TypeCode enum.
         foreach (TypeCode enumType in ((TypeCode[])
Enum.GetValues(typeof(TypeCode))))
         {
            if (enumType == TypeCode.DBNull || enumType ==
TypeCode.Empty) continue;

            try {
               Console.WriteLine("{0} ({1}) --> {2} ({3}).",
                                 value, value.GetType().Name,
                                 Convert.ChangeType(value, enumType,
provider),
                                 enumType.ToString());
            }
            catch (InvalidCastException) {
               Console.WriteLine("Cannot convert a {0} to a {1}",
                                 value.GetType().Name,
enumType.ToString());
            }
            catch (OverflowException) {
               Console.WriteLine("Overflow: {0} is out of the range of a
{1}",
                                 value, enumType.ToString());
            }
         }
         Console.WriteLine();
```

```
        }
    }
}
// The example displays the following output:
//    103.5 (Double) --> 103.5 (Object).
//    103.5 (Double) --> True (Boolean).
//    Cannot convert a Double to a Char
//    103.5 (Double) --> 104 (SByte).
//    103.5 (Double) --> 104 (Byte).
//    103.5 (Double) --> 104 (Int16).
//    103.5 (Double) --> 104 (UInt16).
//    103.5 (Double) --> 104 (Int32).
//    103.5 (Double) --> 104 (UInt32).
//    103.5 (Double) --> 104 (Int64).
//    103.5 (Double) --> 104 (UInt64).
//    103.5 (Double) --> 103.5 (Single).
//    103.5 (Double) --> 103.5 (Double).
//    103.5 (Double) --> 103.5 (Decimal).
//    Cannot convert a Double to a DateTime
//       Returning a fr-FR numeric format provider.
//    103.5 (Double) --> 103,5 (String).
//
//    12/26/2010 2:34:00 PM (DateTime) --> 12/26/2010 2:34:00 PM
(Object).
//    Cannot convert a DateTime to a Boolean
//    Cannot convert a DateTime to a Char
//    Cannot convert a DateTime to a SByte
//    Cannot convert a DateTime to a Byte
//    Cannot convert a DateTime to a Int16
//    Cannot convert a DateTime to a UInt16
//    Cannot convert a DateTime to a Int32
//    Cannot convert a DateTime to a UInt32
//    Cannot convert a DateTime to a Int64
//    Cannot convert a DateTime to a UInt64
//    Cannot convert a DateTime to a Single
//    Cannot convert a DateTime to a Double
//    Cannot convert a DateTime to a Decimal
//    12/26/2010 2:34:00 PM (DateTime) --> 12/26/2010 2:34:00 PM
(DateTime).
//       Returning an en-US date/time format provider.
//    12/26/2010 2:34:00 PM (DateTime) --> 12/26/2010 2:34:00 PM
(String).
```

Remarks

ChangeType(Object, TypeCode, IFormatProvider) is a general-purpose conversion method that converts the object specified by `value` to a predefined type specified by `typeCode`. The `value` parameter can be an object of any type. For the conversion to succeed, `value` must implement the IConvertible interface, because the method

simply wraps a call to an appropriate IConvertible method. The method also requires that conversion of `value` to `typeCode` be supported.

The ChangeType(Object, TypeCode, IFormatProvider) method does not support the conversion of `value` to a custom type. To perform such a conversion, call the ChangeType(Object, Type, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation that supplies formatting information for the conversion. Whether and how this parameter is used depends on the underlying IConvertible implementation. If `value` is a base data type, `provider` is used only for the following conversions. If a `null` IFormatProvider argument is passed to these methods, the CultureInfo object that represents the current culture is used.

- Conversion from a number to a string, or from a string to a number. `provider` must be a CultureInfo object, a NumberFormatInfo object, or a custom IFormatProvider implementation that returns a NumberFormatInfo object. However, because the ChangeType(Object, TypeCode, IFormatProvider) method performs the conversion using the default "G" format specifier, the `provider` parameter has no effect if `value` or the target type is an unsigned integer.
- Conversion from a DateTime value to a string, or from a string to a DateTime value. `provider` must be a CultureInfo or DateTimeFormatInfo object.

If `value` is an application-defined type, its IConvertible implementation may use the `provider` parameter.

Convert.FromBase64CharArray(Char[], Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a subset of a Unicode character array, which encodes binary data as base-64 digits, to an equivalent 8-bit unsigned integer array. Parameters specify the subset in the input array and the number of elements to convert.

```
C#

public static byte[] FromBase64CharArray (char[] inArray, int offset, int
length);
```

Parameters

`inArray` Char[]

A Unicode character array.

`offset` Int32

A position within `inArray`.

`length` Int32

The number of elements in `inArray` to convert.

Returns

Byte[]

An array of 8-bit unsigned integers equivalent to `length` elements at position `offset` in `inArray`.

Exceptions

ArgumentNullException

`inArray` is `null`.

ArgumentOutOfRangeException

`offset` or `length` is less than 0.

-or-

`offset` plus `length` indicates a position not within `inArray`.

FormatException

The length of `inArray`, ignoring white-space characters, is not zero or a multiple of 4.

-or-

The format of `inArray` is invalid. `inArray` contains a non-base-64 character, more than two padding characters, or a non-white-space character among the padding characters.

Examples

The following example demonstrates the use of the FromBase64CharArray(Char[], Int32, Int32) method to decode UUencoded (base-64) data and save it as binary output.

C#

```
public void DecodeWithCharArray() {
   System.IO.StreamReader inFile;
   char[] base64CharArray;

   try {
      inFile = new System.IO.StreamReader(inputFileName,
                              System.Text.Encoding.ASCII);
      base64CharArray = new char[inFile.BaseStream.Length];
      inFile.Read(base64CharArray, 0, (int)inFile.BaseStream.Length);
      inFile.Close();
   }
   catch (System.Exception exp) {
      // Error creating stream or reading from it.
      System.Console.WriteLine("{0}", exp.Message);
      return;
   }

   // Convert the Base64 UUEncoded input into binary output.
   byte[] binaryData;
   try {
      binaryData =
         System.Convert.FromBase64CharArray(base64CharArray,
                                            0,
                                            base64CharArray.Length);
```

```
    }
    catch ( System.ArgumentNullException ) {
       System.Console.WriteLine("Base 64 character array is null.");
       return;
    }
    catch ( System.FormatException ) {
       System.Console.WriteLine("Base 64 Char Array length is not " +
          "4 or is not an even multiple of 4." );
       return;
    }

    // Write out the decoded data.
    System.IO.FileStream outFile;
    try {
       outFile = new System.IO.FileStream(outputFileName,
                                          System.IO.FileMode.Create,
                                          System.IO.FileAccess.Write);
       outFile.Write(binaryData, 0, binaryData.Length);
       outFile.Close();
    }
    catch (System.Exception exp) {
       // Error creating stream or writing to it.
       System.Console.WriteLine("{0}", exp.Message);
    }
 }
```

The following example demonstrates the ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32, Base64FormattingOptions) and FromBase64CharArray(Char[], Int32, Int32) methods. The input is divided into groups of three bytes (24 bits) each. Consequently, each group consists of four 6-bit numbers where each number ranges from decimal 0 to 63. In this example, there are 85 3-byte groups with one byte remaining. The first group consists of the hexadecimal values 00, 01, and 02, which yield four 6-bit values equal to decimal 0, 0, 4, and 2. Those four values correspond to the base-64 digits, "A", "A", "E", and "C", at the beginning of the output.

If an integral number of 3-byte groups does not exist, the remaining bytes are effectively padded with zeros to form a complete group. In this example, the value of the last byte is hexadecimal FF. The first 6 bits are equal to decimal 63, which corresponds to the base-64 digit "/" at the end of the output, and the next 2 bits are padded with zeros to yield decimal 48, which corresponds to the base-64 digit, "w". The last two 6-bit values are padding and correspond to the valueless padding character, "=".

C#

```
// This example demonstrates the Convert.ToBase64CharArray() and
//                                Convert.FromBase64CharArray methods
```

```
using System;

class Sample
{
    public static void Main()
    {
    byte[] byteArray1 = new byte[256];
    byte[] byteArray2 = new byte[256];
    char[] charArray  = new char[352];
    int charArrayLength;
    string nl = Environment.NewLine;

    string ruler1a = "         1         2         3         4";
    string ruler2a = "1234567890123456789012345678901234567890";
    string ruler3a = "----+----+----+----+----+----+----+----+";
    string ruler1b = "         5         6         7      ";
    string ruler2b = "123456789012345678901234567890123456";
    string ruler3b = "----+----+----+----+----+----+----+-";
    string ruler   = String.Concat(ruler1a, ruler1b, nl,
                                   ruler2a, ruler2b, nl,
                                   ruler3a, ruler3b);

// 1) Initialize and display a Byte array of arbitrary data.
    Console.WriteLine("1) Input: A Byte array of arbitrary data.{0}", nl);
    for (int x = 0; x < byteArray1.Length; x++)
    {
    byteArray1[x] = (byte)x;
    Console.Write("{0:X2} ", byteArray1[x]);
    if (((x+1)%20) == 0) Console.WriteLine();
    }
    Console.Write("{0}{0}", nl);

// 2) Convert the input Byte array to a Char array, with newlines inserted.
    charArrayLength =
        Convert.ToBase64CharArray(byteArray1, 0, byteArray1.Length,
                                   charArray, 0,
Base64FormattingOptions.InsertLineBreaks);
    Console.WriteLine("2) Convert the input Byte array to a Char array with
newlines.");
    Console.Write("   Output: A Char array (length = {0}). ",
charArrayLength);
    Console.WriteLine("The elements of the array are:{0}", nl);
    Console.WriteLine(ruler);
    Console.WriteLine(new String(charArray));
    Console.WriteLine();

// 3) Convert the Char array back to a Byte array.
    Console.WriteLine("3) Convert the Char array to an output Byte array.");
    byteArray2 = Convert.FromBase64CharArray(charArray, 0, charArrayLength);

// 4) Are the input and output Byte arrays equivalent?
    Console.WriteLine("4) The output Byte array is equal to the input Byte
array: {0}",
                      ArraysAreEqual(byteArray1, byteArray2));
    }
```

```
    public static bool ArraysAreEqual(byte[] a1, byte[] a2)
    {
    if (a1.Length != a2.Length) return false;
    for (int i = 0; i < a1.Length; i++)
        if (a1[i] != a2[i]) return false;
    return true;
    }
}
/*
This example produces the following results:

1) Input: A Byte array of arbitrary data.

00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13

3) Convert the Char array to an output Byte array.
4) The output Byte array is equal to the input Byte array: True

*/
```

Remarks

`inArray` is composed of base-64 digits, white-space characters, and trailing padding characters. The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", lowercase characters "a" to "z", numerals "0" to "9", and the symbols "+" and "/".

The white-space characters, and their Unicode names and hexadecimal code points, are tab (CHARACTER TABULATION, U+0009), newline (LINE FEED, U+000A), carriage return (CARRIAGE RETURN, U+000D), and blank (SPACE, U+0020). An arbitrary number of white-space characters can appear in `inArray` because all white-space characters are ignored.

The valueless character, "=", is used for trailing padding. The end of `inArray` can consist of zero, one, or two padding characters.

> **Important**
>
> The **FromBase64CharArray** method is designed to process a single character array that contains all the data to be decoded. To decode base-64 character data from a stream, use the **System.Security.Cryptography.FromBase64Transform** class.

Convert.FromBase64String(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string, which encodes binary data as base-64 digits, to an equivalent 8-bit unsigned integer array.

C#

```
public static byte[] FromBase64String (string s);
```

Parameters

s String

The string to convert.

Returns

Byte[]

An array of 8-bit unsigned integers that is equivalent to `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

The length of `s`, ignoring white-space characters, is not zero or a multiple of 4.

-or-

The format of `s` is invalid. `s` contains a non-base-64 character, more than two padding characters, or a non-white space-character among the padding characters.

Examples

The following example uses the ToBase64String(Byte[]) method to convert a byte array to a UUencoded (base-64) string, and then calls the FromBase64String(String) method to restore the original byte array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
       // Define a byte array.
       byte[] bytes = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
       Console.WriteLine("The byte array: ");
       Console.WriteLine("   {0}\n", BitConverter.ToString(bytes));

       // Convert the array to a base 64 string.
       string s = Convert.ToBase64String(bytes);
       Console.WriteLine("The base 64 string:\n   {0}\n", s);

       // Restore the byte array.
       byte[] newBytes = Convert.FromBase64String(s);
       Console.WriteLine("The restored byte array: ");
       Console.WriteLine("   {0}\n", BitConverter.ToString(newBytes));
   }
}
// The example displays the following output:
//     The byte array:
//        02-04-06-08-0A-0C-0E-10-12-14
//
//     The base 64 string:
//        AgQGCAoMDhASFA==
//
//     The restored byte array:
//        02-04-06-08-0A-0C-0E-10-12-14
```

The following is a more complex example that creates a 20-element array of 32-bit integers. It then uses the BitConverter.GetBytes(Int32) method to convert each element into a byte array, which it stores in the appropriate position in a buffer by calling the Array.Copy(Array, Int32, Array, Int32, Int32) method. This buffer is then passed to the ToBase64String(Byte[]) method to create a UUencoded (base-64) string. It then calls the FromBase64String(String) method to decode the UUencoded string, and calls the BitConverter.ToInt32 method to convert each set of four bytes (the size of a 32-bit integer) to an integer. The output from the example shows that the original array has been successfully restored.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define an array of 20 elements and display it.
      int[] arr = new int[20];
      int value = 1;
      for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++) {
         arr[ctr] = value;
         value = value * 2 + 1;
      }
      DisplayArray(arr);

      // Convert the array of integers to a byte array.
      byte[] bytes = new byte[arr.Length * 4];
      for (int ctr = 0; ctr < arr.Length; ctr++) {
         Array.Copy(BitConverter.GetBytes(arr[ctr]), 0,
                    bytes, ctr * 4, 4);
      }

      // Encode the byte array using Base64 encoding
      String base64 = Convert.ToBase64String(bytes);
      Console.WriteLine("The encoded string: ");
      for (int ctr = 0; ctr <= base64.Length / 50; ctr++)
         Console.WriteLine(base64.Substring(ctr * 50,
                                            ctr * 50 + 50 <= base64.Length
                                               ? 50 : base64.Length - ctr *
50));
      Console.WriteLine();

      // Convert the string back to a byte array.
      byte[] newBytes = Convert.FromBase64String(base64);

      // Convert the byte array back to an integer array.
      int[] newArr = new int[newBytes.Length/4];
      for (int ctr = 0; ctr < newBytes.Length / 4; ctr ++)
         newArr[ctr] = BitConverter.ToInt32(newBytes, ctr * 4);

      DisplayArray(newArr);
   }

   private static void DisplayArray(Array arr)
   {
      Console.WriteLine("The array:");
      Console.Write("{ ");
      for (int ctr = 0; ctr < arr.GetUpperBound(0); ctr++) {
         Console.Write("{0}, ", arr.GetValue(ctr));
         if ((ctr + 1) % 10 == 0)
            Console.Write("\n  ");
      }
```

```
        Console.WriteLine("{0} {1}", arr.GetValue(arr.GetUpperBound(0)), "}");
        Console.WriteLine();
    }
}
// The example displays the following output:
// The array:
// { 1, 3, 7, 15, 31, 63, 127, 255, 511, 1023,
//   2047, 4095, 8191, 16383, 32767, 65535, 131071, 262143, 524287, 1048575
}
//
// The encoded string:
// AQAAAAMAAAAHAAAADwAAAB8AAAA/AAAAfwAAAP8AAAD/AQAA/w
// MAAP8HAAD/DwAA/x8AAP8/AAD/fwAA//8AAP//AQD//wMA//8H
//
// The array:
// { 1, 3, 7, 15, 31, 63, 127, 255, 511, 1023,
//   2047, 4095, 8191, 16383, 32767, 65535, 131071, 262143, 524287, 1048575
}
```

Remarks

`s` is composed of base-64 digits, white-space characters, and trailing padding characters. The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", lowercase characters "a" to "z", numerals "0" to "9", and the symbols "+" and "/".

The white-space characters, and their Unicode names and hexadecimal code points, are tab (CHARACTER TABULATION, U+0009), newline (LINE FEED, U+000A), carriage return (CARRIAGE RETURN, U+000D), and blank (SPACE, U+0020). An arbitrary number of white-space characters can appear in `s` because all white-space characters are ignored.

The valueless character, "=", is used for trailing padding. The end of `s` can consist of zero, one, or two padding characters.

Convert.FromHexString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

FromHexString(ReadOnlySpan<Char>)	Converts the span, which encodes binary data as hex characters, to an equivalent 8-bit unsigned integer array.
FromHexString(String)	Converts the specified string, which encodes binary data as hex characters, to an equivalent 8-bit unsigned integer array.

FromHexString(ReadOnlySpan<Char>)

Converts the span, which encodes binary data as hex characters, to an equivalent 8-bit unsigned integer array.

C#

```
public static byte[] FromHexString (ReadOnlySpan<char> chars);
```

Parameters

`chars` ReadOnlySpan<Char>

The span to convert.

Returns

Byte[]

An array of 8-bit unsigned integers that is equivalent to `chars`.

Exceptions

FormatException

The length of `chars`, is not zero or a multiple of 2.

FormatException

The format of `chars` is invalid. `chars` contains a non-hex character.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

FromHexString(String)

Converts the specified string, which encodes binary data as hex characters, to an equivalent 8-bit unsigned integer array.

```
C#

public static byte[] FromHexString (string s);
```

Parameters

s String

The string to convert.

Returns

Byte[]

An array of 8-bit unsigned integers that is equivalent to `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

The length of `s`, is not zero or a multiple of 2.

FormatException

The format of `s` is invalid. `s` contains a non-hex character.

Convert.GetTypeCode(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for the specified object.

C#

```
public static TypeCode GetTypeCode (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

Returns

TypeCode

The TypeCode for `value`, or Empty if `value` is `null`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Convert.IsDBNull(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an indication whether the specified object is of type DBNull.

C#

```
public static bool IsDBNull (object? value);
```

Parameters

value Object

An object.

Returns

Boolean

`true` if `value` is of type DBNull; otherwise, `false`.

Examples

The following example uses a SqlDataReader object to retrieve survey data from a database. It assigns each row's field values to an array, and then passes each array element to the IsDBNull method. If the method returns `true`, the example assigns the string "NA" to the array element. The array is then added to the Rows collection of a System.Windows.Forms.DataGridView control.

C#

```
private void Form1_Load(object sender, EventArgs e)
{
   // Define ADO.NET objects.
   SqlConnection conn = new SqlConnection(connectionString);
   SqlCommand cmd = new SqlCommand();
   SqlDataReader dr;
```

```
   // Open connection, and retrieve dataset.
   conn.Open();

   // Define Command object.
   cmd.CommandText = "Select * From Responses";
   cmd.CommandType = CommandType.Text;
   cmd.Connection = conn;

   // Retrieve data reader.
   dr = cmd.ExecuteReader();

   int fieldCount = dr.FieldCount;
   object[] fieldValues = new object[fieldCount];
   string[] headers = new string[fieldCount];

   // Get names of fields.
   for (int ctr = 0; ctr < fieldCount; ctr++)
      headers[ctr] = dr.GetName(ctr);

   // Set up data grid.
   this.grid.ColumnCount = fieldCount;

   this.grid.ColumnHeadersDefaultCellStyle.BackColor = Color.Navy;
   this.grid.ColumnHeadersDefaultCellStyle.ForeColor = Color.White;
   this.grid.ColumnHeadersDefaultCellStyle.Font = new Font(this.grid.Font,
FontStyle.Bold);

   this.grid.AutoSizeRowsMode =
DataGridViewAutoSizeRowsMode.DisplayedCellsExceptHeaders;
   this.grid.ColumnHeadersBorderStyle =
DataGridViewHeaderBorderStyle.Single;
   this.grid.CellBorderStyle = DataGridViewCellBorderStyle.Single;
   this.grid.GridColor = Color.Black;
   this.grid.RowHeadersVisible = true;

   for (int columnNumber = 0; columnNumber < headers.Length;
columnNumber++)
      this.grid.Columns[columnNumber].Name = headers[columnNumber];

   // Get data, replace missing values with "NA", and display it.
   while (dr.Read())
   {
      dr.GetValues(fieldValues);

      for (int fieldCounter = 0; fieldCounter < fieldCount; fieldCounter++)
      {
         if (Convert.IsDBNull(fieldValues[fieldCounter]))
            fieldValues[fieldCounter] = "NA";
      }
      grid.Rows.Add(fieldValues);
   }
   dr.Close();
}
```

Remarks

The IsDBNull method tests whether the `value` parameter is equal to DBNull.Value. It is equivalent to the following code:

```
C#
return DBNull.Value.Equals(value);
```

> **Note**
>
> **DBNull.Value** is used to indicate a value that is missing. It is not equivalent to `null` or to **String.Empty**. Therefore, code such as `Convert.IsDBNull(null)` in C# or `Convert.IsDBNull(Nothing)` in Visual Basic returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Convert.ToBase64CharArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits.

Overloads

Expand table

ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32, Base64FormattingOptions)	Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits. Parameters specify the subsets as offsets in the input and output arrays, the number of elements in the input array to convert, and whether line breaks are inserted in the output array.
ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32)	Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits. Parameters specify the subsets as offsets in the input and output arrays, and the number of elements in the input array to convert.

ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32, Base64FormattingOptions)

Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits. Parameters specify the subsets as offsets in the input and output arrays, the number of elements in the input array to convert, and whether line breaks are inserted in the output array.

C#

```
public static int ToBase64CharArray (byte[] inArray, int offsetIn, int
length, char[] outArray, int offsetOut, Base64FormattingOptions options);
```

Parameters

`inArray` Byte[]

An input array of 8-bit unsigned integers.

`offsetIn` Int32

A position within `inArray`.

`length` Int32

The number of elements of `inArray` to convert.

`outArray` Char[]

An output array of Unicode characters.

`offsetOut` Int32

A position within `outArray`.

`options` Base64FormattingOptions

InsertLineBreaks to insert a line break every 76 characters, or None to not insert line breaks.

Returns

Int32

A 32-bit signed integer containing the number of bytes in `outArray`.

Exceptions

ArgumentNullException

`inArray` or `outArray` is `null`.

ArgumentOutOfRangeException

`offsetIn`, `offsetOut`, or `length` is negative.

-or-

`offsetIn` plus `length` is greater than the length of `inArray`.

-or-

`offsetOut` plus the number of elements to return is greater than the length of `outArray`.

ArgumentException

`options` is not a valid Base64FormattingOptions value.

Examples

The following example demonstrates the ToBase64CharArray method. The input is divided into groups of three bytes (24 bits) each. Consequently, each group consists of four 6-bit numbers where each number ranges from decimal 0 to 63. In this example, there are 85 3-byte groups with one byte remaining. The first group consists of the hexadecimal values 00, 01, and 02, which yield four 6-bit values equal to decimal 0, 0, 4, and 2. Those four values correspond to the base-64 digits "A", "A", "E", and "C" at the beginning of the output.

If an integral number of 3-byte groups does not exist, the remaining bytes are effectively padded with zeros to form a complete group. In this example, the value of the last byte is hexadecimal FF. The first 6 bits are equal to decimal 63, which corresponds to the base-64 digit "/" at the end of the output, and the next 2 bits are padded with zeros to yield decimal 48, which corresponds to the base-64 digit, "w". The last two 6-bit values are padding and correspond to the valueless padding character, "=".

C#

```
// This example demonstrates the Convert.ToBase64CharArray() and
//                                Convert.FromBase64CharArray methods

using System;

class Sample
{
    public static void Main()
    {
    byte[] byteArray1 = new byte[256];
    byte[] byteArray2 = new byte[256];
    char[] charArray  = new char[352];
    int charArrayLength;
    string nl = Environment.NewLine;

    string ruler1a = "         1         2         3         4";
    string ruler2a = "1234567890123456789012345678901234567890";
    string ruler3a = "----+----+----+----+----+----+----+----+";
    string ruler1b = "         5         6         7      ";
    string ruler2b = "123456789012345678901234567890123456";
```

```
    string ruler3b = "----+----+----+----+----+----+----+-";
    string ruler   = String.Concat(ruler1a, ruler1b, nl,
                                   ruler2a, ruler2b, nl,
                                   ruler3a, ruler3b);

// 1) Initialize and display a Byte array of arbitrary data.
    Console.WriteLine("1) Input: A Byte array of arbitrary data.{0}",
nl);
    for (int x = 0; x < byteArray1.Length; x++)
    {
    byteArray1[x] = (byte)x;
    Console.Write("{0:X2} ", byteArray1[x]);
    if (((x+1)%20) == 0) Console.WriteLine();
    }
    Console.Write("{0}{0}", nl);

// 2) Convert the input Byte array to a Char array, with newlines
inserted.
    charArrayLength =
        Convert.ToBase64CharArray(byteArray1, 0, byteArray1.Length,
                                   charArray, 0,
Base64FormattingOptions.InsertLineBreaks);
    Console.WriteLine("2) Convert the input Byte array to a Char array
with newlines.");
    Console.Write("   Output: A Char array (length = {0}). ",
charArrayLength);
    Console.WriteLine("The elements of the array are:{0}", nl);
    Console.WriteLine(ruler);
    Console.WriteLine(new String(charArray));
    Console.WriteLine();

// 3) Convert the Char array back to a Byte array.
    Console.WriteLine("3) Convert the Char array to an output Byte
array.");
    byteArray2 = Convert.FromBase64CharArray(charArray, 0,
charArrayLength);

// 4) Are the input and output Byte arrays equivalent?
    Console.WriteLine("4) The output Byte array is equal to the input
Byte array: {0}",
                      ArraysAreEqual(byteArray1, byteArray2));
    }

    public static bool ArraysAreEqual(byte[] a1, byte[] a2)
    {
    if (a1.Length != a2.Length) return false;
    for (int i = 0; i < a1.Length; i++)
        if (a1[i] != a2[i]) return false;
    return true;
    }
}
/*
This example produces the following results:

1) Input: A Byte array of arbitrary data.
```

```
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13

3) Convert the Char array to an output Byte array.
4) The output Byte array is equal to the input Byte array: True

*/
```

Remarks

The subset of `length` elements of the `inArray` parameter starting at position `offsetIn`, are taken as a numeric value and converted to a subset of elements in the `outArray` parameter starting at position `offsetOut`. The return value indicates the number of converted elements in `outArray`. The subset of `outArray` consists of base-64 digits.

The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", the lowercase characters "a" to "z", the numerals "0" to "9", and the symbols "+" and "/". The valueless character "=" is used for trailing padding.

The `offset` and `length` parameters are 32-bit signed numbers. The `offsetIn` and `offsetOut` parameters are zero-based array positions.

> **Important**
>
> The **ToBase64CharArray** method is designed to process a single byte array that contains all the data to be encoded. To create a base-64 character array from a byte stream, use the **System.Security.Cryptography.ToBase64Transform** class.

If the `options` parameter is set to InsertLineBreaks and the output of the conversion is longer than 76 characters, a line break is inserted every 76 characters. A line break is defined as a carriage return character (U+000D) followed by a line feed character (U+000A). For more information, see RFC 2045, "Multipurpose Internet Mail Extensions", at https://www.rfc-editor.org/.

ToBase64CharArray(Byte[], Int32, Int32, Char[], Int32)

Converts a subset of an 8-bit unsigned integer array to an equivalent subset of a Unicode character array encoded with base-64 digits. Parameters specify the subsets as offsets in the input and output arrays, and the number of elements in the input array to convert.

```C#
public static int ToBase64CharArray (byte[] inArray, int offsetIn, int length, char[] outArray, int offsetOut);
```

Parameters

`inArray` Byte[]

An input array of 8-bit unsigned integers.

`offsetIn` Int32

A position within `inArray`.

`length` Int32

The number of elements of `inArray` to convert.

`outArray` Char[]

An output array of Unicode characters.

`offsetOut` Int32

A position within `outArray`.

Returns

Int32

A 32-bit signed integer containing the number of bytes in `outArray`.

Exceptions

ArgumentNullException

`inArray` or `outArray` is `null`.

ArgumentOutOfRangeException

`offsetIn`, `offsetOut`, or `length` is negative.

-or-

`offsetIn` plus `length` is greater than the length of `inArray`.

-or-

`offsetOut` plus the number of elements to return is greater than the length of `outArray`.

Examples

The following example demonstrates using the ToBase64CharArray method to UUencode (encode in base 64) a binary stream, then save the encoding to a file.

C#

```
public void EncodeWithCharArray() {
   System.IO.FileStream inFile;
   byte[]             binaryData;

   try {
      inFile = new System.IO.FileStream(inputFileName,
                                        System.IO.FileMode.Open,
                                       System.IO.FileAccess.Read);
      binaryData = new Byte[inFile.Length];
      long bytesRead = inFile.Read(binaryData, 0,
                                   (int) inFile.Length);
      inFile.Close();
   }
   catch (System.Exception exp) {
      // Error creating stream or reading from it.
      System.Console.WriteLine("{0}", exp.Message);
      return;
   }

   // Convert the binary input into Base64 UUEncoded output.
   // Each 3 byte sequence in the source data becomes a 4 byte
   // sequence in the character array.
   long arrayLength = (long) ((4.0d/3.0d) * binaryData.Length);

   // If array length is not divisible by 4, go up to the next
   // multiple of 4.
   if (arrayLength % 4 != 0) {
      arrayLength += 4 - arrayLength % 4;
   }

   char[] base64CharArray = new char[arrayLength];
   try {
      System.Convert.ToBase64CharArray(binaryData,
                                       0,
                                       binaryData.Length,
                                       base64CharArray,
                                       0);
   }
   catch (System.ArgumentNullException) {
      System.Console.WriteLine("Binary data array is null.");
      return;
   }
```

```
    catch (System.ArgumentOutOfRangeException) {
       System.Console.WriteLine("Char Array is not large enough.");
       return;
    }

    // Write the UUEncoded version to the output file.
    System.IO.StreamWriter outFile;
    try {
       outFile = new System.IO.StreamWriter(outputFileName,
                                false,
                                System.Text.Encoding.ASCII);
       outFile.Write(base64CharArray);
       outFile.Close();
    }
    catch (System.Exception exp) {
       // Error creating stream or writing to it.
       System.Console.WriteLine("{0}", exp.Message);
    }
 }
```

Remarks

The subset of `length` elements of `inArray` starting at position `offsetIn`, are taken as a numeric value and converted to a subset of elements in `outArray` starting at position `offsetOut`. The return value indicates the number of converted elements in `outArray`. The subset of `outArray` consists of base-64 digits.

The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", the lowercase characters "a" to "z", the numerals "0" to "9", and the symbols "+" and "/". The valueless character, "=", is used for trailing padding.

The `offset` and `length` parameters are 32-bit signed numbers. The `offsetIn` and `offsetOut` parameters are zero-based array positions.

Convert.ToBase64String Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits.

Overloads

Expand table

ToBase64String(Byte[])	Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits.
ToBase64String(Byte[], Base64FormattingOptions)	Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. You can specify whether to insert line breaks in the return value.
ToBase64String(ReadOnlySpan<Byte>, Base64FormattingOptions)	Converts the 8-bit unsigned integers inside the specified read-only span into their equivalent string representation that is encoded with base-64 digits. You can optionally specify whether to insert line breaks in the return value.
ToBase64String(Byte[], Int32, Int32)	Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. Parameters specify the subset as an offset in the input array, and the number of elements in the array to convert.
ToBase64String(Byte[], Int32, Int32, Base64FormattingOptions)	Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. Parameters specify the subset as an offset in the input array, the number of elements in the array to convert, and whether to insert line breaks in the return value.

ToBase64String(Byte[])

Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits.

```
C#

public static string ToBase64String (byte[] inArray);
```

Parameters

`inArray` Byte[]

An array of 8-bit unsigned integers.

Returns

String

The string representation, in base 64, of the contents of `inArray`.

Exceptions

ArgumentNullException

`inArray` is `null`.

Examples

The following example uses the ToBase64String(Byte[]) method to convert a byte array to a UUencoded (base-64) string, and then calls the FromBase64String(String) method to restore the original byte array.

```
C#

using System;

public class Example
{
   public static void Main()
   {
       // Define a byte array.
       byte[] bytes = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
       Console.WriteLine("The byte array: ");
       Console.WriteLine("   {0}\n", BitConverter.ToString(bytes));

       // Convert the array to a base 64 string.
```

```
        string s = Convert.ToBase64String(bytes);
        Console.WriteLine("The base 64 string:\n   {0}\n", s);

        // Restore the byte array.
        byte[] newBytes = Convert.FromBase64String(s);
        Console.WriteLine("The restored byte array: ");
        Console.WriteLine("   {0}\n", BitConverter.ToString(newBytes));
    }
}
// The example displays the following output:
//     The byte array:
//        02-04-06-08-0A-0C-0E-10-12-14
//
//     The base 64 string:
//        AgQGCAoMDhASFA==
//
//     The restored byte array:
//        02-04-06-08-0A-0C-0E-10-12-14
```

The following is a more complex example that creates a 20-element array of 32-bit integers. It then uses the BitConverter.GetBytes(Int32) method to convert each element into a byte array, which it stores in the appropriate position in a buffer by calling the Array.Copy(Array, Int32, Array, Int32, Int32) method. This buffer is then passed to the ToBase64String(Byte[]) method to create a UUencoded (base-64) string. It then calls the FromBase64String(String) method to decode the UUencoded string, and calls the BitConverter.ToInt32 method to convert each set of four bytes (the size of a 32-bit integer) to an integer. The output from the example shows that the original array has been successfully restored.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define an array of 20 elements and display it.
      int[] arr = new int[20];
      int value = 1;
      for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++) {
         arr[ctr] = value;
         value = value * 2 + 1;
      }
      DisplayArray(arr);

      // Convert the array of integers to a byte array.
      byte[] bytes = new byte[arr.Length * 4];
      for (int ctr = 0; ctr < arr.Length; ctr++) {
         Array.Copy(BitConverter.GetBytes(arr[ctr]), 0,
```

```
                    bytes, ctr * 4, 4);
      }

      // Encode the byte array using Base64 encoding
      String base64 = Convert.ToBase64String(bytes);
      Console.WriteLine("The encoded string: ");
      for (int ctr = 0; ctr <= base64.Length / 50; ctr++)
         Console.WriteLine(base64.Substring(ctr * 50,
                                            ctr * 50 + 50 <=
base64.Length
                                               ? 50 : base64.Length - ctr
* 50));
      Console.WriteLine();

      // Convert the string back to a byte array.
      byte[] newBytes = Convert.FromBase64String(base64);

      // Convert the byte array back to an integer array.
      int[] newArr = new int[newBytes.Length/4];
      for (int ctr = 0; ctr < newBytes.Length / 4; ctr ++)
         newArr[ctr] = BitConverter.ToInt32(newBytes, ctr * 4);

      DisplayArray(newArr);
   }

   private static void DisplayArray(Array arr)
   {
      Console.WriteLine("The array:");
      Console.Write("{ ");
      for (int ctr = 0; ctr < arr.GetUpperBound(0); ctr++) {
         Console.Write("{0}, ", arr.GetValue(ctr));
         if ((ctr + 1) % 10 == 0)
            Console.Write("\n  ");
      }
      Console.WriteLine("{0} {1}", arr.GetValue(arr.GetUpperBound(0)),
"}");
      Console.WriteLine();
   }
}
// The example displays the following output:
// The array:
// { 1, 3, 7, 15, 31, 63, 127, 255, 511, 1023,
//   2047, 4095, 8191, 16383, 32767, 65535, 131071, 262143, 524287,
1048575 }
//
// The encoded string:
// AQAAAAMAAAAHAAAADwAAAB8AAAA/AAAAfwAAAP8AAAD/AQAA/w
// MAAP8HAAD/DwAA/x8AAP8/AAD/fwAA//8AAP//AQD//wMA//8H
//
// The array:
// { 1, 3, 7, 15, 31, 63, 127, 255, 511, 1023,
//   2047, 4095, 8191, 16383, 32767, 65535, 131071, 262143, 524287,
1048575 }
```

Remarks

The elements of `inArray` are taken as a numeric value and converted to a string representation that is encoded with base-64 digits.

The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", the lowercase characters "a" to "z", the numerals "0" to "9", and the symbols "+" and "/". The valueless character, "=", is used for trailing padding.

> ⓘ **Important**
>
> The **ToBase64String** method is designed to process a single byte array that contains all the data to be encoded. To encode data from a stream, use the **System.Security.Cryptography.ToBase64Transform** class.

Ordinarily, the ToBase64String method is not used to round-trip a UUEncoded (base-64 encoded) string. That is, if you decode a string by calling the FromBase64String method, then encode the returned byte array by calling the ToBase64String method, the resulting string will not necessarily be identical to the original string. The string will round-trip only if the original string is a valid base-64 encoded string.

ToBase64String(Byte[], Base64FormattingOptions)

Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. You can specify whether to insert line breaks in the return value.

```
C#

public static string ToBase64String (byte[] inArray,
Base64FormattingOptions options);
```

Parameters

`inArray` Byte[]

An array of 8-bit unsigned integers.

`options` Base64FormattingOptions

InsertLineBreaks to insert a line break every 76 characters, or None to not insert line breaks.

Returns

String

The string representation in base 64 of the elements in `inArray`.

Exceptions

ArgumentNullException

`inArray` is `null`.

ArgumentException

`options` is not a valid Base64FormattingOptions value.

Examples

The following example calls the Convert.ToBase64String(Byte[], Base64FormattingOptions) with a Base64FormattingOptions.InsertLineBreaks argument to insert line breaks in the string that is produced by encoding a 100-element byte array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
       // Define a byte array.
       var bytes = new byte[100];
       int originalTotal = 0;
       for (int ctr = 0; ctr <= bytes.GetUpperBound(0); ctr++) {
          bytes[ctr] = (byte)(ctr + 1);
          originalTotal += bytes[ctr];
       }
       // Display summary information about the array.
       Console.WriteLine("The original byte array:");
       Console.WriteLine("   Total elements: {0}", bytes.Length);
       Console.WriteLine("   Length of String Representation: {0}",
                         BitConverter.ToString(bytes).Length);
       Console.WriteLine("   Sum of elements: {0:N0}", originalTotal);
       Console.WriteLine();

       // Convert the array to a base 64 string.
       string s = Convert.ToBase64String(bytes,

Base64FormattingOptions.InsertLineBreaks);
       Console.WriteLine("The base 64 string:\n   {0}\n", s);

       // Restore the byte array.
       Byte[] newBytes = Convert.FromBase64String(s);
       int newTotal = 0;
       foreach (var newByte in newBytes)
          newTotal += newByte;

       // Display summary information about the restored array.
       Console.WriteLine("   Total elements: {0}", newBytes.Length);
       Console.WriteLine("   Length of String Representation: {0}",
                         BitConverter.ToString(newBytes).Length);
       Console.WriteLine("   Sum of elements: {0:N0}", newTotal);
   }
}
// The example displays the following output:
//   The original byte array:
//      Total elements: 100
//      Length of String Representation: 299
//      Sum of elements: 5,050
//
//   The base 64 string:
//
AQIDBAUGBwgJCgsMDQ4PEBESExQVFhcYGRobHB0eHyAhIiMkJSYnKCkqKywtLi8wMTIzNDU2N
zg5
//   Ojs8PT4/QEFCQ0RFRkdISUpLTE1OT1BRUlNUVVZXWFlaW1xdXl9gYWJjZA==
//
```

```
//      Total elements: 100
//      Length of String Representation: 299
//      Sum of elements: 5,050
```

As the output from the example shows, the Convert.FromBase64String succeeds in restoring the original byte array; the line break characters are ignored during the conversion.

Remarks

The elements of the `inArray` parameter are taken as a numeric value and converted to a string representation in base 64.

The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", the lowercase characters "a" to "z", the numerals "0" to "9", and the symbols "+" and "/". The valueless character "=" is used for trailing padding.

> **Important**
>
> The **ToBase64String** method is designed to process a single byte array that contains all the data to be encoded. To encode data from a stream, use the **System.Security.Cryptography.ToBase64Transform** class.

If the `options` parameter is set to InsertLineBreaks and the output of the conversion is longer than 76 characters, a line break is inserted every 76 characters. A line break is defined as a carriage return character (U+000D) followed by a line feed character (U+000A). Because line breaks are considered white-space characters in a base-64 encoding, they are ignored when converting a base-64 encoded string back to a byte array. The line breaks are simply convenient when displaying the encoded string to a control or a device such as a console window. For more information, see RFC 2045, "Multipurpose Internet Mail Extensions", at https://www.rfc-editor.org/.

.NET Standard	2.0, 2.1

ToBase64String(ReadOnlySpan<Byte>, Base64FormattingOptions)

Converts the 8-bit unsigned integers inside the specified read-only span into their equivalent string representation that is encoded with base-64 digits. You can optionally specify whether to insert line breaks in the return value.

C#

```
public static string ToBase64String (ReadOnlySpan<byte> bytes,
Base64FormattingOptions options = System.Base64FormattingOptions.None);
```

Parameters

`bytes` ReadOnlySpan<Byte>

A read-only span of 8-bit unsigned integers.

`options` Base64FormattingOptions

One of the enumeration values that specify whether to insert line breaks in the return value. The default value is None.

Returns

String

The string representation in base 64 of the elements in `inArray`. If the length of `bytes` is 0, an empty string is returned.

Exceptions

ArgumentException

`options` is not a valid Base64FormattingOptions value.

OutOfMemoryException

The output length was larger than Int32.MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ToBase64String(Byte[], Int32, Int32)

Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. Parameters specify the subset as an offset in the input array, and the number of elements in the array to convert.

```
C#

public static string ToBase64String (byte[] inArray, int offset, int
length);
```

Parameters

`inArray` Byte[]

An array of 8-bit unsigned integers.

`offset` Int32

An offset in `inArray`.

`length` Int32

The number of elements of `inArray` to convert.

Returns

String

The string representation in base 64 of `length` elements of `inArray`, starting at position `offset`.

Exceptions

ArgumentNullException

`inArray` is `null`.

ArgumentOutOfRangeException

`offset` or `length` is negative.

-or-

`offset` plus `length` is greater than the length of `inArray`.

Remarks

The elements of `inArray` are taken as a numeric value and converted to a string representation in base 64.

The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", the lowercase characters "a" to "z", the numerals "0" to "9", and the symbols "+" and "/". The valueless character, "=", is used for trailing padding.

The `offset` and `length` parameters are 32-bit signed numbers. The `offset` parameter is zero-based.

> ⓘ **Important**
>
> The **ToBase64String** method is designed to process a single byte array that contains all the data to be encoded. To encode data from a stream, use the **System.Security.Cryptography.ToBase64Transform** class.

UWP	10.0

ToBase64String(Byte[], Int32, Int32, Base64FormattingOptions)

Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with base-64 digits. Parameters specify the subset as an offset in the input array, the number of elements in the array to convert, and whether to insert line breaks in the return value.

C#

```
public static string ToBase64String (byte[] inArray, int offset, int
length, Base64FormattingOptions options);
```

Parameters

`inArray` Byte[]

An array of 8-bit unsigned integers.

`offset` Int32

An offset in `inArray`.

`length` Int32

The number of elements of `inArray` to convert.

`options` Base64FormattingOptions

InsertLineBreaks to insert a line break every 76 characters, or None to not insert line breaks.

Returns

String

The string representation in base 64 of `length` elements of `inArray`, starting at position `offset`.

Exceptions

ArgumentNullException

`inArray` is `null`.

ArgumentOutOfRangeException

`offset` or `length` is negative.

-or-

`offset` plus `length` is greater than the length of `inArray`.

ArgumentException

`options` is not a valid Base64FormattingOptions value.

Examples

The following example demonstrates the ToBase64String method. The input is divided into groups of three bytes (24 bits) each. Consequently, each group consists of four 6-bit numbers where each number ranges from decimal 0 to 63. In this example, there are 85 3-byte groups with one byte remaining. The first group consists of the hexadecimal values 00, 01, and 02, which yield four 6-bit values equal to decimal 0, 0, 4, and 2. Those four values correspond to the base-64 digits "A", "A", "E", and "C" at the beginning of the output.

If an integral number of 3-byte groups does not exist, the remaining bytes are effectively padded with zeros to form a complete group. In this example, the value of the last byte is hexadecimal FF. The first 6 bits are equal to decimal 63, which corresponds to the base-64 digit "/" at the end of the output, and the next 2 bits are padded with zeros to yield decimal 48, which corresponds to the base-64 digit, "w". The last two 6-bit values are padding and correspond to the valueless padding character, "=".

C#

```
// This example demonstrates the Convert.ToBase64String() and
//                                Convert.FromBase64String() methods
```

```
using System;
class Sample
{
    public static void Main()
    {
    byte[] inArray  = new byte[256];
    byte[] outArray = new byte[256];
    string s2;
    string s3;
    string step1 = "1) The input is a byte array (inArray) of arbitrary
data.";
    string step2 = "2) Convert a subarray of the input data array to a
base 64 string.";
    string step3 = "3) Convert the entire input data array to a base 64
string.";
    string step4 = "4) The two methods in steps 2 and 3 produce the same
result: {0}";
    string step5 = "5) Convert the base 64 string to an output byte array
(outArray).";
    string step6 = "6) The input and output arrays, inArray and outArray,
are equal: {0}";
    int x;
    string nl = Environment.NewLine;
    string ruler1a = "         1         2         3         4";
    string ruler2a = "1234567890123456789012345678901234567890";
    string ruler3a = "----+----+----+----+----+----+----+----+";
    string ruler1b = "         5         6         7      ";
    string ruler2b = "123456789012345678901234567890123456";
    string ruler3b = "----+----+----+----+----+----+----+-";
    string ruler   = String.Concat(ruler1a, ruler1b, nl,
                                   ruler2a, ruler2b, nl,
                                   ruler3a, ruler3b, nl);

// 1) Display an arbitrary array of input data (inArray). The data could
be
//    derived from user input, a file, an algorithm, etc.

    Console.WriteLine(step1);
    Console.WriteLine();
    for (x = 0; x < inArray.Length; x++)
        {
        inArray[x] = (byte)x;
        Console.Write("{0:X2} ", inArray[x]);
        if (((x+1)%20) == 0) Console.WriteLine();
        }
    Console.Write("{0}{0}", nl);

// 2) Convert a subarray of the input data to a base64 string. In this
case,
//    the subarray is the entire input data array. New lines (CRLF) are
inserted.

    Console.WriteLine(step2);
    s2 = Convert.ToBase64String(inArray, 0, inArray.Length,
```

```
Base64FormattingOptions.InsertLineBreaks);
    Console.WriteLine("{0}{1}{2}{3}", nl, ruler, s2, nl);

// 3) Convert the input data to a base64 string. In this case, the entire
//    input data array is converted by default. New lines (CRLF) are
inserted.

    Console.WriteLine(step3);
    s3 = Convert.ToBase64String(inArray,
Base64FormattingOptions.InsertLineBreaks);

// 4) Test whether the methods in steps 2 and 3 produce the same result.
    Console.WriteLine(step4, s2.Equals(s3));

// 5) Convert the base 64 string to an output array (outArray).
    Console.WriteLine(step5);
    outArray = Convert.FromBase64String(s2);

// 6) Is outArray equal to inArray?
   Console.WriteLine(step6, ArraysAreEqual(inArray, outArray));
   }

    public static bool ArraysAreEqual(byte[] a1, byte[] a2)
    {
    if (a1.Length != a2.Length) return false;
    for (int i = 0; i < a1.Length; i++)
        if (a1[i] != a2[i]) return false;
    return true;
    }
}
/*
This example produces the following results:

1) The input is a byte array (inArray) of arbitrary data.

00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13

3) Convert the entire input data array to a base 64 string.
4) The two methods in steps 2 and 3 produce the same result: True
5) Convert the base 64 string to an output byte array (outArray).
6) The input and output arrays, inArray and outArray, are equal: True

*/
```

Remarks

The elements of the `inArray` parameter are taken as a numeric value and converted to a string representation in base 64.

The base-64 digits in ascending order from zero are the uppercase characters "A" to "Z", the lowercase characters "a" to "z", the numerals "0" to "9", and the symbols "+" and "/". The valueless character "=" is used for trailing padding.

The `offset` and `length` parameters are 32-bit signed numbers. The `offset` parameter is zero-based.

> **Important**
>
> The **ToBase64String** method is designed to process a single byte array that contains all the data to be encoded. To encode data from a stream, use the **System.Security.Cryptography.ToBase64Transform** class.

If the `options` parameter is set to InsertLineBreaks and the output of the conversion is longer than 76 characters, a line break is inserted every 76 characters. A line break is defined as a carriage return character (U+000D) followed by a line feed character (U+000A). For more information, see RFC 2045, "Multipurpose Internet Mail Extensions", at https://www.rfc-editor.org/.

Convert.ToBoolean Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to an equivalent Boolean value.

Overloads

Expand table

ToBoolean(SByte)	Converts the value of the specified 8-bit signed integer to an equivalent Boolean value.
ToBoolean(String, IFormatProvider)	Converts the specified string representation of a logical value to its Boolean equivalent, using the specified culture-specific formatting information.
ToBoolean(Object, IFormatProvider)	Converts the value of the specified object to an equivalent Boolean value, using the specified culture-specific formatting information.
ToBoolean(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent Boolean value.
ToBoolean(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent Boolean value.
ToBoolean(UInt16)	Converts the value of the specified 16-bit unsigned integer to an equivalent Boolean value.
ToBoolean(String)	Converts the specified string representation of a logical value to its Boolean equivalent.
ToBoolean(Single)	Converts the value of the specified single-precision floating-point number to an equivalent Boolean value.
ToBoolean(Object)	Converts the value of a specified object to an equivalent Boolean value.
ToBoolean(DateTime)	Calling this method always throws InvalidCastException.
ToBoolean(Int32)	Converts the value of the specified 32-bit signed integer to an

	equivalent Boolean value.
ToBoolean(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent Boolean value.
ToBoolean(Double)	Converts the value of the specified double-precision floating-point number to an equivalent Boolean value.
ToBoolean(Decimal)	Converts the value of the specified decimal number to an equivalent Boolean value.
ToBoolean(Char)	Calling this method always throws InvalidCastException.
ToBoolean(Byte)	Converts the value of the specified 8-bit unsigned integer to an equivalent Boolean value.
ToBoolean(Boolean)	Returns the specified Boolean value; no actual conversion is performed.
ToBoolean(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent Boolean value.

ToBoolean(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to an equivalent Boolean value.

C#

```
[System.CLSCompliant(false)]
public static bool ToBoolean (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of SByte values to Boolean values.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, 100, SByte.MaxValue };
bool result;

foreach (sbyte number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-5}  -->  {1}", number, result);
}
// The example displays the following output:
//       -128   -->  True
//       -1     -->  True
//       0      -->  False
//       10     -->  True
//       100    -->  True
//       127    -->  True
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToBoolean(String, IFormatProvider)

Converts the specified string representation of a logical value to its Boolean equivalent, using the specified culture-specific formatting information.

```
C#

public static bool ToBoolean (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the value of either TrueString or FalseString.

`provider` IFormatProvider

An object that supplies culture-specific formatting information. This parameter is ignored.

Returns

Boolean

`true` if `value` equals TrueString, or `false` if `value` equals FalseString or `null`.

Exceptions

FormatException

`value` is not equal to TrueString or FalseString.

Remarks

If you prefer not to handle an exception if the conversion fails, you can call the Boolean.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToBoolean(Object, IFormatProvider)

Converts the value of the specified object to an equivalent Boolean value, using the specified culture-specific formatting information.

C#

```
public static bool ToBoolean (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Boolean

`true` or `false`, which reflects the value returned by invoking the ToBoolean(IFormatProvider) method for the underlying type of `value`. If `value` is `null`, the method returns `false`.

Exceptions

FormatException

`value` is a string that does not equal TrueString or FalseString.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion of `value` to a Boolean is not supported.

Examples

The following example defines a class that implements IConvertible and a class that implements IFormatProvider. Objects of the class that implements IConvertible hold an array of Double values. An object of each class is passed to the ToBoolean(Object, IFormatProvider) method. This method returns `true` if any of the non-discarded array values are non-zero. The IFormatProvider object determines how elements are discarded for this calculation.

C#

```
using System;
using System.Collections;

// Define the types of averaging available in the class
// implementing IConvertible.
public enum AverageType : short
{
    None = 0,
    GeometricMean = 1,
    ArithmeticMean = 2,
    Median = 3
};

// Pass an instance of this class to methods that require an
// IFormatProvider. The class instance determines the type of
// average to calculate.
public class AverageInfo : IFormatProvider
{
    protected AverageType AvgType;

    // Specify the type of averaging in the constructor.
    public AverageInfo( AverageType avgType )
    {
        this.AvgType = avgType;
    }

    // This method returns a reference to the containing object
    // if an object of AverageInfo type is requested.
    public object GetFormat( Type argType )
    {
        if ( argType == typeof( AverageInfo ) )
            return this;
```

```
        else
            return null;
    }

    // Use this property to set or get the type of averaging.
    public AverageType TypeOfAverage
    {
        get { return this.AvgType; }
        set { this.AvgType = value; }
    }
}

// This class encapsulates an array of double values and implements
// the IConvertible interface. Most of the IConvertible methods
// return an average of the array elements in one of three types:
// arithmetic mean, geometric mean, or median.
public class DataSet : IConvertible

*/
```

Remarks

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. The base types ignore the `provider` parameter; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToBoolean(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent Boolean value.

C#

```
[System.CLSCompliant(false)]
public static bool ToBoolean (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of UInt64 values to Boolean values.

C#

```
ulong[] numbers = { UInt64.MinValue, 6121, 403890774, UInt64.MaxValue };
bool result;

foreach (ulong number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-26:N0}  -->  {1}", number, result);
}
// The example displays the following output:
//       0                          -->  False
//       6,121                      -->  True
//       403,890,774                -->  True
//       18,446,744,073,709,551,615 -->  True
```

ToBoolean(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent Boolean value.

```
C#

[System.CLSCompliant(false)]
public static bool ToBoolean (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of Int32 values to Boolean values.

```
C#

uint[] numbers = { UInt32.MinValue, 612, 4038907, Int32.MaxValue };
bool result;
```

```
foreach (uint number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-15:N0}  -->  {1}", number, result);
}
// The example displays the following output:
//       0                -->  False
//       612              -->  True
//       4,038,907        -->  True
//       2,147,483,647    -->  True
```

ToBoolean(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to an equivalent Boolean value.

C#

```
[System.CLSCompliant(false)]
public static bool ToBoolean (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of UInt16 values to Boolean values.

C#

```
ushort[] numbers = { UInt16.MinValue, 216, 21453, UInt16.MaxValue };
bool result;

foreach (ushort number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-7:N0}  -->  {1}", number, result);
}
// The example displays the following output:
//       0        -->  False
//       216      -->  True
//       21,453   -->  True
//       65,535   -->  True
```

UWP	10.0

ToBoolean(String)

Converts the specified string representation of a logical value to its Boolean equivalent.

C#

```
public static bool ToBoolean (string? value);
```

Parameters

`value` String

A string that contains the value of either TrueString or FalseString.

Returns

Boolean

`true` if `value` equals TrueString, or `false` if `value` equals FalseString or `null`.

Exceptions

FormatException

`value` is not equal to TrueString or FalseString.

Examples

The following example uses the Convert.ToBoolean(String) method to convert various strings to Boolean values.

C#

```
using System;
```

```
public class BooleanConversion
{
   public static void Main()
   {
      String[] values = { null, String.Empty, "true", "TrueString",
                          "False", "    false    ", "-1", "0" };
      foreach (var value in values) {
         try
         {
            Console.WriteLine("Converted '{0}' to {1}.", value,
                              Convert.ToBoolean(value));
         }
         catch (FormatException)
         {
            Console.WriteLine("Unable to convert '{0}' to a Boolean.",
value);
         }
      }
   }
}
// The example displays the following output:
//       Converted '' to False.
//       Unable to convert '' to a Boolean.
//       Converted 'true' to True.
//       Unable to convert 'TrueString' to a Boolean.
//       Converted 'False' to False.
//       Converted '    false    ' to False.
//       Unable to convert '-1' to a Boolean.
//       Unable to convert '0' to a Boolean.
```

Remarks

For a successful conversion to occur, the `value` parameter must equal either Boolean.TrueString, a constant whose value is `True`, Boolean.FalseString, a constant whose value is `False`, or it must be `null`. In comparing `value` with Boolean.TrueString and Boolean.FalseString, the method ignores case as well as leading and trailing white space.

If you prefer not to handle an exception if the conversion fails, you can call the Boolean.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToBoolean(Single)

Converts the value of the specified single-precision floating-point number to an equivalent Boolean value.

C#

```
public static bool ToBoolean (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts an array of Single values to Boolean values.

C#

```
float[] numbers = { Single.MinValue, -193.0012f, 20e-15f, 0f,
                    10551e-10f, 100.3398f, Single.MaxValue };
bool result;

foreach (float number in numbers)
```

```
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-15}  -->  {1}", number, result);
}
// The example displays the following output:
//       -3.402823E+38    -->  True
//       -193.0012        -->  True
//       2E-14            -->  True
//       0                -->  False
//       1.0551E-06       -->  True
//       100.3398         -->  True
//       3.402823E+38     -->  True
```

ToBoolean(Object)

Converts the value of a specified object to an equivalent Boolean value.

C#

```
public static bool ToBoolean (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Boolean

`true` or `false`, which reflects the value returned by invoking the ToBoolean(IFormatProvider) method for the underlying type of `value`. If `value` is `null`, the method returns `false`.

Exceptions

FormatException

`value` is a string that does not equal TrueString or FalseString.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion of `value` to a Boolean is not supported.

Examples

The following example converts an array of object values to Boolean values.

C#

```
object[] objects = { 16.33, -24, 0, "12", "12.7", String.Empty,
                     "1String", "True", "false", null,
                     new System.Collections.ArrayList() };

foreach (object obj in objects)
{
   Console.Write("{0,-40}  -->  ",
                 obj != null ?
                 String.Format("{0} ({1})", obj, obj.GetType().Name) :
                 "null");
   try {
      Console.WriteLine("{0}", Convert.ToBoolean(obj));
   }
   catch (FormatException) {
      Console.WriteLine("Bad Format");
   }
   catch (InvalidCastException) {
      Console.WriteLine("No Conversion");
   }
```

```
}
// The example displays the following output:
//       16.33 (Double)                              -->  True
//       -24 (Int32)                                 -->  True
//       0 (Int32)                                   -->  False
//       12 (String)                                 -->  Bad Format
//       12.7 (String)                               -->  Bad Format
//        (String)                                   -->  Bad Format
//       1String (String)                            -->  Bad Format
//       True (String)                               -->  True
//       false (String)                              -->  False
//       null                                        -->  False
//       System.Collections.ArrayList (ArrayList)    -->  No Conversion

ToBoolean(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static bool ToBoolean (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Boolean

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Examples

The following example demonstrates that an attempt to convert a DateTime value to a Boolean type throws InvalidCastException.

C#

```
public void ConvertBoolean() {
    const int year          = 1979;
    const int month         = 7;
    const int day           = 28;
    const int hour          = 13;
    const int minute        = 26;
    const int second        = 15;
    const int millisecond   = 53;

    DateTime dateTime = new DateTime(year, month, day, hour,
                                     minute, second, millisecond);

    bool boolVal;

    // System.InvalidCastException is always thrown.
    try {
        boolVal = System.Convert.ToBoolean(dateTime);
    }
    catch (System.InvalidCastException) {
        System.Console.WriteLine("Conversion from DateTime to " +
            "Boolean is not supported by the .NET Framework.");
    }
}
```

ToBoolean(Int32)

Converts the value of the specified 32-bit signed integer to an equivalent Boolean value.

C#

```
public static bool ToBoolean (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts an array of Int32 values to Boolean values.

C#

```
int[] numbers = { Int32.MinValue, -201649, -68, 0, 612, 4038907,
                  Int32.MaxValue };
bool result;

foreach (int number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-15:N0}  -->  {1}", number, result);
}
// The example displays the following output:
```

```
//        -2,147,483,648   -->  True
//        -201,649         -->  True
//        -68              -->  True
//        0                -->  False
//        612              -->  True
//        4,038,907        -->  True
//        2,147,483,647    -->  True
```

ToBoolean(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent Boolean value.

C#

```
public static bool ToBoolean (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts an array of Int16 values to Boolean values.

C#

```
short[] numbers = { Int16.MinValue, -10000, -154, 0, 216, 21453,
                    Int16.MaxValue };
bool result;

foreach (short number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-7:N0}  -->  {1}", number, result);
}
// The example displays the following output:
//       -32,768  -->  True
//       -10,000  -->  True
//       -154     -->  True
//       0        -->  False
//       216      -->  True
//       21,453   -->  True
//       32,767   -->  True
```

ToBoolean(Double)

Converts the value of the specified double-precision floating-point number to an equivalent Boolean value.

```
C#

public static bool ToBoolean (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts a Boolean to a Double and a Double to a Boolean value.

```
C#

public void ConvertDoubleBool(double doubleVal) {
    bool    boolVal;
    // Double to bool conversion cannot overflow.
    boolVal = System.Convert.ToBoolean(doubleVal);
    System.Console.WriteLine("{0} as a Boolean is: {1}.",
        doubleVal, boolVal);

    // bool to double conversion cannot overflow.
    doubleVal = System.Convert.ToDouble(boolVal);
    System.Console.WriteLine("{0} as a double is: {1}.",
        boolVal, doubleVal);
}
```

ToBoolean(Decimal)

Converts the value of the specified decimal number to an equivalent Boolean value.

C#

```
public static bool ToBoolean (decimal value);
```

Parameters

`value` Decimal

The number to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts an array of Decimal values to Boolean values.

C#

```
decimal[] numbers = { Decimal.MinValue, -12034.87m, -100m, 0m,
                              300m, 6790823.45m, Decimal.MaxValue };
bool result;
```

```
foreach (decimal number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-30}  -->  {1}", number, result);
}
// The example displays the following output:
//       -79228162514264337593543950335  -->  True
//       -12034.87                       -->  True
//       -100                            -->  True
//       0                               -->  False
//       300                             -->  True
//       6790823.45                      -->  True
//       79228162514264337593543950335   -->  True
```

ToBoolean(Char)

Calling this method always throws InvalidCastException.

C#

```
public static bool ToBoolean (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Boolean

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

ToBoolean(Byte)

Converts the value of the specified 8-bit unsigned integer to an equivalent Boolean value.

C#

```
public static bool ToBoolean (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts an array of Byte values to Boolean values.

C#

```
byte[] bytes = { Byte.MinValue, 100, 200, Byte.MaxValue };
bool result;

foreach (byte byteValue in bytes)
{
   result = Convert.ToBoolean(byteValue);
   Console.WriteLine("{0,-5}  -->  {1}", byteValue, result);
}
// The example displays the following output:
//       0      -->  False
//       100    -->  True
//       200    -->  True
//       255    -->  True

ToBoolean(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent Boolean value.

```
C#

public static bool ToBoolean (long value);
```

Parameters

value Int64

The 64-bit signed integer to convert.

Returns

Boolean

`true` if `value` is not zero; otherwise, `false`.

Examples

The following example converts an array of Int64 values to Boolean values.

```
C#

long[] numbers = { Int64.MinValue, -2016493, -689, 0, 6121,
                   403890774, Int64.MaxValue };
bool result;

foreach (long number in numbers)
{
   result = Convert.ToBoolean(number);
   Console.WriteLine("{0,-26:N0}  -->  {1}", number, result);
}
// The example displays the following output:
//       -9,223,372,036,854,775,808  -->  True
//       -2,016,493                  -->  True
//       -689                        -->  True

Convert.ToByte Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to an 8-bit unsigned integer.

Overloads

Expand table

ToByte(String)	Converts the specified string representation of a number to an equivalent 8-bit unsigned integer.
ToByte(UInt16)	Converts the value of the specified 16-bit unsigned integer to an equivalent 8-bit unsigned integer.
ToByte(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 8-bit unsigned integer.
ToByte(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 8-bit unsigned integer.
ToByte(Object, IFormatProvider)	Converts the value of the specified object to an 8-bit unsigned integer, using the specified culture-specific formatting information.
ToByte(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 8-bit unsigned integer, using specified culture-specific formatting information.
ToByte(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 8-bit unsigned integer.
ToByte(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 8-bit unsigned integer.
ToByte(SByte)	Converts the value of the specified 8-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(DateTime)	Calling this method always throws InvalidCastException.
ToByte(Int64)	Converts the value of the specified 64-bit signed integer to an

	equivalent 8-bit unsigned integer.
ToByte(Byte)	Returns the specified 8-bit unsigned integer; no actual conversion is performed.
ToByte(Char)	Converts the value of the specified Unicode character to the equivalent 8-bit unsigned integer.
ToByte(Decimal)	Converts the value of the specified decimal number to an equivalent 8-bit unsigned integer.
ToByte(Boolean)	Converts the specified Boolean value to the equivalent 8-bit unsigned integer.
ToByte(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 8-bit unsigned integer.
ToByte(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 8-bit unsigned integer.
ToByte(Object)	Converts the value of the specified object to an 8-bit unsigned integer.

ToByte(String)

Converts the specified string representation of a number to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example defines a string array and attempts to convert each string to a Byte. Note that while a `null` string parses to zero, String.Empty throws a FormatException. Also note that while leading and trailing spaces parse successfully, formatting symbols, such as currency symbols, group separators, or decimal separators, do not.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] values = { null, "", "0xC9", "C9", "101", "16.3",
                          "$12", "$12.01", "-4", "1,032", "255",
                          "   16  " };
      foreach (var value in values) {
         try {
            byte number = Convert.ToByte(value);
            Console.WriteLine("'{0}' --> {1}",
                              value == null ? "<null>" : value, number);
         }
         catch (FormatException) {
            Console.WriteLine("Bad Format: '{0}'",
                              value == null ? "<null>" : value);
         }
         catch (OverflowException) {
            Console.WriteLine("OverflowException: '{0}'", value);
         }
      }
   }
}
// The example displays the following output:
//     '<null>' --> 0
//     Bad Format: ''
//     Bad Format: '0xC9'
```

```
//      Bad Format: 'C9'
//      '101' --> 101
//      Bad Format: '16.3'
//      Bad Format: '$12'
//      Bad Format: '$12.01'
//      OverflowException: '-4'
//      Bad Format: '1,032'
//      '255' --> 255
//      '   16  ' --> 16
```

Remarks

Using the ToByte(String) method is equivalent to passing `value` to the Byte.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Byte.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToByte(UInt16)

> Important

This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to an equivalent 8-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static byte ToByte (ushort value);
```

Parameters

value UInt16

The 16-bit unsigned integer to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Byte.MaxValue.

Examples

The following example converts an array of unsigned 16-bit integers to Byte values.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
byte result;
foreach (ushort number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
```

```
    }
    catch (OverflowException) {
       Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                         number.GetType().Name, number);
    }
}
// The example displays the following output:
//       Converted the UInt16 value 0 to the Byte value 0.
//       Converted the UInt16 value 121 to the Byte value 121.
//       The UInt16 value 340 is outside the range of the Byte type.
//       The UInt16 value 65535 is outside the range of the Byte type.
```

ToByte(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 8-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static byte ToByte (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Byte.MaxValue.

Examples

The following example converts an array of unsigned integers to Byte values.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
byte result;
foreach (uint number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//       Converted the UInt32 value 0 to the Byte value 0.
//       Converted the UInt32 value 121 to the Byte value 121.
//       The UInt32 value 340 is outside the range of the Byte type.
//       The UInt32 value 4294967295 is outside the range of the Byte
type.
```

UWP	10.0

ToByte(String, Int32)

Converts the string representation of a number in a specified base to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

Byte

An 8-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

ArgumentOutOfRangeException
`value` is Empty.

FormatException
`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException
`value`, which represents a base 10 unsigned number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example alternately attempts to interpret an array of strings as the representation of binary, octal, decimal, and hexadecimal values.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int[] bases = { 2, 8, 10, 16 };
      string[] values = { "-1", "1", "08", "0F", "11" , "12", "30",
                          "101", "255", "FF", "10000000", "80" };
      byte number;
      foreach (int numBase in bases)
      {
         Console.WriteLine("Base {0}:", numBase);
         foreach (string value in values)
         {
```

```
            try {
               number = Convert.ToByte(value, numBase);
               Console.WriteLine("   Converted '{0}' to {1}.", value,
number);
            }
            catch (FormatException) {
               Console.WriteLine("   '{0}' is not in the correct format
for a base {1} byte value.",
                                 value, numBase);
            }
            catch (OverflowException) {
               Console.WriteLine("   '{0}' is outside the range of the
Byte type.", value);
            }
            catch (ArgumentException) {
               Console.WriteLine("   '{0}' is invalid in base {1}.",
value, numBase);
            }
         }
      }
   }
}
// The example displays the following output:
//    Base 2:
//       '-1' is invalid in base 2.
//       Converted '1' to 1.
//       '08' is not in the correct format for a base 2 conversion.
//       '0F' is not in the correct format for a base 2 conversion.
//       Converted '11' to 3.
//       '12' is not in the correct format for a base 2 conversion.
//       '30' is not in the correct format for a base 2 conversion.
//       Converted '101' to 5.
//       '255' is not in the correct format for a base 2 conversion.
//       'FF' is not in the correct format for a base 2 conversion.
//       Converted '10000000' to 128.
//       '80' is not in the correct format for a base 2 conversion.
//    Base 8:
//       '-1' is invalid in base 8.
//       Converted '1' to 1.
//       '08' is not in the correct format for a base 8 conversion.
//       '0F' is not in the correct format for a base 8 conversion.
//       Converted '11' to 9.
//       Converted '12' to 10.
//       Converted '30' to 24.
//       Converted '101' to 65.
//       Converted '255' to 173.
//       'FF' is not in the correct format for a base 8 conversion.
//       '10000000' is outside the range of the Byte type.
//       '80' is not in the correct format for a base 8 conversion.
//    Base 10:
//       '-1' is outside the range of the Byte type.
//       Converted '1' to 1.
//       Converted '08' to 8.
//       '0F' is not in the correct format for a base 10 conversion.
//       Converted '11' to 11.
```

```
//       Converted '12' to 12.
//       Converted '30' to 30.
//       Converted '101' to 101.
//       Converted '255' to 255.
//       'FF' is not in the correct format for a base 10 conversion.
//       '10000000' is outside the range of the Byte type.
//       Converted '80' to 80.
//    Base 16:
//       '-1' is invalid in base 16.
//       Converted '1' to 1.
//       Converted '08' to 8.
//       Converted '0F' to 15.
//       Converted '11' to 17.
//       Converted '12' to 18.
//       Converted '30' to 48.
//       '101' is outside the range of the Byte type.
//       '255' is outside the range of the Byte type.
//       Converted 'FF' to 255.
//       '10000000' is outside the range of the Byte type.
//       Converted '80' to 128.
```

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the Byte data type supports unsigned values only, the ToByte(String, Int32) method assumes that `value` is expressed using unsigned binary representation. In other words, all eight bits are used to represent the numeric value, and a sign bit is absent. As a result, it is possible to write code in which a signed byte value that is out of the range of the Byte data type is converted to a Byte value without the method throwing an exception. The following example converts MinValue to its hexadecimal string representation, and then calls the ToByte(String, Int32) method. Instead of throwing an exception, the method displays the message, "0x80 converts to 128."

C#

```
// Create a hexadecimal value out of range of the Byte type.
string value = SByte.MinValue.ToString("X");
// Convert it back to a number.
try
{
   byte number = Convert.ToByte(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
}
catch (OverflowException)
{
```

```
    Console.WriteLine("Unable to convert '0x{0}' to a byte.", value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method or operator is using the appropriate numeric representation to interpret a particular value. The following example illustrates one technique for ensuring that the method does not inappropriately use unsigned binary representation when it converts a hexadecimal string representation to a Byte value. The example determines whether a value represents a signed or an unsigned integer while it is converting that value to its string representation. When the example converts the value back to a Byte value, it checks whether the original value was a signed integer. If so, and if its high-order bit is set (which indicates that the value is negative and that it uses two's complement instead of unsigned binary representation), the method throws an exception.

C#

```
// Create a negative hexadecimal value out of range of the Byte type.
sbyte sourceNumber = SByte.MinValue;
bool isSigned =
Math.Sign((sbyte)sourceNumber.GetType().GetField("MinValue").GetValue(nul
l)) == -1;
string value = sourceNumber.ToString("X");
byte targetNumber;
try
{
   targetNumber = Convert.ToByte(value, 16);
   if (isSigned && ((targetNumber & 0x80) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned byte.",
value);
}
// Displays the following to the console:
//    Unable to convert '0x80' to an unsigned byte.
```

ToByte(Object, IFormatProvider)

Converts the value of the specified object to an 8-bit unsigned integer, using the specified culture-specific formatting information.

```
C#

public static byte ToByte (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in the property format for a Byte value.

InvalidCastException

`value` does not implement IConvertible.

-or-

Conversion from `value` to the Byte type is not supported.

OverflowException

`value` represents a number that is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example defines a `ByteString` class that implements the IConvertible interface. The class stores the string representation of a byte value along with a sign field, so that it is able to represent both signed and unsigned byte values.

C#

```
using System;
using System.Globalization;

public enum SignBit { Negative=-1, Zero=0, Positive=1 };

public struct ByteString : IConvertible
{
   private SignBit signBit;
   private string byteString;

   public SignBit Sign
   {
      set { signBit = value; }
      get { return signBit; }
   }

   public string Value
   {
      set {
         if (value.Trim().Length > 2)
            throw new ArgumentException("The string representation of a
byte cannot have more than two characters.");
         else
            byteString = value;
      }
      get { return byteString; }
   }

   // IConvertible implementations.
   public TypeCode GetTypeCode() {
      return TypeCode.Object;
   }

   public bool ToBoolean(IFormatProvider provider)
```

```
    {
        if (signBit == SignBit.Zero)
            return false;
        else
            return true;
    }

    public byte ToByte(IFormatProvider provider)
    {
        if (signBit == SignBit.Negative)
            throw new OverflowException(String.Format("{0} is out of range
of the Byte type.", Convert.ToSByte(byteString, 16)));
        else
            return Byte.Parse(byteString, NumberStyles.HexNumber);
    }

    public char ToChar(IFormatProvider provider)
    {
        if (signBit == SignBit.Negative) {
            throw new OverflowException(String.Format("{0} is out of range
of the Char type.", Convert.ToSByte(byteString, 16)));
        }
        else {
            byte byteValue = Byte.Parse(this.byteString,
NumberStyles.HexNumber);
            return Convert.ToChar(byteValue);
        }
    }

    public DateTime ToDateTime(IFormatProvider provider)
    {
        throw new InvalidCastException("ByteString to DateTime conversion
is not supported.");
    }

    public decimal ToDecimal(IFormatProvider provider)
    {
        if (signBit == SignBit.Negative)
        {
            sbyte byteValue = SByte.Parse(byteString,
NumberStyles.HexNumber);
            return Convert.ToDecimal(byteValue);
        }
        else
        {
            byte byteValue = Byte.Parse(byteString, NumberStyles.HexNumber);
            return Convert.ToDecimal(byteValue);
        }
    }

    public double ToDouble(IFormatProvider provider)
    {
        if (signBit == SignBit.Negative)
            return Convert.ToDouble(SByte.Parse(byteString,
NumberStyles.HexNumber));
```

```
      else
         return Convert.ToDouble(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }

   public short ToInt16(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         return Convert.ToInt16(SByte.Parse(byteString,
NumberStyles.HexNumber));
      else
         return Convert.ToInt16(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }

   public int ToInt32(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         return Convert.ToInt32(SByte.Parse(byteString,
NumberStyles.HexNumber));
      else
         return Convert.ToInt32(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }

   public long ToInt64(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         return Convert.ToInt64(SByte.Parse(byteString,
NumberStyles.HexNumber));
      else
         return Convert.ToInt64(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }

   public sbyte ToSByte(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         try {
            return Convert.ToSByte(Byte.Parse(byteString,
NumberStyles.HexNumber));
         }
         catch (OverflowException e) {
            throw new OverflowException(String.Format("{0} is outside the
range of the SByte type.",
                                                        Byte.Parse(byteString,
NumberStyles.HexNumber)), e);
         }
      else
         return SByte.Parse(byteString, NumberStyles.HexNumber);
   }

   public float ToSingle(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
```

```
            return Convert.ToSingle(SByte.Parse(byteString,
NumberStyles.HexNumber));
         else
            return Convert.ToSingle(Byte.Parse(byteString,
NumberStyles.HexNumber));
      }

      public string ToString(IFormatProvider provider)
      {
         return "0x" + this.byteString;
      }

      public object ToType(Type conversionType, IFormatProvider provider)
      {
         switch (Type.GetTypeCode(conversionType))
         {
            case TypeCode.Boolean:
               return this.ToBoolean(null);
            case TypeCode.Byte:
               return this.ToByte(null);
            case TypeCode.Char:
               return this.ToChar(null);

               return this.ToDouble(null);
            case TypeCode.Int16:
               return this.ToInt16(null);
            case TypeCode.Int32:
               return this.ToInt32(null);
            case TypeCode.Int64:
               return this.ToInt64(null);
            case TypeCode.Object:
               if (typeof(ByteString).Equals(conversionType))
                  return this;
               else
                  throw new InvalidCastException(String.Format("Conversion
to a {0} is not supported.", conversionType.Name));
            case TypeCode.SByte:
               return this.ToSByte(null);
            case TypeCode.Single:
               return this.ToSingle(null);
            case TypeCode.String:
               return this.ToString(null);
            case TypeCode.UInt16:
               return this.ToUInt16(null);
            case TypeCode.UInt32:
               return this.ToUInt32(null);
            case TypeCode.UInt64:
               return this.ToUInt64(null);
            default:
               throw new InvalidCastException(String.Format("Conversion to
{0} is not supported.", conversionType.Name));
```

```
      }
   }

   public UInt16 ToUInt16(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt16 type.",

SByte.Parse(byteString, NumberStyles.HexNumber)));
      else
         return Convert.ToUInt16(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }

   public UInt32 ToUInt32(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt32 type.",

SByte.Parse(byteString, NumberStyles.HexNumber)));
      else
         return Convert.ToUInt32(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }

   public UInt64 ToUInt64(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt64 type.",

SByte.Parse(byteString, NumberStyles.HexNumber)));
      else
         return Convert.ToUInt64(Byte.Parse(byteString,
NumberStyles.HexNumber));
   }
}
```

The following example instantiates several `ByteString` objects and calls the ToByte(Object, IFormatProvider) method to convert them to byte values. It illustrates that the ToByte(Object, IFormatProvider) method wraps a call to the IConvertible.ToByte method of the object to be converted.

C#

```
public class Class1
{
   public static void Main()
   {
      byte positiveByte = 216;
```

```
        sbyte negativeByte = -101;

        ByteString positiveString = new ByteString();
        positiveString.Sign = (SignBit) Math.Sign(positiveByte);
        positiveString.Value = positiveByte.ToString("X2");

        ByteString negativeString = new ByteString();
        negativeString.Sign = (SignBit) Math.Sign(negativeByte);
        negativeString.Value = negativeByte.ToString("X2");

        try {
           Console.WriteLine("'{0}' converts to {1}.",
positiveString.Value, Convert.ToByte(positiveString));
        }
        catch (OverflowException) {
           Console.WriteLine("0x{0} is outside the range of the Byte
type.", positiveString.Value);
        }

        try {
           Console.WriteLine("'{0}' converts to {1}.",
negativeString.Value, Convert.ToByte(negativeString));
        }
        catch (OverflowException) {
           Console.WriteLine("0x{0} is outside the range of the Byte
type.", negativeString.Value);
        }
    }
}
// The example displays the following output:
//       'D8' converts to 216.
//       0x9B is outside the range of the Byte type.
```

Remarks

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

UWP	10.0

ToByte(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent 8-bit unsigned integer, using specified culture-specific formatting information.

C#

```
public static byte ToByte (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example creates a custom NumberFormatInfo object that defines the positive sign as "pos" and the negative sign as "neg", which it uses in calls to the ToByte(String, IFormatProvider) method. It then calls the ToByte(String, IFormatProvider) method repeatedly to convert each element in a string array to a Byte value.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Create a NumberFormatInfo object and set several of its
      // properties that apply to unsigned bytes.
      NumberFormatInfo provider = new NumberFormatInfo();

      // These properties affect the conversion.
      provider.PositiveSign = "pos ";
      provider.NegativeSign = "neg ";

      // This property does not affect the conversion.
      // The input string cannot have a decimal separator.
      provider.NumberDecimalSeparator = ".";

      // Define an array of numeric strings.
      string[] numericStrings = { "234", "+234", "pos 234", "234.",
"255",
                                  "256", "-1" };

      foreach (string numericString in numericStrings)
      {
         Console.Write("'{0,-8}' ->   ", numericString);
         try {
            byte number = Convert.ToByte(numericString, provider);
            Console.WriteLine(number);
         }
         catch (FormatException) {
            Console.WriteLine("Incorrect Format");
         }
         catch (OverflowException) {
            Console.WriteLine("Overflows a Byte");
         }
      }
   }
}
// The example displays the following output:
//       '234     ' ->   234
```

```
//       '+234    ' ->   Incorrect Format
//       'pos 234 ' ->   234
//       '234.    ' ->   Incorrect Format
//       '255     ' ->   255
//       '256     ' ->   Overflows a Byte
//       '-1      ' ->   Incorrect Format
```

Remarks

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Byte.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToByte(Single)

Converts the value of the specified single-precision floating-point number to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (float value);
```

Parameters

`value` Single

A single-precision floating-point number.

Returns

Byte

`value`, rounded to the nearest 8-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Byte.MaxValue or less than Byte.MinValue.

Examples

The following example converts a Single value to a Byte.

C#

```
public void ConvertByteSingle(byte byteVal) {
    float floatVal;

    // Byte to float conversion will not overflow.
    floatVal = System.Convert.ToSingle(byteVal);
    System.Console.WriteLine("The byte as a float is {0}.",
        floatVal);

    // Float to byte conversion can overflow.
    try {
        byteVal = System.Convert.ToByte(floatVal);
        System.Console.WriteLine("The float as a byte is {0}.",
            byteVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "The float value is too large for a byte.");
```

```
    }
}

ToByte(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 8-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static byte ToByte (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Byte.MaxValue.

Examples

The following example converts an array of unsigned long integers to Byte values.

C#

```
ulong[] numbers= { UInt64.MinValue, 121, 340, UInt64.MaxValue };
byte result;
foreach (ulong number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//       Converted the UInt64 value 0 to the Byte value 0.
//       Converted the UInt64 value 121 to the Byte value 121.
//       The UInt64 value 340 is outside the range of the Byte type.
//       The UInt64 value 18446744073709551615 is outside the range of
the Byte type.
```

ToByte(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to an equivalent 8-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static byte ToByte (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to be converted.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than Byte.MinValue.

Examples

The following example converts an array of SByte values to Byte values.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
byte result;
foreach (sbyte number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//       The SByte value -128 is outside the range of the Byte type.
//       The SByte value -1 is outside the range of the Byte type.
//       Converted the SByte value 0 to the Byte value 0.
//       Converted the SByte value 10 to the Byte value 10.
//       Converted the SByte value 127 to the Byte value 127.
```

ToByte(DateTime)

Calling this method always throws InvalidCastException.

```
C#

public static byte ToByte (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Byte

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

ToByte(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Exceptions

OverflowException

`value` is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example converts an array of Int64 values to Byte values.

C#

```
long[] numbers = { Int64.MinValue, -1, 0, 121, 340, Int64.MaxValue };
byte result;
foreach (long number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//       The Int64 value -9223372036854775808 is outside the range of the
Byte type.
//       The Int64 value -1 is outside the range of the Byte type.
```

```
//       Converted the Int64 value 0 to the Byte value 0.
//       Converted the Int64 value 121 to the Byte value 121.
//       The Int64 value 340 is outside the range of the Byte type.
//       The Int64 value 9223372036854775807 is outside the range of the
Byte type.
```

UWP	10.0

ToByte(Byte)

Returns the specified 8-bit unsigned integer; no actual conversion is performed.

C#

```
public static byte ToByte (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to return.

Returns

Byte

`value` is returned unchanged.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToByte(Char)

Converts the value of the specified Unicode character to the equivalent 8-bit unsigned integer.

```
C#
public static byte ToByte (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Exceptions

OverflowException

`value` represents a number that is greater than Byte.MaxValue.

Examples

The following example converts an array of Char values to Byte values.

C#

```
char[] chars = { 'a', 'z', '\x0007', '\x03FF' };
foreach (char ch in chars)
{
   try {
      byte result = Convert.ToByte(ch);
      Console.WriteLine("{0} is converted to {1}.", ch, result);
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to convert u+{0} to a byte.",
                        Convert.ToInt16(ch).ToString("X4"));
   }
}
// The example displays the following output:
//       a is converted to 97.
//       z is converted to 122.
//        is converted to 7.
//       Unable to convert u+03FF to a byte.
```

Remarks

This method returns an unsigned byte value that represents the numeric code of the Char object passed to it. In .NET, a Char object is a 16-bit value. This means that the method is suitable for returning the numeric codes of characters in the ASCII character range or in the Unicode C0 Controls and Basic Latin, and C1 Controls and Latin-1 Supplement ranges, from U+0000 to U+00FF.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToByte(Decimal)

Converts the value of the specified decimal number to an equivalent 8-bit unsigned integer.

```C#
public static byte ToByte (decimal value);
```

Parameters

`value` Decimal

The number to convert.

Returns

Byte

`value`, rounded to the nearest 8-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Byte.MaxValue or less than Byte.MinValue.

Remarks

The following example converts a Byte value to a Decimal and a Decimal value to a Byte.

```C#
public void ConvertByteDecimal(byte byteVal) {
    decimal decimalVal;

    // Byte to decimal conversion will not overflow.
    decimalVal = System.Convert.ToDecimal(byteVal);
    System.Console.WriteLine("The byte as a decimal is {0}.",
        decimalVal);

    // Decimal to byte conversion can overflow.
    try {
        byteVal = System.Convert.ToByte(decimalVal);
        System.Console.WriteLine("The Decimal as a byte is {0}.",
            byteVal);
```

```
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "The decimal value is too large for a byte.");
    }
}
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToByte(Boolean)

Converts the specified Boolean value to the equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Byte

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example illustrates the conversion of Boolean to Byte values.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToByte(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToByte(trueFlag));
// The example displays the following output:
//       False converts to 0.
//       True converts to 1.
```

ToByte(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Exceptions

OverflowException

`value` is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example converts an array of Int16 values to Byte values.

C#

```
short[] numbers = { Int16.MinValue, -1, 0, 121, 340, Int16.MaxValue };
byte result;
foreach (short number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//       The Int16 value -32768 is outside the range of the Byte type.
//       The Int16 value -1 is outside the range of the Byte type.
//       Converted the Int16 value 0 to the Byte value 0.
//       Converted the Int16 value 121 to the Byte value 121.
//       The Int16 value 340 is outside the range of the Byte type.
//       The Int16 value 32767 is outside the range of the Byte type.
```

ToByte(Int32)

Converts the value of the specified 32-bit signed integer to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`.

Exceptions

OverflowException

`value` is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example converts an array of Int32 values to Byte values.

C#

```
int[] numbers = { Int32.MinValue, -1, 0, 121, 340, Int32.MaxValue };
byte result;
foreach (int number in numbers)
{
   try {
      result = Convert.ToByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//       The Int32 value -2147483648 is outside the range of the Byte
type.
//       The Int32 value -1 is outside the range of the Byte type.
//       Converted the Int32 value 0 to the Byte value 0.
//       Converted the Int32 value 121 to the Byte value 121.
//       The Int32 value 340 is outside the range of the Byte type.
//       The Int32 value 2147483647 is outside the range of the Byte
type.
```

ToByte(Double)

Converts the value of the specified double-precision floating-point number to an equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Byte

`value`, rounded to the nearest 8-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Byte.MaxValue or less than Byte.MinValue.

Examples

The following example converts a Byte value to a Double and a Double value to a Byte.

C#

```
public void ConvertDoubleByte(double doubleVal) {
    byte    byteVal = 0;

    // Double to byte conversion can overflow.
    try {
        byteVal = System.Convert.ToByte(doubleVal);
        System.Console.WriteLine("{0} as a byte is: {1}.",
            doubleVal, byteVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in double-to-byte conversion.");
    }

    // Byte to double conversion cannot overflow.
    doubleVal = System.Convert.ToDouble(byteVal);
    System.Console.WriteLine("{0} as a double is: {1}.",
```

```
        byteVal, doubleVal);
}
```

UWP	10.0

ToByte(Object)

Converts the value of the specified object to an 8-bit unsigned integer.

C#

```
public static byte ToByte (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Byte

An 8-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in the property format for a Byte value.

InvalidCastException

`value` does not implement IConvertible.

-or-

Conversion from `value` to the Byte type is not supported.

OverflowException

`value` represents a number that is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example uses the ToByte(Object) method to convert an array of objects to Byte values.

C#

```
object[] values = { true, -12, 163, 935, 'x', "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2};
byte result;
foreach (object value in values)
{
   try {
      result = Convert.ToByte(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("The {0} value {1} is outside the range of the
Byte type.",
                        value.GetType().Name, value);
   }
   catch (FormatException)
   {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException)
   {
      Console.WriteLine("No conversion to a Byte exists for the {0} value
{1}.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
```

```
//       Converted the Boolean value True to the Byte value 1.
//       The Int32 value -12 is outside the range of the Byte type.
//       Converted the Int32 value 163 to the Byte value 163.
//       The Int32 value 935 is outside the range of the Byte type.
//       Converted the Char value x to the Byte value 120.
//       Converted the String value 104 to the Byte value 104.
//       The String value 103.0 is not in a recognizable format.
//       The String value -1 is outside the range of the Byte type.
//       The String value 1.00e2 is not in a recognizable format.
//       The String value One is not in a recognizable format.
//       Converted the Double value 100 to the Byte value 100.
```

Remarks

If `value` is not `null`, this method wraps a call to the IConvertible.ToByte implementation of the underlying type of `value`.

Convert.ToChar Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a Unicode character.

Overloads

Expand table

ToChar(String, IFormatProvider)	Converts the first character of a specified string to a Unicode character, using specified culture-specific formatting information.
ToChar(Object)	Converts the value of the specified object to a Unicode character.
ToChar(Object, IFormatProvider)	Converts the value of the specified object to its equivalent Unicode character, using the specified culture-specific formatting information.
ToChar(UInt64)	Converts the value of the specified 64-bit unsigned integer to its equivalent Unicode character.
ToChar(UInt32)	Converts the value of the specified 32-bit unsigned integer to its equivalent Unicode character.
ToChar(UInt16)	Converts the value of the specified 16-bit unsigned integer to its equivalent Unicode character.
ToChar(String)	Converts the first character of a specified string to a Unicode character.
ToChar(Single)	Calling this method always throws InvalidCastException.
ToChar(SByte)	Converts the value of the specified 8-bit signed integer to its equivalent Unicode character.
ToChar(Int64)	Converts the value of the specified 64-bit signed integer to its equivalent Unicode character.
ToChar(Int16)	Converts the value of the specified 16-bit signed integer to its equivalent Unicode character.
ToChar(Double)	Calling this method always throws InvalidCastException.

ToChar(Decimal)	Calling this method always throws InvalidCastException.
ToChar(DateTime)	Calling this method always throws InvalidCastException.
ToChar(Char)	Returns the specified Unicode character value; no actual conversion is performed.
ToChar(Byte)	Converts the value of the specified 8-bit unsigned integer to its equivalent Unicode character.
ToChar(Boolean)	Calling this method always throws InvalidCastException.
ToChar(Int32)	Converts the value of the specified 32-bit signed integer to its equivalent Unicode character.

ToChar(String, IFormatProvider)

Converts the first character of a specified string to a Unicode character, using specified culture-specific formatting information.

C#

```
public static char ToChar (string value, IFormatProvider? provider);
```

Parameters

`value` String

A string of length 1 or `null`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information. This parameter is ignored.

Returns

Char

A Unicode character that is equivalent to the first and only character in `value`.

Exceptions

ArgumentNullException

`value` is `null`.

FormatException

The length of `value` is not 1.

Examples

The following example converts a string representation of a Char value with the `ToChar` method, using an IFormatProvider object that displays the type of the format provider for which it is called. The example shows that the format provider is not referenced.

C#

```
using System;
using System.Globalization;

public class DummyProvider : IFormatProvider
{
    // Normally, GetFormat returns an object of the requested type
    // (usually itself) if it is able; otherwise, it returns Nothing.
    public object GetFormat(Type argType)
    {
        // Here, GetFormat displays the name of argType, after removing
        // the namespace information. GetFormat always returns null.
        string argStr = argType.ToString( );
        if( argStr == "" )
            argStr = "Empty";
        argStr = argStr.Substring( argStr.LastIndexOf( '.' ) + 1 );

        Console.Write( "{0,-20}", argStr );
        return null;
    }
}

class ConvertNonNumericProviderDemo
{
    public static void Main( )
    {
        // Create an instance of IFormatProvider.
        DummyProvider provider = new DummyProvider( );
        string format   = "{0,-17}{1,-17}{2}";

        // Convert these values using DummyProvider.
        string Int32A   = "-252645135";
        string DoubleA  = "61680.3855";
        string DayTimeA = "2001/9/11 13:45";

        string BoolA    = "True";
        string StringA  = "Qwerty";
        string CharA    = "$";

        Console.WriteLine( "This example of selected " +
```

```
            "Convert.To<Type>( String, IFormatProvider ) \nmethods " +
            "generates the following output. The example displays " +
            "the \nprovider type if the IFormatProvider is called." );
        Console.WriteLine( "\nNote: For the " +
            "ToBoolean, ToString, and ToChar methods, the \n" +
            "IFormatProvider object is not referenced." );

        // The format provider is called for the following conversions.
        Console.WriteLine( );
        Console.WriteLine( format, "ToInt32", Int32A,
            Convert.ToInt32( Int32A, provider ) );
        Console.WriteLine( format, "ToDouble", DoubleA,
            Convert.ToDouble( DoubleA, provider ) );
        Console.WriteLine( format, "ToDateTime", DayTimeA,
            Convert.ToDateTime( DayTimeA, provider ) );

        // The format provider is not called for these conversions.
        Console.WriteLine( );
        Console.WriteLine( format, "ToBoolean", BoolA,
            Convert.ToBoolean( BoolA, provider ) );
        Console.WriteLine( format, "ToString", StringA,
            Convert.ToString( StringA, provider ) );
        Console.WriteLine( format, "ToChar", CharA,
            Convert.ToChar( CharA, provider ) );
    }
}

/*
This example of selected Convert.To<Type>( String, IFormatProvider )
methods generates the following output. The example displays the
provider type if the IFormatProvider is called.

Note: For the ToBoolean, ToString, and ToChar methods, the
IFormatProvider object is not referenced.

NumberFormatInfo    ToInt32          -252645135       -252645135
NumberFormatInfo    ToDouble         61680.3855       61680.3855
DateTimeFormatInfo  ToDateTime       2001/9/11 13:45  9/11/2001 1:45:00
PM

ToBoolean        True             True
ToString         Qwerty           Qwerty
ToChar           $                $
*/
```

Remarks

`value` must be a string that contains a single character.

If you prefer not to handle an exception if the conversion fails, you can call the Char.TryParse method instead. It returns a Boolean value that indicates whether the

conversion succeeded or failed.

ToChar(Object)

Converts the value of the specified object to a Unicode character.

C#

```
public static char ToChar (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

Returns

Char

A Unicode character that is equivalent to value, or Char.MinValue if `value` is `null`.

Exceptions

ArgumentNullException

`value` is a null string.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion of `value` to a Char is not supported.

OverflowException

`value` is less than Char.MinValue or greater than Char.MaxValue.

Examples

The following example attempts to convert each element in an object array to a Char value.

C#

```
object[] values = { 'r', "s", "word", (byte) 83, 77, 109324, 335812911,
                    new DateTime(2009, 3, 10), (uint) 1934,
                    (sbyte) -17, 169.34, 175.6m, null };
char result;

foreach (object value in values)
{
   try {
      result = Convert.ToChar(value);
      Console.WriteLine("The {0} value {1} converts to {2}.",
                        value.GetType().Name, value, result);
   }
   catch (FormatException e) {
      Console.WriteLine(e.Message);
   }
   catch (InvalidCastException) {
      Console.WriteLine("Conversion of the {0} value {1} to a Char is not
supported.",
                        value.GetType().Name, value);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Char data type.",
                        value.GetType().Name, value);
   }
   catch (NullReferenceException) {
      Console.WriteLine("Cannot convert a null reference to a Char.");
   }
}
// The example displays the following output:
//       The Char value r converts to r.
//       The String value s converts to s.
//       String must be exactly one character long.
//       The Byte value 83 converts to S.
```

```
//       The Int32 value 77 converts to M.
//       The Int32 value 109324 is outside the range of the Char data
type.
//       The Int32 value 335812911 is outside the range of the Char data
type.
//       Conversion of the DateTime value 3/10/2009 12:00:00 AM to a Char
is not supported.
//       The UInt32 value 1934 converts to ?.
//       The SByte value -17 is outside the range of the Char data type.
//       Conversion of the Double value 169.34 to a Char is not
supported.
//       Conversion of the Decimal value 175.6 to a Char is not
supported.
//       Cannot convert a null reference to a Char.
```

Remarks

If `value` is not `null`, this method wraps a call to the IConvertible.ToChar implementation of the underlying type of `value`.

ToChar(Object, IFormatProvider)

Converts the value of the specified object to its equivalent Unicode character, using the specified culture-specific formatting information.

C#

```
public static char ToChar (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Char

A Unicode character that is equivalent to `value`, or Char.MinValue if `value` is `null`.

Exceptions

ArgumentNullException

`value` is a null string.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion of `value` to a Char is not supported.

OverflowException

`value` is less than Char.MinValue or greater than Char.MaxValue.

Examples

The following example defines a class that implements IConvertible and a class that implements IFormatProvider. Objects of the class that implements IConvertible hold an array of Double values. An object of each class is passed to the `ToChar` method. This method returns a character whose Unicode value is the average of the array of Double values, using the object that implements IFormatProvider to determine how to calculate the average.

C#

```
using System;
using System.Collections;

// Define the types of averaging available in the class
```

```
// implementing IConvertible.
public enum AverageType : short
{
    None = 0,
    GeometricMean = 1,
    ArithmeticMean = 2,
    Median = 3
};

// Pass an instance of this class to methods that require an
// IFormatProvider. The class instance determines the type of
// average to calculate.
public class AverageInfo : IFormatProvider
{
    protected AverageType AvgType;

    // Specify the type of averaging in the constructor.
    public AverageInfo( AverageType avgType )
    {
        this.AvgType = avgType;
    }

    // This method returns a reference to the containing object
    // if an object of AverageInfo type is requested.
    public object GetFormat( Type argType )
    {
        if ( argType == typeof( AverageInfo ) )
            return this;
        else
            return null;
    }

    // Use this property to set or get the type of averaging.
    public AverageType TypeOfAverage
    {
        get { return this.AvgType; }
        set { this.AvgType = value; }
    }
}

// This class encapsulates an array of double values and implements
// the IConvertible interface. Most of the IConvertible methods
// return an average of the array elements in one of three types:
// arithmetic mean, geometric mean, or median.
public class DataSet : IConvertible
{
    protected ArrayList     data;
    protected AverageInfo   defaultProvider;

    // Construct the object and add an initial list of values.
    // Create a default format provider.
    public DataSet( params double[ ] values )
    {
        data = new ArrayList( values );
        defaultProvider =
```

```
            new AverageInfo( AverageType.ArithmeticMean );
    }

    // Add additional values with this method.
    public int Add( double value )
    {
        data.Add( value );
        return data.Count;
    }

    // Get, set, and add values with this indexer property.
    public double this[ int index ]
    {
        get
        {
            if( index >= 0 && index < data.Count )
                return (double)data[ index ];
            else
                throw new InvalidOperationException(
                    "[DataSet.get] Index out of range." );
        }
        set
        {
            if( index >= 0 && index < data.Count )
                data[ index ] = value;

            else if( index == data.Count )
                data.Add( value );
            else
                throw new InvalidOperationException(
                    "[DataSet.set] Index out of range." );
        }
    }

    // This property returns the number of elements in the object.
    public int Count
    {
        get { return data.Count; }
    }

    // This method calculates the average of the object's elements.
    protected double Average( AverageType avgType )
    {
        double  SumProd;

        if( data.Count == 0 )
            return 0.0;

        switch( avgType )
        {
            case AverageType.GeometricMean:

*/
```

Remarks

The return value is the result of invoking the IConvertible.ToChar method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToChar(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to its equivalent Unicode character.

```
C#

[System.CLSCompliant(false)]
public static char ToChar (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Char.MaxValue.

Examples

The following example converts each element in an array of unsigned long integers to a Char value.

```
C#

ulong[] numbers = { UInt64.MinValue, 40, 160, 255, 1028,
                    2011, 30001, 207154, Int64.MaxValue };
char result;
```

```
foreach (ulong number in numbers)
{
   try {
      result = Convert.ToChar(number);
      Console.WriteLine("{0} converts to '{1}'.", number, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Char data
type.",
                        number);
   }
}
// The example displays the following output:
//       0 converts to ' '.
//       40 converts to '('.
//       160 converts to ' '.
//       255 converts to 'ÿ'.
//       1028 converts to 'Є'.
//       2011 converts to 'ۂ'.
//       30001 converts to '由'.
//       207154 is outside the range of the Char data type.
//       9223372036854775807 is outside the range of the Char data type.
```

ToChar(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to its equivalent Unicode character.

```
C#

[System.CLSCompliant(false)]
public static char ToChar (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Char.MaxValue.

Examples

The following example converts each element in an array of unsigned integers to a Char value.

```
C#

uint[] numbers = { UInt32.MinValue, 40, 160, 255, 1028,
                   2011, 30001, 207154, Int32.MaxValue };
char result;
foreach (uint number in numbers)
{
   try {
      result = Convert.ToChar(number);
      Console.WriteLine("{0} converts to '{1}'.", number, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Char data
type.",
```

```
                                number);
    }
}
// The example displays the following output:
//       0 converts to ' '.
//       40 converts to '('.
//       160 converts to ' '.
//       255 converts to 'ÿ'.
//       1028 converts to 'Є'.
//       2011 converts to 'ϖ'.
//       30001 converts to '由'.
//       207154 is outside the range of the Char data type.
//       2147483647 is outside the range of the Char data type.
```

ToChar(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to its equivalent Unicode character.

C#

```
[System.CLSCompliant(false)]
public static char ToChar (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned 16-bit integers to a Char value.

C#

```
ushort[] numbers = { UInt16.MinValue, 40, 160, 255, 1028,
                     2011, UInt16.MaxValue };
char result;
foreach (ushort number in numbers)
{
   result = Convert.ToChar(number);
   Console.WriteLine("{0} converts to '{1}'.", number, result);
}
// The example displays the following output:
//       0 converts to ' '.
//       40 converts to '('.
//       160 converts to ' '.
//       255 converts to 'ÿ'.
//       1028 converts to 'Є'.
//       2011 converts to 'ϖ'.
//       65535 converts to '￿'.
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToChar(String)

Converts the first character of a specified string to a Unicode character.

```
C#
public static char ToChar (string value);
```

Parameters

`value` String

A string of length 1.

Returns

Char

A Unicode character that is equivalent to the first and only character in `value`.

Exceptions

ArgumentNullException

`value` is `null`.

FormatException

The length of `value` is not 1.

Examples

The following example converts each element in a string array to a Char value.

```
C#
```

```
string nullString = null;
string[] strings = { "A", "This",  '\u0007'.ToString(), nullString };
char result;
foreach (string strng in strings)
{
   try {
      result = Convert.ToChar(strng);
      Console.WriteLine("'{0}' converts to '{1}'.", strng, result);
   }
   catch (FormatException)
   {
      Console.WriteLine("'{0}' is not in the correct format for
conversion to a Char.",
                        strng);
   }
   catch (ArgumentNullException) {
      Console.WriteLine("A null string cannot be converted to a Char.");
   }
}
// The example displays the following output:
//       'A' converts to 'A'.
//       'This' is not in the correct format for conversion to a Char.
//       '       ' converts to ' '.
//       A null string cannot be converted to a Char.
```

Remarks

`value` must be a string that contains a single character.

If you prefer not to handle an exception if the conversion fails, you can call the Char.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToChar(Single)

Calling this method always throws InvalidCastException.

C#

```
public static char ToChar (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Char

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToChar(SByte)

Important

This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to its equivalent Unicode character.

C#

```
[System.CLSCompliant(false)]
public static char ToChar (sbyte value);
```

Parameters

value SByte

The 8-bit signed integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than Char.MinValue.

Examples

The following example converts an array of signed bytes to Char values.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 40, 80, 120, SByte.MaxValue };
char result;
foreach (sbyte number in numbers)
{
   try {
      result = Convert.ToChar(number);
      Console.WriteLine("{0} converts to '{1}'.", number, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Char data
```

```
type.",
                                number);
    }
}
// The example displays the following output:
//       -128 is outside the range of the Char data type.
//       -1 is outside the range of the Char data type.
//       40 converts to '('.
//       80 converts to 'P'.
//       120 converts to 'x'.
//       127 converts to '⌂'.
```

Applies to

▼ .NET 9 and other versions

Product	Versions

UWP	10.0

ToChar(Int64)

Converts the value of the specified 64-bit signed integer to its equivalent Unicode character.

C#

```
public static char ToChar (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Exceptions

OverflowException

`value` is less than Char.MinValue or greater than Char.MaxValue.

Examples

The following example attempts to convert a long integer to a Char, and throws a OverflowException on failure.

C#

```
public void ConvertLongChar(long longVal) {

    char    charVal = 'a';

    try {
        charVal = System.Convert.ToChar(longVal);
        System.Console.WriteLine("{0} as a char is {1}",
            longVal, charVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in long-to-char conversion.");
    }

    // A conversion from Char to long cannot overflow.
    longVal = System.Convert.ToInt64(charVal);
    System.Console.WriteLine("{0} as an Int64 is {1}",
        charVal, longVal);
}
```

ToChar(Int16)

Converts the value of the specified 16-bit signed integer to its equivalent Unicode character.

```
C#

public static char ToChar (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Exceptions

OverflowException

`value` is less than Char.MinValue.

Examples

The following example converts an array of signed 16-bit integers to Char values.

```
C#

short[] numbers = { Int16.MinValue, 0, 40, 160, 255, 1028,
                    2011, Int16.MaxValue };
char result;
foreach (short number in numbers)
{
   try {
      result = Convert.ToChar(number);
      Console.WriteLine("{0} converts to '{1}'.", number, result);
```

```
    }
    catch (OverflowException) {
       Console.WriteLine("{0} is outside the range of the Char data
type.",
                         number);
    }
}
// The example displays the following output:
//       -32768 is outside the range of the Char data type.
//       0 converts to ' '.
//       40 converts to '('.
//       160 converts to ' '.
//       255 converts to 'ÿ'.
//       1028 converts to 'Є'.
//       2011 converts to 'ˆ'.
//       32767 converts to '翻'.
```

ToChar(Double)

Calling this method always throws InvalidCastException.

C#

```
public static char ToChar (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Char

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToChar(Decimal)

Calling this method always throws InvalidCastException.

C#

```
public static char ToChar (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Char

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Examples

The following example attempts to convert a Decimal to Char, and throws InvalidCastException on failure.

C#

```
public void ConvertCharDecimal(char charVal) {
    Decimal decimalVal = 0;

    // Char to decimal conversion is not supported and will always
    // throw an InvalidCastException.
    try {
        decimalVal = System.Convert.ToDecimal(charVal);
    }
    catch (System.InvalidCastException) {
        System.Console.WriteLine(
            "Char-to-Decimal conversion is not supported " +
            "by the .NET Framework.");
    }

    //Decimal to char conversion is also not supported.
    try {
        charVal = System.Convert.ToChar(decimalVal);
    }
    catch (System.InvalidCastException) {
        System.Console.WriteLine(
            "Decimal-to-Char conversion is not supported " +
            "by the .NET Framework.");
    }
}
```

.NET Standard	2.0, 2.1

ToChar(DateTime)

Calling this method always throws InvalidCastException.

```
C#

public static char ToChar (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Char

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

.NET Standard	2.0, 2.1

ToChar(Char)

Returns the specified Unicode character value; no actual conversion is performed.

```
C#
```

```
public static char ToChar (char value);
```

Parameters

`value` Char

The Unicode character to return.

Returns

Char

`value` is returned unchanged.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToChar(Byte)

Converts the value of the specified 8-bit unsigned integer to its equivalent Unicode character.

C#

```
public static char ToChar (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Examples

The following example converts an array of unsigned bytes to Char values.

C#

```
byte[] bytes = {Byte.MinValue, 40, 80, 120, 180, Byte.MaxValue};
char result;
foreach (byte number in bytes)
{
   result = Convert.ToChar(number);
   Console.WriteLine("{0} converts to '{1}'.", number, result);
}
// The example displays the following output:
//       0 converts to ' '.
//       40 converts to '('.
//       80 converts to 'P'.
//       120 converts to 'x'.
//       180 converts to '''.
//       255 converts to 'ÿ'.
```

ToChar(Int32)

Converts the value of the specified 32-bit signed integer to its equivalent Unicode character.

C#

```
public static char ToChar (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Char

A Unicode character that is equivalent to `value`.

Exceptions

OverflowException

`value` is less than Char.MinValue or greater than Char.MaxValue.

Examples

The following example converts an array of signed integers to Char values.

C#

```
int[] numbers = { -1, 0, 40, 160, 255, 1028,
                  2011, 30001, 207154, Int32.MaxValue };
char result;
foreach (int number in numbers)
{
   try {
      result = Convert.ToChar(number);
      Console.WriteLine("{0} converts to '{1}'.", number, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Char data
type.",
                        number);
   }
}
//       -1 is outside the range of the Char data type.
//       0 converts to ' '.
//       40 converts to '('.
//       160 converts to ' '.
//       255 converts to 'ÿ'.
//       1028 converts to 'Є'.
//       2011 converts to 'ϖ'.
//       30001 converts to '由'.
//       207154 is outside the range of the Char data type.
//       2147483647 is outside the range of the Char data type.

Convert.ToDateTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a DateTime value.

Overloads

Expand table

ToDateTime(Single)	Calling this method always throws InvalidCastException.
ToDateTime(String)	Converts the specified string representation of a date and time to an equivalent date and time value.
ToDateTime(UInt16)	Calling this method always throws InvalidCastException.
ToDateTime(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent date and time, using the specified culture-specific formatting information.
ToDateTime(UInt64)	Calling this method always throws InvalidCastException.
ToDateTime(Object, IFormatProvider)	Converts the value of the specified object to a DateTime object, using the specified culture-specific formatting information.
ToDateTime(SByte)	Calling this method always throws InvalidCastException.
ToDateTime(UInt32)	Calling this method always throws InvalidCastException.
ToDateTime(Object)	Converts the value of the specified object to a DateTime object.
ToDateTime(Int16)	Calling this method always throws InvalidCastException.
ToDateTime(Int32)	Calling this method always throws InvalidCastException.
ToDateTime(Int64)	Calling this method always throws InvalidCastException.
ToDateTime(Double)	Calling this method always throws InvalidCastException.
ToDateTime(Decimal)	Calling this method always throws InvalidCastException.

ToDateTime(DateTime)	Returns the specified DateTime object; no actual conversion is performed.
ToDateTime(Char)	Calling this method always throws InvalidCastException.
ToDateTime(Byte)	Calling this method always throws InvalidCastException.
ToDateTime(Boolean)	Calling this method always throws InvalidCastException.

ToDateTime(Single)

Calling this method always throws InvalidCastException.

```
C#
public static DateTime ToDateTime (float value);
```

Parameters

`value` Single

The single-precision floating-point value to convert.

Returns

DateTime

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToDateTime(String)

Converts the specified string representation of a date and time to an equivalent date and time value.

C#

```
public static DateTime ToDateTime (string? value);
```

Parameters

`value` String

The string representation of a date and time.

Returns

DateTime

The date and time equivalent of the value of `value`, or the date and time equivalent of DateTime.MinValue if `value` is `null`.

Exceptions

FormatException

`value` is not a properly formatted date and time string.

Examples

The following example uses the ToDateTime method to convert various string representations of dates and times to DateTime values.

C#

```
using System;

public class ConversionToDateTime
{
   public static void Main()
   {
      string dateString = null;

      // Convert a null string.
      ConvertToDateTime(dateString);

      // Convert an empty string.
      dateString = String.Empty;
      ConvertToDateTime(dateString);

      // Convert a non-date string.
      dateString = "not a date";
      ConvertToDateTime(dateString);

      // Try to convert various date strings.
      dateString = "05/01/1996";
      ConvertToDateTime(dateString);
      dateString = "Tue Apr 28, 2009";
      ConvertToDateTime(dateString);
      dateString = "Wed Apr 28, 2009";
      ConvertToDateTime(dateString);
      dateString = "06 July 2008 7:32:47 AM";
      ConvertToDateTime(dateString);
      dateString = "17:32:47.003";
      ConvertToDateTime(dateString);
      // Convert a string returned by DateTime.ToString("R").
      dateString = "Sat, 10 May 2008 14:32:17 GMT";
      ConvertToDateTime(dateString);
      // Convert a string returned by DateTime.ToString("o").
      dateString = "2009-05-01T07:54:59.9843750-04:00";
      ConvertToDateTime(dateString);
   }

   private static void ConvertToDateTime(string value)
   {
      DateTime convertedDate;
      try {
         convertedDate = Convert.ToDateTime(value);
         Console.WriteLine("'{0}' converts to {1} {2} time.",
                           value, convertedDate,
                           convertedDate.Kind.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in the proper format.", value);
      }
   }
}
// The example displays the following output:
//    '' converts to 1/1/0001 12:00:00 AM Unspecified time.
```

```
//    '' is not in the proper format.
//    'not a date' is not in the proper format.
//    '05/01/1996' converts to 5/1/1996 12:00:00 AM Unspecified time.
//    'Tue Apr 28, 2009' converts to 4/28/2009 12:00:00 AM Unspecified
time.
//    'Wed Apr 28, 2009' is not in the proper format.
//    '06 July 2008 7:32:47 AM' converts to 7/6/2008 7:32:47 AM
Unspecified time.
//    '17:32:47.003' converts to 5/30/2008 5:32:47 PM Unspecified time.
//    'Sat, 10 May 2008 14:32:17 GMT' converts to 5/10/2008 7:32:17 AM
Local time.
//    '2009-05-01T07:54:59.9843750-04:00' converts to 5/1/2009 4:54:59 AM
Local time.
```

Remarks

If `value` is not `null`, the return value is the result of invoking the DateTime.Parse method on `value` using the formatting information in a DateTimeFormatInfo object that is initialized for the current culture. The `value` argument must contain the representation of a date and time in one of the formats described in the DateTimeFormatInfo topic. If `value` is `null`, the method returns DateTime.MinValue.

This method tries to parse `value` completely and avoid throwing a FormatException. It completes missing month, day, and year information with the current date. If `value` contains only a date and no time, this method assumes a time of midnight. Any leading, inner, or trailing white-space characters in `value` are ignored.

If you prefer not to handle an exception if the conversion fails, you can call the DateTime.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

>
> This API is not CLS-compliant.

Calling this method always throws InvalidCastException.

C#

```
[System.CLSCompliant(false)]
public static DateTime ToDateTime (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

DateTime

This conversion is not supported. No value is returned.

Attributes CLSCompliantAttribute

Exceptions

InvalidCastException

This conversion is not supported.

.NET Standard	2.0, 2.1

ToDateTime(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent date and time, using the specified culture-specific formatting information.

C#

```
public static DateTime ToDateTime (string? value, IFormatProvider?
provider);
```

Parameters

`value` String

A string that contains a date and time to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

DateTime

The date and time equivalent of the value of `value`, or the date and time equivalent of DateTime.MinValue if `value` is `null`.

Exceptions

FormatException

`value` is not a properly formatted date and time string.

Examples

The following example converts string representations of date values with the `ToDateTime` method, using an IFormatProvider object.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("{0,-18}{1,-12}{2}\n", "Date String", "Culture",
"Result");

      string[] cultureNames = { "en-US", "ru-RU","ja-JP" };
      string[] dateStrings = { "01/02/09", "2009/02/03",  "01/2009/03",
                               "01/02/2009", "21/02/09", "01/22/09",
                               "01/02/23" };
      // Iterate each culture name in the array.
      foreach (string cultureName in cultureNames)
      {
         CultureInfo culture = new CultureInfo(cultureName);

         // Parse each date using the designated culture.
         foreach (string dateStr in dateStrings)
         {
            DateTime dateTimeValue;
            try {
               dateTimeValue = Convert.ToDateTime(dateStr, culture);
                // Display the date and time in a fixed format.
                Console.WriteLine("{0,-18}{1,-12}{2:yyyy-MMM-dd}",
                                  dateStr, cultureName, dateTimeValue);
            }
            catch (FormatException e) {
                Console.WriteLine("{0,-18}{1,-12}{2}",
                                  dateStr, cultureName,
e.GetType().Name);
            }
         }
         Console.WriteLine();
      }
   }
}
```

Remarks

The return value is the result of invoking the DateTime.Parse(String, IFormatProvider) method on `value`.

`provider` is an IFormatProvider instance that obtains a DateTimeFormatInfo object. The DateTimeFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the DateTimeFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the DateTime.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

.NET Standard	2.0, 2.1

ToDateTime(Object, IFormatProvider)

Converts the value of the specified object to a DateTime object, using the specified culture-specific formatting information.

```
C#

public static DateTime ToDateTime (object? value, IFormatProvider?
provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

DateTime

The date and time equivalent of the value of `value`, or the date and time equivalent of DateTime.MinValue if `value` is `null`.

Exceptions

FormatException

`value` is not a valid date and time value.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

Examples

The following example defines a custom format provider, `CustomProvider`, whose GetFormat method outputs a message to the console that it has been invoked, and then returns the DateTimeFormatInfo object of the culture whose name was passed as a parameter to its class constructor. Each of these `CustomProvider` objects is used to convert the elements in an object array to date and time values. The output

indicates that the `CustomProvider` object is used in the conversion only when the type of the `value` parameter is a String.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] cultureNames = { "en-US", "hu-HU", "pt-PT" };
      object[] objects = { 12, 17.2, false, new DateTime(2010, 1, 1),
"today",
                           new System.Collections.ArrayList(), 'c',
                           "05/10/2009 6:13:18 PM", "September 8, 1899"
};

      foreach (string cultureName in cultureNames)
      {
         Console.WriteLine("{0} culture:", cultureName);
         CustomProvider provider = new CustomProvider(cultureName);
         foreach (object obj in objects)
         {
            try {
               DateTime dateValue = Convert.ToDateTime(obj, provider);
               Console.WriteLine("{0} --> {1}", obj,
                                 dateValue.ToString(new
CultureInfo(cultureName)));
            }
            catch (FormatException) {
               Console.WriteLine("{0} --> Bad Format", obj);
            }
            catch (InvalidCastException) {
               Console.WriteLine("{0} --> Conversion Not Supported",
obj);
            }
         }
         Console.WriteLine();
      }
   }
}

public class CustomProvider : IFormatProvider
{
   private string cultureName;

   public CustomProvider(string cultureName)
   {
      this.cultureName = cultureName;
   }
```

```
    public object GetFormat(Type formatType)
    {
        if (formatType == typeof(DateTimeFormatInfo))
        {
            Console.Write("(CustomProvider retrieved.) ");
            return new CultureInfo(cultureName).GetFormat(formatType);
        }
        else
        {
            return null;
        }
    }
}
// The example displays the following output:
//    en-US culture:
//    12 --> Conversion Not Supported
//    17.2 --> Conversion Not Supported
//    False --> Conversion Not Supported
//    1/1/2010 12:00:00 AM --> 1/1/2010 12:00:00 AM
//    (CustomProvider retrieved.) today --> Bad Format
//    System.Collections.ArrayList --> Conversion Not Supported
//    c --> Conversion Not Supported
//    (CustomProvider retrieved.) 05/10/2009 6:13:18 PM --> 5/10/2009
6:13:18 PM
//    (CustomProvider retrieved.) September 8, 1899 --> 9/8/1899 12:00:00
AM
//
//    hu-HU culture:
//    12 --> Conversion Not Supported
//    17.2 --> Conversion Not Supported
//    False --> Conversion Not Supported
//    1/1/2010 12:00:00 AM --> 2010. 01. 01. 0:00:00
//    (CustomProvider retrieved.) today --> Bad Format
//    System.Collections.ArrayList --> Conversion Not Supported
//    c --> Conversion Not Supported
//    (CustomProvider retrieved.) 05/10/2009 6:13:18 PM --> 2009. 05. 10.
18:13:18
//    (CustomProvider retrieved.) September 8, 1899 --> 1899. 09. 08.
0:00:00
//
//    pt-PT culture:
//    12 --> Conversion Not Supported
//    17.2 --> Conversion Not Supported
//    False --> Conversion Not Supported
//    1/1/2010 12:00:00 AM --> 01-01-2010 0:00:00
//    (CustomProvider retrieved.) today --> Bad Format
//    System.Collections.ArrayList --> Conversion Not Supported
//    c --> Conversion Not Supported
//    (CustomProvider retrieved.) 05/10/2009 6:13:18 PM --> 05-10-2009
18:13:18
//    (CustomProvider retrieved.) September 8, 1899 --> 08-09-1899
0:00:00
```

Remarks

The return value is the result of invoking the IConvertible.ToDateTime method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a date, `provider` could supply culture-specific information about the notation used to represent that date. `provider` is involved in the conversion of `value` if the runtime type of `value` is a String, or if `value` is a user-defined type whose IConvertible.ToDateTime implementation makes use of `provider`. If the runtime type of `value` is String and `provider` is `null`, the CultureInfo object that represents the current culture is used.

.NET Standard	2.0, 2.1

ToDateTime(Object)

Converts the value of the specified object to a DateTime object.

```
C#

public static DateTime ToDateTime (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

DateTime

The date and time equivalent of the value of `value`, or a date and time equivalent of DateTime.MinValue if `value` is `null`.

Exceptions

FormatException

`value` is not a valid date and time value.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

Examples

The following example calls the ToDateTime(Object) method with a variety of Object variables.

C#

```
using System;

public class ConversionToDateTime
{
   public static void Main()
   {
      // Try converting an integer.
      int number = 16352;
      ConvertToDateTime(number);

      // Convert a null.
      object obj = null;
      ConvertToDateTime(obj);

      // Convert a non-date string.
      string nonDateString = "monthly";
      ConvertToDateTime(nonDateString);

      // Try to convert various date strings.
      string dateString;
      dateString = "05/01/1996";
      ConvertToDateTime(dateString);
      dateString = "Tue Apr 28, 2009";
      ConvertToDateTime(dateString);
      dateString = "06 July 2008 7:32:47 AM";
      ConvertToDateTime(dateString);
      dateString = "17:32:47.003";
      ConvertToDateTime(dateString);
   }

   private static void ConvertToDateTime(object value)
   {
      DateTime convertedDate;
      try {
         convertedDate = Convert.ToDateTime(value);
         Console.WriteLine("'{0}' converts to {1}.", value,
convertedDate);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in the proper format.", value);
      }
      catch (InvalidCastException) {
         Console.WriteLine("Conversion of the {0} '{1}' is not
supported",
                           value.GetType().Name, value);
      }
   }
}
// The example displays the following output:
```

```
//       Conversion of the Int32 '16352' is not supported
//       '' converts to 1/1/0001 12:00:00 AM.
//       'monthly' is not in the proper format.
//       '05/01/1996' converts to 5/1/1996 12:00:00 AM.
//       'Tue Apr 28, 2009' converts to 4/28/2009 12:00:00 AM.
//       '06 July 2008 7:32:47 AM' converts to 7/6/2008 7:32:47 AM.
//       '17:32:47.003' converts to 5/28/2008 5:32:47 PM.
```

Remarks

For the conversion to succeed, the runtime type of the `value` parameter must be either a DateTime or a String, or `value` must be `null`. Otherwise, the method throws an InvalidCastException. In addition, if `value` is a string, it must contain a valid representation of a date and time value in the current culture or a FormatException is thrown.

The return value is the result of invoking the IConvertible.ToDateTime method of the underlying type of `value`.

.NET Standard	2.0, 2.1

ToDateTime(Byte)

Calling this method always throws InvalidCastException.

```
C#
public static DateTime ToDateTime (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

DateTime

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Convert.ToDecimal Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a decimal number.

Overloads

Expand table

ToDecimal(Single)	Converts the value of the specified single-precision floating-point number to the equivalent decimal number.
ToDecimal(String)	Converts the specified string representation of a number to an equivalent decimal number.
ToDecimal(UInt16)	Converts the value of the specified 16-bit unsigned integer to an equivalent decimal number.
ToDecimal(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent decimal number, using the specified culture-specific formatting information.
ToDecimal(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent decimal number.
ToDecimal(Object, IFormatProvider)	Converts the value of the specified object to an equivalent decimal number, using the specified culture-specific formatting information.
ToDecimal(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent decimal number.
ToDecimal(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent decimal number.
ToDecimal(Object)	Converts the value of the specified object to an equivalent decimal number.
ToDecimal(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent decimal number.

ToDecimal(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent decimal number.
ToDecimal(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent decimal number.
ToDecimal(Double)	Converts the value of the specified double-precision floating-point number to an equivalent decimal number.
ToDecimal(Decimal)	Returns the specified decimal number; no actual conversion is performed.
ToDecimal(DateTime)	Calling this method always throws InvalidCastException.
ToDecimal(Char)	Calling this method always throws InvalidCastException.
ToDecimal(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent decimal number.
ToDecimal(Boolean)	Converts the specified Boolean value to the equivalent decimal number.

ToDecimal(Single)

Converts the value of the specified single-precision floating-point number to the equivalent decimal number.

C#

```
public static decimal ToDecimal (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Exceptions

OverflowException

`value` is greater than Decimal.MaxValue or less than Decimal.MinValue.

Examples

The following example tries to convert each element in an array of Single values to a Decimal value.

C#

```
float[] numbers = { Single.MinValue, -3e10f, -1093.54f, 0f, 1e-03f,
                    1034.23f, Single.MaxValue };
decimal result;

foreach (float number in numbers)
{
   try {
      result = Convert.ToDecimal(number);
      Console.WriteLine("Converted the Single value {0} to {1}.", number,
result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is out of range of the Decimal type.",
number);
   }
}
// The example displays the following output:
//       -3.402823E+38 is out of range of the Decimal type.
//       Converted the Single value -3E+10 to -30000000000.
//       Converted the Single value -1093.54 to -1093.54.
//       Converted the Single value 0 to 0.
//       Converted the Single value 0.001 to 0.001.
//       Converted the Single value 1034.23 to 1034.23.
//       3.402823E+38 is out of range of the Decimal type.
```

Remarks

The Decimal value returned by this method contains a maximum of seven significant digits. If the `value` parameter contains more than seven significant digits, it is rounded using rounding to nearest. The following example illustrates how the ToDecimal(Single) method uses rounding to nearest to return a Decimal value with seven significant digits.

C#

```
Console.WriteLine(Convert.ToDecimal(1234567500.12F));  // Displays
1234568000
Console.WriteLine(Convert.ToDecimal(1234568500.12F));  // Displays
1234568000
```

```
Console.WriteLine(Convert.ToDecimal(10.980365F));      // Displays
10.98036
Console.WriteLine(Convert.ToDecimal(10.980355F));      // Displays
10.98036
```

UWP	10.0

ToDecimal(String)

Converts the specified string representation of a number to an equivalent decimal number.

C#

```
public static decimal ToDecimal (string? value);
```

Parameters

`value` String

A string that contains a number to convert.

Returns

Decimal

A decimal number that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not a number in a valid format.

OverflowException

`value` represents a number that is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example illustrates the use of `ToDecimal`. It attempts to convert a String to a Decimal, and throws the possible exceptions that may arise during the conversion.

C#

```
public void ConvertStringDecimal(string stringVal) {
    decimal decimalVal = 0;

    try {
        decimalVal = System.Convert.ToDecimal(stringVal);
        System.Console.WriteLine(
            "The string as a decimal is {0}.", decimalVal);
    }
    catch (System.OverflowException){
        System.Console.WriteLine(
            "The conversion from string to decimal overflowed.");
    }
    catch (System.FormatException) {
        System.Console.WriteLine(
            "The string is not formatted as a decimal.");
    }
    catch (System.ArgumentNullException) {
        System.Console.WriteLine(
            "The string is null.");
    }

    // Decimal to string conversion will not overflow.
    stringVal = System.Convert.ToString(decimalVal);
    System.Console.WriteLine(
        "The decimal as a string is {0}.", stringVal);
}
```

Remarks

Using the ToDecimal(String) method is equivalent to passing `value` to the Decimal.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Decimal.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToDecimal(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to an equivalent decimal number.

C#

```
[System.CLSCompliant(false)]
public static decimal ToDecimal (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Decimal

The decimal number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of 16-bit unsigned integers to Decimal values.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 12345, UInt16.MaxValue };
decimal result;

foreach (ushort number in numbers)
{
   result = Convert.ToDecimal(number);
   Console.WriteLine("Converted the UInt16 value {0} to {1}.",
                     number, result);
}
// The example displays the following output:
//       Converted the UInt16 value 0 to 0.
//       Converted the UInt16 value 121 to 121.
//       Converted the UInt16 value 12345 to 12345.
//       Converted the UInt16 value 65535 to 65535.
```

ToDecimal(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent decimal number, using the specified culture-specific formatting information.

```
C#

public static decimal ToDecimal (string? value, IFormatProvider?
provider);
```

Parameters

`value` String

A string that contains a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Decimal

A decimal number that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not a number in a valid format.

OverflowException

`value` represents a number that is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example attempts to convert an array of strings to Decimal values by using NumberFormatInfo objects that represent two different cultures.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] values = { "123456789", "12345.6789", "12 345,6789",
                          "123,456.789", "123 456,789",
"123,456,789.0123",
                          "123 456 789,0123" };
      CultureInfo[] cultures = { new CultureInfo("en-US"),
                                 new CultureInfo("fr-FR") };

      foreach (CultureInfo culture in cultures)
      {
         Console.WriteLine("String -> Decimal Conversion Using the {0}
Culture",
                           culture.Name);
         foreach (string value in values)
         {
            Console.Write("{0,20}  ->  ", value);
            try {
               Console.WriteLine(Convert.ToDecimal(value, culture));
            }
            catch (FormatException) {
               Console.WriteLine("FormatException");
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       String -> Decimal Conversion Using the en-US Culture
//                  123456789  ->  123456789
//                 12345.6789  ->  12345.6789
//                12 345,6789  ->  FormatException
//                123,456.789  ->  123456.789
//                123 456,789  ->  FormatException
//           123,456,789.0123  ->  123456789.0123
//           123 456 789,0123  ->  FormatException
```

```
//
//       String -> Decimal Conversion Using the fr-FR Culture
//                   123456789  ->  123456789
//                  12345.6789  ->  FormatException
//                12 345,6789  ->  12345.6789
//                123,456.789  ->  FormatException
//                123 456,789  ->  123456.789
//            123,456,789.0123  ->  FormatException
//            123 456 789,0123  ->  123456789.0123
```

Remarks

The return value is the result of invoking the Decimal.Parse method on `value`.

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Decimal.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToDecimal(UInt64)

Important

This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent decimal number.

C#

```
[System.CLSCompliant(false)]
public static decimal ToDecimal (ulong value);
```

Parameters

value UInt64

The 64-bit unsigned integer to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of unsigned long integers to Decimal values.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 12345, UInt64.MaxValue };
decimal result;

foreach (ulong number in numbers)
{
   result = Convert.ToDecimal(number);
   Console.WriteLine("Converted the UInt64 value {0} to {1}.",
                     number, result);
}
// The example displays the following output:
//    Converted the UInt64 value 0 to 0.
//    Converted the UInt64 value 121 to 121.
//    Converted the UInt64 value 12345 to 12345.
```

```
//    Converted the UInt64 value 18446744073709551615 to
18446744073709551615.
```

ToDecimal(Object, IFormatProvider)

Converts the value of the specified object to an equivalent decimal number, using the specified culture-specific formatting information.

C#

```
public static decimal ToDecimal (object? value, IFormatProvider?
provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Decimal

A decimal number that is equivalent to `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format for a Decimal type.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example defines a `Temperature` class that implements the IConvertible interface.

C#

```
using System;
using System.Globalization;

public class Temperature : IConvertible
{
   private decimal m_Temp;

   public Temperature(decimal temperature)
   {
      this.m_Temp = temperature;
   }

   public decimal Celsius
   {
      get { return this.m_Temp; }
   }

   public decimal Kelvin
   {
      get { return this.m_Temp + 273.15m; }
```

```
    }

    public decimal Fahrenheit
    {
       get { return Math.Round((decimal) (this.m_Temp * 9 / 5 + 32), 2); }
    }

    public override string ToString()
    {
       return m_Temp.ToString("N2") + " °C";
    }

    // IConvertible implementations.
    public TypeCode GetTypeCode()
    {
       return TypeCode.Object;
    }

    public bool ToBoolean(IFormatProvider provider)
    {
       if (m_Temp == 0)
          return false;
       else
          return true;
    }

    public byte ToByte(IFormatProvider provider)
    {
       if (m_Temp < Byte.MinValue || m_Temp > Byte.MaxValue)
          throw new OverflowException(String.Format("{0} is out of range
of the Byte type.",
                                                     this.m_Temp));
       else
          return Decimal.ToByte(this.m_Temp);
    }

    public char ToChar(IFormatProvider provider)
    {
       throw new InvalidCastException("Temperature to Char conversion is
not supported.");
    }

    public DateTime ToDateTime(IFormatProvider provider)
    {
       throw new InvalidCastException("Temperature to DateTime conversion
is not supported.");
    }

    public decimal ToDecimal(IFormatProvider provider)
    {
       return this.m_Temp;
    }

    }

    public string ToString(IFormatProvider provider)
    {
        return m_Temp.ToString("N2", provider) + " °C";
    }

    public object ToType(Type conversionType, IFormatProvider provider)
    {
```

```
      switch (Type.GetTypeCode(conversionType))
      {
         case TypeCode.Boolean:
            return this.ToBoolean(null);
         case TypeCode.Byte:
            return this.ToByte(null);
         case TypeCode.Char:
            return this.ToChar(null);
         case TypeCode.DateTime:
            return this.ToDateTime(null);
         case TypeCode.Decimal:
            return this.ToDecimal(null);
         case TypeCode.Double:
            return this.ToDouble(null);
         case TypeCode.Int16:
            return this.ToInt16(null);
         case TypeCode.Int32:
            return this.ToInt32(null);
         case TypeCode.Int64:
            return this.ToInt64(null);
         case TypeCode.Object:
            if (typeof(Temperature).Equals(conversionType))
               return this;
            else
               throw new InvalidCastException(String.Format("Conversion
to a {0} is not supported.",

conversionType.Name));
         case TypeCode.SByte:
            return this.ToSByte(null);
         case TypeCode.Single:
            return this.ToSingle(null);
         case TypeCode.String:
            return this.ToString(provider);
         case TypeCode.UInt16:
            return this.ToUInt16(null);
         case TypeCode.UInt32:
            return this.ToUInt32(null);
         case TypeCode.UInt64:
            return this.ToUInt64(null);
         default:
            throw new InvalidCastException(String.Format("Conversion to
{0} is not supported.", conversionType.Name));
      }
   }

   public ushort ToUInt16(IFormatProvider provider)
   {
      if (this.m_Temp < UInt16.MinValue || this.m_Temp > UInt16.MaxValue)
         throw new OverflowException(String.Format("{0} is out of range
of the UInt16 type.",
                                                     this.m_Temp));
      else
         return Decimal.ToUInt16(this.m_Temp);
   }
```

```
   public uint ToUInt32(IFormatProvider provider)
   {
      if (this.m_Temp < UInt32.MinValue || this.m_Temp > UInt32.MaxValue)
         throw new OverflowException(String.Format("{0} is out of range
of the UInt32 type.",
                                                    this.m_Temp));
      else
         return Decimal.ToUInt32(this.m_Temp);
   }

   public ulong ToUInt64(IFormatProvider provider)
   {
      if (this.m_Temp < UInt64.MinValue || this.m_Temp > UInt64.MaxValue)
         throw new OverflowException(String.Format("{0} is out of range
of the UInt64 type.",
                                                    this.m_Temp));
      else
         return Decimal.ToUInt64(this.m_Temp);
   }
}
```

The following example shows that when a `Temperature` object is passed as a parameter to the ToDecimal(Object, IFormatProvider) method, the IConvertible.ToDecimal implementation of the `Temperature` class is called to perform the conversion.

C#

```
public class Example
{
   public static void Main()
   {
      Temperature cold = new Temperature(-40);
      Temperature freezing = new Temperature(0);
      Temperature boiling = new Temperature(100);

      Console.WriteLine(Convert.ToDecimal(cold, null));
      Console.WriteLine(Convert.ToDecimal(freezing, null));
      Console.WriteLine(Convert.ToDecimal(boiling, null));
   }
}
// The example dosplays the following output:
//       -40
//       0
//       100
```

Remarks

The return value is the result of invoking the IConvertible.ToDecimal method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToDecimal(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent decimal number.

C#

```
[System.CLSCompliant(false)]
public static decimal ToDecimal (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of signed bytes to a Decimal value.

C#

```
sbyte[] numbers = { SByte.MinValue, -23, 0, 17, SByte.MaxValue };
decimal result;

foreach (sbyte number in numbers)
{
   result = Convert.ToDecimal(number);
   Console.WriteLine("Converted the SByte value {0} to {1}.", number,
result);
}
//       Converted the SByte value -128 to -128.
//       Converted the SByte value -23 to -23.
//       Converted the SByte value 0 to 0.
//       Converted the SByte value 17 to 17.
//       Converted the SByte value 127 to 127.
```

ToDecimal(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent decimal number.

C#

```
[System.CLSCompliant(false)]
public static decimal ToDecimal (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts an array of unsigned integers to Decimal values.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 12345, UInt32.MaxValue };
decimal result;

foreach (uint number in numbers)
{
   result = Convert.ToDecimal(number);
   Console.WriteLine("Converted the UInt32 value {0} to {1}.",
                     number, result);
}
// The example displays the following output:
//       Converted the UInt32 value 0 to 0.
//       Converted the UInt32 value 121 to 121.
//       Converted the UInt32 value 12345 to 12345.
//       Converted the UInt32 value 4294967295 to 4294967295.
```

UWP	10.0

ToDecimal(Object)

Converts the value of the specified object to an equivalent decimal number.

C#

```
public static decimal ToDecimal (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Decimal

A decimal number that is equivalent to `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format for a Decimal type.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example tries to convert each element in an object array to a Decimal value.

C#

```
object[] values = { true, 'a', 123, 1.764e32, "9.78", "1e-02",
                    1.67e03, "A100", "1,033.67", DateTime.Now,
                    Double.MaxValue };
decimal result;

foreach (object value in values)
{
   try {
      result = Convert.ToDecimal(value);
      Console.WriteLine("Converted the {0} value {1} to {2}.",
                        value.GetType().Name, value, result);
   }
```

```
    catch (OverflowException) {
       Console.WriteLine("The {0} value {1} is out of range of the Decimal
type.",
                         value.GetType().Name, value);
    }
    catch (FormatException) {
       Console.WriteLine("The {0} value {1} is not recognized as a valid
Decimal value.",
                         value.GetType().Name, value);
    }
    catch (InvalidCastException) {
       Console.WriteLine("Conversion of the {0} value {1} to a Decimal is
not supported.",
                         value.GetType().Name, value);
    }
}
// The example displays the following output:
//    Converted the Boolean value True to 1.
//    Conversion of the Char value a to a Decimal is not supported.
//    Converted the Int32 value 123 to 123.
//    The Double value 1.764E+32 is out of range of the Decimal type.
//    Converted the String value 9.78 to 9.78.
//    The String value 1e-02 is not recognized as a valid Decimal value.
//    Converted the Double value 1670 to 1670.
//    The String value A100 is not recognized as a valid Decimal value.
//    Converted the String value 1,033.67 to 1033.67.
//    Conversion of the DateTime value 10/15/2008 05:40:42 PM to a
Decimal is not supported.
//    The Double value 1.79769313486232E+308 is out of range of the
Decimal type.
```

Remarks

The return value is the result of invoking the IConvertible.ToDecimal method of the underlying type of `value`.

ToDecimal(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent decimal number.

C#

```
public static decimal ToDecimal (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Examples

The following example converts an Int64 value to a Decimal value.

C#

```
public void ConvertLongDecimal(long longVal) {

    decimal decimalVal;

    // Long to decimal conversion cannot overflow.
    decimalVal = System.Convert.ToDecimal(longVal);
    System.Console.WriteLine("{0} as a decimal is {1}",
            longVal, decimalVal);

    // Decimal to long conversion can overflow.
```

```
    try {
        longVal = System.Convert.ToInt64(decimalVal);
        System.Console.WriteLine("{0} as a long is {1}",
            decimalVal, longVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in decimal-to-long conversion.");
    }
}
```

UWP	10.0

ToDecimal(Int32)

Converts the value of the specified 32-bit signed integer to an equivalent decimal number.

C#

```
public static decimal ToDecimal (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Examples

The following example converts an array of signed integers to Decimal values.

C#

```
int[] numbers = { Int32.MinValue, -1000, 0, 1000, Int32.MaxValue };
decimal result;

foreach (int number in numbers)
{
   result = Convert.ToDecimal(number);
   Console.WriteLine("Converted the Int32 value {0} to the Decimal value
{1}.",
                     number, result);
}
// The example displays the following output:
//    Converted the Int32 value -2147483648 to the Decimal value
-2147483648.
//    Converted the Int32 value -1000 to the Decimal value -1000.
//    Converted the Int32 value 0 to the Decimal value 0.
//    Converted the Int32 value 1000 to the Decimal value 1000.
//    Converted the Int32 value 2147483647 to the Decimal value
2147483647.
```

ToDecimal(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent decimal number.

C#

```
public static decimal ToDecimal (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Examples

The following example converts an array of 16-bit signed integers to Decimal values.

C#

```
short[] numbers = { Int16.MinValue, -1000, 0, 1000, Int16.MaxValue };
decimal result;

foreach (short number in numbers)
{
   result = Convert.ToDecimal(number);
   Console.WriteLine("Converted the Int16 value {0} to the Decimal value
{1}.",
                     number, result);
}
// The example displays the following output:
//       Converted the Int16 value -32768 to the Decimal value -32768.
//       Converted the Int16 value -1000 to the Decimal value -1000.
```

```
//       Converted the Int16 value 0 to the Decimal value 0.
//       Converted the Int16 value 1000 to the Decimal value 1000.
//       Converted the Int16 value 32767 to the Decimal value 32767.
```

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToDecimal(Double)

Converts the value of the specified double-precision floating-point number to an equivalent decimal number.

C#

```
public static decimal ToDecimal (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Decimal

A decimal number that is equivalent to `value`.

Exceptions

OverflowException

`value` is greater than Decimal.MaxValue or less than Decimal.MinValue.

Examples

The following example converts a Double value to a Decimal value.

C#

```
public void ConvertDoubleDecimal(decimal decimalVal){

    double doubleVal;

    // Decimal to double conversion cannot overflow.
 doubleVal = System.Convert.ToDouble(decimalVal);
    System.Console.WriteLine("{0} as a double is: {1}",
            decimalVal, doubleVal);

    // Conversion from double to decimal can overflow.
    try
 {
       decimalVal = System.Convert.ToDecimal(doubleVal);
    System.Console.WriteLine ("{0} as a decimal is: {1}",
        doubleVal, decimalVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in double-to-double conversion.");
    }
}
```

Remarks

The Decimal value returned by this method contains a maximum of 15 significant digits. If the `value` parameter contains more than 15 significant digits, it is rounded using rounding to nearest. The following example illustrates how the Convert.ToDecimal(Double) method uses rounding to nearest to return a Decimal value with 15 significant digits.

C#

```
Console.WriteLine(Convert.ToDecimal(123456789012345500.12D));  //
Displays 123456789012346000
Console.WriteLine(Convert.ToDecimal(123456789012346500.12D));  //
Displays 123456789012346000
```

```
Console.WriteLine(Convert.ToDecimal(10030.12345678905D));      //
Displays 10030.123456789
Console.WriteLine(Convert.ToDecimal(10030.12345678915D));      //
Displays 10030.1234567892
```

ToDecimal(Decimal)

Returns the specified decimal number; no actual conversion is performed.

C#

```
public static decimal ToDecimal (decimal value);
```

Parameters

`value` Decimal

A decimal number.

Returns

Decimal

`value` is returned unchanged.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UWP	10.0

ToDecimal(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static decimal ToDecimal (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Decimal

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToDecimal(Char)

Calling this method always throws InvalidCastException.

C#

```
public static decimal ToDecimal (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Decimal

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Examples

The following example attempts to convert a Char value to Decimal, and throws InvalidCastException upon failure.

C#

```
public void ConvertCharDecimal(char charVal) {
    Decimal decimalVal = 0;

    // Char to decimal conversion is not supported and will always
    // throw an InvalidCastException.
    try {
        decimalVal = System.Convert.ToDecimal(charVal);
    }
    catch (System.InvalidCastException) {
        System.Console.WriteLine(
            "Char-to-Decimal conversion is not supported " +
            "by the .NET Framework.");
    }

    //Decimal to char conversion is also not supported.
    try {
        charVal = System.Convert.ToChar(decimalVal);
    }
    catch (System.InvalidCastException) {
        System.Console.WriteLine(
            "Decimal-to-Char conversion is not supported " +
            "by the .NET Framework.");
    }
}

.NET Standard	2.0, 2.1

ToDecimal(Byte)

Converts the value of the specified 8-bit unsigned integer to the equivalent decimal number.

C#

```
public static decimal ToDecimal (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Decimal

The decimal number that is equivalent to `value`.

Examples

The following example converts a Byte value to a Decimal value.

C#

```
public void ConvertByteDecimal(byte byteVal) {
    decimal decimalVal;

    // Byte to decimal conversion will not overflow.
    decimalVal = System.Convert.ToDecimal(byteVal);
    System.Console.WriteLine("The byte as a decimal is {0}.",
        decimalVal);

    // Decimal to byte conversion can overflow.
    try {
        byteVal = System.Convert.ToByte(decimalVal);
        System.Console.WriteLine("The Decimal as a byte is {0}.",
            byteVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "The decimal value is too large for a byte.");
    }
}
```

ToDecimal(Boolean)

Converts the specified Boolean value to the equivalent decimal number.

C#

```
public static decimal ToDecimal (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Decimal

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example illustrates the conversion of Boolean to Decimal values.

C#

```
bool[] flags = { true, false };
decimal result;
```

```
foreach (bool flag in flags)
{
   result = Convert.ToDecimal(flag);
   Console.WriteLine("Converted {0} to {1}.", flag, result);
}
// The example displays the following output:
//       Converted True to 1.
//       Converted False to 0.
```

Convert.ToDouble Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a double-precision floating-point number.

Overloads

Expand table

ToDouble(Object, IFormatProvider)	Converts the value of the specified object to an double-precision floating-point number, using the specified culture-specific formatting information.
ToDouble(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent double-precision floating-point number.
ToDouble(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent double-precision floating-point number.
ToDouble(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent double-precision floating-point number.
ToDouble(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent double-precision floating-point number, using the specified culture-specific formatting information.
ToDouble(Single)	Converts the value of the specified single-precision floating-point number to an equivalent double-precision floating-point number.
ToDouble(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent double-precision floating-point number.
ToDouble(Object)	Converts the value of the specified object to a double-precision floating-point number.
ToDouble(String)	Converts the specified string representation of a number to an equivalent double-precision floating-point number.
ToDouble(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent double-precision floating-point number.

ToDouble(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent double-precision floating-point number.
ToDouble(Double)	Returns the specified double-precision floating-point number; no actual conversion is performed.
ToDouble(Decimal)	Converts the value of the specified decimal number to an equivalent double-precision floating-point number.
ToDouble(DateTime)	Calling this method always throws InvalidCastException.
ToDouble(Char)	Calling this method always throws InvalidCastException.
ToDouble(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent double-precision floating-point number.
ToDouble(Boolean)	Converts the specified Boolean value to the equivalent double-precision floating-point number.
ToDouble(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent double-precision floating-point number.

ToDouble(Object, IFormatProvider)

Converts the value of the specified object to an double-precision floating-point number, using the specified culture-specific formatting information.

C#

```
public static double ToDouble (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Double

A double-precision floating-point number that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format for a Double type.

InvalidCastException

`value` does not implement the IConvertible interface.

OverflowException

`value` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example defines a class that implements IConvertible and a class that implements IFormatProvider. Objects of the class that implements IConvertible hold an array of Double values. An object of each class is passed to the `ToDouble` method. This method returns an average of the array of Double values, using the object that implements IFormatProvider to determine how to calculate the average.

C#

```
using System;
using System.Collections;

// Define the types of averaging available in the class
// implementing IConvertible.
public enum AverageType : short
{
    None = 0,
    GeometricMean = 1,
    ArithmeticMean = 2,
    Median = 3
};

// Pass an instance of this class to methods that require an
// IFormatProvider. The class instance determines the type of
// average to calculate.
public class AverageInfo : IFormatProvider
{
    protected AverageType AvgType;

    // Specify the type of averaging in the constructor.
    public AverageInfo( AverageType avgType )
    {
        this.AvgType = avgType;
    }
```

```
    // This method returns a reference to the containing object
    // if an object of AverageInfo type is requested.
    public object GetFormat( Type argType )
    {
        if ( argType == typeof( AverageInfo ) )
            return this;
        else
            return null;
    }

    // Use this property to set or get the type of averaging.
    public AverageType TypeOfAverage
    {
        get { return this.AvgType; }
        set { this.AvgType = value; }
    }
}

// This class encapsulates an array of double values and implements
// the IConvertible interface. Most of the IConvertible methods
// return an average of the array elements in one of three types:
// arithmetic mean, geometric mean, or median.
public class DataSet : IConvertible
{
    protected ArrayList     data;
    protected AverageInfo   defaultProvider;

    // Construct the object and add an initial list of values.
    // Create a default format provider.
    public DataSet( params double[ ] values )
    {
        data = new ArrayList( values );
        defaultProvider =
            new AverageInfo( AverageType.ArithmeticMean );
    }

    // Add additional values with this method.
    public int Add( double value )
    {
        data.Add( value );
        return data.Count;
    }

    // Get, set, and add values with this indexer property.
    public double this[ int index ]
    {
        get
        {
            if( index >= 0 && index < data.Count )
                return (double)data[ index ];
            else
                throw new InvalidOperationException(
                    "[DataSet.get] Index out of range." );
        }
        set
```

```
        {
            if( index >= 0 && index < data.Count )
                data[ index ] = value;

            else if( index == data.Count )
                data.Add( value );
            else
                throw new InvalidOperationException(
                    "[DataSet.set] Index out of range." );
        }
    }

    // This property returns the number of elements in the object.

*/
```

Remarks

The return value is the result of invoking the IConvertible.ToDouble method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToDouble(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent double-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static double ToDouble (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of UInt64 values to a Double value.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 12345, UInt64.MaxValue };
double result;

foreach (ulong number in numbers)
{
   result = Convert.ToDouble(number);
   Console.WriteLine("Converted the UInt64 value {0} to {1}.",
                     number, result);
}
// The example displays the following output:
//    Converted the UInt64 value 0 to 0.
//    Converted the UInt64 value 121 to 121.
//    Converted the UInt64 value 12345 to 12345.
//    Converted the UInt64 value 18446744073709551615 to
1.84467440737096E+19.
```

ToDouble(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent double-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static double ToDouble (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of UInt32 values to a Double value.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 12345, UInt32.MaxValue };
double result;

foreach (uint number in numbers)
{
   result = Convert.ToDouble(number);
   Console.WriteLine("Converted the UInt32 value {0} to {1}.",
                     number, result);
}
// The example displays the following output:
//       Converted the UInt32 value 0 to 0.
//       Converted the UInt32 value 121 to 121.
//       Converted the UInt32 value 12345 to 12345.
//       Converted the UInt32 value 4294967295 to 4294967295.
```

ToDouble(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent double-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static double ToDouble (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of UInt16 values to a Double value.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 12345, UInt16.MaxValue };
double result;

foreach (ushort number in numbers)
{
   result = Convert.ToDouble(number);
   Console.WriteLine("Converted the UInt16 value {0} to {1}.",
                     number, result);
}
// The example displays the following output:
//       Converted the UInt16 value 0 to 0.
//       Converted the UInt16 value 121 to 121.
//       Converted the UInt16 value 12345 to 12345.
//       Converted the UInt16 value 65535 to 65535.
```

ToDouble(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent double-precision floating-point number, using the specified culture-specific formatting information.

```
C#
public static double ToDouble (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Double

A double-precision floating-point number that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not a number in a valid format.

OverflowException

`value` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example converts string representations of Double values with the `ToDouble` method, using an IFormatProvider object.

C#

```
using System;
using System.Globalization;

class Example
{
    static void Main()
    {
        // Create a NumberFormatInfo object and set some of its
properties.
        NumberFormatInfo provider = new NumberFormatInfo();
        provider.NumberDecimalSeparator = ",";
        provider.NumberGroupSeparator = ".";
        provider.NumberGroupSizes = new int[] { 3 };

        // Define an array of numeric strings to convert.
        String[] values = { "123456789", "12345.6789", "12345,6789",
                             "123,456.789", "123.456,789",
                             "123,456,789.0123", "123.456.789,0123" };

        Console.WriteLine("Default Culture: {0}\n",
                          CultureInfo.CurrentCulture.Name);
        Console.WriteLine("{0,-22} {1,-20} {2,-20}\n", "String to
Convert",
                          "Default/Exception", "Provider/Exception");

        // Convert each string to a Double with and without the provider.
        foreach (var value in values) {
           Console.Write("{0,-22} ", value);
           try {
              Console.Write("{0,-20} ", Convert.ToDouble(value));
           }
           catch (FormatException e) {
              Console.Write("{0,-20} ", e.GetType().Name);
           }
           try {
              Console.WriteLine("{0,-20} ", Convert.ToDouble(value,
provider));
           }
           catch (FormatException e) {
              Console.WriteLine("{0,-20} ", e.GetType().Name);
           }
        }
```

```
    }
}
// The example displays the following output:
//       Default Culture: en-US
//
//       String to Convert      Default/Exception    Provider/Exception
//
//       123456789              123456789            123456789
//       12345.6789             12345.6789           123456789
//       12345,6789             123456789            12345.6789
//       123,456.789            123456.789           FormatException
//       123.456,789            FormatException      123456.789
//       123,456,789.0123       123456789.0123       FormatException
//       123.456.789,0123       FormatException      123456789.0123
```

Remarks

The return value is the result of invoking the Double.Parse method on `value`.

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Double.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToDouble(Single)

Converts the value of the specified single-precision floating-point number to an equivalent double-precision floating-point number.

```C#
public static double ToDouble (float value);
```

Parameters

`value` Single

The single-precision floating-point number.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Examples

The following example converts a Single value to a Double value.

```C#
public void CovertDoubleFloat(double doubleVal) {
    float floatVal = 0;

    // Double to float conversion cannot overflow.
        floatVal = System.Convert.ToSingle(doubleVal);
        System.Console.WriteLine("{0} as a float is {1}",
            doubleVal, floatVal);

    // Conversion from float to double cannot overflow.
    doubleVal = System.Convert.ToDouble(floatVal);
    System.Console.WriteLine("{0} as a double is: {1}",
        floatVal, doubleVal);
}
```

ToDouble(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent double-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static double ToDouble (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Double

The 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of SByte values to a Double value.

C#

```
sbyte[] numbers = { SByte.MinValue, -23, 0, 17, SByte.MaxValue };
double result;

foreach (sbyte number in numbers)
{
   result = Convert.ToDouble(number);
   Console.WriteLine("Converted the SByte value {0} to {1}.", number,
result);
}
//       Converted the SByte value -128 to -128.
//       Converted the SByte value -23 to -23.
//       Converted the SByte value 0 to 0.
//       Converted the SByte value 17 to 17.
//       Converted the SByte value 127 to 127.
```

ToDouble(Object)

Converts the value of the specified object to a double-precision floating-point number.

C#

```
public static double ToDouble (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Double

A double-precision floating-point number that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format for a Double type.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example attempts to convert each value in an object array to a Double.

C#

```
object[] values = { true, 'a', 123, 1.764e32f, "9.78", "1e-02",
                    1.67e03f, "A100", "1,033.67", DateTime.Now,
                    Decimal.MaxValue };
double result;

foreach (object value in values)
{
   try {
      result = Convert.ToDouble(value);
      Console.WriteLine("Converted the {0} value {1} to {2}.",
                        value.GetType().Name, value, result);
   }
```

```
    catch (FormatException) {
       Console.WriteLine("The {0} value {1} is not recognized as a valid
Double value.",
                         value.GetType().Name, value);
    }
    catch (InvalidCastException) {
       Console.WriteLine("Conversion of the {0} value {1} to a Double is
not supported.",
                         value.GetType().Name, value);
    }
}
// The example displays the following output:
//    Converted the Boolean value True to 1.
//    Conversion of the Char value a to a Double is not supported.
//    Converted the Int32 value 123 to 123.
//    Converted the Single value 1.764E+32 to 1.76399995098587E+32.
//    Converted the String value 9.78 to 9.78.
//    Converted the String value 1e-02 to 0.01.
//    Converted the Single value 1670 to 1670.
//    The String value A100 is not recognized as a valid Double value.
//    Converted the String value 1,033.67 to 1033.67.
//    Conversion of the DateTime value 10/21/2008 07:12:12 AM to a Double
is not supported.
//    Converted the Decimal value 79228162514264337593543950335 to
7.92281625142643E+28.
```

Remarks

If `value` is not `null`, this method wraps a call to the IConvertible.ToDouble implementation of the underlying type of `value`.

Applies to

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToDouble(String)

Converts the specified string representation of a number to an equivalent double-precision floating-point number.

```
C#

public static double ToDouble (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

Double

A double-precision floating-point number that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not a number in a valid format.

OverflowException

`value` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example attempts to convert each element in an array of numeric strings to a Double. The example's output is from a system whose current culture is en-US.

```
C#

using System;

public class Example
{
   public static void Main()
```

```
    {
       string[] values= { "-1,035.77219", "1AFF", "1e-35",
                          "1,635,592,999,999,999,999,999,999", "-17.455",
                          "190.34001", "1.29e325"};
       double result;

       foreach (string value in values)
       {
          try {
             result = Convert.ToDouble(value);
             Console.WriteLine("Converted '{0}' to {1}.", value, result);
          }
          catch (FormatException) {
             Console.WriteLine("Unable to convert '{0}' to a Double.",
value);
          }
          catch (OverflowException) {
             Console.WriteLine("'{0}' is outside the range of a Double.",
value);
          }
       }
    }
}
// The example displays the following output:
//       Converted '-1,035.77219' to -1035.77219.
//       Unable to convert '1AFF' to a Double.
//       Converted '1e-35' to 1E-35.
//       Converted '1,635,592,999,999,999,999,999,999' to 1.635593E+24.
//       Converted '-17.455' to -17.455.
//       Converted '190.34001' to 190.34001.
//       '1.29e325' is outside the range of a Double.
```

Remarks

Using the ToDouble(String) method is equivalent to passing `value` to the Double.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Double.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToDouble(Int32)

Converts the value of the specified 32-bit signed integer to an equivalent double-precision floating-point number.

C#

```
public static double ToDouble (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Examples

The following example converts an Int32 value to a Double value.

C#

```
public void ConvertDoubleInt(double doubleVal) {

    int     intVal = 0;
    // Double to int conversion can overflow.
    try {
        intVal = System.Convert.ToInt32(doubleVal);
        System.Console.WriteLine("{0} as an int is: {1}",
```

```
            doubleVal, intVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in double-to-int conversion.");
    }

    // Int to double conversion cannot overflow.
    doubleVal = System.Convert.ToDouble(intVal);
    System.Console.WriteLine("{0} as a double is: {1}",
        intVal, doubleVal);
}
```

UWP	10.0

ToDouble(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent double-precision floating-point number.

C#

```
public static double ToDouble (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Double

A double-precision floating-point number equivalent to `value`.

Examples

The following example converts each element in an array of 16-bit signed integers to a Double value.

C#

```
short[] numbers = { Int16.MinValue, -1032, 0, 192, Int16.MaxValue };
double result;

foreach (short number in numbers)
{
   result = Convert.ToDouble(number);
   Console.WriteLine("Converted the UInt16 value {0} to {1}.",
                     number, result);
}
//       Converted the UInt16 value -32768 to -32768.
//       Converted the UInt16 value -1032 to -1032.
//       Converted the UInt16 value 0 to 0.
//       Converted the UInt16 value 192 to 192.
//       Converted the UInt16 value 32767 to 32767.
```

UWP	10.0

ToDouble(Double)

Returns the specified double-precision floating-point number; no actual conversion is performed.

```
C#
```

```
public static double ToDouble (double value);
```

Parameters

`value` Double

The double-precision floating-point number to return.

Returns

Double

`value` is returned unchanged.

ToDouble(Decimal)

Converts the value of the specified decimal number to an equivalent double-precision floating-point number.

```
C#
```

```
public static double ToDouble (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Examples

The following example converts a Decimal value to a Double value.

C#

```
public void ConvertDoubleDecimal(decimal decimalVal){

    double doubleVal;

    // Decimal to double conversion cannot overflow.
 doubleVal = System.Convert.ToDouble(decimalVal);
    System.Console.WriteLine("{0} as a double is: {1}",
            decimalVal, doubleVal);

    // Conversion from double to decimal can overflow.
    try
 {
       decimalVal = System.Convert.ToDecimal(doubleVal);
    System.Console.WriteLine ("{0} as a decimal is: {1}",
        doubleVal, decimalVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in double-to-double conversion.");
    }
}
```

ToDouble(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static double ToDouble (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Double

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

ToDouble(Char)

Calling this method always throws InvalidCastException.

C#

```
public static double ToDouble (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Double

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

ToDouble(Byte)

Converts the value of the specified 8-bit unsigned integer to the equivalent double-precision floating-point number.

C#

```
public static double ToDouble (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Double

The double-precision floating-point number that is equivalent to `value`.

Examples

The following example converts a Byte value to a Double value.

C#

```
public void ConvertDoubleByte(double doubleVal) {
    byte    byteVal = 0;

    // Double to byte conversion can overflow.
    try {
        byteVal = System.Convert.ToByte(doubleVal);
        System.Console.WriteLine("{0} as a byte is: {1}.",
            doubleVal, byteVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Overflow in double-to-byte conversion.");
```

```
    }

    // Byte to double conversion cannot overflow.

UWP	10.0

ToDouble(Boolean)

Converts the specified Boolean value to the equivalent double-precision floating-point number.

C#

```
public static double ToDouble (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Double

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example converts a Boolean value to a Double value.

C#

```
public void ConvertDoubleBool(double doubleVal) {
    bool    boolVal;
    // Double to bool conversion cannot overflow.
    boolVal = System.Convert.ToBoolean(doubleVal);
    System.Console.WriteLine("{0} as a Boolean is: {1}.",
        doubleVal, boolVal);

    // bool to double conversion cannot overflow.

ToDouble(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent double-precision floating-point number.

C#

```
public static double ToDouble (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Double

A double-precision floating-point number that is equivalent to `value`.

Examples

The following example converts each element in an array of signed long integers to a Double value.

C#

```
long[] numbers = { Int64.MinValue, -903, 0, 172, Int64.MaxValue};
double result;

foreach (long number in numbers)
{
   result = Convert.ToDouble(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int64 value '-9223372036854775808' to the Double
value -9.22337203685478E+18.
//    Converted the Int64 value '-903' to the Double value -903.
//    Converted the Int64 value '0' to the Double value 0.
//    Converted the Int64 value '172' to the Double value 172.
//    Converted the Int64 value '9223372036854775807' to the Double value
9.22337203685478E+18.
```

Convert.ToHexString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToHexString(ReadOnlySpan<Byte>)	Converts a span of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters.
ToHexString(Byte[], Int32, Int32)	Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters. Parameters specify the subset as an offset in the input array and the number of elements in the array to convert.
ToHexString(Byte[])	Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters.

ToHexString(ReadOnlySpan<Byte>)

Converts a span of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters.

C#

```
public static string ToHexString (ReadOnlySpan<byte> bytes);
```

Parameters

`bytes` ReadOnlySpan<Byte>

A span of 8-bit unsigned integers.

Returns

String

The string representation in hex of the elements in `bytes`.

Exceptions

ArgumentOutOfRangeException

`bytes` is too large to be encoded.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToHexString(Byte[], Int32, Int32)

Converts a subset of an array of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters. Parameters specify the subset as an offset in the input array and the number of elements in the array to convert.

```
C#

public static string ToHexString (byte[] inArray, int offset, int
length);
```

Parameters

`inArray` Byte[]

An array of 8-bit unsigned integers.

`offset` Int32

An offset in `inArray`.

`length` Int32

The number of elements of `inArray` to convert.

Returns

String

The string representation in hex of `length` elements of `inArray`, starting at position `offset`.

Exceptions

ArgumentNullException

`inArray` is `null`.

ArgumentOutOfRangeException

`offset` or `length` is negative.

ArgumentOutOfRangeException

`offset` plus `length` is greater than the length of `inArray`.

ArgumentOutOfRangeException

`inArray` is too large to be encoded.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToHexString(Byte[])

Converts an array of 8-bit unsigned integers to its equivalent string representation that is encoded with uppercase hex characters.

C#

```
public static string ToHexString (byte[] inArray);
```

Parameters

`inArray` Byte[]

An array of 8-bit unsigned integers.

Returns

String

The string representation in hex of the elements in `inArray`.

Exceptions

ArgumentNullException

`inArray` is `null`.

ArgumentOutOfRangeException

`inArray` is too large to be encoded.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Convert.ToInt16 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a 16-bit signed integer.

Overloads

Expand table

ToInt16(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 16-bit signed integer.
ToInt16(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 16-bit signed integer, using the specified culture-specific formatting information.
ToInt16(Object, IFormatProvider)	Converts the value of the specified object to a 16-bit signed integer, using the specified culture-specific formatting information.
ToInt16(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 16-bit signed integer.
ToInt16(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 16-bit signed integer.
ToInt16(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 16-bit signed integer.
ToInt16(String)	Converts the specified string representation of a number to an equivalent 16-bit signed integer.
ToInt16(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 16-bit signed integer.
ToInt16(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 16-bit signed integer.
ToInt16(Int16)	Returns the specified 16-bit signed integer; no actual conversion is performed.

ToInt16(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 16-bit signed integer.
ToInt16(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 16-bit signed integer.
ToInt16(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 16-bit signed integer.
ToInt16(Decimal)	Converts the value of the specified decimal number to an equivalent 16-bit signed integer.
ToInt16(DateTime)	Calling this method always throws InvalidCastException.
ToInt16(Char)	Converts the value of the specified Unicode character to the equivalent 16-bit signed integer.
ToInt16(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 16-bit signed integer.
ToInt16(Boolean)	Converts the specified Boolean value to the equivalent 16-bit signed integer.
ToInt16(Object)	Converts the value of the specified object to a 16-bit signed integer.

ToInt16(Single)

Converts the value of the specified single-precision floating-point number to an equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Int16

`value`, rounded to the nearest 16-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int16.MaxValue or less than Int16.MinValue.

Examples

The following example attempts to convert each element in an array of Single values to a 16-bit signed integer.

C#

```
float[] values = { Single.MinValue, -1.38e10f, -1023.299f, -12.98f,
                   0f, 9.113e-16f, 103.919f, 17834.191f, Single.MaxValue
};
short result;

foreach (float value in values)
{
   try {
      result = Convert.ToInt16(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int16 type.",
value);
   }
}
// The example displays the following output:
//    -3.4028235E+38 is outside the range of the Int16 type.
//    -1.38E+10 is outside the range of the Int16 type.
//    Converted the Single value -1023.299 to the Int16 value -1023.
//    Converted the Single value -12.98 to the Int16 value -13.
//    Converted the Single value 0 to the Int16 value 0.
//    Converted the Single value 9.113E-16 to the Int16 value 0.
//    Converted the Single value 103.919 to the Int16 value 104.
//    Converted the Single value 17834.191 to the Int16 value 17834.
//    3.4028235E+38 is outside the range of the Int16 type.
```

ToInt16(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent 16-bit signed integer, using the specified culture-specific formatting information.

C#

```
public static short ToInt16 (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Int16

A 16-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example converts string representations of 16-bit integers with the `ToInt16` method, using an IFormatProvider object.

C#

```
// Example of the Convert.ToInt16( string ) and
// Convert.ToInt16( string, IFormatProvider ) methods.
using System;
using System.Globalization;

class ToInt16ProviderDemo
{
    static string format = "{0,-20}{1,-20}{2}";

     // Get the exception type name; remove the namespace prefix.
    static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    static void ConvertToInt16( string numericStr,
        IFormatProvider provider )
    {
        object defaultValue;
        object providerValue;

        // Convert numericStr to Int16 without a format provider.
        try
        {
            defaultValue = Convert.ToInt16( numericStr );
        }
        catch( Exception ex )
        {
            defaultValue = GetExceptionType( ex );
        }

        // Convert numericStr to Int16 with a format provider.
        try
        {
            providerValue = Convert.ToInt16( numericStr, provider );
        }
        catch( Exception ex )
        {
```

```
            providerValue = GetExceptionType( ex );
        }

        Console.WriteLine( format, numericStr,
            defaultValue, providerValue );
    }

    public static void Main( )
    {
        // Create a NumberFormatInfo object and set several of its
        // properties that apply to numbers.
        NumberFormatInfo provider = new NumberFormatInfo();

        // These properties affect the conversion.
        provider.NegativeSign = "neg ";
        provider.PositiveSign = "pos ";

        // These properties do not affect the conversion.
        // The input string cannot have decimal and group separators.
        provider.NumberDecimalSeparator = ".";
        provider.NumberGroupSeparator = ",";
        provider.NumberGroupSizes = new int[ ] { 3 };
        provider.NumberNegativePattern = 0;

        Console.WriteLine("This example of\n" +
            "  Convert.ToInt16( string ) and \n" +
            "  Convert.ToInt16( string, IFormatProvider ) " +
            "\ngenerates the following output. It converts " +
            "several strings to \nshort values, using " +
            "default formatting or a NumberFormatInfo object.\n" );
        Console.WriteLine( format, "String to convert",
            "Default/exception", "Provider/exception" );
        Console.WriteLine( format, "-----------------",
            "-----------------", "-----------------" );

        // Convert strings, with and without an IFormatProvider.
        ConvertToInt16( "12345", provider );
        ConvertToInt16( "+12345", provider );
        ConvertToInt16( "pos 12345", provider );
        ConvertToInt16( "-12345", provider );
        ConvertToInt16( "neg 12345", provider );
        ConvertToInt16( "12345.", provider );
        ConvertToInt16( "12,345", provider );
        ConvertToInt16( "(12345)", provider );
        ConvertToInt16( "32768", provider );
        ConvertToInt16( "-32769", provider );
    }
}

/*
This example of
  Convert.ToInt16( string ) and
  Convert.ToInt16( string, IFormatProvider )
generates the following output. It converts several strings to
short values, using default formatting or a NumberFormatInfo object.
```

```
String to convert   Default/exception   Provider/exception
-----------------   -----------------   ------------------
12345               12345               12345
+12345              12345               FormatException
pos 12345           FormatException     12345
-12345              -12345              FormatException
neg 12345           FormatException     -12345
12345.              FormatException     FormatException
12,345              FormatException     FormatException
(12345)             FormatException     FormatException
32768               OverflowException   OverflowException
-32769              OverflowException   FormatException
*/
```

Remarks

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Int16.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToInt16(Object, IFormatProvider)

Converts the value of the specified object to a 16-bit signed integer, using the specified culture-specific formatting information.

```
C#

public static short ToInt16 (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format for an Int16 type.

InvalidCastException

`value` does not implement IConvertible.

OverflowException

`value` represents a number that is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example defines a class that implements IConvertible and a class that implements IFormatProvider. Objects of the class that implements IConvertible hold an array of Double values. An object of each class is passed to the `ToInt16` method.

This method returns an average of the array of Double values, using the object that implements IFormatProvider to determine how to calculate the average.

C#

```
using System;
using System.Collections;

// Define the types of averaging available in the class
// implementing IConvertible.
public enum AverageType : short
{
    None = 0,
    GeometricMean = 1,
    ArithmeticMean = 2,
    Median = 3
};

// Pass an instance of this class to methods that require an
// IFormatProvider. The class instance determines the type of
// average to calculate.
public class AverageInfo : IFormatProvider
{
    protected AverageType AvgType;

    // Specify the type of averaging in the constructor.
    public AverageInfo( AverageType avgType )
    {
        this.AvgType = avgType;
    }

    // This method returns a reference to the containing object
    // if an object of AverageInfo type is requested.
    public object GetFormat( Type argType )
    {
        if ( argType == typeof( AverageInfo ) )
            return this;
        else
            return null;
    }

    // Use this property to set or get the type of averaging.
    public AverageType TypeOfAverage
    {
        get { return this.AvgType; }
        set { this.AvgType = value; }
    }
}

// This class encapsulates an array of double values and implements
// the IConvertible interface. Most of the IConvertible methods
// return an average of the array elements in one of three types:
// arithmetic mean, geometric mean, or median.
public class DataSet : IConvertible
```

```
{
    protected ArrayList     data;
    protected AverageInfo   defaultProvider;

    // Construct the object and add an initial list of values.
    // Create a default format provider.
    public DataSet( params double[ ] values )
    {
        data = new ArrayList( values );
        defaultProvider =
            new AverageInfo( AverageType.ArithmeticMean );
    }

    // Add additional values with this method.
    public int Add( double value )
    {
        data.Add( value );
        return data.Count;
    }

    // Get, set, and add values with this indexer property.
    public double this[ int index ]
    {
        get
        {
            if( index >= 0 && index < data.Count )
                return (double)data[ index ];
            else
                throw new InvalidOperationException(
                    "[DataSet.get] Index out of range." );
        }
        set
        {
            if( index >= 0 && index < data.Count )
                data[ index ] = value;

            else if( index == data.Count )
                data.Add( value );
            else
                throw new InvalidOperationException(
                    "[DataSet.set] Index out of range." );
        }
    }

    // This property returns the number of elements in the object.

*/
```

Remarks

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToInt16(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 16-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static short ToInt16 (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Int16.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned long integers to a 16-bit signed integer.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 340, UInt64.MaxValue };
short result;

foreach (ulong number in numbers)
{
   try {
      result = Convert.ToInt16(number);
      Console.WriteLine("Converted the {0} value {1} to a {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt64 value 0 to a Int16 value 0.
//    Converted the UInt64 value 121 to a Int16 value 121.
//    Converted the UInt64 value 340 to a Int16 value 340.
//    The UInt64 value 18446744073709551615 is outside the range of the
Int16 type.
```

ToInt16(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 16-bit signed integer.

```
C#

[System.CLSCompliant(false)]
public static short ToInt16 (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Int16.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned integers to a 16-bit signed integer.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
short result;

foreach (uint number in numbers)
{
   try {
      result = Convert.ToInt16(number);
      Console.WriteLine("Converted the {0} value {1} to a {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt32 value 0 to a Int16 value 0.
//    Converted the UInt32 value 121 to a Int16 value 121.
//    Converted the UInt32 value 340 to a Int16 value 340.
//    The UInt32 value 4294967295 is outside the range of the Int16 type.
```

ToInt16(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent 16-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static short ToInt16 (ushort value);
```

Parameters

value UInt16

The 16-bit unsigned integer to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Int16.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned 16-bit integers to a 16-bit signed integer.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
short result;
foreach (ushort number in numbers)
{
   try {
      result = Convert.ToInt16(number);
      Console.WriteLine("Converted the {0} value {1} to a {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
```

```
        Console.WriteLine("The {0} value {1} is outside the range of the
Int16 type.",
                          number.GetType().Name, number);
    }
}
// The example displays the following output:
//       Converted the UInt16 value 0 to a Int16 value 0.
//       Converted the UInt16 value 121 to a Int16 value 121.
//       Converted the UInt16 value 340 to a Int16 value 340.
//       The UInt16 value 65535 is outside the range of the Int16 type.
```

ToInt16(String)

Converts the specified string representation of a number to an equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example converts string representations of 16-bit integers with the `ToInt16` method, using default formatting.

C#

```
// Example of the Convert.ToInt16( string ) and
// Convert.ToInt16( string, IFormatProvider ) methods.
using System;
using System.Globalization;

class ToInt16ProviderDemo
{
    static string format = "{0,-20}{1,-20}{2}";

     // Get the exception type name; remove the namespace prefix.
    static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    static void ConvertToInt16( string numericStr,
        IFormatProvider provider )
    {

pos 12345           FormatException     12345
-12345              -12345              FormatException
neg 12345           FormatException     -12345
12345.              FormatException     FormatException
12,345              FormatException     FormatException
(12345)             FormatException     FormatException
32768               OverflowException   OverflowException
-32769              OverflowException   FormatException
*/
```

Remarks

Using the ToInt16(String) method is equivalent to passing `value` to the Int16.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Int16.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToInt16(String, Int32)

Converts the string representation of a number in a specified base to an equivalent 16-bit signed integer.

```
C#

public static short ToInt16 (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

Int16

A 16-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

ArgumentOutOfRangeException

`value` is Empty.

FormatException

`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException

`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example attempts to interpret each element in a string array as a hexadecimal string and to convert it to a 16-bit signed integer.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] hexStrings = { "8000", "0FFF", "f000", "00A30", "D",
"-13",
                              "9AC61", "GAD" };
      foreach (string hexString in hexStrings)
      {
         try {
            short number = Convert.ToInt16(hexString, 16);
            Console.WriteLine("Converted '{0}' to {1:N0}.", hexString,
number);
         }
         catch (FormatException) {
            Console.WriteLine("'{0}' is not in the correct format for a
```

```
hexadecimal number.",
                                hexString);
         }
         catch (OverflowException) {
            Console.WriteLine("'{0}' is outside the range of an Int16.",
hexString);
         }
         catch (ArgumentException) {
            Console.WriteLine("'{0}' is invalid in base 16.", hexString);
         }
      }
   }
}
// The example displays the following output:
//       Converted '8000' to -32,768.
//       Converted '0FFF' to 4,095.
//       Converted 'f000' to -4,096.
//       Converted '00A30' to 2,608.
//       Converted 'D' to 13.
//       '-13' is invalid in base 16.
//       '9AC61' is outside the range of an Int16.
//       'GAD' is not in the correct format for a hexadecimal number.
```

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the negative sign is not supported for non-base 10 numeric representations, the ToInt16(String, Int32) method assumes that negative numbers use two's complement representation. In other words, the method always interprets the highest-order binary bit of an integer (bit 15) as its sign bit. As a result, it is possible to write code in which a non-base 10 number that is out of the range of the Int16 data type is converted to an Int16 value without the method throwing an exception. The following example increments Int16.MaxValue by one, converts the resulting number to its hexadecimal string representation, and then calls the ToInt16(String, Int32) method. Instead of throwing an exception, the method displays the message, "0x8000 converts to -32768."

C#

```
// Create a hexadecimal value out of range of the Int16 type.
string value = Convert.ToString((int) short.MaxValue + 1, 16);
// Convert it back to a number.
try
{
   short number = Convert.ToInt16(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
```

```
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to a 16-bit integer.",
value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method is using the appropriate numeric representation to interpret a particular value. As the following example illustrates, you can ensure that the method handles overflows appropriately by first retrieving the sign of the numeric value before converting it to its hexadecimal string representation. Throw an exception if the original value was positive but the conversion back to an integer yields a negative value.

C#

```
// Create a hexadecimal value out of range of the Short type.
int sourceNumber = (int) short.MaxValue + 1;
bool isNegative = (Math.Sign(sourceNumber) == -1);
string value = Convert.ToString(sourceNumber, 16);
short targetNumber;
try
{
   targetNumber = Convert.ToInt16(value, 16);
   if (! isNegative && ((targetNumber & 0x8000) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to a 16-bit integer.",
value);
}
// Displays the following to the console:
//    Unable to convert '0x8000' to a 16-bit integer.
```

ToInt16(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent 16-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static short ToInt16 (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Int16

A 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of signed bytes to a 16-bit signed integer.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
short result;

foreach (sbyte number in numbers)
{
   result = Convert.ToInt16(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the SByte value -128 to the Int16 value -128.
//       Converted the SByte value -1 to the Int16 value -1.
//       Converted the SByte value 0 to the Int16 value 0.
//       Converted the SByte value 10 to the Int16 value 10.
//       Converted the SByte value 127 to the Int16 value 127.
```

UWP	10.0

ToInt16(Int16)

Returns the specified 16-bit signed integer; no actual conversion is performed.

C#

```
public static short ToInt16 (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to return.

Returns

Int16

`value` is returned unchanged.

ToInt16(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`.

Exceptions

OverflowException

`value` is greater than Int16.MaxValue or less than Int16.MinValue.

Examples

The following example attempts to convert each element in an array of long integers to a 16-bit signed integer.

C#

```
long[] numbers = { Int64.MinValue, -1, 0, 121, 340, Int64.MaxValue };
short result;

foreach (long number in numbers)
{
   try {
      result = Convert.ToInt16(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int64 value -9223372036854775808 is outside the range of the
Int16 type.
//    Converted the Int64 value -1 to the Int16 value -1.
//    Converted the Int64 value 0 to the Int16 value 0.
//    Converted the Int64 value 121 to the Int16 value 121.
//    Converted the Int64 value 340 to the Int16 value 340.
//    The Int64 value 9223372036854775807 is outside the range of the
Int16 type.

ToInt16(Int32)

Converts the value of the specified 32-bit signed integer to an equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Int16

The 16-bit signed integer equivalent of `value`.

Exceptions

OverflowException

`value` is greater than Int16.MaxValue or less than Int16.MinValue.

Examples

The following example attempts to convert each element in an array of integers to a 16-bit signed integer.

C#

```
int[] numbers = { Int32.MinValue, -1, 0, 121, 340, Int32.MaxValue };
short result;
```

```
foreach (int number in numbers)
{
   try {
      result = Convert.ToInt16(number);
      Console.WriteLine("Converted the {0} value {1} to a {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int32 value -2147483648 is outside the range of the Int16 type.
//    Converted the Int32 value -1 to a Int16 value -1.
//    Converted the Int32 value 0 to a Int16 value 0.
//    Converted the Int32 value 121 to a Int16 value 121.
//    Converted the Int32 value 340 to a Int16 value 340.
//    The Int32 value 2147483647 is outside the range of the Int16 type.
```

ToInt16(Double)

Converts the value of the specified double-precision floating-point number to an equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Int16

`value`, rounded to the nearest 16-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int16.MaxValue or less than Int16.MinValue.

Examples

The following example converts each element in an array of Double values to a 16-bit signed integer. The example illustrates that any fractional part of a Double value is rounded before performing the conversion.

C#

```
double[] values = { Double.MinValue, -1.38e10, -1023.299, -12.98,
                    0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
short result;

foreach (double value in values)
{
   try {
      result = Convert.ToInt16(value);
      Console.WriteLine("Converted {0} to {1}.", value, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("{0} is outside the range of the Int16 type.",
value);
   }
}
//       -1.79769313486232E+308 is outside the range of the Int16 type.
```

```
//       -13800000000 is outside the range of the Int16 type.
//       Converted -1023.299 to -1023.
//       Converted -12.98 to -13.
//       Converted 0 to 0.
//       Converted 9.113E-16 to 0.
//       Converted 103.919 to 104.
//       Converted 17834.191 to 17834.
//       1.79769313486232E+308 is outside the range of the Int16 type.
```

ToInt16(Decimal)

Converts the value of the specified decimal number to an equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Int16

`value`, rounded to the nearest 16-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int16.MaxValue or less than Int16.MinValue.

Examples

The following example attempts to convert each element in an array of Decimal values to a 16-bit signed integer. The example illustrates that any fractional part of a Decimal value is rounded when performing the conversion.

C#

```
decimal[] values = { Decimal.MinValue, -1034.23m, -12m, 0m, 147m,
                             9214.16m, Decimal.MaxValue };
short result;

foreach (decimal value in values)
{
   try {
      result = Convert.ToInt16(value);
      Console.WriteLine("Converted {0} to {1}.", value, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("{0} is outside the range of the Int16 type.",
                        value);
   }
}
// The example displays the following output:
//    -79228162514264337593543950335 is outside the range of the Int16
type.
//    Converted -1034.23 to -1034.
//    Converted -12 to -12.
//    Converted 0 to 0.
//    Converted 147 to 147.
//    Converted 9214.16 to 9214.
//    79228162514264337593543950335 is outside the range of the Int16
type.

ToInt16(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static short ToInt16 (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Int16

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

.NET Standard	2.0, 2.1

ToInt16(Char)

Converts the value of the specified Unicode character to the equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`.

Exceptions

OverflowException

`value` is greater than Int16.MaxValue.

Examples

The following example attempts to convert each element in an array of Char values to a 16-bit signed integer.

C#

```
char[] chars = { 'a', 'z', '\x0007', '\x03FF',
                 '\x7FFF', '\xFFFE' };
short result;

foreach (char ch in chars)
{
   try {
      result = Convert.ToInt16(ch);
      Console.WriteLine("'{0}' converts to {1}.", ch, result);
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to convert u+{0} to an Int16.",
                        ((int)ch).ToString("X4"));
   }
}
// The example displays the following output:
//       'a' converts to 97.
//       'z' converts to 122.
//       '•' converts to 7.
//       'Ϗ' converts to 1023.
//       '翻' converts to 32767.
//       Unable to convert u+FFFE to an Int16.
```

UWP	10.0

ToInt16(Byte)

Converts the value of the specified 8-bit unsigned integer to the equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in an array of Byte values to a 16-bit signed integer.

C#

```
byte[] bytes = { Byte.MinValue, 14, 122, Byte.MaxValue};
short result;

foreach (byte byteValue in bytes)
{
   result = Convert.ToInt16(byteValue);
   Console.WriteLine("The Byte value {0} converts to {1}.",
                     byteValue, result);
}
// The example displays the following output:
//       The Byte value 0 converts to 0.
//       The Byte value 14 converts to 14.
//       The Byte value 122 converts to 122.
//       The Byte value 255 converts to 255.
```

UWP	10.0

ToInt16(Boolean)

Converts the specified Boolean value to the equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Int16

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example converts the Boolean values `true` and `false` to Int16 values.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToInt16(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToInt16(trueFlag));
// The example displays the following output:
//       False converts to 0.
//       True converts to 1.
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UWP	10.0

ToInt16(Object)

Converts the value of the specified object to a 16-bit signed integer.

C#

```
public static short ToInt16 (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Int16

A 16-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format for an Int16 type.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example attempts to convert each element in an object array to a 16-bit signed integer.

C#

```
object[] values= { true, -12, 163, 935, 'x', new DateTime(2009, 5, 12),
                   "104", "103.0", "-1", "1.00e2", "One", 1.00e2};
short result;

foreach (object value in values)
{
   try {
      result = Convert.ToInt16(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int16 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to an Int16 exists for the {0}
value {1}.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value True to the Int16 value 1.
//    Converted the Int32 value -12 to the Int16 value -12.
//    Converted the Int32 value 163 to the Int16 value 163.
//    Converted the Int32 value 935 to the Int16 value 935.
//    Converted the Char value x to the Int16 value 120.
```

```
//    No conversion to an Int16 exists for the DateTime value 5/12/2009
12:00:00 AM.
//    Converted the String value 104 to the Int16 value 104.
//    The String value 103.0 is not in a recognizable format.
//    Converted the String value -1 to the Int16 value -1.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the Int16 value 100.
```

Remarks

If `value` is not `null`, this method wraps a call to the IConvertible.ToInt16 implementation of the underlying type of `value`.

Convert.ToInt32 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a 32-bit signed integer.

Overloads

Expand table

ToInt32(String)	Converts the specified string representation of a number to an equivalent 32-bit signed integer.
ToInt32(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 32-bit signed integer.
ToInt32(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 32-bit signed integer.
ToInt32(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 32-bit signed integer.
ToInt32(Object, IFormatProvider)	Converts the value of the specified object to a 32-bit signed integer, using the specified culture-specific formatting information.
ToInt32(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 32-bit signed integer, using the specified culture-specific formatting information.
ToInt32(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 32-bit signed integer.
ToInt32(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 32-bit signed integer.
ToInt32(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 32-bit signed integer.
ToInt32(Object)	Converts the value of the specified object to a 32-bit signed integer.
ToInt32(Int64)	Converts the value of the specified 64-bit signed integer to an

	equivalent 32-bit signed integer.
ToInt32(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 32-bit signed integer.
ToInt32(Char)	Converts the value of the specified Unicode character to the equivalent 32-bit signed integer.
ToInt32(DateTime)	Calling this method always throws InvalidCastException.
ToInt32(Boolean)	Converts the specified Boolean value to the equivalent 32-bit signed integer.
ToInt32(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 32-bit signed integer.
ToInt32(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent 32-bit signed integer.
ToInt32(Int32)	Returns the specified 32-bit signed integer; no actual conversion is performed.
ToInt32(Decimal)	Converts the value of the specified decimal number to an equivalent 32-bit signed integer.

ToInt32(String)

Converts the specified string representation of a number to an equivalent 32-bit signed integer.

```
C#

public static int ToInt32 (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example attempts to convert each element in a numeric string array to an integer.

C#

```
string[] values = { "One", "1.34e28", "-26.87", "-18", "-6.00",
                    " 0", "137", "1601.9", Int32.MaxValue.ToString() };
int result;

foreach (string value in values)
{
   try {
      result = Convert.ToInt32(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int32 type.",
value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value '{1}' is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    The String value 'One' is not in a recognizable format.
//    The String value '1.34e28' is not in a recognizable format.
//    The String value '-26.87' is not in a recognizable format.
//    Converted the String value '-18' to the Int32 value -18.
//    The String value '-6.00' is not in a recognizable format.
//    Converted the String value ' 0' to the Int32 value 0.
//    Converted the String value '137' to the Int32 value 137.
//    The String value '1601.9' is not in a recognizable format.
```

```
//    Converted the String value '2147483647' to the Int32 value
2147483647.
```

Remarks

Using the ToInt32(String) method is equivalent to passing `value` to the Int32.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Int32.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToInt32(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent 32-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static int ToInt32 (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of 16-bit unsigned integers to an integer.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
int result;
foreach (ushort number in numbers)
{
   try {
      result = Convert.ToInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt16 value 0 to the Int32 value 0.
//    Converted the UInt16 value 121 to the Int32 value 121.
//    Converted the UInt16 value 340 to the Int32 value 340.
//    Converted the UInt16 value 65535 to the Int32 value 65535.
```

ToInt32(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 32-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static int ToInt32 (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Int32.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned integers to a signed integer.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
int result;
foreach (uint number in numbers)
{
   try {
      result = Convert.ToInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt32 value 0 to the Int32 value 0.
//    Converted the UInt32 value 121 to the Int32 value 121.
//    Converted the UInt32 value 340 to the Int32 value 340.
//    The UInt32 value 4294967295 is outside the range of the Int32 type.
```

UWP	10.0

ToInt32(Single)

Converts the value of the specified single-precision floating-point number to an equivalent 32-bit signed integer.

```
C#

public static int ToInt32 (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Int32

`value`, rounded to the nearest 32-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int32.MaxValue or less than Int32.MinValue.

Examples

The following example attempts to convert each element in an array of Single values to an integer.

```
C#

float[] values= { Single.MinValue, -1.38e10f, -1023.299f, -12.98f,
                  0f, 9.113e-16f, 103.919f, 17834.191f, Single.MaxValue
};
int result;

foreach (float value in values)
{
   try {
      result = Convert.ToInt32(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
```

```
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int32 type.",
value);
   }
}
// The example displays the following output:
//    -3.40282346638529E+38 is outside the range of the Int32 type.
//    -13799999488 is outside the range of the Int32 type.
//    Converted the Double value -1023.29901123047 to the Int32 value
-1023.
//    Converted the Double value -12.9799995422363 to the Int32 value
-13.
//    Converted the Double value 0 to the Int32 value 0.
//    Converted the Double value 9.11299983940444E-16 to the Int32 value
0.
//    Converted the Double value 103.918998718262 to the Int32 value 104.
//    Converted the Double value 17834.19140625 to the Int32 value 17834.
//    3.40282346638529E+38 is outside the range of the Int32 type.
```

ToInt32(Object, IFormatProvider)

Converts the value of the specified object to a 32-bit signed integer, using the specified culture-specific formatting information.

```
C#

public static int ToInt32 (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement IConvertible.

OverflowException

`value` represents a number that is less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example defines a class that implements IConvertible and a class that implements IFormatProvider. Objects of the class that implements IConvertible hold an array of Double values. An object of each class is passed to the `ToInt32` method. This method returns an average of the array of Double values, using the object that implements IFormatProvider to determine how to calculate the average.

C#

```
using System;
using System.Collections;

// Define the types of averaging available in the class
// implementing IConvertible.
public enum AverageType : short
{
    None = 0,
    GeometricMean = 1,
    ArithmeticMean = 2,
    Median = 3
};

// Pass an instance of this class to methods that require an
// IFormatProvider. The class instance determines the type of
// average to calculate.
public class AverageInfo : IFormatProvider
{
    protected AverageType AvgType;

    // Specify the type of averaging in the constructor.
    public AverageInfo( AverageType avgType )
    {
        this.AvgType = avgType;
    }

    // This method returns a reference to the containing object
    // if an object of AverageInfo type is requested.
    public object GetFormat( Type argType )
    {
        if ( argType == typeof( AverageInfo ) )
            return this;
        else
            return null;
    }

    // Use this property to set or get the type of averaging.
    public AverageType TypeOfAverage
    {
        get { return this.AvgType; }
        set { this.AvgType = value; }
    }
}

// This class encapsulates an array of double values and implements
// the IConvertible interface. Most of the IConvertible methods
// return an average of the array elements in one of three types:
// arithmetic mean, geometric mean, or median.
public class DataSet : IConvertible
{
    protected ArrayList     data;
    protected AverageInfo   defaultProvider;
```

```
    // Construct the object and add an initial list of values.
    // Create a default format provider.
    public DataSet( params double[ ] values )
    {
        data = new ArrayList( values );
        defaultProvider =
            new AverageInfo( AverageType.ArithmeticMean );
    }

    // Add additional values with this method.
    public int Add( double value )
    {
        data.Add( value );
        return data.Count;
    }

*/
```

Remarks

The return value is the result of invoking the IConvertible.ToInt32 method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToInt32(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent 32-bit signed integer, using the specified culture-specific formatting information.

C#

```
public static int ToInt32 (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Int32

A 32-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example defines a custom NumberFormatInfo object that recognizes the string "pos" as the positive sign and the string "neg" as the negative sign. It then attempts to convert each element of a numeric string array to an integer using both this provider and the NumberFormatInfo provider for the invariant culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Create a custom NumberFormatInfo object and set its two
properties
      // used by default in parsing numeric strings.
      NumberFormatInfo customProvider = new NumberFormatInfo();
      customProvider.NegativeSign = "neg ";
      customProvider.PositiveSign = "pos ";

      // Add custom and invariant provider to an array of providers.
      NumberFormatInfo[] providers = { customProvider,
NumberFormatInfo.InvariantInfo };

      // Define an array of strings to convert.
      string[] numericStrings = { "123456789", "+123456789", "pos
123456789",
                                  "-123456789", "neg 123456789",
"123456789.",
                                  "123,456,789", "(123456789)",
"2147483648",
                                  "-2147483649" };

      // Use each provider to parse all the numeric strings.
      for (int ctr = 0; ctr <= 1; ctr++)
      {
         IFormatProvider provider = providers[ctr];
         Console.WriteLine(ctr == 0 ? "Custom Provider:" : "Invariant
Provider:");
         foreach (string numericString in numericStrings)
         {
            Console.Write("{0,15}  --> ", numericString);
            try {
               Console.WriteLine("{0,20}", Convert.ToInt32(numericString,
provider));
```

```
            }
            catch (FormatException) {
               Console.WriteLine("{0,20}", "FormatException");
            }
            catch (OverflowException) {
               Console.WriteLine("{0,20}", "OverflowException");
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       Custom Provider:
//             123456789  -->            123456789
//            +123456789  -->      FormatException
//         pos 123456789  -->            123456789
//            -123456789  -->      FormatException
//         neg 123456789  -->           -123456789
//            123456789.  -->      FormatException
//           123,456,789  -->      FormatException
//           (123456789)  -->      FormatException
//            2147483648  -->    OverflowException
//           -2147483649  -->      FormatException
//
//       Invariant Provider:
//             123456789  -->            123456789
//            +123456789  -->            123456789
//         pos 123456789  -->      FormatException
//            -123456789  -->           -123456789
//         neg 123456789  -->      FormatException
//            123456789.  -->      FormatException
//           123,456,789  -->      FormatException
//           (123456789)  -->      FormatException
//            2147483648  -->    OverflowException
//           -2147483649  -->    OverflowException
```

Remarks

The return value is the result of invoking the Int32.Parse method on `value`.

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Int32.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToInt32(String, Int32)

Converts the string representation of a number in a specified base to an equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

Int32

A 32-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

ArgumentOutOfRangeException
`value` is Empty.

FormatException
`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException
`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than Int32.MinValue or greater than Int32.MaxValue.

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the negative sign is not supported for non-base 10 numeric representations, the ToInt32(String, Int32) method assumes that negative numbers use two's complement representation. In other words, the method always interprets the highest-order binary bit of an integer (bit 31) as its sign bit. As a result, it is possible to write code in which a non-base 10 number that is out of the range of the Int32 data type is converted to an Int32 value without the method throwing an exception. The following example increments Int32.MaxValue by one, converts the resulting number to its hexadecimal string representation, and then calls the ToInt32(String, Int32) method. Instead of throwing an exception, the method displays the message, "0x80000000 converts to -2147483648."

```
C#
```

```
// Create a hexadecimal value out of range of the Integer type.
string value = Convert.ToString((long) int.MaxValue + 1, 16);
// Convert it back to a number.
try
{
   int number = Convert.ToInt32(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number.ToString());
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an integer.", value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method is using the appropriate numeric representation to interpret a particular value. As the following example illustrates, you can ensure that the method handles overflows appropriately by first retrieving the sign of the numeric value before converting it to its hexadecimal string representation. Throw an exception if the original value was positive but the conversion back to an integer yields a negative value.

C#

```
// Create a hexadecimal value out of range of the Integer type.
long sourceNumber = (long) int.MaxValue + 1;
bool isNegative = Math.Sign(sourceNumber) == -1;
string value = Convert.ToString(sourceNumber, 16);
int targetNumber;
try
{
   targetNumber = Convert.ToInt32(value, 16);
   if (!(isNegative) & (targetNumber & 0x80000000) != 0)
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an integer.", value);
}
// Displays the following to the console:
//    Unable to convert '0x80000000' to an integer.
```

ToInt32(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 32-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static int ToInt32 (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Int32.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned long integers to a signed integer.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 340, UInt64.MaxValue };
int result;
foreach (ulong number in numbers)
{
   try {
      result = Convert.ToInt32(number);
      Console.WriteLine("Converted the {0} value {1} to a {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt64 value 0 to a Int32 value 0.
//    Converted the UInt64 value 121 to a Int32 value 121.
//    Converted the UInt64 value 340 to a Int32 value 340.
//    The UInt64 value 18446744073709551615 is outside the range of the
Int32 type.
```

ToInt32(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent 32-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static int ToInt32 (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Int32

A 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of signed bytes to an integer.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
int result;

foreach (sbyte number in numbers)
{
   result = Convert.ToInt32(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
```

```
}
// The example displays the following output:
//       Converted the SByte value -128 to the Int32 value -128.
//       Converted the SByte value -1 to the Int32 value -1.
//       Converted the SByte value 0 to the Int32 value 0.
//       Converted the SByte value 10 to the Int32 value 10.
//       Converted the SByte value 127 to the Int32 value 127.
```

ToInt32(Object)

Converts the value of the specified object to a 32-bit signed integer.

C#

```
public static int ToInt32 (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Int32

A 32-bit signed integer equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example attempts to convert each element in an object array to an integer.

C#

```
object[] values = { true, -12, 163, 935, 'x', new DateTime(2009, 5, 12),
                    "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2, 16.3e42};
int result;

foreach (object value in values)
{
   try {
      result = Convert.ToInt32(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int32 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to an Int32 exists for the {0}
```

```
value {1}.",
                        value.GetType().Name, value);
    }
}
// The example displays the following output:
//    Converted the Boolean value True to the Int32 value 1.
//    Converted the Int32 value -12 to the Int32 value -12.
//    Converted the Int32 value 163 to the Int32 value 163.
//    Converted the Int32 value 935 to the Int32 value 935.
//    Converted the Char value x to the Int32 value 120.
//    No conversion to an Int32 exists for the DateTime value 5/12/2009
12:00:00 AM.
//    Converted the String value 104 to the Int32 value 104.
//    The String value 103.0 is not in a recognizable format.
//    Converted the String value -1 to the Int32 value -1.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the Int32 value 100.
//    The Double value 1.63E+43 is outside the range of the Int32 type.
```

Remarks

If `value` is not `null`, this method wraps a call to the IConvertible.ToInt32 implementation of the underlying type of `value`.

ToInt32(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Exceptions

OverflowException

`value` is greater than Int32.MaxValue or less than Int32.MinValue.

Examples

The following example attempts to convert each element in an array of long integers to an integer.

C#

```
long[] numbers = { Int64.MinValue, -1, 0, 121, 340, Int64.MaxValue };
int result;
foreach (long number in numbers)
{
   try {
      result = Convert.ToInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int64 value -9223372036854775808 is outside the range of the
Int32 type.
```

```
//    Converted the Int64 value -1 to the Int32 value -1.
//    Converted the Int64 value 0 to the Int32 value 0.
//    Converted the Int64 value 121 to the Int32 value 121.
//    Converted the Int64 value 340 to the Int32 value 340.
//    The Int64 value 9223372036854775807 is outside the range of the
Int32 type.
```

UWP	10.0

ToInt32(Byte)

Converts the value of the specified 8-bit unsigned integer to the equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in an array of bytes to an integer.

C#

```
byte[] bytes = { Byte.MinValue, 14, 122, Byte.MaxValue};
int result;

foreach (byte byteValue in bytes)
{
   result = Convert.ToInt32(byteValue);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     byteValue.GetType().Name, byteValue,
                     result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the Byte value 0 to the Int32 value 0.
//       Converted the Byte value 14 to the Int32 value 14.
//       Converted the Byte value 122 to the Int32 value 122.
//       Converted the Byte value 255 to the Int32 value 255.
```

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToInt32(Char)

Converts the value of the specified Unicode character to the equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in an array of Char values to an integer.

C#

```
char[] chars = { 'a', 'z', '\u0007', '\u03FF',
                 '\u7FFF', '\uFFFE' };
int result;

foreach (char ch in chars)
{
   try {
      result = Convert.ToInt32(ch);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        ch.GetType().Name, ch,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to convert u+{0} to an Int32.",
                        ((int)ch).ToString("X4"));
   }
}
// The example displays the following output:
//       Converted the Char value 'a' to the Int32 value 97.
//       Converted the Char value 'z' to the Int32 value 122.
//       Converted the Char value '' to the Int32 value 7.
//       Converted the Char value 'Ϗ' to the Int32 value 1023.
//       Converted the Char value '翻' to the Int32 value 32767.
//       Converted the Char value '￾' to the Int32 value 65534.
```

Remarks

The ToInt32(Char) method returns a 32-bit signed integer that represents the UTF-16 encoded code unit of the `value` argument. If `value` is not a low surrogate or a high

surrogate, this return value also represents the Unicode code point of value.

UWP	10.0

ToInt32(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static int ToInt32 (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Int32

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

.NET Standard	2.0, 2.1

ToInt32(Boolean)

Converts the specified Boolean value to the equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Int32

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example converts the Boolean values `true` and `false` to integers.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToInt32(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToInt32(trueFlag));
// The example displays the following output:
```

```
//        False converts to 0.
//        True converts to 1.
```

ToInt32(Double)

Converts the value of the specified double-precision floating-point number to an equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Int32

`value`, rounded to the nearest 32-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int32.MaxValue or less than Int32.MinValue.

Examples

The following example attempts to convert each element in an array of Double values to an integer.

C#

```
double[] values= { Double.MinValue, -1.38e10, -1023.299, -12.98,
                   0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
int result;

foreach (double value in values)
{
   try {
      result = Convert.ToInt32(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int32 type.",
value);
   }
}
//    -1.79769313486232E+308 is outside the range of the Int32 type.
//    -13800000000 is outside the range of the Int32 type.
//    Converted the Double value '-1023.299' to the Int32 value -1023.
//    Converted the Double value '-12.98' to the Int32 value -13.
//    Converted the Double value '0' to the Int32 value 0.
//    Converted the Double value '9.113E-16' to the Int32 value 0.
//    Converted the Double value '103.919' to the Int32 value 104.
//    Converted the Double value '17834.191' to the Int32 value 17834.
//    1.79769313486232E+308 is outside the range of the Int32 type.

ToInt32(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Int32

A 32-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in an array of 16-bit signed integers to an integer.

C#

```
short[] numbers= { Int16.MinValue, -1, 0, 121, 340, Int16.MaxValue };
int result;

foreach (short number in numbers)
{
```

```
    result = Convert.ToInt32(number);
    Console.WriteLine("Converted the {0} value {1} to a {2} value {3}.",
                      number.GetType().Name, number,
                      result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int16 value -32768 to a Int32 value -32768.
//    Converted the Int16 value -1 to a Int32 value -1.
//    Converted the Int16 value 0 to a Int32 value 0.
//    Converted the Int16 value 121 to a Int32 value 121.
//    Converted the Int16 value 340 to a Int32 value 340.
//    Converted the Int16 value 32767 to a Int32 value 32767.
```

UWP	10.0

ToInt32(Int32)

Returns the specified 32-bit signed integer; no actual conversion is performed.

C#

```
public static int ToInt32 (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to return.

Returns

Int32

`value` is returned unchanged.

ToInt32(Decimal)

Converts the value of the specified decimal number to an equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Int32

`value`, rounded to the nearest 32-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

Convert.ToInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a 64-bit signed integer.

Overloads

Expand table

ToInt64(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 64-bit signed integer.
ToInt64(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 64-bit signed integer.
ToInt64(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 64-bit signed integer, using the specified culture-specific formatting information.
ToInt64(Object, IFormatProvider)	Converts the value of the specified object to a 64-bit signed integer, using the specified culture-specific formatting information.
ToInt64(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 64-bit signed integer.
ToInt64(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 64-bit signed integer.
ToInt64(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 64-bit signed integer.
ToInt64(String)	Converts the specified string representation of a number to an equivalent 64-bit signed integer.
ToInt64(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 64-bit signed integer.
ToInt64(Object)	Converts the value of the specified object to a 64-bit signed integer.
ToInt64(Int64)	Returns the specified 64-bit signed integer; no actual conversion is

	performed.
ToInt64(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 64-bit signed integer.
ToInt64(Char)	Converts the value of the specified Unicode character to the equivalent 64-bit signed integer.
ToInt64(DateTime)	Calling this method always throws InvalidCastException.
ToInt64(Boolean)	Converts the specified Boolean value to the equivalent 64-bit signed integer.
ToInt64(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 64-bit signed integer.
ToInt64(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent 64-bit signed integer.
ToInt64(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 64-bit signed integer.
ToInt64(Decimal)	Converts the value of the specified decimal number to an equivalent 64-bit signed integer.

ToInt64(Single)

Converts the value of the specified single-precision floating-point number to an equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Int64

`value`, rounded to the nearest 64-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int64.MaxValue or less than Int64.MinValue.

Examples

The following example attempts to convert each element in an array of Single values to a long integer.

C#

```
float[] values= { Single.MinValue, -1.38e10f, -1023.299f, -12.98f,
                  0f, 9.113e-16f, 103.919f, 17834.191f, Single.MaxValue
};
long result;

foreach (float value in values)
{
   try {
      result = Convert.ToInt64(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int64 type.",
value);
   }
}
// The example displays the following output:
//    -3.4028235E+38 is outside the range of the Int64 type.
//    Converted the Single value -1.38E+10 to the Int64 value
-13799999488.
//    Converted the Single value -1023.299 to the Int64 value -1023.
//    Converted the Single value -12.98 to the Int64 value -13.
//    Converted the Single value 0 to the Int64 value 0.
//    Converted the Single value 9.113E-16 to the Int64 value 0.
//    Converted the Single value 103.919 to the Int64 value 104.
//    Converted the Single value 17834.191 to the Int64 value 17834.
//    3.4028235E+38 is outside the range of the Int64 type.
```

ToInt64(String, Int32)

Converts the string representation of a number in a specified base to an equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

Int64

A 64-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

ArgumentOutOfRangeException
`value` is Empty.

FormatException
`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException
`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than Int64.MinValue or greater than Int64.MaxValue.

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the negative sign is not supported for non-base 10 numeric representations, the ToInt64(String, Int32) method assumes that negative numbers use two's complement representation. In other words, the method always interprets the highest-order binary bit of a long integer (bit 63) as its sign bit. As a result, it is possible to write code in which a non-base 10 number that is out of the range of the Int64 data type is converted to an Int64 value without the method throwing an exception. The following example converts MaxValue to its hexadecimal string representation, and then calls the ToInt64(String, Int32) method. Instead of throwing an exception, the method displays the message, "0xFFFFFFFFFFFFFFFF converts to -1."

```
C#
```

```
// Create a hexadecimal value out of range of the long type.
string value = ulong.MaxValue.ToString("X");
// Use Convert.ToInt64 to convert it back to a number.
try
{
   long number = Convert.ToInt64(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to a long integer.",
value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method is using the appropriate numeric representation to interpret a particular value. As the following example illustrates, you can ensure that the method handles overflows appropriately by first determining whether a value represents an unsigned or a signed type when converting it to its hexadecimal string representation. Throw an exception if the original value was an unsigned type but the conversion back to an integer yields a value whose sign bit is on.

C#

```
// Create a negative hexadecimal value out of range of the Byte type.
ulong sourceNumber = ulong.MaxValue;
bool isSigned =
Math.Sign(Convert.ToDouble(sourceNumber.GetType().GetField("MinValue").Ge
tValue(null))) == -1;
string value = sourceNumber.ToString("X");
long targetNumber;
try
{
   targetNumber = Convert.ToInt64(value, 16);
   if (! isSigned && ((targetNumber & 0x80000000) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to a long integer.",
value);
}
// Displays the following to the console:
//    Unable to convert '0xFFFFFFFFFFFFFFFF' to a long integer.
```

The following example attempts to interpret each element in a string array as a hexadecimal string and convert it to a long integer.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] hexStrings = { "8000000000000000", "0FFFFFFFFFFFFFFF",
                              "f0000000000001000", "00A30", "D", "-13",
"GAD" };
      foreach (string hexString in hexStrings)
      {
         try {
            long number = Convert.ToInt64(hexString, 16);
            Console.WriteLine("Converted '{0}' to {1:N0}.", hexString,
number);
         }
         catch (FormatException) {
            Console.WriteLine("'{0}' is not in the correct format for a
hexadecimal number.",
                              hexString);
         }
         catch (OverflowException) {
            Console.WriteLine("'{0}' is outside the range of an Int64.",
hexString);
         }
         catch (ArgumentException) {
            Console.WriteLine("'{0}' is invalid in base 16.", hexString);
         }
      }
   }
}
// The example displays the following output:
//       Converted '8000000000000000' to -9,223,372,036,854,775,808.
//       Converted '0FFFFFFFFFFFFFFF' to 1,152,921,504,606,846,975.
//       'f0000000000001000' is outside the range of an Int64.
//       Converted '00A30' to 2,608.
//       Converted 'D' to 13.
//       '-13' is invalid in base 16.
//       'GAD' is not in the correct format for a hexadecimal number.
```

ToInt64(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent 64-bit signed integer, using the specified culture-specific formatting information.

C#

```
public static long ToInt64 (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Int64

A 64-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example defines a custom NumberFormatInfo object that recognizes the string "pos" as the positive sign and the string "neg" as the negative sign. It then attempts to convert each element of a numeric string array to an integer using both this provider and the NumberFormatInfo provider for the invariant culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Create a NumberFormatInfo object and set the properties that
      // affect conversions using Convert.ToInt64(String,
IFormatProvider).
      NumberFormatInfo customProvider = new NumberFormatInfo();
      customProvider.NegativeSign = "neg ";
      customProvider.PositiveSign = "pos ";

      // Create an array of providers with the custom provider and the
      // NumberFormatInfo object for the invariant culture.
      NumberFormatInfo[] providers = { customProvider,
                                       NumberFormatInfo.InvariantInfo };

      // Define an array of strings to parse.
      string[] numericStrings = { "123456789", "+123456789", "pos
123456789",
                                  "-123456789", "neg 123456789",
"123456789.",
                                  "123,456,789", "(123456789)",
                                  "9223372036854775808",
"-9223372036854775809" };

      for (int ctr = 0; ctr < 2; ctr++)
      {
         IFormatProvider provider = providers[ctr];
         Console.WriteLine(ctr == 0 ? "Custom Provider:" : "Invariant
Culture:");
         foreach (string numericString in numericStrings)
         {
            Console.Write("   {0,-22} -->  ", numericString);
            try {
               Console.WriteLine("{0,22}", Convert.ToInt32(numericString,
provider));
```

```
            }
            catch (FormatException) {
               Console.WriteLine("{0,22}", "Unrecognized Format");
            }
            catch (OverflowException) {
               Console.WriteLine("{0,22}", "Overflow");
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       Custom Provider:
//          123456789              -->               123456789
//          +123456789             -->     Unrecognized Format
//          pos 123456789          -->               123456789
//          -123456789             -->     Unrecognized Format
//          neg 123456789          -->              -123456789
//          123456789.             -->     Unrecognized Format
//          123,456,789            -->     Unrecognized Format
//          (123456789)            -->     Unrecognized Format
//          9223372036854775808    -->                Overflow
//          -9223372036854775809   -->     Unrecognized Format
//
//       Invariant Culture:
//          123456789              -->               123456789
//          +123456789             -->               123456789
//          pos 123456789          -->     Unrecognized Format
//          -123456789             -->              -123456789
//          neg 123456789          -->     Unrecognized Format
//          123456789.             -->     Unrecognized Format
//          123,456,789            -->     Unrecognized Format
//          (123456789)            -->     Unrecognized Format
//          9223372036854775808    -->                Overflow
//          -9223372036854775809   -->                Overflow
```

Remarks

The return value is the result of invoking the Int64.Parse method on `value`.

`provider` is an `IFormatProvider` instance that obtains a NumberFormatInfo object. The `NumberFormatInfo` object provides culture-specific information about the format of `value`. If `provider` is `null`, the `NumberFormatInfo` for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Int64.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToInt64(Object, IFormatProvider)

Converts the value of the specified object to a 64-bit signed integer, using the specified culture-specific formatting information.

C#

```
public static long ToInt64 (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example defines a class that implements IConvertible and a class that implements IFormatProvider. Objects of the class that implements IConvertible hold an array of Double values. An object of each class is passed to the `ToInt64` method. This method returns an average of the array of Double values, using the object that implements IFormatProvider to determine how to calculate the average.

C#

```
using System;
using System.Collections;

// Define the types of averaging available in the class
// implementing IConvertible.
public enum AverageType : short
{
    None = 0,
    GeometricMean = 1,
    ArithmeticMean = 2,
    Median = 3
};

// Pass an instance of this class to methods that require an
// IFormatProvider. The class instance determines the type of
// average to calculate.
public class AverageInfo : IFormatProvider
{
    protected AverageType AvgType;

    // Specify the type of averaging in the constructor.
    public AverageInfo( AverageType avgType )
    {
        this.AvgType = avgType;
    }

    // This method returns a reference to the containing object
    // if an object of AverageInfo type is requested.
```

```
    public object GetFormat( Type argType )
    {
        if ( argType == typeof( AverageInfo ) )
            return this;
        else
            return null;
    }

    // Use this property to set or get the type of averaging.
    public AverageType TypeOfAverage
    {
        get { return this.AvgType; }
        set { this.AvgType = value; }
    }
}

// This class encapsulates an array of double values and implements
// the IConvertible interface. Most of the IConvertible methods
// return an average of the array elements in one of three types:
// arithmetic mean, geometric mean, or median.
public class DataSet : IConvertible
{
    protected ArrayList     data;
    protected AverageInfo   defaultProvider;

    // Construct the object and add an initial list of values.
    // Create a default format provider.
    public DataSet( params double[ ] values )
    {
        data = new ArrayList( values );
        defaultProvider =
            new AverageInfo( AverageType.ArithmeticMean );
    }

    // Add additional values with this method.
    public int Add( double value )
    {
        data.Add( value );
        return data.Count;
    }

    // Get, set, and add values with this indexer property.
    public double this[ int index ]
    {
        get
        {
            if( index >= 0 && index < data.Count )
                return (double)data[ index ];
            else
                throw new InvalidOperationException(
                    "[DataSet.get] Index out of range." );
        }
        set
        {
            if( index >= 0 && index < data.Count )
```

```
                data[ index ] = value;

            else if( index == data.Count )
                data.Add( value );
            else
                throw new InvalidOperationException(
                    "[DataSet.set] Index out of range." );
        }
    }

    // This property returns the number of elements in the object.
    public int Count
    {
        get { return data.Count; }
    }

    // This method calculates the average of the object's elements.

*/
```

Remarks

The return value is the result of invoking the IConvertible.ToInt64 method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToInt64(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 64-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static long ToInt64 (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than Int64.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned long integers to a long integer.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 340, UInt64.MaxValue };
long result;
foreach (ulong number in numbers)
{
   try {
      result = Convert.ToInt64(number);
      Console.WriteLine("Converted the {0} value {1} to a {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int64 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt64 value 0 to a Int32 value 0.
//    Converted the UInt64 value 121 to a Int32 value 121.
//    Converted the UInt64 value 340 to a Int32 value 340.
```

```
//    The UInt64 value 18446744073709551615 is outside the range of the
Int64 type.
```

ToInt64(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 64-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static long ToInt64 (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned integers to a long integer.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
long result;
foreach (uint number in numbers)
{
   result = Convert.ToInt64(number);
   Console.WriteLine("Converted the {0} value {1:N0} to the {2} value
{3:N0}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt32 value 0 to the Int64 value 0.
//    Converted the UInt32 value 121 to the Int64 value 121.
//    Converted the UInt32 value 340 to the Int64 value 340.
//    Converted the UInt32 value 4,294,967,295 to the Int64 value
4,294,967,295.
```

ToInt64(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent 64-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static long ToInt64 (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of 16-bit unsigned integers to a long integer.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
long result;
foreach (ushort number in numbers)
{
   try {
      result = Convert.ToInt64(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
```

```
        Console.WriteLine("The {0} value {1} is outside the range of the
Int64 type.",
                          number.GetType().Name, number);
    }
}
// The example displays the following output:
//    Converted the UInt16 value 0 to the Int64 value 0.
//    Converted the UInt16 value 121 to the Int64 value 121.
//    Converted the UInt16 value 340 to the Int64 value 340.
//    Converted the UInt16 value 65535 to the Int64 value 65535.
```

ToInt64(String)

Converts the specified string representation of a number to an equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (string? value);
```

Parameters

`value` String

A string that contains a number to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example attempts to convert each element in an array of numeric strings to a long integer.

C#

```
string[] values = { "One", "1.34e28", "-26.87", "-18", "-6.00",
                    " 0", "137", "1601.9", Int32.MaxValue.ToString() };
long result;

foreach (string value in values)
{
   try {
      result = Convert.ToInt64(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int64 type.",
value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value '{1}' is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    The String value 'One' is not in a recognizable format.
//    The String value '1.34e28' is not in a recognizable format.
//    The String value '-26.87' is not in a recognizable format.
//    Converted the String value '-18' to the Int64 value -18.
```

```
//    The String value '-6.00' is not in a recognizable format.
//    Converted the String value ' 0' to the Int64 value 0.
//    Converted the String value '137' to the Int64 value 137.
//    The String value '1601.9' is not in a recognizable format.
//    Converted the String value '2147483647' to the Int64 value
2147483647.
```

Remarks

Using the ToInt64(String) method is equivalent to passing `value` to the Int64.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Int64.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToInt64(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent 64-bit signed integer.

```
C#
```

```
[System.CLSCompliant(false)]
public static long ToInt64 (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a signed byte array to a long integer.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
long result;

foreach (sbyte number in numbers)
{
   result = Convert.ToInt64(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the SByte value -128 to the Int64 value -128.
//       Converted the SByte value -1 to the Int64 value -1.
//       Converted the SByte value 0 to the Int64 value 0.
//       Converted the SByte value 10 to the Int64 value 10.
//       Converted the SByte value 127 to the Int64 value 127.
```

ToInt64(Object)

Converts the value of the specified object to a 64-bit signed integer.

C#

```
public static long ToInt64 (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example attempts to convert each element in an object array to a long integer.

C#

```
object[] values = { true, -12, 163, 935, 'x', new DateTime(2009, 5, 12),
                    "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2, 16.3e42};
long result;

foreach (object value in values)
{
   try {
      result = Convert.ToInt64(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Int64 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to an Int64 exists for the {0}
value {1}.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value True to the Int64 value 1.
//    Converted the Int32 value -12 to the Int64 value -12.
//    Converted the Int32 value 163 to the Int64 value 163.
//    Converted the Int32 value 935 to the Int64 value 935.
//    Converted the Char value x to the Int64 value 120.
//    No conversion to an Int64 exists for the DateTime value 5/12/2009
12:00:00 AM.
//    Converted the String value 104 to the Int64 value 104.
//    The String value 103.0 is not in a recognizable format.
```

```
//    Converted the String value -1 to the Int64 value -1.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the Int64 value 100.
//    The Double value 1.63E+43 is outside the range of the Int64 type.
```

Remarks

If `value` is not `null`, this method wraps a call to the IConvertible.ToInt64 implementation of the underlying type of `value`.

ToInt64(Int64)

Returns the specified 64-bit signed integer; no actual conversion is performed.

C#

```
public static long ToInt64 (long value);
```

Parameters

`value` Int64

A 64-bit signed integer.

Returns

Int64

`value` is returned unchanged.

Examples

The following example converts each element in an array of integers to a long integer.

C#

```
int[] numbers = { Int32.MinValue, -1, 0, 121, 340, Int32.MaxValue };
long result;
foreach (int number in numbers)
{
   result = Convert.ToInt64(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int32 value -2147483648 to the Int64 value
-2147483648.
//    Converted the Int32 value -1 to the Int64 value -1.
//    Converted the Int32 value 0 to the Int64 value 0.
//    Converted the Int32 value 121 to the Int64 value 121.
//    Converted the Int32 value 340 to the Int64 value 340.
//    Converted the Int32 value 2147483647 to the Int64 value 2147483647.

ToInt64(Byte)

Converts the value of the specified 8-bit unsigned integer to the equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in an array of bytes to a long integer.

C#

```
byte[] bytes = { Byte.MinValue, 14, 122, Byte.MaxValue};
long result;

foreach (byte byteValue in bytes)
{
   result = Convert.ToInt64(byteValue);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     byteValue.GetType().Name, byteValue,
                     result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the Byte value 0 to the Int64 value 0.
//       Converted the Byte value 14 to the Int64 value 14.
//       Converted the Byte value 122 to the Int64 value 122.
//       Converted the Byte value 255 to the Int64 value 255.
```

ToInt64(Char)

Converts the value of the specified Unicode character to the equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in a Char array to a long integer.

C#

```
char[] chars = { 'a', 'z', '\u0007', '\u03FF',
                 '\u7FFF', '\uFFFE' };
long result;

foreach (char ch in chars)
{
   result = Convert.ToInt64(ch);
```

```
    Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                      ch.GetType().Name, ch,
                      result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the Char value 'a' to the Int64 value 97.
//       Converted the Char value 'z' to the Int64 value 122.
//       Converted the Char value '•' to the Int64 value 7.
//       Converted the Char value 'Ɔ' to the Int64 value 1023.
//       Converted the Char value '翿' to the Int64 value 32767.
//       Converted the Char value '￾' to the Int64 value 65534.
```

ToInt64(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static long ToInt64 (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Int64

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

ToInt64(Boolean)

Converts the specified Boolean value to the equivalent 64-bit signed integer.

```
C#
public static long ToInt64 (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Int64

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example converts the Boolean values `true` and `false` to long integers.

```C#
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToInt64(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToInt64(trueFlag));
// The example displays the following output:
//       False converts to 0.
//       True converts to 1.
```

UWP	10.0

ToInt64(Double)

Converts the value of the specified double-precision floating-point number to an equivalent 64-bit signed integer.

```C#
public static long ToInt64 (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Int64

`value`, rounded to the nearest 64-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Exceptions

OverflowException

`value` is greater than Int64.MaxValue or less than Int64.MinValue.

Examples

The following example attempts to convert each element in an array of Double values to a long integer.

C#

```
double[] values= { Double.MinValue, -1.38e10, -1023.299, -12.98,
                   0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
long result;

foreach (double value in values)
{
   try {
      result = Convert.ToInt64(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int64 type.",
value);
   }
}
//    -1.7976931348623157E+308 is outside the range of the Int64 type.

ToInt64(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Int64

A 64-bit signed integer that is equivalent to `value`.

Examples

The following example converts each element in an array of 16-bit integers to a long integer.

C#

```
short[] numbers= { Int16.MinValue, -1, 0, 121, 340, Int16.MaxValue };
long result;

foreach (short number in numbers)
{
   result = Convert.ToInt64(number);
   Console.WriteLine("Converted the {0} value {1} to a {2} value {3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int16 value -32768 to a Int32 value -32768.
//    Converted the Int16 value -1 to a Int32 value -1.
//    Converted the Int16 value 0 to a Int32 value 0.
//    Converted the Int16 value 121 to a Int32 value 121.
//    Converted the Int16 value 340 to a Int32 value 340.
//    Converted the Int16 value 32767 to a Int32 value 32767.
```

`value` is greater than Int64.MaxValue or less than Int64.MinValue.

Examples

The following example attempts to convert each element in an array of Decimal values to a long integer.

C#

```
decimal[] values= { Decimal.MinValue, -1034.23m, -12m, 0m, 147m,
                    199.55m, 9214.16m, Decimal.MaxValue };
long result;

foreach (decimal value in values)
{
   try {
      result = Convert.ToInt64(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the Int64 type.",
                        value);
   }
}
// The example displays the following output:
//    -79228162514264337593543950335 is outside the range of the Int64
type.
//    Converted the Decimal value '-1034.23' to the Int64 value -1034.
//    Converted the Decimal value '-12' to the Int64 value -12.
//    Converted the Decimal value '0' to the Int64 value 0.
//    Converted the Decimal value '147' to the Int64 value 147.
//    Converted the Decimal value '199.55' to the Int64 value 200.
//    Converted the Decimal value '9214.16' to the Int64 value 9214.
//    79228162514264337593543950335 is outside the range of the Int64
type.
```

Convert.ToSByte Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to an 8-bit signed integer.

Overloads

Expand table

ToSByte(SByte)	Returns the specified 8-bit signed integer; no actual conversion is performed.
ToSByte(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 8-bit signed integer.
ToSByte(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 8-bit signed integer, using the specified culture-specific formatting information.
ToSByte(Object, IFormatProvider)	Converts the value of the specified object to an 8-bit signed integer, using the specified culture-specific formatting information.
ToSByte(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 8-bit signed integer.
ToSByte(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 8-bit signed integer.
ToSByte(String)	Converts the specified string representation of a number to an equivalent 8-bit signed integer.
ToSByte(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 8-bit signed integer.
ToSByte(Object)	Converts the value of the specified object to an 8-bit signed integer.
ToSByte(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 8-bit signed integer.
ToSByte(Int32)	Converts the value of the specified 32-bit signed integer to an

	equivalent 8-bit signed integer.
ToSByte(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 8-bit signed integer.
ToSByte(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 8-bit signed integer.
ToSByte(Char)	Converts the value of the specified Unicode character to the equivalent 8-bit signed integer.
ToSByte(DateTime)	Calling this method always throws InvalidCastException.
ToSByte(Boolean)	Converts the specified Boolean value to the equivalent 8-bit signed integer.
ToSByte(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 8-bit signed integer.
ToSByte(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 8-bit signed integer.
ToSByte(Decimal)	Converts the value of the specified decimal number to an equivalent 8-bit signed integer.

ToSByte(SByte)

> Important
>
> This API is not CLS-compliant.

Returns the specified 8-bit signed integer; no actual conversion is performed.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to return.

Returns

SByte

`value` is returned unchanged.

Attributes CLSCompliantAttribute

ToSByte(String, Int32)

> Important
>
> This API is not CLS-compliant.

Converts the string representation of a number in a specified base to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

SByte

An 8-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

ArgumentOutOfRangeException

`value` is Empty.

FormatException

`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException

`value`, which represents a non-base 10 signed number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example attempts to interpret the elements in a string array as the binary, octal, and hexadecimal representation of numeric values in order to convert them to unsigned bytes.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int[] baseValues = { 2, 8, 16};
      string[] values = { "FF", "81", "03", "11", "8F", "01", "1C",
"111",
                          "123", "18A" };

      // Convert to each supported base.
      foreach (int baseValue in baseValues)
      {
         Console.WriteLine("Converting strings in base {0}:", baseValue);
         foreach (string value in values)
         {
            Console.Write("   '{0,-5}  -->  ", value + "'");
            try {
               Console.WriteLine(Convert.ToSByte(value, baseValue));
            }
            catch (FormatException) {
               Console.WriteLine("Bad Format");
            }
            catch (OverflowException) {
               Console.WriteLine("Out of Range");
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       Converting strings in base 2:
//          'FF'    -->  Bad Format
//          '81'    -->  Bad Format
//          '03'    -->  Bad Format
//          '11'    -->  3
//          '8F'    -->  Bad Format
//          '01'    -->  1
//          '1C'    -->  Bad Format
//          '111'   -->  7
//          '123'   -->  Bad Format
//          '18A'   -->  Bad Format
//
//       Converting strings in base 8:
//          'FF'    -->  Bad Format
```

```
//          '81'    -->  Bad Format
//          '03'    -->  3
//          '11'    -->  9
//          '8F'    -->  Bad Format
//          '01'    -->  1
//          '1C'    -->  Bad Format
//          '111'   -->  73
//          '123'   -->  83
//          '18A'   -->  Bad Format
//
//       Converting strings in base 16:
//          'FF'    -->  -1
//          '81'    -->  -127
//          '03'    -->  3
//          '11'    -->  17
//          '8F'    -->  -113
//          '01'    -->  1
//          '1C'    -->  28
//          '111'   -->  Out of Range
//          '123'   -->  Out of Range
//          '18A'   -->  Out of Range
```

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the negative sign is not supported for non-base 10 numeric representations, the ToSByte(String, Int32) method assumes that negative numbers use two's complement representation. In other words, the method always interprets the high-order bit of a byte (bit 7) as its sign bit. As a result, it is possible to write code in which a non-base 10 number that is out of the range of the SByte data type is converted to an SByte value without the method throwing an exception. The following example converts MaxValue to its hexadecimal string representation, and then calls the ToSByte(String, Int32) method. Instead of throwing an exception, the method displays the message, "0xff converts to -1."

C#

```
// Create a hexadecimal value out of range of the SByte type.
string value = Convert.ToString(byte.MaxValue, 16);
// Convert it back to a number.
try
{
   sbyte number = Convert.ToSByte(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
}
catch (OverflowException)
```

```
{
   Console.WriteLine("Unable to convert '0x{0}' to a signed byte.",
value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method is using the appropriate numeric representation to interpret a particular value. As the following example illustrates, you can ensure that the method handles overflows appropriately by first determining whether a value represents an unsigned or a signed type when converting it to its hexadecimal string representation. Throw an exception if the original value was an unsigned type but the conversion back to a signed byte yields a value whose sign bit is on.

C#

```
// Create a hexadecimal value out of range of the SByte type.
byte sourceNumber = byte.MaxValue;
bool isSigned =
Math.Sign(Convert.ToDouble(sourceNumber.GetType().GetField("MinValue").Ge
tValue(null))) == -1;
string value = Convert.ToString(sourceNumber, 16);
sbyte targetNumber;
try
{
   targetNumber = Convert.ToSByte(value, 16);
   if (! isSigned && ((targetNumber & 0x80) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to a signed byte.",
value);
}
// Displays the following to the console:
//    Unable to convert '0xff' to a signed byte.
```

ToSByte(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 8-bit signed integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (string value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentNullException

`value` is `null`.

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example converts string representations of SByte values with the `ToSByte` method, using an IFormatProvider object.

C#

```
// Example of the Convert.ToSByte( string ) and
// Convert.ToSByte( string, IFormatProvider ) methods.
using System;
using System.Globalization;

class ToSByteProviderDemo
{
    static string format = "{0,-20}{1,-20}{2}";

     // Get the exception type name; remove the namespace prefix.
    static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    static void ConvertToSByte( string numericStr,
        IFormatProvider provider )
    {
        object defaultValue;
        object providerValue;

        // Convert numericStr to SByte without a format provider.
        try
        {
            defaultValue = Convert.ToSByte( numericStr );
        }
        catch( Exception ex )
        {
            defaultValue = GetExceptionType( ex );
        }
```

```
        // Convert numericStr to SByte with a format provider.
        try
        {
            providerValue = Convert.ToSByte( numericStr, provider );
        }
        catch( Exception ex )
        {
            providerValue = GetExceptionType( ex );
        }

        Console.WriteLine( format, numericStr,
            defaultValue, providerValue );
    }

    public static void Main( )
    {
        // Create a NumberFormatInfo object and set several of its
        // properties that apply to numbers.
        NumberFormatInfo provider = new NumberFormatInfo();

        // These properties affect the conversion.
        provider.NegativeSign = "neg ";
        provider.PositiveSign = "pos ";

        // These properties do not affect the conversion.
        // The input string cannot have decimal and group separators.
        provider.NumberDecimalSeparator = ".";
        provider.NumberNegativePattern = 0;

        Console.WriteLine("This example of\n" +
            "  Convert.ToSByte( string ) and \n" +
            "  Convert.ToSByte( string, IFormatProvider ) " +
            "\ngenerates the following output. It converts " +
            "several strings to \nSByte values, using " +
            "default formatting or a NumberFormatInfo object.\n" );
        Console.WriteLine( format, "String to convert",
            "Default/exception", "Provider/exception" );
        Console.WriteLine( format, "-----------------",
            "-----------------", "-----------------" );

        // Convert strings, with and without an IFormatProvider.
        ConvertToSByte( "123", provider );
        ConvertToSByte( "+123", provider );
        ConvertToSByte( "pos 123", provider );
        ConvertToSByte( "-123", provider );
        ConvertToSByte( "neg 123", provider );
        ConvertToSByte( "123.", provider );
        ConvertToSByte( "(123)", provider );
        ConvertToSByte( "128", provider );
        ConvertToSByte( "-129", provider );
    }
}

/*
```

```
This example of
  Convert.ToSByte( string ) and
  Convert.ToSByte( string, IFormatProvider )
generates the following output. It converts several strings to
SByte values, using default formatting or a NumberFormatInfo object.

String to convert   Default/exception   Provider/exception
-----------------   -----------------   ------------------
123                 123                 123
+123                123                 FormatException
pos 123             FormatException     123
-123                -123                FormatException
neg 123             FormatException     -123
123.                FormatException     FormatException
(123)               FormatException     FormatException
128                 OverflowException   OverflowException
-129                OverflowException   FormatException
*/
```

Remarks

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the SByte.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToSByte(Object, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to an 8-bit signed integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example defines a `ByteString` class that stores both signed and unsigned bytes as hexadecimal strings along with a field that indicates the sign of the byte. The `ByteString` class implements the IConvertible interface. Its IConvertible.ToSByte method calls the Parse(String, IFormatProvider) method to perform the conversion. If it fails, it throws an OverflowException.

C#

```
using System;
using System.Globalization;

public enum SignBit { Negative=-1, Zero=0, Positive=1 };

public struct ByteString : IConvertible
{
   private SignBit signBit;
   private string byteString;

   public SignBit Sign
   {
      set { signBit = value; }
      get { return signBit; }
   }

   public string Value
   {
      set {
         if (value.Trim().Length > 2)
            throw new ArgumentException("The string representation of a
byte cannot have more than two characters.");
         else
            byteString = value;
      }
      get { return byteString; }
   }
```

```
   // IConvertible implementations.
   public TypeCode GetTypeCode() {
      return TypeCode.Object;
   }

   public bool ToBoolean(IFormatProvider provider)
   {
      if (signBit == SignBit.Zero)
         return false;
      else
         return true;
   }

   public byte ToByte(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is out of range
of the Byte type.", Convert.ToSByte(byteString, 16)));
      else
         return Byte.Parse(byteString, NumberStyles.HexNumber);
   }

   public char ToChar(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative) {
         throw new OverflowException(String.Format("{0} is out of range
of the Char type.", Convert.ToSByte(byteString, 16)));
      }
      else {
         byte byteValue = Byte.Parse(this.byteString,
NumberStyles.HexNumber);
         return Convert.ToChar(byteValue);
      }
   }

   public DateTime ToDateTime(IFormatProvider provider)
   {
      throw new InvalidCastException("ByteString to DateTime conversion
is not supported.");
   }

   public decimal ToDecimal(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
      {
         sbyte byteValue = SByte.Parse(byteString,
NumberStyles.HexNumber);
         return Convert.ToDecimal(byteValue);
      }
      else
      {
         byte byteValue = Byte.Parse(byteString, NumberStyles.HexNumber);
         return Convert.ToDecimal(byteValue);
      }
```

```
    }

    public double ToDouble(IFormatProvider provider)
    {
       if (signBit == SignBit.Negative)
          return Convert.ToDouble(SByte.Parse(byteString,
NumberStyles.HexNumber));
       else
          return Convert.ToDouble(Byte.Parse(byteString,
NumberStyles.HexNumber));
    }

            return Convert.ToUInt32(Byte.Parse(byteString,
NumberStyles.HexNumber));
      }

      public UInt64 ToUInt64(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative)
            throw new OverflowException(String.Format("{0} is outside the
range of the UInt64 type.",

SByte.Parse(byteString, NumberStyles.HexNumber)));
         else
            return Convert.ToUInt64(Byte.Parse(byteString,
NumberStyles.HexNumber));
      }
   }
```

The following example shows how the IConvertible.ToSByte implementation of the `ByteString` class is called by the Convert.ToSByte(Object, IFormatProvider) method.

```
C#

public class Class1
{
   public static void Main()
   {
      sbyte positiveByte = 120;
```

```
        sbyte negativeByte = -101;

        ByteString positiveString = new ByteString();
        positiveString.Sign = (SignBit) Math.Sign(positiveByte);
        positiveString.Value = positiveByte.ToString("X2");

        ByteString negativeString = new ByteString();
        negativeString.Sign = (SignBit) Math.Sign(negativeByte);
        negativeString.Value = negativeByte.ToString("X2");

        try {
           Console.WriteLine("'{0}' converts to {1}.",
positiveString.Value, Convert.ToSByte(positiveString));
        }
        catch (OverflowException) {
           Console.WriteLine("0x{0} is outside the range of the Byte
type.", positiveString.Value);
        }

        try {
           Console.WriteLine("'{0}' converts to {1}.",
negativeString.Value, Convert.ToSByte(negativeString));
        }
        catch (OverflowException) {
           Console.WriteLine("0x{0} is outside the range of the Byte
type.", negativeString.Value);
        }
    }
}
// The example displays the following output:
//       '78' converts to 120.
//       '9B' converts to -101.
```

Remarks

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToSByte(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of long integers to a signed byte.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 340, UInt64.MaxValue };
sbyte result;

foreach (ulong number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt64 value 0 to the SByte value 0.
//    Converted the UInt64 value 121 to the SByte value 121.
//    The UInt64 value 340 is outside the range of the SByte type.
//    The UInt64 value 18446744073709551615 is outside the range of the
SByte type.
```

ToSByte(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an integer array to a signed byte.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
sbyte result;

foreach (uint number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt32 value 0 to the SByte value 0.
//    Converted the UInt32 value 121 to the SByte value 121.
//    The UInt32 value 340 is outside the range of the SByte type.
//    The UInt32 value 4294967295 is outside the range of the SByte type.
```

ToSByte(String)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 8-bit signed integer.

```
C#

[System.CLSCompliant(false)]
public static sbyte ToSByte (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if value is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example converts string representations of SByte values with the `ToSByte` method, using default formatting.

```
C#

// Example of the Convert.ToSByte( string ) and
// Convert.ToSByte( string, IFormatProvider ) methods.
using System;
using System.Globalization;
```

```
class ToSByteProviderDemo
{
    static string format = "{0,-20}{1,-20}{2}";

     // Get the exception type name; remove the namespace prefix.
    static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    static void ConvertToSByte( string numericStr,
        IFormatProvider provider )
    {
        object defaultValue;
        object providerValue;

        // Convert numericStr to SByte without a format provider.
        try
        {
            defaultValue = Convert.ToSByte( numericStr );
        }
        catch( Exception ex )
        {
            defaultValue = GetExceptionType( ex );
        }

        // Convert numericStr to SByte with a format provider.
        try
        {
            providerValue = Convert.ToSByte( numericStr, provider );
        }
        catch( Exception ex )
        {
            providerValue = GetExceptionType( ex );
        }

        Console.WriteLine( format, numericStr,
            defaultValue, providerValue );
    }

    public static void Main( )
    {
        // Create a NumberFormatInfo object and set several of its
        // properties that apply to numbers.
        NumberFormatInfo provider = new NumberFormatInfo();

        // These properties affect the conversion.
        provider.NegativeSign = "neg ";
        provider.PositiveSign = "pos ";

        // These properties do not affect the conversion.
        // The input string cannot have decimal and group separators.
```

```
        provider.NumberDecimalSeparator = ".";
        provider.NumberNegativePattern = 0;

        Console.WriteLine("This example of\n" +
            "  Convert.ToSByte( string ) and \n" +
            "  Convert.ToSByte( string, IFormatProvider ) " +
            "\ngenerates the following output. It converts " +
            "several strings to \nSByte values, using " +
            "default formatting or a NumberFormatInfo object.\n" );
        Console.WriteLine( format, "String to convert",
            "Default/exception", "Provider/exception" );
        Console.WriteLine( format, "-----------------",
            "-----------------", "------------------" );

        // Convert strings, with and without an IFormatProvider.
        ConvertToSByte( "123", provider );
        ConvertToSByte( "+123", provider );
        ConvertToSByte( "pos 123", provider );
        ConvertToSByte( "-123", provider );
        ConvertToSByte( "neg 123", provider );
        ConvertToSByte( "123.", provider );
        ConvertToSByte( "(123)", provider );
        ConvertToSByte( "128", provider );
        ConvertToSByte( "-129", provider );
    }
}

/*
This example of
  Convert.ToSByte( string ) and
  Convert.ToSByte( string, IFormatProvider )
generates the following output. It converts several strings to
SByte values, using default formatting or a NumberFormatInfo object.

String to convert   Default/exception   Provider/exception
-----------------   -----------------   ------------------
123                 123                 123
+123                123                 FormatException
pos 123             FormatException     123
-123                -123                FormatException
neg 123             FormatException     -123
123.                FormatException     FormatException
(123)               FormatException     FormatException
128                 OverflowException   OverflowException
-129                OverflowException   FormatException
*/
```

Remarks

Using the ToSByte(String) method is equivalent to passing `value` to the SByte.Parse(String) method. `value` is interpreted by using the formatting

conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the SByte.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToSByte(Single)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified single-precision floating-point number to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

SByte

`value`, rounded to the nearest 8-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of Single values to a signed byte.

C#

```
object[] values = { true, -12, 163, 935, 'x', "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2};
sbyte result;

foreach (object value in values)
{
   try {
      result = Convert.ToSByte(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
```

```
    }
    catch (InvalidCastException) {
        Console.WriteLine("No conversion to a Byte exists for the {0} value
{1}.",
                          value.GetType().Name, value);
    }
}
// The example displays the following output:
//    Converted the Boolean value true to the SByte value 1.
//    Converted the Int32 value -12 to the SByte value -12.
//    The Int32 value 163 is outside the range of the SByte type.
//    The Int32 value 935 is outside the range of the SByte type.
//    Converted the Char value x to the SByte value 120.
//    Converted the String value 104 to the SByte value 104.
//    The String value 103.0 is not in a recognizable format.
//    Converted the String value -1 to the SByte value -1.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the SByte value 100.
```

ToSByte(Object)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to an 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example attempts to convert each element in an object array to a signed byte.

C#

```
object[] values = { true, -12, 163, 935, 'x', "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2};
sbyte result;

foreach (object value in values)
{
   try {
      result = Convert.ToSByte(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to a Byte exists for the {0} value
{1}.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value true to the SByte value 1.
//    Converted the Int32 value -12 to the SByte value -12.
//    The Int32 value 163 is outside the range of the SByte type.
//    The Int32 value 935 is outside the range of the SByte type.
//    Converted the Char value x to the SByte value 120.
//    Converted the String value 104 to the SByte value 104.
//    The String value 103.0 is not in a recognizable format.
//    Converted the String value -1 to the SByte value -1.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the SByte value 100.
```

Remarks

The return value is the result of invoking the IConvertible.ToSByte method of the underlying type of `value`.

ToSByte(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned 16-bit integers to a signed byte.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
sbyte result;

foreach (ushort number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt16 value 0 to the SByte value 0.
//    Converted the UInt16 value 121 to the SByte value 121.
//    The UInt16 value 340 is outside the range of the SByte type.
//    The UInt16 value 65535 is outside the range of the SByte type.
```

ToSByte(Int32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit signed integer to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of signed integers to a signed byte.

C#

```
int[] numbers = { Int32.MinValue, -1, 0, 121, 340, Int32.MaxValue };
sbyte result;

foreach (int number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int32 value -2147483648 is outside the range of the SByte type.
//    Converted the Int32 value -1 to the SByte value -1.
//    Converted the Int32 value 0 to the SByte value 0.
//    Converted the Int32 value 121 to the SByte value 121.
//    The Int32 value 340 is outside the range of the SByte type.
//    The Int32 value 2147483647 is outside the range of the SByte type.
```

ToSByte(Int64)

Important

This API is not CLS-compliant.

Converts the value of the specified 64-bit signed integer to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (long value);
```

Parameters

value Int64

The 64-bit signed integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of long integers to a signed byte.

C#

```
long[] numbers = { Int64.MinValue, -1, 0, 121, 340, Int64.MaxValue };
sbyte result;
foreach (long number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
```

```
                        result.GetType().Name, result);
    }
    catch (OverflowException) {

ToSByte(Byte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit unsigned integer to the equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue.

Examples

The following example attempts to convert each element in a byte array to a signed byte.

C#

```
byte[] numbers = { Byte.MinValue, 10, 100, Byte.MaxValue };
sbyte result;

foreach (byte number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
```

```
}
// The example displays the following output:
//    Converted the Byte value 0 to the SByte value 0.
//    Converted the Byte value 10 to the SByte value 10.
//    Converted the Byte value 100 to the SByte value 100.
//    The Byte value 255 is outside the range of the SByte type.

ToSByte(Char)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified Unicode character to the equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue.

Examples

The following example attempts to convert each element in an array of Char values to a signed byte.

C#

```
char[] chars = { 'a', 'z', '\u0007', '\u0200', '\u1023' };
foreach (char ch in chars)
{
   try {
      sbyte result = Convert.ToSByte(ch);
      Console.WriteLine("{0} is converted to {1}.", ch, result);
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to convert u+{0} to a byte.",
                        Convert.ToInt16(ch).ToString("X4"));
   }
}
// The example displays the following output:
//    a is converted to 97.
//    z is converted to 122.
//     is converted to 7.
//    Unable to convert u+00C8 to a byte.
//    Unable to convert u+03FF to a byte.
```

ToSByte(DateTime)

> Important
>
> This API is not CLS-compliant.

Calling this method always throws InvalidCastException.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

SByte

This conversion is not supported. No value is returned.

Attributes CLSCompliantAttribute

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

ToSByte(Boolean)

> Important
>
> This API is not CLS-compliant.

Converts the specified Boolean value to the equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

SByte

The number 1 if `value` is `true`; otherwise, 0.

Attributes CLSCompliantAttribute

Examples

The following example converts the Boolean values `true` and `false` to signed byte values.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToSByte(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToSByte(trueFlag));
// The example displays the following output:
//       false converts to 0.
//       true converts to 1.
```

ToSByte(Double)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified double-precision floating-point number to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
```

```
public static sbyte ToSByte (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

SByte

`value`, rounded to the nearest 8-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of Double values to a signed byte.

C#

```
double[] numbers = { Double.MinValue, -129.5, -12.7, 0, 16,
                     103.6, 255.0, 1.63509e17, Double.MaxValue};
sbyte result;

foreach (double number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
```

```
    }
}
// The example displays the following output:
//    The Double value -1.79769313486232E+308 is outside the range of the
SByte type.
//    The Double value -129.5 is outside the range of the SByte type.
//    Converted the Double value -12.7 to the SByte value -13.
//    Converted the Double value 0 to the SByte value 0.
//    Converted the Double value 16 to the SByte value 16.
//    Converted the Double value 103.6 to the SByte value 104.
//    The Double value 255 is outside the range of the SByte type.
//    The Double value 1.63509E+17 is outside the range of the SByte
type.
//    The Double value 1.79769313486232E+308 is outside the range of the

ToSByte(Int16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit signed integer to the equivalent 8-bit signed integer.

```C#
[System.CLSCompliant(false)]
public static sbyte ToSByte (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

SByte

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of signed 16-bit integers to a signed byte.

```C#
short[] numbers = { Int16.MinValue, -1, 0, 121, 340, Int16.MaxValue };
sbyte result;
foreach (short number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
```

```
}
// The example displays the following output:
//    The Int16 value -32768 is outside the range of the SByte type.
//    Converted the Int16 value -1 to the SByte value -1.
//    Converted the Int16 value 0 to the SByte value 0.
//    Converted the Int16 value 121 to the SByte value 121.
//    The Int16 value 340 is outside the range of the SByte type.
//    The Int16 value 32767 is outside the range of the SByte type.

ToSByte(Decimal)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified decimal number to an equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

SByte

`value`, rounded to the nearest 8-bit signed integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than SByte.MaxValue or less than SByte.MinValue.

Examples

The following example attempts to convert each element in an array of Decimal values to a signed byte.

C#

```
decimal[] numbers = { Decimal.MinValue, -129.5m, -12.7m, 0m, 16m,
                      103.6m, 255.0m, Decimal.MaxValue };
sbyte result;

foreach (decimal number in numbers)
{
   try {
      result = Convert.ToSByte(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
SByte type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Decimal value -79228162514264337593543950335 is outside the
range of the SByte type.
//    The Decimal value -129.5 is outside the range of the SByte type.
//    Converted the Decimal value -12.7 to the SByte value -13.
//    Converted the Decimal value 0 to the SByte value 0.
//    Converted the Decimal value 16 to the SByte value 16.
//    Converted the Decimal value 103.6 to the SByte value 104.
```

```
//    The Decimal value 255 is outside the range of the SByte type.
//    The Decimal value 79228162514264337593543950335 is outside the
range of the SByte type.
```

Convert.ToSingle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a single-precision floating-point number.

Overloads

Expand table

ToSingle(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent single-precision floating-point number, using the specified culture-specific formatting information.
ToSingle(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent single-precision floating-point number.
ToSingle(Object, IFormatProvider)	Converts the value of the specified object to an single-precision floating-point number, using the specified culture-specific formatting information.
ToSingle(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent single-precision floating-point number.
ToSingle(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent single-precision floating-point number.
ToSingle(String)	Converts the specified string representation of a number to an equivalent single-precision floating-point number.
ToSingle(Single)	Returns the specified single-precision floating-point number; no actual conversion is performed.
ToSingle(Object)	Converts the value of the specified object to a single-precision floating-point number.
ToSingle(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent single-precision floating-point number.
ToSingle(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent single-precision floating-point number.

ToSingle(Int16)	Converts the value of the specified 16-bit signed integer to an equivalent single-precision floating-point number.
ToSingle(Double)	Converts the value of the specified double-precision floating-point number to an equivalent single-precision floating-point number.
ToSingle(Decimal)	Converts the value of the specified decimal number to an equivalent single-precision floating-point number.
ToSingle(DateTime)	Calling this method always throws InvalidCastException.
ToSingle(Char)	Calling this method always throws InvalidCastException.
ToSingle(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent single-precision floating-point number.
ToSingle(Boolean)	Converts the specified Boolean value to the equivalent single-precision floating-point number.
ToSingle(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent single-precision floating-point number.

ToSingle(String, IFormatProvider)

Converts the specified string representation of a number to an equivalent single-precision floating-point number, using the specified culture-specific formatting information.

C#

```
public static float ToSingle (string? value, IFormatProvider? provider);
```

Parameters

value String

A string that contains the number to convert.

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Single

A single-precision floating-point number that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not a number in a valid format.

OverflowException

`value` represents a number that is less than Single.MinValue or greater than Single.MaxValue.

Examples

The following example uses IFormatProvider objects that represent the en-US and fr-FR cultures when it converts the elements in an array of numeric strings to Single values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] values = { "123456789", "12345.6789", "12 345,6789",
                          "123,456.789", "123 456,789",
"123,456,789.0123",
                          "123 456 789,0123", "1.235e12", "1.03221e-05",
                          Double.MaxValue.ToString() };
      CultureInfo[] cultures = { new CultureInfo("en-US"),
                                 new CultureInfo("fr-FR") };

      foreach (CultureInfo culture in cultures)
      {
         Console.WriteLine("String -> Single Conversion Using the {0}
Culture",
                           culture.Name);
         foreach (string value in values)
         {
            Console.Write("{0,22}  ->  ", value);
            try {
               Console.WriteLine(Convert.ToSingle(value, culture));
            }
            catch (FormatException) {
               Console.WriteLine("FormatException");
```

```
            }
            catch (OverflowException) {
               Console.WriteLine("OverflowException");
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    String -> Single Conversion Using the en-US Culture
//                 123456789  ->  1.234568E+08
//                12345.6789  ->  12345.68
//               12 345,6789  ->  FormatException
//               123,456.789  ->  123456.8
//               123 456,789  ->  FormatException
//          123,456,789.0123  ->  1.234568E+08
//          123 456 789,0123  ->  FormatException
//                  1.235e12  ->  1.235E+12
//               1.03221e-05  ->  1.03221E-05
//     1.79769313486232E+308  ->  Overflow
//
//    String -> Single Conversion Using the fr-FR Culture
//                 123456789  ->  1.234568E+08
//                12345.6789  ->  FormatException
//               12 345,6789  ->  12345.68
//               123,456.789  ->  FormatException
//               123 456,789  ->  123456.8
//          123,456,789.0123  ->  FormatException
//          123 456 789,0123  ->  1.234568E+08
//                  1.235e12  ->  FormatException
//               1.03221e-05  ->  FormatException
//     1.79769313486232E+308  ->  FormatException
```

Remarks

The return value is the result of invoking the Single.Parse method on `value`.

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the Single.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToSingle(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent single-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static float ToSingle (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Single

An 8-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a signed byte array to a Single value.

C#

```
sbyte[] numbers = { SByte.MinValue, -23, 0, 17, SByte.MaxValue };
float result;

foreach (sbyte number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the SByte value '-128' to the Single value -128.
//    Converted the SByte value '-23' to the Single value -23.
//    Converted the SByte value '0' to the Single value 0.
//    Converted the SByte value '17' to the Single value 17.
//    Converted the SByte value '127' to the Single value 127.
```

ToSingle(Object, IFormatProvider)

Converts the value of the specified object to an single-precision floating-point number, using the specified culture-specific formatting information.

C#

```
public static float ToSingle (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Single

A single-precision floating-point number that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement IConvertible.

OverflowException

`value` represents a number that is less than Single.MinValue or greater than Single.MaxValue.

Examples

The following example defines a `Temperature` class that implements the IConvertible interface. Its implementation of the IConvertible.ToSingle method returns the internal value of a private Single variable that represents the temperature.

C#

```
using System;
using System.Globalization;

public class Temperature : IConvertible
{
```

```
    private float m_Temp;

    public Temperature(float temperature)
    {
       this.m_Temp = temperature;
    }

    public float Celsius
    {
       get { return this.m_Temp; }
    }

    public float Kelvin
    {
       get { return this.m_Temp + 273.15f; }
    }

    public float Fahrenheit
    {
       get { return (float) Math.Round(this.m_Temp * 9 / 5 + 32, 2); }
    }

    public override string ToString()
    {
       return m_Temp.ToString("N2") + " °C";
    }

    // IConvertible implementations.
    public TypeCode GetTypeCode()
    {
       return TypeCode.Object;
    }

    public bool ToBoolean(IFormatProvider provider)
    {
       if (m_Temp == 0)
          return false;
       else
          return true;
    }

    public byte ToByte(IFormatProvider provider)
    {
       if (m_Temp < Byte.MinValue || m_Temp > Byte.MaxValue)
          throw new OverflowException(String.Format("{0} is out of range
of the Byte type.",
                                                     this.m_Temp));
       else
          return Convert.ToByte(this.m_Temp);
    }

    public char ToChar(IFormatProvider provider)
    {
       throw new InvalidCastException("Temperature to Char conversion is
not supported.");
```

```
   }

   public DateTime ToDateTime(IFormatProvider provider)
   {
      throw new InvalidCastException("Temperature to DateTime conversion
is not supported.");
   }

   public decimal ToDecimal(IFormatProvider provider)
   {
      return Convert.ToDecimal(this.m_Temp);
   }

   public double ToDouble(IFormatProvider provider)
   {
      return Convert.ToDouble(this.m_Temp);
   }

                    return this.ToDecimal(null);
                case TypeCode.Double:
                    return this.ToDouble(null);
                case TypeCode.Int16:
                    return this.ToInt16(null);
                case TypeCode.Int32:
                    return this.ToInt32(null);
                case TypeCode.Int64:
                    return this.ToInt64(null);
                case TypeCode.Object:
                    if (typeof(Temperature).Equals(conversionType))
                        return this;
                    else
                        throw new InvalidCastException(String.Format("Conversion
to a {0} is not supported.",

conversionType.Name));
                case TypeCode.SByte:
                    return this.ToSByte(null);
                case TypeCode.Single:
                    return this.ToSingle(null);
                case TypeCode.String:
                    return this.ToString(provider);
                case TypeCode.UInt16:
                    return this.ToUInt16(null);
                case TypeCode.UInt32:
                    return this.ToUInt32(null);
                case TypeCode.UInt64:
                    return this.ToUInt64(null);
```

```
            default:
               throw new InvalidCastException(String.Format("Conversion to
{0} is not supported.", conversionType.Name));
         }
      }

      public ushort ToUInt16(IFormatProvider provider)
      {
         if (this.m_Temp < UInt16.MinValue || this.m_Temp > UInt16.MaxValue)
            throw new OverflowException(String.Format("{0} is out of range
of the UInt16 type.",
                                                       this.m_Temp));
         else
            return Convert.ToUInt16(this.m_Temp);
      }

      public uint ToUInt32(IFormatProvider provider)
      {
         if (this.m_Temp < UInt32.MinValue || this.m_Temp > UInt32.MaxValue)
            throw new OverflowException(String.Format("{0} is out of range
of the UInt32 type.",
                                                       this.m_Temp));
         else
            return Convert.ToUInt32(this.m_Temp);
      }

      public ulong ToUInt64(IFormatProvider provider)
      {
         if (this.m_Temp < UInt64.MinValue || this.m_Temp > UInt64.MaxValue)
            throw new OverflowException(String.Format("{0} is out of range
of the UInt64 type.",
                                                       this.m_Temp));
         else
            return Convert.ToUInt64(this.m_Temp);
      }
   }
```

The following example illustrates how a call to the Convert.ToSingle(Object, IFormatProvider) method, in turn, calls the IConvertible.ToSingle implementation of the `Temperature` class.

C#

```
public class Example
{
   public static void Main()
   {
      Temperature cold = new Temperature(-40);
      Temperature freezing = new Temperature(0);
      Temperature boiling = new Temperature(100);

      Console.WriteLine(Convert.ToInt32(cold, null));
```

```
        Console.WriteLine(Convert.ToInt32(freezing, null));
        Console.WriteLine(Convert.ToDouble(boiling, null));
    }
}
// The example dosplays the following output:
//       -40
//       0
//       100
```

Remarks

The return value is the result of invoking the IConvertible.ToSingle method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToSingle(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent single-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static float ToSingle (ulong value);
```

Parameters

value UInt64

The 64-bit unsigned integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned long integers to a Single value.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 12345, UInt64.MaxValue };
float result;

foreach (ulong number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt64 value '0' to the Single value 0.
//    Converted the UInt64 value '121' to the Single value 121.
//    Converted the UInt64 value '12345' to the Single value 12345.
//    Converted the UInt64 value '18446744073709551615' to the Single
value 1.844674E+19.
```

ToSingle(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent single-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static float ToSingle (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned integers to a Single value.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 12345, UInt32.MaxValue };
float result;

foreach (uint number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt32 value '0' to the Single value 0.
//    Converted the UInt32 value '121' to the Single value 121.
//    Converted the UInt32 value '12345' to the Single value 12345.
//    Converted the UInt32 value '4294967295' to the Single value
4.294967E+09.
```

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToSingle(String)

Converts the specified string representation of a number to an equivalent single-precision floating-point number.

C#

```
public static float ToSingle (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

Single

A single-precision floating-point number that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Exceptions

FormatException

`value` is not a number in a valid format.

OverflowException

`value` represents a number that is less than Single.MinValue or greater than Single.MaxValue.

Examples

The following example attempts to convert each element in an array of numeric strings to a Single value.

C#

```
string[] values= { "-1,035.77219", "1AFF", "1e-35", "1.63f",
                   "1,635,592,999,999,999,999,999,999", "-17.455",
                   "190.34001", "1.29e325"};
float result;

foreach (string value in values)
{
   try {
      result = Convert.ToSingle(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
```

```
    catch (FormatException) {
       Console.WriteLine("Unable to convert '{0}' to a Single.", value);
    }
    catch (OverflowException) {
       Console.WriteLine("'{0}' is outside the range of a Single.",
value);
    }
}
// The example displays the following output:
//    Converted the String value '-1,035.77219' to the Single value
-1035.772.
//    Unable to convert '1AFF' to a Single.
//    Converted the String value '1e-35' to the Single value 1E-35.
//    Unable to convert '1.63f' to a Single.
//    Converted the String value '1,635,592,999,999,999,999,999,999' to
the Single value 1.635593E+24.
//    Converted the String value '-17.455' to the Single value -17.455.
//    Converted the String value '190.34001' to the Single value 190.34.
//    1.29e325' is outside the range of a Single.
```

Remarks

Using the ToSingle(String) method is equivalent to passing `value` to the Single.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the Single.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToSingle(Single)

Returns the specified single-precision floating-point number; no actual conversion is performed.

```
C#
public static float ToSingle (float value);
```

Parameters

`value` Single

The single-precision floating-point number to return.

Returns

Single

`value` is returned unchanged.

UWP	10.0

ToSingle(Object)

Converts the value of the specified object to a single-precision floating-point number.

```
C#

public static float ToSingle (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

Single

A single-precision floating-point number that is equivalent to `value`, or zero if `value` is `null`.

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than Single.MinValue or greater than Single.MaxValue.

Examples

The following example attempts to convert each element in an object array to a Single value.

```
C#
```

```
object[] values = { true, 'a', 123, 1.764e32, "9.78", "1e-02",
                    1.67e03, "A100", "1,033.67", DateTime.Now,
                    Decimal.MaxValue };
float result;

foreach (object value in values)
{
   try {
      result = Convert.ToSingle(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not recognized as a valid
Single value.",
                        value.GetType().Name, value);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
Single type.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("Conversion of the {0} value {1} to a Single is
not supported.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value 'True' to the Single value 1.
//    Conversion of the Char value a to a Single is not supported.
//    Converted the Int32 value '123' to the Single value 123.
//    Converted the Double value '1.764E+32' to the Single value
1.764E+32.
//    Converted the String value '9.78' to the Single value 9.78.
//    Converted the String value '1e-02' to the Single value 0.01.
//    Converted the Double value '1670' to the Single value 1670.
//    The String value A100 is not recognized as a valid Single value.
//    Converted the String value '1,033.67' to the Single value 1033.67.
//    Conversion of the DateTime value 11/7/2008 08:02:35 AM to a Single
is not supported.
//    Converted the Decimal value '79228162514264337593543950335' to the
Single value 7.922816E+28.
```

Remarks

The return value is the result of invoking the IConvertible.ToSingle method of the underlying type of `value`.

ToSingle(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent single-precision floating-point number.

C#

```
[System.CLSCompliant(false)]
public static float ToSingle (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned 16-bit integers to a Single value.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 12345, UInt16.MaxValue };
float result;

foreach (ushort number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt16 value '0' to the Single value 0.
//    Converted the UInt16 value '121' to the Single value 121.
//    Converted the UInt16 value '12345' to the Single value 12345.
//    Converted the UInt16 value '65535' to the Single value 65535.
```

ToSingle(Int32)

Converts the value of the specified 32-bit signed integer to an equivalent single-precision floating-point number.

C#

```
public static float ToSingle (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Examples

The following example converts each element in an integer array to a Single value.

C#

```
int[] numbers = { Int32.MinValue, -1000, 0, 1000, Int32.MaxValue };
float result;

foreach (int number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int32 value '-2147483648' to the Single value
-2.147484E+09.
//    Converted the Int32 value '-1000' to the Single value -1000.
//    Converted the Int32 value '0' to the Single value 0.
//    Converted the Int32 value '1000' to the Single value 1000.
//    Converted the Int32 value '2147483647' to the Single value
2.147484E+09.
```

ToSingle(Int16)

Converts the value of the specified 16-bit signed integer to an equivalent single-precision floating-point number.

```
C#

public static float ToSingle (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Examples

The following example converts each element in an array of 16-bit integers to a Single value.

```
C#

short[] numbers = { Int16.MinValue, -1032, 0, 192, Int16.MaxValue };
float result;

foreach (short number in numbers)
{
```

```
    result = Convert.ToSingle(number);
    Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                      number.GetType().Name, number,
                      result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int16 value '-32768' to the Single value -32768.
//    Converted the Int16 value '-1032' to the Single value -1032.
//    Converted the Int16 value '0' to the Single value 0.
//    Converted the Int16 value '192' to the Single value 192.
//    Converted the Int16 value '32767' to the Single value 32767.
```

UWP	10.0

ToSingle(Double)

Converts the value of the specified double-precision floating-point number to an equivalent single-precision floating-point number.

C#

```
public static float ToSingle (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

`value` is rounded using rounding to nearest. For example, when rounded to two decimals, the value 2.345 becomes 2.34 and the value 2.355 becomes 2.36.

Examples

The following example converts each element in an array of Double values to a Single value.

C#

```
double[] values = { Double.MinValue, -1.38e10, -1023.299, -12.98,
                    0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
float result;

foreach (double value in values)
{
   result = Convert.ToSingle(value);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     value.GetType().Name, value,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Double value '-1.79769313486232E+308' to the Single
value -Infinity.
//    Converted the Double value '-13800000000' to the Single value
-1.38E+10.
//    Converted the Double value '-1023.299' to the Single value
-1023.299.
//    Converted the Double value '-12.98' to the Single value -12.98.
//    Converted the Double value '0' to the Single value 0.
//   Converted the Double value '9.113E-16' to the Single value 9.113E-
16.
//    Converted the Double value '103.919' to the Single value 103.919.
//    Converted the Double value '17834.191' to the Single value
17834.19.
//    Converted the Double value '1.79769313486232E+308' to the Single
value Infinity.
```

ToSingle(Decimal)

Converts the value of the specified decimal number to an equivalent single-precision floating-point number.

```
C#

public static float ToSingle (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

`value` is rounded using rounding to nearest. For example, when rounded to two decimals, the value 2.345 becomes 2.34 and the value 2.355 becomes 2.36.

Examples

The following example converts each element in an array of Decimal values to a Single value.

C#

```
decimal[] values = { Decimal.MinValue, -1034.23m, -12m, 0m, 147m,
                             199.55m, 9214.16m, Decimal.MaxValue };
float result;

foreach (var value in values)
{
   result = Convert.ToSingle(value);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     value.GetType().Name, value,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Decimal value '-79228162514264337593543950335' to the
Single value -7.9228163E+28.
//    Converted the Decimal value '-1034.23' to the Single value
-1034.23.
//    Converted the Decimal value '-12' to the Single value -12.
//    Converted the Decimal value '0' to the Single value 0.
//    Converted the Decimal value '147' to the Single value 147.
//    Converted the Decimal value '199.55' to the Single value 199.55.
//    Converted the Decimal value '9214.16' to the Single value 9214.16.
//    Converted the Decimal value '79228162514264337593543950335' to the
Single value 7.9228163E+28.

ToSingle(DateTime)

Calling this method always throws InvalidCastException.

C#

```
public static float ToSingle (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

Single

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

Applies to

▼ .NET 9 and other versions

.NET Standard	2.0, 2.1

ToSingle(Char)

Calling this method always throws InvalidCastException.

C#

```
public static float ToSingle (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Single

This conversion is not supported. No value is returned.

Exceptions

InvalidCastException

This conversion is not supported.

.NET Standard	2.0, 2.1

ToSingle(Byte)

Converts the value of the specified 8-bit unsigned integer to the equivalent single-precision floating-point number.

```
C#
```

```
public static float ToSingle (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Examples

The following example converts each element in an array of byte values to a Single value.

C#

```
byte[] numbers = { Byte.MinValue, 10, 100, Byte.MaxValue };
float result;

foreach (byte number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the Byte value 0 to the Single value 0.
//       Converted the Byte value 10 to the Single value 10.
//       Converted the Byte value 100 to the Single value 100.
//       Converted the Byte value 255 to the Single value 255.
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToSingle(Boolean)

Converts the specified Boolean value to the equivalent single-precision floating-point number.

C#

```
public static float ToSingle (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

Single

The number 1 if `value` is `true`; otherwise, 0.

Examples

The following example converts the Boolean values `true` and `false` to Single values.

C#

```
bool[] flags = { true, false };
float result;

foreach (bool flag in flags)
{
   result = Convert.ToSingle(flag);
   Console.WriteLine("Converted {0} to {1}.", flag, result);
}
// The example displays the following output:
```

```
//       Converted True to 1.
//       Converted False to 0.
```

ToSingle(Int64)

Converts the value of the specified 64-bit signed integer to an equivalent single-precision floating-point number.

C#

```
public static float ToSingle (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Single

A single-precision floating-point number that is equivalent to `value`.

Examples

The following example converts each element in an array of long integers to a Single value.

C#

```
long[] numbers = { Int64.MinValue, -903, 0, 172, Int64.MaxValue};
float result;

foreach (long number in numbers)
{
   result = Convert.ToSingle(number);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int64 value '-9223372036854775808' to the Single
value -9.223372E+18.
//    Converted the Int64 value '-903' to the Single value -903.
//    Converted the Int64 value '0' to the Single value 0.
//    Converted the Int64 value '172' to the Single value 172.
//    Converted the Int64 value '9223372036854775807' to the Single value
9.223372E+18.

Convert.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified value to its equivalent string representation.

Overloads

Expand table

ToString(Int32, IFormatProvider)	Converts the value of the specified 32-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int16, Int32)	Converts the value of a 16-bit signed integer to its equivalent string representation in a specified base.
ToString(DateTime, IFormatProvider)	Converts the value of the specified DateTime to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Double, IFormatProvider)	Converts the value of the specified double-precision floating-point number to its equivalent string representation.
ToString(Decimal, IFormatProvider)	Converts the value of the specified decimal number to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int32, Int32)	Converts the value of a 32-bit signed integer to its equivalent string representation in a specified base.
ToString(Int16, IFormatProvider)	Converts the value of the specified 16-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int64, IFormatProvider)	Converts the value of the specified 64-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Single, IFormatProvider)	Converts the value of the specified single-precision floating-point number to its equivalent string representation, using the specified

	culture-specific formatting information.
ToString(Object, IFormatProvider)	Converts the value of the specified object to its equivalent string representation using the specified culture-specific formatting information.
ToString(SByte, IFormatProvider)	Converts the value of the specified 8-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(String, IFormatProvider)	Returns the specified string instance; no actual conversion is performed.
ToString(UInt16, IFormatProvider)	Converts the value of the specified 16-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(UInt32, IFormatProvider)	Converts the value of the specified 32-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(UInt64, IFormatProvider)	Converts the value of the specified 64-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Char, IFormatProvider)	Converts the value of the specified Unicode character to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Int64, Int32)	Converts the value of a 64-bit signed integer to its equivalent string representation in a specified base.
ToString(Byte, Int32)	Converts the value of an 8-bit unsigned integer to its equivalent string representation in a specified base.
ToString(Boolean, IFormatProvider)	Converts the specified Boolean value to its equivalent string representation.
ToString(Byte, IFormatProvider)	Converts the value of the specified 8-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.
ToString(Boolean)	Converts the specified Boolean value to its equivalent string representation.
ToString(Byte)	Converts the value of the specified 8-bit unsigned integer to its equivalent string representation.
ToString(Char)	Converts the value of the specified Unicode character to its equivalent string representation.

ToString(DateTime)	Converts the value of the specified DateTime to its equivalent string representation.
ToString(Double)	Converts the value of the specified double-precision floating-point number to its equivalent string representation.
ToString(Int16)	Converts the value of the specified 16-bit signed integer to its equivalent string representation.
ToString(Int32)	Converts the value of the specified 32-bit signed integer to its equivalent string representation.
ToString(Decimal)	Converts the value of the specified decimal number to its equivalent string representation.
ToString(Object)	Converts the value of the specified object to its equivalent string representation.
ToString(SByte)	Converts the value of the specified 8-bit signed integer to its equivalent string representation.
ToString(Single)	Converts the value of the specified single-precision floating-point number to its equivalent string representation.
ToString(String)	Returns the specified string instance; no actual conversion is performed.
ToString(UInt16)	Converts the value of the specified 16-bit unsigned integer to its equivalent string representation.
ToString(UInt32)	Converts the value of the specified 32-bit unsigned integer to its equivalent string representation.
ToString(UInt64)	Converts the value of the specified 64-bit unsigned integer to its equivalent string representation.
ToString(Int64)	Converts the value of the specified 64-bit signed integer to its equivalent string representation.

ToString(Int32, IFormatProvider)

Converts the value of the specified 32-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (int value, IFormatProvider? provider);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the ToString(Int32, IFormatProvider) method to convert each element in an array of integers to its equivalent string representation. The conversion uses the invariant culture as well as the custom NumberFormatInfo object.

C#

```
int[] numbers = { Int32.MinValue, Int32.MaxValue};
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";

foreach (int number in numbers)
   Console.WriteLine("{0,-12}  -->  {1,12}",
                     Convert.ToString(number,
System.Globalization.CultureInfo.InvariantCulture),
                     Convert.ToString(number, nfi));
// The example displays the following output:
//       -2147483648  -->  ~2147483648
//       2147483647  -->  2147483647
```

Remarks

This implementation is identical to Int32.ToString(IFormatProvider).

Applies to

UWP	10.0

ToString(Int16, Int32)

Converts the value of a 16-bit signed integer to its equivalent string representation in a specified base.

C#

```
public static string ToString (short value, int toBase);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

`toBase` Int32

The base of the return value, which must be 2, 8, 10, or 16.

Returns

String

The string representation of `value` in base `toBase`.

Exceptions

ArgumentException

`toBase` is not 2, 8, 10, or 16.

Examples

The following example converts each element in an array of 16-bit signed integers to its equivalent binary, octal, decimal, and hexadecimal string representations.

C#

```
int[] bases = { 2, 8, 10, 16};
short[] numbers = { Int16.MinValue, -13621, -18, 12, 19142,
Int16.MaxValue };

foreach (int baseValue in bases)
{
   Console.WriteLine("Base {0} conversion:", baseValue);
   foreach (short number in numbers)
   {
      Console.WriteLine("   {0,-8}  -->  0x{1}",
                        number, Convert.ToString(number, baseValue));
   }
}
// The example displays the following output:
//       Base 2 conversion:
//          -32768    -->  0x1000000000000000
//          -13621    -->  0x1100101011001011
//          -18       -->  0x1111111111101110
//          12        -->  0x1100
//          19142     -->  0x100101011000110
//          32767     -->  0x111111111111111
//       Base 8 conversion:
//          -32768    -->  0x100000
//          -13621    -->  0x145313
//          -18       -->  0x177756
//          12        -->  0x14
//          19142     -->  0x45306
//          32767     -->  0x77777
//       Base 10 conversion:
//          -32768    -->  0x-32768
//          -13621    -->  0x-13621
//          -18       -->  0x-18
//          12        -->  0x12
//          19142     -->  0x19142
//          32767     -->  0x32767
//       Base 16 conversion:
//          -32768    -->  0x8000
//          -13621    -->  0xcacb
//          -18       -->  0xffee
//          12        -->  0xc
//          19142     -->  0x4ac6
//          32767     -->  0x7fff
```

Remarks

If `value` is positive and `toBase` is 2, 8, or 16, the returned string uses sign-and-magnitude representation. If `value` is negative and `toBase` is 2, 8, or 16, the returned string uses two's complement representation. This means that the high-order bit of the high-order byte (bit 15) is interpreted as the sign bit. If the ToString(Int16, Int32) method is called to create a string that will later be converted back to a number, a corresponding method that assumes a similar numeric representation should be called to perform the conversion. Such methods include Convert.ToInt16(String, Int32) and Int16.Parse(String, NumberStyles).

ToString(DateTime, IFormatProvider)

Converts the value of the specified DateTime to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (DateTime value, IFormatProvider?
provider);
```

Parameters

`value` DateTime

The date and time value to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example converts a DateTime value to its equivalent string representation in eight different cultures.

C#

```
// Specify the date to be formatted using various cultures.
DateTime tDate = new DateTime(2010, 4, 15, 20, 30, 40, 333);
// Specify the cultures.
string[] cultureNames = { "en-US", "es-AR", "fr-FR", "hi-IN",
                          "ja-JP", "nl-NL", "ru-RU", "ur-PK" };

Console.WriteLine("Converting the date {0}: ",
                  Convert.ToString(tDate,

System.Globalization.CultureInfo.InvariantCulture));

foreach (string cultureName in cultureNames)
{
   System.Globalization.CultureInfo culture = new
System.Globalization.CultureInfo(cultureName);
   string dateString = Convert.ToString(tDate, culture);
   Console.WriteLine("   {0}:  {1,-12}",
                     culture.Name, dateString);
}
// The example displays the following output:
//       Converting the date 04/15/2010 20:30:40:
//          en-US:  4/15/2010 8:30:40 PM
//          es-AR:  15/04/2010 08:30:40 p.m.
//          fr-FR:  15/04/2010 20:30:40
//          hi-IN:  15-04-2010 20:30:40
//          ja-JP:  2010/04/15 20:30:40
//          nl-NL:  15-4-2010 20:30:40
//          ru-RU:  15.04.2010 20:30:40
//          ur-PK:  15/04/2010 8:30:40 PM
```

Remarks

This implementation is identical to DateTime.ToString(IFormatProvider).

ToString(Double, IFormatProvider)

Converts the value of the specified double-precision floating-point number to its equivalent string representation.

C#

```
public static string ToString (double value, IFormatProvider? provider);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an array of Double values to its equivalent string representation in four different cultures.

C#

```
// Define an array of numbers to display.
double[] numbers = { -1.5345e16, -123.4321, 19092.123, 1.1734231911290e16
};
// Define the culture names used to display them.
string[] cultureNames = { "en-US", "fr-FR", "ja-JP", "ru-RU" };

foreach (double number in numbers)
{
   Console.WriteLine("{0}:", Convert.ToString(number,

System.Globalization.CultureInfo.InvariantCulture));
   foreach (string cultureName in cultureNames)
   {
      System.Globalization.CultureInfo culture = new
System.Globalization.CultureInfo(cultureName);
      Console.WriteLine("   {0}: {1,20}",
                        culture.Name, Convert.ToString(number, culture));
   }
   Console.WriteLine();
}
// The example displays the following output:
//    -1.5345E+16:
//       en-US:          -1.5345E+16
//       fr-FR:          -1,5345E+16
//       ja-JP:          -1.5345E+16
//       ru-RU:          -1,5345E+16
//
//    -123.4321:
//       en-US:            -123.4321
//       fr-FR:            -123,4321
//       ja-JP:            -123.4321
//       ru-RU:            -123,4321
//
//    19092.123:
//       en-US:            19092.123
//       fr-FR:            19092,123
//       ja-JP:            19092.123
//       ru-RU:            19092,123
//
//    1.173423191129E+16:
//       en-US:   1.173423191129E+16
//       fr-FR:   1,173423191129E+16
//       ja-JP:   1.173423191129E+16
//       ru-RU:   1,173423191129E+16
```

Remarks

This implementation is identical to Double.ToString(IFormatProvider)

Applies to

ToString(Decimal, IFormatProvider)

Converts the value of the specified decimal number to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (decimal value, IFormatProvider? provider);
```

Parameters

`value` Decimal

The decimal number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an array of Decimal values to its equivalent string representation in four different cultures.

C#

```
// Define an array of numbers to display.
decimal[] numbers = { 1734231911290.16m, -17394.32921m,
                      3193.23m, 98012368321.684m };
// Define the culture names used to display them.
string[] cultureNames = { "en-US", "fr-FR", "ja-JP", "ru-RU" };

foreach (decimal number in numbers)
{
   Console.WriteLine("{0}:", Convert.ToString(number,

System.Globalization.CultureInfo.InvariantCulture));
   foreach (string cultureName in cultureNames)
   {
      System.Globalization.CultureInfo culture = new
System.Globalization.CultureInfo(cultureName);
      Console.WriteLine("   {0}: {1,20}",
                        culture.Name, Convert.ToString(number, culture));
   }
   Console.WriteLine();
}
// The example displays the following output:
//    1734231911290.16:
//       en-US:     1734231911290.16
//       fr-FR:     1734231911290,16
//       ja-JP:     1734231911290.16
//       ru-RU:     1734231911290,16
//
//    -17394.32921:
//       en-US:         -17394.32921
//       fr-FR:         -17394,32921
//       ja-JP:         -17394.32921
//       ru-RU:         -17394,32921
//
//    3193.23:
//       en-US:              3193.23
//       fr-FR:              3193,23
//       ja-JP:              3193.23
//       ru-RU:              3193,23
//
//    98012368321.684:
//       en-US:      98012368321.684
//       fr-FR:      98012368321,684
//       ja-JP:      98012368321.684
//       ru-RU:      98012368321,684
```

ToString(Int32, Int32)

Converts the value of a 32-bit signed integer to its equivalent string representation in a specified base.

C#

```
public static string ToString (int value, int toBase);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

`toBase` Int32

The base of the return value, which must be 2, 8, 10, or 16.

Returns

String

The string representation of `value` in base `toBase`.

Exceptions

ArgumentException

`toBase` is not 2, 8, 10, or 16.

Examples

The following example converts each element in an integer array to its equivalent binary, hexadecimal, decimal, and hexadecimal string representations.

C#

```
int[] bases = { 2, 8, 10, 16};
int[] numbers = { Int32.MinValue, -19327543, -13621, -18, 12,
                              19142, Int32.MaxValue };

foreach (int baseValue in bases)
{
   Console.WriteLine("Base {0} conversion:", baseValue);
   foreach (int number in numbers)
   {
      Console.WriteLine("   {0,-15}  -->  0x{1}",
                        number, Convert.ToString(number, baseValue));
   }
}
// The example displays the following output:
//    Base 2 conversion:
//       -2147483648      -->  0x10000000000000000000000000000000
//       -19327543        -->  0x11111110110110010001010111001001
//       -13621           -->  0x11111111111111111100101011001011
//       -18              -->  0x11111111111111111111111111101110
//       12               -->  0x1100
//       19142            -->  0x100101011000110
//       2147483647       -->  0x11111111111111111111111111111111
//    Base 8 conversion:
//       -2147483648      -->  0x20000000000
//       -19327543        -->  0x37666212711
//       -13621           -->  0x37777745313
//       -18              -->  0x37777777756
//       12               -->  0x14
//       19142            -->  0x45306
//       2147483647       -->  0x17777777777
//    Base 10 conversion:
//       -2147483648      -->  0x-2147483648
//       -19327543        -->  0x-19327543
//       -13621           -->  0x-13621
//       -18              -->  0x-18
//       12               -->  0x12
//       19142            -->  0x19142
//       2147483647       -->  0x2147483647
//    Base 16 conversion:
//       -2147483648      -->  0x80000000
//       -19327543        -->  0xfed915c9
//       -13621           -->  0xffffcacb
//       -18              -->  0xffffffee
//       12               -->  0xc
//       19142            -->  0x4ac6
//       2147483647       -->  0x7fffffff
```

Remarks

If `value` is positive and `toBase` is 2, 8, or 16, the returned string uses sign-and-magnitude representation. If `value` is negative and `toBase` is 2, 8, or 16, the returned string uses two's complement representation. This means that the high-order bit of the highest-order byte (bit 31) is interpreted as the sign bit. If the ToString(Int32, Int32) method is called to create a string that will later be converted back to a number, a corresponding method that assumes a similar numeric representation should be called to perform the conversion. Such methods include Convert.ToInt32(String, Int32) and Int32.Parse(String, NumberStyles).

ToString(Int16, IFormatProvider)

Converts the value of the specified 16-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (short value, IFormatProvider? provider);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the ToString(Int16, IFormatProvider) method to convert each element in an array of 16-bit integers to its equivalent string representation. The conversion uses the invariant culture as well as the custom NumberFormatInfo object.

C#

```
short[] numbers = { Int16.MinValue, Int16.MaxValue};
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";

foreach (short number in numbers)
   Console.WriteLine("{0,-8}  -->  {1,8}",
                     Convert.ToString(number,
System.Globalization.CultureInfo.InvariantCulture),
                     Convert.ToString(number, nfi));
// The example displays the following output:
//       -32768    -->    ~32768
//       32767     -->     32767
```

Remarks

This implementation is identical to Int16.ToString(IFormatProvider).

ToString(Int64, IFormatProvider)

Converts the value of the specified 64-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (long value, IFormatProvider? provider);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the ToString(Int64, IFormatProvider) method to convert each element in a long integer array to its equivalent string representation. The conversion uses the invariant culture as well as the custom NumberFormatInfo object.

C#

```
long[] numbers = { ((long) Int32.MinValue) * 2, ((long) Int32.MaxValue) *
2};
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";

foreach (long number in numbers)
   Console.WriteLine("{0,-12}  -->  {1,12}",
                     Convert.ToString(number,
System.Globalization.CultureInfo.InvariantCulture),
                     Convert.ToString(number, nfi));
// The example displays the following output:
//       -4294967296  -->  ~4294967296
//       4294967294  -->  4294967294
```

Remarks

This implementation is identical to Int64.ToString(IFormatProvider).

ToString(Single, IFormatProvider)

Converts the value of the specified single-precision floating-point number to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (float value, IFormatProvider? provider);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an array of Single values to its equivalent string representation in four different cultures.

C#

```
// Define an array of numbers to display.
float[] numbers = { -1.5345e16f, -123.4321f, 19092.123f,
1.1734231911290e16f };
// Define the culture names used to display them.
string[] cultureNames = { "en-US", "fr-FR", "ja-JP", "ru-RU" };

foreach (float number in numbers)
{
   Console.WriteLine("{0}:", Convert.ToString(number,

System.Globalization.CultureInfo.InvariantCulture));
   foreach (string cultureName in cultureNames)
   {
      System.Globalization.CultureInfo culture = new
System.Globalization.CultureInfo(cultureName);
      Console.WriteLine("   {0}: {1,20}",
                        culture.Name, Convert.ToString(number, culture));
   }
   Console.WriteLine();
}
// The example displays the following output:
//    -1.5345E+16:
//       en-US:          -1.5345E+16
//       fr-FR:          -1,5345E+16
```

```
//       ja-JP:          -1.5345E+16
//       ru-RU:          -1,5345E+16
//
//    -123.4321:
//       en-US:            -123.4321
//       fr-FR:            -123,4321
//       ja-JP:            -123.4321
//       ru-RU:            -123,4321
//
//    19092.123:
//       en-US:            19092.123
//       fr-FR:            19092,123
//       ja-JP:            19092.123
//       ru-RU:            19092,123
//
//    1.173423191129E+16:
//       en-US:   1.173423191129E+16
//       fr-FR:   1,173423191129E+16
//       ja-JP:   1.173423191129E+16
//       ru-RU:   1,173423191129E+16
```

Remarks

This implementation is identical to Single.ToString(IFormatProvider).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ToString(Object, IFormatProvider)

Converts the value of the specified object to its equivalent string representation using the specified culture-specific formatting information.

```
C#
```

```
public static string? ToString (object? value, IFormatProvider?
provider);
```

Parameters

`value` Object

An object that supplies the value to convert, or `null`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`, or Empty if `value` is an object whose value is `null`. If `value` is `null`, the method returns `null`.

Examples

The following example defines a `Temperature` class that overrides the Object.ToString method but does not implement the IConvertible interface. The example illustrates how calls to the Convert.ToString(Object, IFormatProvider) method, in turn, call the `Temperature.ToString` method.

C#

```
using System;

public class Temperature
{
   private decimal m_Temp;

   public Temperature(decimal temperature)
   {
      this.m_Temp = temperature;
   }

   public decimal Celsius
   {
      get { return this.m_Temp; }
   }

   public decimal Kelvin
   {
```

```
        get { return this.m_Temp + 273.15m; }
    }

    public decimal Fahrenheit
    {
        get { return Math.Round((decimal) (this.m_Temp * 9 / 5 + 32), 2); }
    }

    public override string ToString()
    {
        return m_Temp.ToString("N2") + " °C";
    }
}

public class Example
{
    public static void Main()
    {
        Temperature cold = new Temperature(-40);
        Temperature freezing = new Temperature(0);
        Temperature boiling = new Temperature(100);

        Console.WriteLine(Convert.ToString(cold, null));
        Console.WriteLine(Convert.ToString(freezing, null));
        Console.WriteLine(Convert.ToString(boiling, null));
    }
}
// The example dosplays the following output:
//       -40.00 °C
//       0.00 °C
//       100.00 °C
```

The following example defines a `Temperature` class that implements the IFormattable interface but does not implement the IConvertible interface. Its IFormattable.ToString implementation represents the `Temperature` value in Celsius, Fahrenheit, or Kelvin, depending on the format string. The example also defines a `TemperatureProvider` class that implements IFormatProvider and provides a randomly generated format string that is used by the IFormattable implementation of the `Temperature` class.

C#

```
using System;

public class Temperature : IFormattable
{
    private decimal m_Temp;

    public Temperature(decimal temperature)
    {
        this.m_Temp = temperature;
    }
```

```
   public decimal Celsius
   { get { return this.m_Temp; } }

   public decimal Kelvin
   { get { return this.m_Temp + 273.15m; } }

   public decimal Fahrenheit
   {  get { return Math.Round(this.m_Temp * 9m / 5m + 32m, 2); } }

   public override String ToString()
   {
      return ToString("G", null);
   }

   public String ToString(String fmt, IFormatProvider provider)
   {
      TemperatureProvider formatter = null;
      if (provider != null)
         formatter = provider.GetFormat(typeof(TemperatureProvider))
                                       as TemperatureProvider;

      if (String.IsNullOrWhiteSpace(fmt)) {
         if (formatter != null)
            fmt = formatter.Format;
         else
            fmt = "G";
      }

      switch (fmt.ToUpper()) {
         case "G":
         case "C":
            return m_Temp.ToString("N2") + " °C";
         case "F":
            return Fahrenheit.ToString("N2") + " °F";
         case "K":
            return Kelvin.ToString("N2") + " K";
         default:
            throw new FormatException(String.Format("'{0}' is not a valid
format specifier.", fmt));
      }
   }
}

public class TemperatureProvider : IFormatProvider
{
   private String[] fmtStrings = { "C", "G", "F", "K" };
   private Random rnd = new Random();

   public Object GetFormat(Type formatType)
   {
      return this;
   }

   public String Format
```

```
    { get { return fmtStrings[rnd.Next(0, fmtStrings.Length)]; } }
}

public class Example
{
   public static void Main()
   {
      Temperature cold = new Temperature (-40);
      Temperature freezing = new Temperature (0);
      Temperature boiling = new Temperature (100);

      TemperatureProvider tp = new TemperatureProvider();

      Console.WriteLine(Convert.ToString(cold, tp));
      Console.WriteLine(Convert.ToString(freezing, tp));
      Console.WriteLine(Convert.ToString(boiling, tp));
   }
}
// The example displays output like the following:
//       -40.00 °C
//       273.15 K
//       100.00 °C
```

Remarks

If the `value` parameter implements the IConvertible interface, the method calls the IConvertible.ToString(IFormatProvider) implementation of `value`. Otherwise, if the `value` parameter implements the IFormattable interface, the method calls its IFormattable.ToString(String, IFormatProvider) implementation. If `value` implements neither interface, the method calls the `value` parameter's `ToString()` method, and the `provider` parameter is ignored.

The `provider` parameter is used if the `value` parameter implements the IConvertible or IFormattable interface. The most common use of the `provider` parameter is to specify culture-specific information used in the conversion of `value`. For example, if the `value` parameter is a negative decimal number, the `provider` parameter can supply culture-specific information about the notation used for the negative sign and decimal separator. The second example in the next section illustrates a format provider that does not supply culture-sensitive formatting information.

ToString(SByte, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static string ToString (sbyte value, IFormatProvider? provider);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the Convert.ToString(SByte, IFormatProvider) method to convert each element in signed byte array to its equivalent string representation. The conversion uses the invariant culture as well as the custom NumberFormatInfo object.

C#

```
sbyte[] numbers = { SByte.MinValue, -12, 17, SByte.MaxValue};
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";
foreach (sbyte number in numbers)
   Console.WriteLine(Convert.ToString(number, nfi));
// The example displays the following output:
//       ~128
//       ~12
//       17
//       127
```

Remarks

This implementation is identical to SByte.ToString(IFormatProvider).

ToString(String, IFormatProvider)

Returns the specified string instance; no actual conversion is performed.

```
C#

public static string? ToString (string? value, IFormatProvider?
provider);
```

Parameters

`value` String

The string to return.

`provider` IFormatProvider

An object that supplies culture-specific formatting information. This parameter is ignored.

Returns

String

`value` is returned unchanged.

Examples

The following example calls the `ToString` method with a String parameter. The method returns the unmodified String without referencing the IFormatProvider object.

```
C#

// Example of Convert.ToString( non-numeric types, IFormatProvider ).
using System;
using System.Globalization;

// An instance of this class can be passed to methods that require
// an IFormatProvider.
public class DummyProvider : IFormatProvider
{
    // Normally, GetFormat returns an object of the requested type
    // (usually itself) if it is able; otherwise, it returns Nothing.
    public object GetFormat( Type argType )
    {
        // Here, the type of argType is displayed, and GetFormat
        // always returns Nothing.
        Console.Write( "{0,-40}", argType.ToString( ) );
        return null;
```

```
    }
}

class ConvertNonNumericProviderDemo
{
    static void Main( )
    {
        // Create an instance of the IFormatProvider.
        DummyProvider provider = new DummyProvider( );
        string converted;

        // Convert these values using DummyProvider.
        int      Int32A     = -252645135;
        double   DoubleA    = 61680.3855;
        object   ObjDouble  = (object)( -98765.4321 );
        DateTime DayTimeA   = new DateTime( 2001, 9, 11, 13, 45, 0 );

ToString(UInt16, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static string ToString (ushort value, IFormatProvider? provider);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the ToString(UInt16, IFormatProvider) method to convert a 16-bit unsigned integer value to its equivalent string representation. The conversion uses both the invariant culture and the custom NumberFormatInfo object. The output indicates that this formatting information is not used, because by default the "G" format specifier does not include a positive sign with positive values.

C#

```
ushort number = UInt16.MaxValue;
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";

Console.WriteLine("{0,-6}  -->  {1,6}",
                  Convert.ToString(number,
System.Globalization.CultureInfo.InvariantCulture),
                  Convert.ToString(number, nfi));
// The example displays the following output:
//       65535   -->   65535
```

Remarks

This implementation is identical to UInt16.ToString(IFormatProvider).

ToString(UInt32, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static string ToString (uint value, IFormatProvider? provider);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the ToString(UInt32, IFormatProvider) method to convert an unsigned integer value to its equivalent string representation. The conversion uses both the invariant culture and the custom NumberFormatInfo object. The output indicates that this formatting information is not used, because by default the "G" format specifier does not include a positive sign with positive values.

C#

```
uint number = UInt32.MaxValue;
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";

Console.WriteLine("{0,-8}  -->  {1,8}",
                  Convert.ToString(number,
System.Globalization.CultureInfo.InvariantCulture),
                  Convert.ToString(number, nfi));
// The example displays the following output:
//       4294967295  -->  4294967295
```

Remarks

This implementation is identical to UInt32.ToString(IFormatProvider).

ToString(UInt64, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static string ToString (ulong value, IFormatProvider? provider);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example defines a custom NumberFormatInfo class that defines its negative sign as the string "~" and its positive sign as the string "!". It then calls the ToString(UInt64, IFormatProvider) method to convert an unsigned long integer value to its equivalent string representation. The conversion uses both the invariant culture and the custom NumberFormatInfo object. The output indicates that this formatting information is not used, because by default the "G" format specifier does not include a positive sign with positive values.

C#

```
ulong number = UInt64.MaxValue;
System.Globalization.NumberFormatInfo nfi = new
System.Globalization.NumberFormatInfo();
nfi.NegativeSign = "~";
nfi.PositiveSign = "!";

Console.WriteLine("{0,-12}  -->  {1,12}",
                  Convert.ToString(number,
System.Globalization.CultureInfo.InvariantCulture),
                  Convert.ToString(number, nfi));
// The example displays the following output:
//    18446744073709551615  -->  18446744073709551615
```

Remarks

This implementation is identical to UInt64.ToString(IFormatProvider).

ToString(Char, IFormatProvider)

Converts the value of the specified Unicode character to its equivalent string representation, using the specified culture-specific formatting information.

```
C#

public static string ToString (char value, IFormatProvider? provider);
```

Parameters

`value` Char

The Unicode character to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information. This parameter is ignored.

Returns

String

The string representation of `value`.

Examples

The following example converts a Char value to a String with the `ToString` method, using an IFormatProvider object that displays the type of the format provider for which it is called. The example shows that the IFormatProvider object is not referenced.

```
C#

// Example of Convert.ToString( non-numeric types, IFormatProvider ).
using System;
using System.Globalization;

// An instance of this class can be passed to methods that require
// an IFormatProvider.
public class DummyProvider : IFormatProvider
{
    // Normally, GetFormat returns an object of the requested type
    // (usually itself) if it is able; otherwise, it returns Nothing.
    public object GetFormat( Type argType )
    {
        // Here, the type of argType is displayed, and GetFormat
        // always returns Nothing.
```

```
        Console.Write( "{0,-40}", argType.ToString( ) );
        return null;
    }
}

class ConvertNonNumericProviderDemo
{
    static void Main( )
    {
        // Create an instance of the IFormatProvider.
        DummyProvider provider = new DummyProvider( );
        string converted;

        // Convert these values using DummyProvider.
        int      Int32A     = -252645135;
        double   DoubleA    = 61680.3855;
        object   ObjDouble  = (object)( -98765.4321 );
        DateTime DayTimeA   = new DateTime( 2001, 9, 11, 13, 45, 0 );

        bool     BoolA      = true;
        string   StringA    = "Qwerty";
        char     CharA      = '$';
        TimeSpan TSpanA     = new TimeSpan( 0, 18, 0 );
        object   ObjOther   = (object)provider;

        Console.WriteLine( "This example of " +
            "Convert.ToString( non-numeric, IFormatProvider ) \n" +
            "generates the following output. The provider type, " +
            "argument type, \nand argument value are displayed." );

ToString(Int64, Int32)

Converts the value of a 64-bit signed integer to its equivalent string representation in a specified base.

```
C#

public static string ToString (long value, int toBase);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

`toBase` Int32

The base of the return value, which must be 2, 8, 10, or 16.

Returns

String

The string representation of `value` in base `toBase`.

Exceptions

ArgumentException

`toBase` is not 2, 8, 10, or 16.

Examples

The following example converts each element in a long integer array to its equivalent binary, hexadecimal, decimal, and hexadecimal string representations.

```
C#

int[] bases = { 2, 8, 10, 16};
long[] numbers = { Int64.MinValue, -193275430, -13621, -18, 12,
                   1914206117, Int64.MaxValue };

foreach (int baseValue in bases)
{
   Console.WriteLine("Base {0} conversion:", baseValue);
   foreach (long number in numbers)
   {
      Console.WriteLine("   {0,-23}  -->  0x{1}",
                        number, Convert.ToString(number, baseValue));
   }
```

```
}
// The example displays the following output:
//    Base 2 conversion:
//       -9223372036854775808     -->
0x1000000000000000000000000000000000000000000000000000000000000000
//       -193275430               -->
0x11111111111111111111111111111111101000111010110110011101101 0
//       -13621                   -->

//       9223372036854775807      -->  0x9223372036854775807
//    Base 16 conversion:
//       -9223372036854775808     -->  0x8000000000000000
//       -193275430               -->  0xffffffff47ad9da
//       -13621                   -->  0xffffffffffffcacb
//       -18                      -->  0xffffffffffffffee
//       12                       -->  0xc
//       1914206117               -->  0x721877a5
//       9223372036854775807      -->  0x7fffffffffffffff
```

Remarks

If `value` is positive and `toBase` is not 10, the returned string uses sign-and-magnitude representation. If `value` is negative and `toBase` is not 10, the returned string uses two's complement representation. This means that the high-order bit of the highest-order byte (bit 63) is interpreted as the sign bit. If the ToString(Int64, Int32) method is called to create a string that will later be converted back to a number, a corresponding method that assumes a similar numeric representation should be called to perform the conversion. Such methods include Convert.ToInt64(String, Int32) and Int64.Parse(String, NumberStyles).

UWP	10.0

ToString(Byte, Int32)

Converts the value of an 8-bit unsigned integer to its equivalent string representation in a specified base.

C#

```
public static string ToString (byte value, int toBase);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

`toBase` Int32

The base of the return value, which must be 2, 8, 10, or 16.

Returns

String

The string representation of `value` in base `toBase`.

Exceptions

ArgumentException

`toBase` is not 2, 8, 10, or 16.

Examples

The following example converts each element in a byte array to its equivalent binary, hexadecimal, decimal, and hexadecimal string representations.

C#

```
int[] bases = { 2, 8, 10, 16};
byte[] numbers = { Byte.MinValue, 12, 103, Byte.MaxValue};

foreach (int baseValue in bases)
{
   Console.WriteLine("Base {0} conversion:", baseValue);
   foreach (byte number in numbers)
   {
      Console.WriteLine("   {0,-5}  -->  0x{1}",
                        number, Convert.ToString(number, baseValue));
   }
}
// The example displays the following output:
//       Base 2 conversion:
//          0      -->  0x0
//          12     -->  0x1100
//          103    -->  0x1100111
//          255    -->  0x11111111
//       Base 8 conversion:
//          0      -->  0x0
//          12     -->  0x14
//          103    -->  0x147
//          255    -->  0x377
//       Base 10 conversion:
//          0      -->  0x0
//          12     -->  0x12
//          103    -->  0x103
//          255    -->  0x255
//       Base 16 conversion:
//          0      -->  0x0
//          12     -->  0xc
//          103    -->  0x67
//          255    -->  0xff
```

Remarks

If `toBase` does not equal 10, the string that is returned by the Convert.ToString(Byte, Int32) method represents `value` by its magnitude only. If the method is called to create a string that will later be converted back to a number, a corresponding method that assumes a magnitude-only numeric representation should be called to perform the conversion. Such methods include Convert.ToByte(String, Int32) or Byte.Parse(String, NumberStyles).

ToString(Boolean, IFormatProvider)

Converts the specified Boolean value to its equivalent string representation.

C#

```
public static string ToString (bool value, IFormatProvider? provider);
```

Parameters

`value` Boolean

The Boolean value to convert.

`provider` IFormatProvider

An instance of an object. This parameter is ignored.

Returns

String

The string representation of `value`.

Examples

The following example converts a Boolean value to a String with the `ToString` method, using an IFormatProvider object that displays the type of the format

provider for which it is called. The example shows that the IFormatProvider object is not referenced.

C#

```
// Example of Convert.ToString( non-numeric types, IFormatProvider ).
using System;
using System.Globalization;

// An instance of this class can be passed to methods that require
// an IFormatProvider.
public class DummyProvider : IFormatProvider
{
    // Normally, GetFormat returns an object of the requested type
    // (usually itself) if it is able; otherwise, it returns Nothing.
    public object GetFormat( Type argType )
    {
        // Here, the type of argType is displayed, and GetFormat
        // always returns Nothing.
        Console.Write( "{0,-40}", argType.ToString( ) );
        return null;
    }
}

class ConvertNonNumericProviderDemo
{
    static void Main( )
    {
        // Create an instance of the IFormatProvider.
        DummyProvider provider = new DummyProvider( );
        string converted;

        // Convert these values using DummyProvider.
        int      Int32A     = -252645135;
        double   DoubleA    = 61680.3855;
        object   ObjDouble  = (object)( -98765.4321 );
        DateTime DayTimeA   = new DateTime( 2001, 9, 11, 13, 45, 0 );

        bool     BoolA      = true;
        string   StringA    = "Qwerty";
        char     CharA      = '$';
        TimeSpan TSpanA     = new TimeSpan( 0, 18, 0 );
        object   ObjOther   = (object)provider;

        Console.WriteLine( "This example of " +
            "Convert.ToString( non-numeric, IFormatProvider ) \n" +
            "generates the following output. The provider type, " +
            "argument type, \nand argument value are displayed." );
        Console.WriteLine( "\nNote: The IFormatProvider object is " +
            "not called for Boolean, String, \nChar, TimeSpan, " +
            "and non-numeric Object." );

        // The format provider is called for these conversions.
        Console.WriteLine( );
```

```
        converted = Convert.ToString( Int32A, provider );
        Console.WriteLine( "int      {0}", converted );
        converted = Convert.ToString( DoubleA, provider );
        Console.WriteLine( "double   {0}", converted );
        converted = Convert.ToString( ObjDouble, provider );
        Console.WriteLine( "object   {0}", converted );
        converted = Convert.ToString( DayTimeA, provider );
        Console.WriteLine( "DateTime {0}", converted );

        // The format provider is not called for these conversions.
        Console.WriteLine( );
        converted = Convert.ToString( BoolA, provider );
        Console.WriteLine( "bool     {0}", converted );
        converted = Convert.ToString( StringA, provider );
        Console.WriteLine( "string   {0}", converted );
        converted = Convert.ToString( CharA, provider );
        Console.WriteLine( "char     {0}", converted );
        converted = Convert.ToString( TSpanA, provider );
        Console.WriteLine( "TimeSpan {0}", converted );
        converted = Convert.ToString( ObjOther, provider );
        Console.WriteLine( "object   {0}", converted );
    }
}

/*
This example of Convert.ToString( non-numeric, IFormatProvider )
generates the following output. The provider type, argument type,
and argument value are displayed.

Note: The IFormatProvider object is not called for Boolean, String,
Char, TimeSpan, and non-numeric Object.

System.Globalization.NumberFormatInfo   int      -252645135
System.Globalization.NumberFormatInfo   double   61680.3855
System.Globalization.NumberFormatInfo   object   -98765.4321
System.Globalization.DateTimeFormatInfo DateTime 9/11/2001 1:45:00 PM

bool     True
string   Qwerty
char     $
TimeSpan 00:18:00
object   DummyProvider

*/
```

Remarks

This implementation is identical to Boolean.ToString. It returns Boolean.TrueString for `true` values and Boolean.FalseString for `false` values.

ToString(Byte, IFormatProvider)

Converts the value of the specified 8-bit unsigned integer to its equivalent string representation, using the specified culture-specific formatting information.

C#

```
public static string ToString (byte value, IFormatProvider? provider);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an unsigned byte array to its equivalent string representation using the formatting conventions of the en-US and fr-FR cultures. Because the "G" specifier by default outputs only decimal digits in a

byte value's string representation, the `provider` parameter does not affect the formatting of the returned string.

C#

```
byte[] numbers = { 12, 100, Byte.MaxValue };
// Define the culture names used to display them.
string[] cultureNames = { "en-US", "fr-FR" };

foreach (byte number in numbers)
{
   Console.WriteLine("{0}:", Convert.ToString(number,

System.Globalization.CultureInfo.InvariantCulture));
   foreach (string cultureName in cultureNames)
   {
      System.Globalization.CultureInfo culture = new
System.Globalization.CultureInfo(cultureName);
      Console.WriteLine("   {0}: {1,20}",
                        culture.Name, Convert.ToString(number, culture));
   }
   Console.WriteLine();
}
// The example displays the following output:
//       12:
//          en-US:                   12
//          fr-FR:                   12
//
//       100:
//          en-US:                  100
//          fr-FR:                  100
//
//       255:
//          en-US:                  255
//          fr-FR:                  255
```

Remarks

This implementation is identical to Byte.ToString.

Applies to

▼ .NET 9 and other versions

ToString(Boolean)

Converts the specified Boolean value to its equivalent string representation.

C#

```
public static string ToString (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

String

The string representation of `value`.

Examples

The following example illustrates the conversion of a Boolean to a String, using `ToString`. It also illustrates that the string returned by the conversion equals either Boolean.TrueString or Boolean.FalseString.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine(Convert.ToString(falseFlag));
Console.WriteLine(Convert.ToString(falseFlag).Equals(Boolean.FalseString)
);
Console.WriteLine(Convert.ToString(trueFlag));
Console.WriteLine(Convert.ToString(trueFlag).Equals(Boolean.TrueString));
```

```
// The example displays the following output:
//       False
//       True
//       True
//       True
```

Remarks

This implementation is identical to Boolean.ToString. It returns Boolean.TrueString for `true` values and Boolean.FalseString for `false` values.

ToString(Byte)

Converts the value of the specified 8-bit unsigned integer to its equivalent string representation.

C#

```
public static string ToString (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts each value in a Byte array to a string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      byte[] values = { Byte.MinValue, 12, 100, 179, Byte.MaxValue } ;

      foreach (var value in values)
         Console.WriteLine("{0,3} ({1}) --> {2}", value,
                           value.GetType().Name,
                           Convert.ToString(value));
   }
}
// The example displays the following output:
//       0 (Byte) --> 0
//      12 (Byte) --> 12
//     100 (Byte) --> 100
//     179 (Byte) --> 179
//     255 (Byte) --> 255
```

Remarks

This implementation is identical to Byte.ToString().

ToString(Char)

Converts the value of the specified Unicode character to its equivalent string representation.

C#

```
public static string ToString (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts a Char to a String.

C#

```
public void ConvertStringChar(string stringVal) {
    char charVal = 'a';

    // A string must be one character long to convert to char.
    try {
        charVal = System.Convert.ToChar(stringVal);
        System.Console.WriteLine("{0} as a char is {1}",
            stringVal, charVal);
    }
    catch (System.FormatException) {
        System.Console.WriteLine(
            "The string is longer than one character.");
    }
```

```
    catch (System.ArgumentNullException) {
        System.Console.WriteLine("The string is null.");
    }

    // A char to string conversion will always succeed.
    stringVal = System.Convert.ToString(charVal);
    System.Console.WriteLine("The character as a string is {0}",
            stringVal);
}
```

Remarks

This implementation is identical to Char.ToString.

ToString(DateTime)

Converts the value of the specified DateTime to its equivalent string representation.

C#

```
public static string ToString (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an array of a DateTime value to a String value.

C#

```
DateTime[] dates = { new DateTime(2009, 7, 14),
                     new DateTime(1, 1, 1, 18, 32, 0),
                     new DateTime(2009, 2, 12, 7, 16, 0) };
string result;

foreach (DateTime dateValue in dates)
{
   result = Convert.ToString(dateValue);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        dateValue.GetType().Name, dateValue,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the DateTime value 7/14/2009 12:00:00 AM to a String
value 7/14/2009 12:00:00 AM.
//    Converted the DateTime value 1/1/0001 06:32:00 PM to a String value
1/1/0001 06:32:00 PM.
//    Converted the DateTime value 2/12/2009 07:16:00 AM to a String
value 2/12/2009 07:16:00 AM.
```

Remarks

This implementation is identical to DateTime.ToString(). It uses the formatting conventions of the current culture and the "G" format specifier to convert a DateTime value to its string representation.

ToString(Double)

Converts the value of the specified double-precision floating-point number to its equivalent string representation.

C#

```
public static string ToString (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts a Double to a String.

C#

```
public void ConvertDoubleString(double doubleVal) {

    string  stringVal;

    // A conversion from Double to string cannot overflow.
    stringVal = System.Convert.ToString(doubleVal);
    System.Console.WriteLine("{0} as a string is: {1}",
        doubleVal, stringVal);
```

```
    try {
        doubleVal = System.Convert.ToDouble(stringVal);
        System.Console.WriteLine("{0} as a double is: {1}",
            stringVal, doubleVal);
    }
    catch (System.OverflowException) {
        System.Console.WriteLine(
            "Conversion from string-to-double overflowed.");
    }
    catch (System.FormatException) {
        System.Console.WriteLine(
            "The string was not formatted as a double.");
    }
    catch (System.ArgumentException) {
        System.Console.WriteLine(
            "The string pointed to null.");
    }
}
```

Remarks

This implementation is identical to Double.ToString().

ToString(Int16)

Converts the value of the specified 16-bit signed integer to its equivalent string representation.

```
C#
```

```
public static string ToString (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an array of 16-bit integers to its equivalent string representation.

C#

```
short[] numbers = { Int16.MinValue, -138, 0, 19, Int16.MaxValue };
string result;

foreach (short number in numbers)
{
   result = Convert.ToString(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Int16 value -32768 to the String value -32768.
//    Converted the Int16 value -138 to the String value -138.
//    Converted the Int16 value 0 to the String value 0.
//    Converted the Int16 value 19 to the String value 19.
//    Converted the Int16 value 32767 to the String value 32767.
```

Remarks

This implementation is identical to Int16.ToString().

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UWP	10.0

ToString(Int32)

Converts the value of the specified 32-bit signed integer to its equivalent string representation.

C#

```
public static string ToString (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

String

The string representation of `value`.

Examples

The following example compares the ToString(Int32) method with the ToString(UInt16, IFormatProvider) method. It defines a custom NumberFormatInfo object that uses the sting "minus" to represent the negative sign. It converts each element in an integer array to its equivalent string representation using default formatting (the formatting conventions of the current culture) and the custom format provider.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Create a NumberFormatInfo object and set its NegativeSigns
      // property to use for integer formatting.
      NumberFormatInfo provider = new NumberFormatInfo();
      provider.NegativeSign = "minus ";

      int[] values = { -20, 0, 100 };

      Console.WriteLine("{0,-8} --> {1,10} {2,10}\n", "Value",
                        CultureInfo.CurrentCulture.Name,
                        "Custom");
      foreach (int value in values)
         Console.WriteLine("{0,-8} --> {1,10} {2,10}",
                           value, Convert.ToString(value),
                           Convert.ToString(value, provider));
      // The example displays output like the following:
      //       Value    -->      en-US     Custom
      //
      //       -20      -->        -20   minus 20
      //       0        -->          0          0
      //       100      -->        100        100
   }
}
```

Remarks

This implementation is identical to Int32.ToString(). It formats `value` by using the formatting conventions of the current culture.

Applies to

ToString(Decimal)

Converts the value of the specified decimal number to its equivalent string representation.

C#

```
public static string ToString (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts a Decimal to a String.

C#

```
public void ConvertStringDecimal(string stringVal) {
    decimal decimalVal = 0;

    try {
        decimalVal = System.Convert.ToDecimal(stringVal);
        System.Console.WriteLine(
            "The string as a decimal is {0}.", decimalVal);
    }
    catch (System.OverflowException){
        System.Console.WriteLine(
            "The conversion from string to decimal overflowed.");
    }
    catch (System.FormatException) {
        System.Console.WriteLine(
            "The string is not formatted as a decimal.");
```

```
    }
    catch (System.ArgumentNullException) {
        System.Console.WriteLine(
            "The string is null.");
    }

    // Decimal to string conversion will not overflow.
    stringVal = System.Convert.ToString(decimalVal);
    System.Console.WriteLine(
        "The decimal as a string is {0}.", stringVal);
}
```

Remarks

This implementation is identical to Decimal.ToString().

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(Object)

Converts the value of the specified object to its equivalent string representation.

C#

```
public static string? ToString (object? value);
```

Parameters

`value` Object

An object that supplies the value to convert, or `null`.

Returns

String

The string representation of `value`, or Empty if `value` is `null`.

Examples

The following example converts each element in an object array to its equivalent string representation.

C#

```
object[] values = { false, 12.63m, new DateTime(2009, 6, 1, 6, 32, 15),
16.09e-12,
                    'Z', 15.15322, SByte.MinValue, Int32.MaxValue };
string result;

foreach (object value in values)
{
   result = Convert.ToString(value);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Boolean value False to the String value False.
//    Converted the Decimal value 12.63 to the String value 12.63.
//    Converted the DateTime value 6/1/2009 06:32:15 AM to the String
value 6/1/2009 06:32:15 AM.
//    Converted the Double value 1.609E-11 to the String value 1.609E-11.
//    Converted the Char value Z to the String value Z.
//    Converted the Double value 15.15322 to the String value 15.15322.
//    Converted the SByte value -128 to the String value -128.
//    Converted the Int32 value 2147483647 to the String value
2147483647.
```

Remarks

To convert `value` to its string representation, the method tries to call the IConvertible.ToString implementation of `value`. If `value` does not implement the IConvertible interface, the method tries to call the IFormattable.ToString implementation of `value`. If value does not implement the IFormattable interface, the method calls the `ToString` method of the underlying type of `value`.

ToString(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to its equivalent string representation.

C#

```
[System.CLSCompliant(false)]
public static string ToString (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a signed byte array to its equivalent string representation.

C#

```
sbyte[] numbers = { SByte.MinValue, -12, 0, 16, SByte.MaxValue };
string result;

foreach (sbyte number in numbers)
{
   result = Convert.ToString(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the SByte value -128 to the String value -128.
//    Converted the SByte value -12 to the String value -12.
//    Converted the SByte value 0 to the String value 0.
//    Converted the SByte value 16 to the String value 16.
//    Converted the SByte value 127 to the String value 127.
```

Remarks

This implementation is identical to SByte.ToString().

ToString(Single)

Converts the value of the specified single-precision floating-point number to its equivalent string representation.

```
C#

public static string ToString (float value);
```

Parameters

value Single

The single-precision floating-point number to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in an array of Single values to its equivalent string representation.

```
C#

float[] numbers = { Single.MinValue, -1011.351f, -17.45f, -3e-16f,
                    0f, 4.56e-12f, 16.0001f, 10345.1221f, Single.MaxValue
};
string result;

foreach (float number in numbers)
{
   result = Convert.ToString(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Single value -3.402823E+38 to the String value
-3.402823E+38.
//    Converted the Single value -1011.351 to the String value -1011.351.
//    Converted the Single value -17.45 to the String value -17.45.
//    Converted the Single value -3E-16 to the String value -3E-16.
//    Converted the Single value 0 to the String value 0.
//    Converted the Single value 4.56E-12 to the String value 4.56E-12.
//    Converted the Single value 16.0001 to the String value 16.0001.
//    Converted the Single value 10345.12 to the String value 10345.12.
//    Converted the Single value 3.402823E+38 to the String value
3.402823E+38.
```

Remarks

This implementation is identical to Single.ToString().

Applies to

UWP	10.0

ToString(String)

Returns the specified string instance; no actual conversion is performed.

C#

```
public static string? ToString (string? value);
```

Parameters

`value` String

The string to return.

Returns

String

`value` is returned unchanged.

Examples

The following example passes a string to the ToString(String) method and calls the Object.ReferenceEquals method to confirm that the method returns the original

string. The example also calls the String.IsInterned method to ensure that the two strings are not identical because the original string is interned.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String article = "An";
      String noun = "apple";
      String str1 = String.Format("{0} {1}", article, noun);
      String str2 = Convert.ToString(str1);

      Console.WriteLine("str1 is interned: {0}",
                        ! (String.IsInterned(str1) == null));
      Console.WriteLine("str1 and str2 are the same reference: {0}",
                        Object.ReferenceEquals(str1, str2));
   }
}
// The example displays the following output:
//       str1 is interned: False
//       str1 and str2 are the same reference: True
```

.NET Standard	2.0, 2.1

ToString(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to its equivalent string representation.

C#

```
[System.CLSCompliant(false)]
public static string ToString (ushort value);
```

Parameters

value UInt16

The 16-bit unsigned integer to convert.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned 16-bit integer values to its equivalent string representation.

C#

```
ushort[] numbers = { UInt16.MinValue, 103, 1045, UInt16.MaxValue };
string result;

foreach (ushort number in numbers)
{
   result = Convert.ToString(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt16 value 0 to the String value 0.
//    Converted the UInt16 value 103 to the String value 103.
//    Converted the UInt16 value 1045 to the String value 1045.
//    Converted the UInt16 value 65535 to the String value 65535.
```

Remarks

This implementation is identical to UInt16.ToString().

Applies to

ToString(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to its equivalent string representation.

C#

```
[System.CLSCompliant(false)]
public static string ToString (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an unsigned integer array to its equivalent string representation.

C#

```
uint[] numbers = { UInt32.MinValue, 103, 1045, 119543, UInt32.MaxValue };
string result;

foreach (uint number in numbers)
{
   result = Convert.ToString(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt32 value 0 to the String value 0.
//    Converted the UInt32 value 103 to the String value 103.
//    Converted the UInt32 value 1045 to the String value 1045.
//    Converted the UInt32 value 119543 to the String value 119543.
//    Converted the UInt32 value 4294967295 to the String value
4294967295.
```

ToString(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to its equivalent string representation.

C#

```
[System.CLSCompliant(false)]
public static string ToString (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

String

The string representation of `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an unsigned long integer array to its equivalent string representation.

C#

```
ulong[] numbers = { UInt64.MinValue, 1031, 189045, UInt64.MaxValue };
string result;

foreach (ulong number in numbers)
{
   result = Convert.ToString(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
```

```
}
// The example displays the following output:
//    Converted the UInt64 value 0 to the String value 0.
//    Converted the UInt64 value 1031 to the String value 1031.
//    Converted the UInt64 value 189045 to the String value 189045.
//    Converted the UInt64 value 18446744073709551615 to the String value
18446744073709551615.
```

Remarks

This implementation is identical to UInt64.ToString().

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UWP	10.0

ToString(Int64)

Converts the value of the specified 64-bit signed integer to its equivalent string representation.

C#

```
public static string ToString (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

String

The string representation of `value`.

Examples

The following example converts each element in a long integer array to its equivalent string representation.

C#

```
// Create a NumberFormatInfo object and set several of its
// properties that control default integer formatting.
System.Globalization.NumberFormatInfo provider = new
System.Globalization.NumberFormatInfo();
provider.NegativeSign = "minus ";

long[] values = { -200, 0, 1000 };

foreach (long value in values)
   Console.WriteLine("{0,-6}  -->  {1,10}",
                     value, Convert.ToString(value, provider));
// The example displays the following output:
//       -200    -->   minus 200
//       0       -->           0
//       1000    -->        1000
```

Remarks

This implementation is identical to Int64.ToString().

Convert.ToUInt16 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a 16-bit unsigned integer.

Overloads

Expand table

ToUInt16(String)	Converts the specified string representation of a number to an equivalent 16-bit unsigned integer.
ToUInt16(UInt16)	Returns the specified 16-bit unsigned integer; no actual conversion is performed.
ToUInt16(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 16-bit unsigned integer.
ToUInt16(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 16-bit unsigned integer.
ToUInt16(Object, IFormatProvider)	Converts the value of the specified object to a 16-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt16(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 16-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt16(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 16-bit unsigned integer.
ToUInt16(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 16-bit unsigned integer.
ToUInt16(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 16-bit unsigned integer.
ToUInt16(Char)	Converts the value of the specified Unicode character to the equivalent 16-bit unsigned integer.

ToUInt16(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 16-bit unsigned integer.
ToUInt16(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 16-bit unsigned integer.
ToUInt16(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 16-bit unsigned integer.
ToUInt16(Decimal)	Converts the value of the specified decimal number to an equivalent 16-bit unsigned integer.
ToUInt16(DateTime)	Calling this method always throws InvalidCastException.
ToUInt16(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 16-bit unsigned integer.
ToUInt16(Boolean)	Converts the specified Boolean value to the equivalent 16-bit unsigned integer.
ToUInt16(Object)	Converts the value of the specified object to a 16-bit unsigned integer.
ToUInt16(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 16-bit unsigned integer.

ToUInt16(String)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example attempts to convert each element in a numeric string array to a 16-bit unsigned integer.

C#

```
string[] values = { "1603", "1,603", "one", "1.6e03", "1.2e-02",
                    "-1326", "1074122" };
ushort result;

foreach (string value in values)
{
   try {
      result = Convert.ToUInt16(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt16 type.",
value);
```

```
    }
}
// The example displays the following output:
//    Converted the String value '1603' to the UInt16 value 1603.
//    The String value 1,603 is not in a recognizable format.
//    The String value one is not in a recognizable format.
//    The String value 1.6e03 is not in a recognizable format.
//    The String value 1.2e-02 is not in a recognizable format.
//    -1326 is outside the range of the UInt16 type.
//    1074122 is outside the range of the UInt16 type.
```

Remarks

Using the ToUInt16(String) method is equivalent to passing `value` to the UInt16.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the UInt16.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToUInt16(UInt16)

> Important
>
> This API is not CLS-compliant.

Returns the specified 16-bit unsigned integer; no actual conversion is performed.

```
C#

[System.CLSCompliant(false)]
public static ushort ToUInt16 (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to return.

Returns

UInt16

`value` is returned unchanged.

ToUInt16(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than UInt16.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned integers to an unsigned 16-bit integer.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
ushort result;

foreach (uint number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
```

```
    catch (OverflowException) {
       Console.WriteLine("The {0} value {1} is outside the range of the
UInt16 type.",
                         number.GetType().Name, number);
    }
}
// The example displays the following output:
//    Converted the UInt32 value '0' to the UInt16 value 0.
//    Converted the UInt32 value '121' to the UInt16 value 121.
//    Converted the UInt32 value '340' to the UInt16 value 340.
//    The UInt32 value 4294967295 is outside the range of the UInt16
type.
```

ToUInt16(String, Int32)

> Important
>
> This API is not CLS-compliant.

Converts the string representation of a number in a specified base to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

ArgumentOutOfRangeException

`value` is Empty.

FormatException

`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example attempts to interpret each element in an array of numeric strings as a hexadecimal value and to convert it to an unsigned 16-bit integer.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] hexStrings = { "8000", "0FFF", "f000", "00A30", "D",
"-13",
                              "9AC61", "GAD" };
      foreach (string hexString in hexStrings)
      {
         try {
            ushort number = Convert.ToUInt16(hexString, 16);
            Console.WriteLine("Converted '{0}' to {1:N0}.", hexString,
number);
         }
         catch (FormatException) {
            Console.WriteLine("'{0}' is not in the correct format for a
hexadecimal number.",
                              hexString);
         }
         catch (OverflowException) {
            Console.WriteLine("'{0}' is outside the range of an Int16.",
hexString);
         }
         catch (ArgumentException) {
            Console.WriteLine("'{0}' is invalid in base 16.", hexString);
         }
      }
   }
}
// The example displays the following output:
//    Converted '8000' to 32,768.
//    Converted '0FFF' to 4,095.
//    Converted 'f000' to 61,440.
//    Converted '00A30' to 2,608.
//    Converted 'D' to 13.
//    '-13' is invalid in base 16.
//    '9AC61' is outside the range of an Int16.
//    'GAD' is not in the correct format for a hexadecimal number.
```

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the UInt16 data type supports unsigned values only, the ToUInt16(String, Int32) method assumes that `value` is expressed using unsigned binary representation. In other words, all 16 bits are used to represent the numeric value, and a sign bit is absent. As a result, it is possible to write code in which a signed integer value that is out of the range of the UInt16 data type is converted to a UInt16 value without the method throwing an exception. The following example converts Int16.MinValue to its hexadecimal string representation, and then calls the ToUInt16(String, Int32) method. Instead of throwing an exception, the method displays the message, "0x8000 converts to 32768."

C#

```
// Create a hexadecimal value out of range of the UInt16 type.
string value = Convert.ToString(Int16.MinValue, 16);
// Convert it back to a number.
try
{
   UInt16 number = Convert.ToUInt16(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned short
integer.",
                     value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method or operator is using the appropriate numeric representation to interpret a particular value. The following example illustrates one technique for ensuring that the method does not inappropriately use binary representation to interpret a value that uses two's complement representation when converting a hexadecimal string to a UInt16 value. The example determines whether a value represents a signed or an unsigned integer while it is converting that value to its string representation. When the example converts the value to a UInt16 value, it checks whether the original value was a signed integer. If so, and if its high-order bit is set (which indicates that the original value was negative), the method throws an exception.

C#

```
// Create a negative hexadecimal value out of range of the UInt16 type.
short sourceNumber = Int16.MinValue;
bool isSigned =
Math.Sign((short)sourceNumber.GetType().GetField("MinValue").GetValue(nul
l)) == -1;
string value = Convert.ToString(sourceNumber, 16);
UInt16 targetNumber;
try
{
   targetNumber = Convert.ToUInt16(value, 16);
   if (isSigned && ((targetNumber & 0x8000) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned short
integer.", value);
}
// Displays the following to the console:
//    Unable to convert '0x8000' to an unsigned short integer.
```

ToUInt16(Object, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to a 16-bit unsigned integer, using the specified culture-specific formatting information.

```
C#

[System.CLSCompliant(false)]
public static ushort ToUInt16 (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example defines a `HexString` class that implements the IConvertible interface and that is designed to hold the string representation of both 16-bit signed and 16-bit unsigned values. The class includes a `Sign` property that indicates the sign of its hexadecimal value.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;

public enum SignBit { Negative=-1, Zero=0, Positive=1 };

public struct HexString : IConvertible
{
   private SignBit signBit;
   private string hexString;

   public SignBit Sign
   {
      set { signBit = value; }
      get { return signBit; }
   }

   public string Value
   {
      set {
         if (value.Trim().Length > 4)
            throw new ArgumentException("The string representation of a
160bit integer cannot have more than four characters.");
         else if (! Regex.IsMatch(value, "([0-9,A-F]){1,4}",
RegexOptions.IgnoreCase))
            throw new ArgumentException("The hexadecimal representation
of a 16-bit integer contains invalid characters.");
         else
            hexString = value;
      }
      get { return hexString; }
   }

   // IConvertible implementations.
   public TypeCode GetTypeCode() {
      return TypeCode.Object;
   }

   public bool ToBoolean(IFormatProvider provider)
   {
      return signBit != SignBit.Zero;
   }

   public byte ToByte(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
```

```
            throw new OverflowException(String.Format("{0} is out of range
of the Byte type.", Convert.ToInt16(hexString, 16)));
         else
            try {
               return Convert.ToByte(UInt16.Parse(hexString,
NumberStyles.HexNumber));
            }
            catch (OverflowException e) {
               throw new OverflowException(String.Format("{0} is out of
range of the UInt16 type.", Convert.ToUInt16(hexString, 16)), e);
            }
      }

      public char ToChar(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative) {
            throw new OverflowException(String.Format("{0} is out of range
of the Char type.", Convert.ToInt16(hexString, 16)));
         }

         UInt16 codePoint = UInt16.Parse(this.hexString,
NumberStyles.HexNumber);
         return Convert.ToChar(codePoint);
      }

      public DateTime ToDateTime(IFormatProvider provider)
      {
         throw new InvalidCastException("Hexadecimal to DateTime conversion
is not supported.");
      }

      public decimal ToDecimal(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative)
         {
            short hexValue = Int16.Parse(hexString, NumberStyles.HexNumber);
            return Convert.ToDecimal(hexValue);
         }
         else
         {
            ushort hexValue = UInt16.Parse(hexString,
NumberStyles.HexNumber);
            return Convert.ToDecimal(hexValue);
         }
      }

      public double ToDouble(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative)
            return Convert.ToDouble(Int16.Parse(hexString,
NumberStyles.HexNumber));
         else
            return Convert.ToDouble(UInt16.Parse(hexString,
NumberStyles.HexNumber));
      }
```

```
   public short ToInt16(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         return Int16.Parse(hexString, NumberStyles.HexNumber);
      else
         try {
            return Convert.ToInt16(UInt16.Parse(hexString,
NumberStyles.HexNumber));
         }
         catch (OverflowException e) {
            throw new OverflowException(String.Format("{0} is out of

         }
      }

      public UInt16 ToUInt16(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative)
            throw new OverflowException(String.Format("{0} is outside the
range of the UInt16 type.",
                                                        Int16.Parse(hexString,
NumberStyles.HexNumber)));
         else
            return UInt16.Parse(hexString, NumberStyles.HexNumber);
      }

      public UInt32 ToUInt32(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative)
            throw new OverflowException(String.Format("{0} is outside the
range of the UInt32 type.",
                                                        Int16.Parse(hexString,
NumberStyles.HexNumber)));
         else
            return Convert.ToUInt32(hexString, 16);
      }

      public UInt64 ToUInt64(IFormatProvider provider)
      {
         if (signBit == SignBit.Negative)
            throw new OverflowException(String.Format("{0} is outside the
range of the UInt64 type.",
                                                        Int64.Parse(hexString,
NumberStyles.HexNumber)));
         else
            return Convert.ToUInt64(hexString, 16);
      }
   }
```

The following example shows that a call to the ToUInt16(Object, IFormatProvider) method that passes a `HexString` object as a parameter, in turn, calls the IConvertible.ToUInt16 implementation of the `HexString` class.

C#

```
public class Example
{
   public static void Main()
   {
      ushort positiveValue = 32000;
      short negativeValue = -1;

      HexString positiveString = new HexString();
      positiveString.Sign = (SignBit) Math.Sign(positiveValue);
      positiveString.Value = positiveValue.ToString("X2");

      HexString negativeString = new HexString();
      negativeString.Sign = (SignBit) Math.Sign(negativeValue);
      negativeString.Value = negativeValue.ToString("X2");

      try {
         Console.WriteLine("0x{0} converts to {1}.",
positiveString.Value, Convert.ToUInt16(positiveString));
      }
      catch (OverflowException) {
         Console.WriteLine("{0} is outside the range of the UInt16
type.",
                           Int16.Parse(negativeString.Value,
NumberStyles.HexNumber));
      }

      try {
         Console.WriteLine("0x{0} converts to {1}.",
negativeString.Value, Convert.ToUInt16(negativeString));
      }
      catch (OverflowException) {
         Console.WriteLine("{0} is outside the range of the UInt16
type.",
                           Int16.Parse(negativeString.Value,
NumberStyles.HexNumber));
      }
   }
}
// The example displays the following output:
//       0x7D00 converts to 32000.
//       -1 is outside the range of the UInt16 type.
```

Remarks

The return value is the result of invoking the IConvertible.ToUInt16 method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number,

`provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToUInt16(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 16-bit unsigned integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example defines a custom NumberFormatInfo object that recognizes the string "pos" as the positive sign and the string "neg" as the negative sign. It then attempts to convert each element of a numeric string array to an integer using both this provider and the NumberFormatInfo provider for the invariant culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Create a NumberFormatInfo object and set several of its
      // properties that apply to numbers.
      NumberFormatInfo provider = new NumberFormatInfo();
      provider.PositiveSign = "pos ";
      provider.NegativeSign = "neg ";

      // Define an array of strings to convert to UInt16 values.
      string[] values= { "34567", "+34567", "pos 34567", "34567.",
```

```
                          "34567.", "65535", "65535", "65535" };

      foreach (string value in values)
      {
         Console.Write("{0,-12:}  -->  ", value);
         try {
            Console.WriteLine("{0,17}", Convert.ToUInt16(value,
provider));
         }
         catch (FormatException e) {
            Console.WriteLine("{0,17}", e.GetType().Name);
         }
      }
   }
}
// The example displays the following output:
//       34567         -->              34567
//       +34567        -->    FormatException
//       pos 34567     -->              34567
//       34567.        -->    FormatException
//       34567.        -->    FormatException
//       65535         -->              65535
//       65535         -->              65535
//       65535         -->              65535
```

Remarks

The return value is the result of invoking UInt16.Parse on `value`.

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the UInt16.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToUInt16(Single)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified single-precision floating-point number to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

UInt16

`value`, rounded to the nearest 16-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt16.MaxValue.

Examples

The following example converts each element in an array of String values to an unsigned 16-bit integer.

C#

```
float[] numbers = { Single.MinValue, -1.38e10f, -1023.299f, -12.98f,
                    0f, 9.113e-16f, 103.919f, 17834.191f, Single.MaxValue
};
ushort result;

foreach (float number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt16 type.",
number);
   }
}
// The example displays the following output:
//    -3.402823E+38 is outside the range of the UInt16 type.
//    -1.38E+10 is outside the range of the UInt16 type.
//    -1023.299 is outside the range of the UInt16 type.
//    -12.98 is outside the range of the UInt16 type.
//    Converted the Single value '0' to the UInt16 value 0.
//    Converted the Single value '9.113E-16' to the UInt16 value 0.
//    Converted the Single value '103.919' to the UInt16 value 104.
//    Converted the Single value '17834.19' to the UInt16 value 17834.
//    3.402823E+38 is outside the range of the UInt16 type.
```

ToUInt16(UInt64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than UInt16.MaxValue.

Examples

The following example attempts to convert each element in an array of unsigned long integers to an unsigned 16-bit integer.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 340, UInt64.MaxValue };
ushort result;

foreach (ulong number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt64 value '0' to the UInt16 value 0.
//    Converted the UInt64 value '121' to the UInt16 value 121.
//    Converted the UInt64 value '340' to the UInt16 value 340.
//    The UInt64 value 18446744073709551615 is outside the range of the
UInt16 type.

ToUInt16(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example converts each element in a signed byte array to an unsigned 16-bit integer.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
ushort result;

foreach (sbyte number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt16 type.",
number);
   }
}
// The example displays the following output:
//    -128 is outside the range of the UInt16 type.
//    -1 is outside the range of the UInt16 type.
//    Converted the SByte value '0' to the UInt16 value 0.
//    Converted the SByte value '10' to the UInt16 value 10.
//    Converted the SByte value '127' to the UInt16 value 127.
```

ToUInt16(Char)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified Unicode character to the equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

UInt16

The 16-bit unsigned integer equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a character array to an unsigned 16-bit integer.

C#

```
char[] chars = { 'a', 'z', '\x0007', '\x03FF',
                 '\x7FFF', '\xFFFE' };
ushort result;

foreach (char ch in chars)
{
   try {
      result = Convert.ToUInt16(ch);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        ch.GetType().Name, ch,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to convert u+{0} to a UInt16.",
                        ((int)ch).ToString("X4"));
   }
}
// The example displays the following output:
```

```
//    Converted the Char value 'a' to the UInt16 value 97.
//    Converted the Char value 'z' to the UInt16 value 122.
//    Converted the Char value '' to the UInt16 value 7.
//    Converted the Char value '?' to the UInt16 value 1023.
//    Converted the Char value '?' to the UInt16 value 32767.
//    Converted the Char value '?' to the UInt16 value 65534.
```

ToUInt16(Int64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit signed integer to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt16.MaxValue.

Examples

The following example converts each element in a long integer array to an unsigned 16-bit integer.

C#

```
long[] numbers = { Int64.MinValue, -1, 0, 121, 340, Int64.MaxValue };
ushort result;

foreach (long number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int64 value -9223372036854775808 is outside the range of the
UInt16 type.
//    The Int64 value -1 is outside the range of the UInt16 type.
//    Converted the Int64 value '0' to the UInt16 value 0.
//    Converted the Int64 value '121' to the UInt16 value 121.
//    Converted the Int64 value '340' to the UInt16 value 340.
//    The Int64 value 9223372036854775807 is outside the range of the
UInt16 type.
```

ToUInt16(Int32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit signed integer to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt16.MaxValue.

Examples

The following example converts each element in an integer array to an unsigned 16-bit integer.

C#

```
int[] numbers = { Int32.MinValue, -1, 0, 121, 340, Int32.MaxValue };
ushort result;

foreach (int number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int32 value -2147483648 is outside the range of the UInt16
type.
//    The Int32 value -1 is outside the range of the UInt16 type.
//    Converted the Int32 value '0' to the UInt16 value 0.
//    Converted the Int32 value '121' to the UInt16 value 121.
//    Converted the Int32 value '340' to the UInt16 value 340.
//    The Int32 value 2147483647 is outside the range of the UInt16 type.
```

ToUInt16(Int16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit signed integer to the equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in a 16-bit integer array to an unsigned 16-bit integer.

C#

```
short[] numbers = { Int16.MinValue, -132, 0, 121, 16103, Int16.MaxValue
};
ushort result;

foreach (short number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt16 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int16 value -32768 is outside the range of the UInt16 type.
//    The Int16 value -132 is outside the range of the UInt16 type.
//    Converted the Int16 value '0' to the UInt16 value 0.
//    Converted the Int16 value '121' to the UInt16 value 121.
//    Converted the Int16 value '16103' to the UInt16 value 16103.
//    Converted the Int16 value '32767' to the UInt16 value 32767.

ToUInt16(Decimal)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified decimal number to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

UInt16

`value`, rounded to the nearest 16-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt16.MaxValue.

Examples

The following example converts each element in an array of Decimal values to an unsigned 16-bit integer.

C#

```
decimal[] numbers = { Decimal.MinValue, -1034.23m, -12m, 0m, 147m,
                            9214.16m, Decimal.MaxValue };
ushort result;

foreach (decimal number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("{0} is outside the range of the UInt16 type.",
                        number);
   }
}
// The example displays the following output:
//    -79228162514264337593543950335 is outside the range of the UInt16
type.
//    -1034.23 is outside the range of the UInt16 type.
//    -12 is outside the range of the UInt16 type.
//    Converted the Decimal value '0' to the UInt16 value 0.
//    Converted the Decimal value '147' to the UInt16 value 147.
//    Converted the Decimal value '9214.16' to the UInt16 value 9214.
//    79228162514264337593543950335 is outside the range of the UInt16
type.
```

ToUInt16(DateTime)

> Important
>
> This API is not CLS-compliant.

Calling this method always throws InvalidCastException.

```
C#

[System.CLSCompliant(false)]
public static ushort ToUInt16 (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

UInt16

This conversion is not supported. No value is returned.

Attributes CLSCompliantAttribute

Exceptions

InvalidCastException

This conversion is not supported.

ToUInt16(Byte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit unsigned integer to the equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a byte array to an unsigned 16-bit integer.

C#

```
byte[] bytes = { Byte.MinValue, 14, 122, Byte.MaxValue};
ushort result;

foreach (byte byteValue in bytes)
```

```
{
   result = Convert.ToUInt16(byteValue);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     byteValue.GetType().Name, byteValue,
                     result.GetType().Name, result);
}
// The example displays the following output:
//       Converted the Byte value '0' to the UInt16 value 0.
//       Converted the Byte value '14' to the UInt16 value 14.
//       Converted the Byte value '122' to the UInt16 value 122.
//       Converted the Byte value '255' to the UInt16 value 255.
```

ToUInt16(Boolean)

> Important
>
> This API is not CLS-compliant.

Converts the specified Boolean value to the equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

UInt16

The number 1 if `value` is `true`; otherwise, 0.

Attributes CLSCompliantAttribute

Examples

The following example converts the Boolean values `true` and `false` to unsigned 16-bit integers.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToInt16(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToUInt16(trueFlag));
// The example displays the following output:
//       False converts to 0.
//       True converts to 1.
```

UWP	10.0

ToUInt16(Object)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to a 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

UInt16

A 16-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example attempts to convert each element in an object array to an unsigned 16-bit integer.

C#

```
object[] values= { true, -12, 163, 935, 'x', new DateTime(2009, 5, 12),
                   "104", "103.0", "-1", "1.00e2", "One", 1.00e2};
ushort result;

foreach (object value in values)
{
   try {
      result = Convert.ToUInt16(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt16 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to a UInt16 exists for the {0}
value {1}.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value 'True' to the UInt16 value 1.
//    The Int32 value -12 is outside the range of the UInt16 type.
//    Converted the Int32 value '163' to the UInt16 value 163.
//    Converted the Int32 value '935' to the UInt16 value 935.
//    Converted the Char value 'x' to the UInt16 value 120.
//    No conversion to a UInt16 exists for the DateTime value 5/12/2009
12:00:00 AM.
//    Converted the String value '104' to the UInt16 value 104.
//    The String value 103.0 is not in a recognizable format.
//    The String value -1 is outside the range of the UInt16 type.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value '100' to the UInt16 value 100.
```

Remarks

The return value is the result of invoking the IConvertible.ToUInt16 method of the underlying type of `value`.

ToUInt16(Double)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified double-precision floating-point number to an equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

UInt16

`value`, rounded to the nearest 16-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt16.MaxValue.

Examples

The following example converts each element in an array of Double values to an unsigned 16-bit integer.

C#

```
double[] numbers = { Double.MinValue, -1.38e10, -1023.299, -12.98,
                     0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
ushort result;

foreach (double number in numbers)
{
   try {
      result = Convert.ToUInt16(number);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException)
   {
      Console.WriteLine("{0} is outside the range of the UInt16 type.",
number);
   }
}
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the UInt16 type.
//    -13800000000 is outside the range of the UInt16 type.
//    -1023.299 is outside the range of the UInt16 type.
//    -12.98 is outside the range of the UInt16 type.
//    Converted the Double value '0' to the UInt16 value 0.
//    Converted the Double value '9.113E-16' to the UInt16 value 0.
//    Converted the Double value '103.919' to the UInt16 value 104.
```

```
//    Converted the Double value '17834.191' to the UInt16 value 17834.
//    1.79769313486232E+308 is outside the range of the UInt16 type.
```

Convert.ToUInt32 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a 32-bit unsigned integer.

Overloads

Expand table

ToUInt32(String)	Converts the specified string representation of a number to an equivalent 32-bit unsigned integer.
ToUInt32(UInt64)	Converts the value of the specified 64-bit unsigned integer to an equivalent 32-bit unsigned integer.
ToUInt32(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 32-bit unsigned integer.
ToUInt32(UInt32)	Returns the specified 32-bit unsigned integer; no actual conversion is performed.
ToUInt32(DateTime)	Calling this method always throws InvalidCastException.
ToUInt32(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 32-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt32(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 32-bit unsigned integer.
ToUInt32(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 32-bit unsigned integer.
ToUInt32(Object, IFormatProvider)	Converts the value of the specified object to a 32-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt32(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 32-bit unsigned integer.
ToUInt32(Char)	Converts the value of the specified Unicode character to the

	equivalent 32-bit unsigned integer.
ToUInt32(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 32-bit unsigned integer.
ToUInt32(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 32-bit unsigned integer.
ToUInt32(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 32-bit unsigned integer.
ToUInt32(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 32-bit unsigned integer.
ToUInt32(Decimal)	Converts the value of the specified decimal number to an equivalent 32-bit unsigned integer.
ToUInt32(Object)	Converts the value of the specified object to a 32-bit unsigned integer.
ToUInt32(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 32-bit unsigned integer.
ToUInt32(Boolean)	Converts the specified Boolean value to the equivalent 32-bit unsigned integer.

ToUInt32(String)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example interprets the elements in a string array as numeric strings and attempts to convert them to unsigned integers.

C#

```
string[] values = { "One", "1.34e28", "-26.87", "-18", "-6.00",
                    " 0", "137", "1601.9", Int32.MaxValue.ToString() };
uint result;

foreach (string value in values)
{
   try {
      result = Convert.ToUInt32(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value '{1}' is outside the range of the
UInt32 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value '{1}' is not in a recognizable
format.",
```

```
                                value.GetType().Name, value);
    }
}
// The example displays the following output:
//    The String value 'One' is not in a recognizable format.
//    The String value '1.34e28' is not in a recognizable format.
//    The String value '-26.87' is not in a recognizable format.
//    The String value '-18' is outside the range of the UInt32 type.
//    The String value '-6.00' is not in a recognizable format.
//    Converted the String value ' 0' to the UInt32 value 0.
//    Converted the String value '137' to the UInt32 value 137.
//    The String value '1601.9' is not in a recognizable format.
//    Converted the String value '2147483647' to the UInt32 value
2147483647.
```

Remarks

Using the ToUInt32(String) method is equivalent to passing `value` to the UInt32.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the UInt32.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToUInt32(UInt64)

Important

This API is not CLS-compliant.

Converts the value of the specified 64-bit unsigned integer to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (ulong value);
```

Parameters

value UInt64

The 64-bit unsigned integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than UInt32.MaxValue.

Examples

The following example attempts to convert each element in an unsigned long integer array to an unsigned integer value.

C#

```
ulong[] numbers = { UInt64.MinValue, 121, 340, UInt64.MaxValue };
uint result;
foreach (ulong number in numbers)
{
   try {
      result = Convert.ToUInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
```

```
                        result.GetType().Name, result);
    }
    catch (OverflowException) {
       Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        number.GetType().Name, number);
    }
}
// The example displays the following output:
//    Converted the UInt64 value 0 to the UInt32 value 0.
//    Converted the UInt64 value 121 to the UInt32 value 121.
//    Converted the UInt64 value 340 to the UInt32 value 340.
//    The UInt64 value 18446744073709551615 is outside the range of the
UInt32 type.
```

ToUInt32(UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an unsigned 16-bit integer array to an unsigned integer value.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
uint result;
foreach (ushort number in numbers)
{
   result = Convert.ToUInt32(number);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     number.GetType().Name, number,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the UInt16 value 0 to the UInt32 value 0.
//    Converted the UInt16 value 121 to the UInt32 value 121.
//    Converted the UInt16 value 340 to the UInt32 value 340.
//    Converted the UInt16 value 65535 to the UInt32 value 65535.
```

ToUInt32(UInt32)

> Important
>
> This API is not CLS-compliant.

Returns the specified 32-bit unsigned integer; no actual conversion is performed.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to return.

Returns

UInt32

`value` is returned unchanged.

ToUInt32(DateTime)

> Important
>
> This API is not CLS-compliant.

Calling this method always throws InvalidCastException.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

UInt32

This conversion is not supported. No value is returned.

Attributes CLSCompliantAttribute

Exceptions

InvalidCastException

This conversion is not supported.

.NET Standard	2.0, 2.1

ToUInt32(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 32-bit unsigned integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example defines a custom NumberFormatInfo object that recognizes the string "pos" as the positive sign and the string "neg" as the negative sign. It then attempts to convert each element of a numeric string array to an integer using both this provider and the NumberFormatInfo provider for the invariant culture.

C#

```
using System;
using System.Globalization;

public class Class1
{
   public static void Main()
   {
      // Create a NumberFormatInfo object and set several of its
      // properties that apply to numbers.
      NumberFormatInfo provider = new NumberFormatInfo();
      provider.PositiveSign = "pos ";
      provider.NegativeSign = "neg ";

      // Define an array of numeric strings.
      string[] values = { "123456789", "+123456789", "pos 123456789",
                          "123456789.", "123,456,789",  "4294967295",
                          "4294967296", "-1", "neg 1" };

      foreach (string value in values)
      {
         Console.Write("{0,-20} -->", value);
         try {
            Console.WriteLine("{0,20}", Convert.ToUInt32(value,
provider));
         }
         catch (FormatException) {
            Console.WriteLine("{0,20}", "Bad Format");
         }
         catch (OverflowException) {
            Console.WriteLine("{0,20}", "Numeric Overflow");
```

```
            }
        }
    }
}
// The example displays the following output:
//       123456789            -->           123456789
//       +123456789           -->          Bad Format
//       pos 123456789        -->           123456789
//       123456789.           -->          Bad Format
//       123,456,789          -->          Bad Format
//       4294967295           -->          4294967295
//       4294967296           -->    Numeric Overflow
//       -1                   -->          Bad Format
//       neg 1                -->    Numeric Overflow
```

Remarks

The return value is the result of invoking UInt32.Parse on `value`.

`provider` is an IFormatProvider instance that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the UInt32.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToUInt32(String, Int32)

> Important
>
> This API is not CLS-compliant.

Converts the string representation of a number in a specified base to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

ArgumentOutOfRangeException

`value` is Empty.

FormatException

`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example attempts to interpret each element in an array of numeric strings as a hexadecimal value and to convert it to an unsigned integer.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] hexStrings = { "80000000", "0FFFFFFF", "F0000000",
"00A3000", "D",
                              "-13", "9AC61", "GAD", "FFFFFFFFFF" };

      foreach (string hexString in hexStrings)
      {
         Console.Write("{0,-12}  -->  ", hexString);
         try {
            uint number = Convert.ToUInt32(hexString, 16);
            Console.WriteLine("{0,18:N0}", number);
         }
         catch (FormatException) {
            Console.WriteLine("{0,18}", "Bad Format");
         }
         catch (OverflowException)
         {
            Console.WriteLine("{0,18}", "Numeric Overflow");
         }
         catch (ArgumentException) {
            Console.WriteLine("{0,18}", "Invalid in Base 16");
```

```
            }
        }
    }
}
// The example displays the following output:
//       80000000      -->       2,147,483,648
//       0FFFFFFF      -->         268,435,455
//       F0000000      -->       4,026,531,840
//       00A3000       -->             667,648
//       D             -->                  13
//       -13           -->  Invalid in Base 16
//       9AC61         -->             633,953
//       GAD           -->          Bad Format
//       FFFFFFFFFF    -->    Numeric Overflow
```

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the UInt32 data type supports unsigned values only, the ToUInt32(String, Int32) method assumes that `value` is expressed using unsigned binary representation. In other words, all 32 bits are used to represent the numeric value, and a sign bit is absent. As a result, it is possible to write code in which a signed integer value that is out of the range of the UInt32 data type is converted to a UInt32 value without the method throwing an exception. The following example converts MinValue to its hexadecimal string representation, and then calls the ToUInt32(String, Int32) method. Instead of throwing an exception, the method displays the message, "0x80000000 converts to 2147483648."

C#

```
// Create a hexadecimal value out of range of the UInt32 type.
string value = Convert.ToString(Int32.MinValue, 16);
// Convert it back to a number.
try
{
   UInt32 number = Convert.ToUInt32(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned integer.",
                     value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method or operator is using the appropriate numeric representation to interpret a particular value. The following example illustrates one technique for ensuring that the method does not inappropriately use binary representation to interpret a value that uses two's complement representation when converting a hexadecimal string to a UInt32 value. The example determines whether a value represents a signed or an unsigned integer while it is converting that value to its string representation. When the example converts the value to a UInt32 value, it checks whether the original value was a signed integer. If so, and if its high-order bit is set (which indicates that the original value was negative), the method throws an exception.

C#

```
// Create a negative hexadecimal value out of range of the UInt32 type.
int sourceNumber = Int32.MinValue;
bool isSigned =
Math.Sign((int)sourceNumber.GetType().GetField("MinValue").GetValue(null)
) == -1;
string value = Convert.ToString(sourceNumber, 16);
UInt32 targetNumber;
try
{
   targetNumber = Convert.ToUInt32(value, 16);
   if (isSigned && ((targetNumber & 0x80000000) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned integer.",
                     value);
}
// Displays the following to the console:
//    Unable to convert '0x80000000' to an unsigned integer.
```

ToUInt32(Single)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified single-precision floating-point number to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

UInt32

`value`, rounded to the nearest 32-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt32.MaxValue.

Examples

The following example attempts to convert each element in an array of Single values to an unsigned integer.

C#

```
float[] values= { Single.MinValue, -1.38e10f, -1023.299f, -12.98f,
                  0f, 9.113e-16f, 103.919f, 17834.191f, Single.MaxValue
};
uint result;

foreach (float value in values)
{
   try {
      result = Convert.ToUInt32(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",

ToUInt32(Object, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to a 32-bit unsigned integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example defines a `HexString` class that implements the IConvertible interface and that is designed to hold the string representation of both 32-bit signed and 32-bit unsigned values. The class includes a `Sign` property that indicates the sign of its hexadecimal value.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;

public enum SignBit { Negative=-1, Zero=0, Positive=1 };

public struct HexString : IConvertible
{
   private SignBit signBit;
   private string hexString;

   public SignBit Sign
   {
      set { signBit = value; }
      get { return signBit; }
   }

   public string Value
   {
```

```
      set {
         if (value.Trim().Length > 8)
            throw new ArgumentException("The string representation of a
32-bit integer cannot have more than 8 characters.");
         else if (! Regex.IsMatch(value, "([0-9,A-F]){1,8}",
RegexOptions.IgnoreCase))
            throw new ArgumentException("The hexadecimal representation
of a 32-bit integer contains invalid characters.");
         else
            hexString = value;
      }
      get { return hexString; }
   }

   // IConvertible implementations.
   public TypeCode GetTypeCode()
   {
      return TypeCode.Object;
   }

   public bool ToBoolean(IFormatProvider provider)
   {
      return signBit != SignBit.Zero;
   }

                case TypeCode.UInt64:
                    return this.ToUInt64(null);
                default:
                    throw new InvalidCastException(String.Format("Conversion to
{0} is not supported.", conversionType.Name));
            }
        }
```

```
   public ushort ToUInt16(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt16 type.",
                                                     Int32.Parse(hexString,
NumberStyles.HexNumber)));
      else
         try {
            return Convert.ToUInt16(UInt32.Parse(hexString,
NumberStyles.HexNumber));
         }
         catch (OverflowException e) {
            throw new OverflowException(String.Format("{0} is out of
range of the UInt16 type.", Convert.ToUInt32(hexString, 16)), e);
         }
   }

   public uint ToUInt32(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt32 type.",
                                                     Int32.Parse(hexString,
NumberStyles.HexNumber)));
      else
         return Convert.ToUInt32(hexString, 16);
   }

   public ulong ToUInt64(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt64 type.",
                                                     Int32.Parse(hexString,
NumberStyles.HexNumber)));
      else
         return Convert.ToUInt64(hexString, 16);
   }
}
```

The following example shows that a call to the ToUInt32(Object, IFormatProvider) method that passes a `HexString` object as a parameter, in turn, calls the IConvertible.ToUInt32 implementation of the `HexString` class.

C#

```
public class Example
{
   public static void Main()
   {
      uint positiveValue = 320000000;
```

```
      int negativeValue = -1;

      HexString positiveString = new HexString();
      positiveString.Sign = (SignBit) Math.Sign(positiveValue);
      positiveString.Value = positiveValue.ToString("X4");

      HexString negativeString = new HexString();
      negativeString.Sign = (SignBit) Math.Sign(negativeValue);
      negativeString.Value = negativeValue.ToString("X4");

      try {
         Console.WriteLine("0x{0} converts to {1}.",
positiveString.Value, Convert.ToUInt32(positiveString));
      }
      catch (OverflowException) {
         Console.WriteLine("{0} is outside the range of the UInt32
type.",
                           Int32.Parse(positiveString.Value,
NumberStyles.HexNumber));
      }

      try {
         Console.WriteLine("0x{0} converts to {1}.",
negativeString.Value, Convert.ToUInt32(negativeString));
      }
      catch (OverflowException) {
         Console.WriteLine("{0} is outside the range of the UInt32
type.",
                           Int32.Parse(negativeString.Value,
NumberStyles.HexNumber));
      }
   }
}
// The example dosplays the following output:
//       0x1312D000 converts to 320000000.
//       -1 is outside the range of the UInt32 type.
```

Remarks

The return value is the result of invoking the IConvertible.ToUInt32 method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number, `provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToUInt32(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in a signed byte array to an unsigned integer.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
uint result;

foreach (sbyte number in numbers)
{
   try {
      result = Convert.ToUInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The SByte value -128 is outside the range of the UInt32 type.
//    The SByte value -1 is outside the range of the UInt32 type.
//    Converted the SByte value 0 to the UInt32 value 0.
//    Converted the SByte value 10 to the UInt32 value 10.
//    Converted the SByte value 127 to the UInt32 value 127.
```

ToUInt32(Char)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified Unicode character to the equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a character array to an unsigned integer.

C#

```
char[] chars = { 'a', 'z', '\u0007', '\u03FF',
                 '\u7FFF', '\uFFFE' };
```

```
uint result;

foreach (char ch in chars)
{
   result = Convert.ToUInt32(ch);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     ch.GetType().Name, ch,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Char value 'a' to the UInt32 value 97.
//    Converted the Char value 'z' to the UInt32 value 122.
//    Converted the Char value '•' to the UInt32 value 7.
//    Converted the Char value 'Ɔ' to the UInt32 value 1023.
//    Converted the Char value '翻' to the UInt32 value 32767.
//    Converted the Char value '￾' to the UInt32 value 65534.
```

ToUInt32(Int64)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 64-bit signed integer to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt32.MaxValue.

Examples

The following example attempts to convert each element in a long integer array to an unsigned integer.

C#

```
long[] numbers = { Int64.MinValue, -1, 0, 121, 340, Int64.MaxValue };
uint result;
foreach (long number in numbers)
{
   try {
      result = Convert.ToUInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        number.GetType().Name, number);
   }
}
```

```
// The example displays the following output:
//    The Int64 value -9223372036854775808 is outside the range of the
UInt32 type.
//    The Int64 value -1 is outside the range of the UInt32 type.
//    Converted the Int64 value 0 to the UInt32 value 0.
//    Converted the Int64 value 121 to the UInt32 value 121.
//    Converted the Int64 value 340 to the UInt32 value 340.
//    The Int64 value 9223372036854775807 is outside the range of the
UInt32 type.
```

ToUInt32(Int32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit signed integer to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in an integer array to an unsigned integer.

C#

```
int[] numbers = { Int32.MinValue, -1203, 0, 121, 1340, Int32.MaxValue };
uint result;
foreach (int number in numbers)
{
   try {
      result = Convert.ToUInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int32 value -2147483648 is outside the range of the UInt32
type.
//    The Int32 value -1203 is outside the range of the UInt32 type.
//    Converted the Int32 value 0 to the UInt32 value 0.
//    Converted the Int32 value 121 to the UInt32 value 121.
//    Converted the Int32 value 1340 to the UInt32 value 1340.
//    Converted the Int32 value 2147483647 to the UInt32 value
2147483647.
```

ToUInt32(Int16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit signed integer to the equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in a 16-bit integer array to an unsigned integer.

C#

```
short[] numbers= { Int16.MinValue, -1, 0, 121, 340, Int16.MaxValue };
uint result;

foreach (short number in numbers)
{
   try {
      result = Convert.ToUInt32(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                           number.GetType().Name, number,
                           result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int16 value -32768 is outside the range of the UInt32 type.
//    The Int16 value -1 is outside the range of the UInt32 type.
//    Converted the Int16 value 0 to the UInt32 value 0.
//    Converted the Int16 value 121 to the UInt32 value 121.
//    Converted the Int16 value 340 to the UInt32 value 340.
//    Converted the Int16 value 32767 to the UInt32 value 32767.
```

ToUInt32(Double)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified double-precision floating-point number to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

UInt32

`value`, rounded to the nearest 32-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt32.MaxValue.

Examples

The following example attempts to convert each element in an array of Double values to an unsigned integer.

C#

```
double[] values= { Double.MinValue, -1.38e10, -1023.299, -12.98,
                   0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
uint result;

foreach (double value in values)
{
   try {
      result = Convert.ToUInt32(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    The Double value -1.79769313486232E+308 is outside the range of the
UInt32 type.
//    The Double value -13800000000 is outside the range of the UInt32
type.
//    The Double value -1023.299 is outside the range of the UInt32 type.
//    The Double value -12.98 is outside the range of the UInt32 type.
//    Converted the Double value '0' to the UInt32 value 0.
//    Converted the Double value '9.113E-16' to the UInt32 value 0.
//    Converted the Double value '103.919' to the UInt32 value 104.
//    Converted the Double value '17834.191' to the UInt32 value 17834.
//    The Double value 1.79769313486232E+308 is outside the range of the
UInt32 type.
```

ToUInt32(Decimal)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified decimal number to an equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

UInt32

`value`, rounded to the nearest 32-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt32.MaxValue.

Examples

The following example attempts to convert each element in an array of Decimal values to an unsigned integer.

C#

```
decimal[] values= { Decimal.MinValue, -1034.23m, -12m, 0m, 147m,
                    199.55m, 9214.16m, Decimal.MaxValue };
uint result;

foreach (decimal value in values)
{
   try {
      result = Convert.ToUInt32(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt32 type.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    The Decimal value -79228162514264337593543950335 is outside the
range of the UInt32 type.
//    The Decimal value -1034.23 is outside the range of the UInt32 type.
//    The Decimal value -12 is outside the range of the UInt32 type.
//    Converted the Decimal value '0' to the UInt32 value 0.
//    Converted the Decimal value '147' to the UInt32 value 147.
//    Converted the Decimal value '199.55' to the UInt32 value 200.
//    Converted the Decimal value '9214.16' to the UInt32 value 9214.
//    The Decimal value 79228162514264337593543950335 is outside the
range of the UInt32 type.
```

ToUInt32(Object)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to a 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example attempts to convert each element in an object array to an unsigned integer.

C#

```
object[] values = { true, -12, 163, 935, 'x', new DateTime(2009, 5, 12),
                    "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2, 16.3e42};
uint result;

foreach (object value in values)
{
   try {
      result = Convert.ToUInt32(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value '{1}' is outside the range of the
UInt32 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to a UInt32 exists for the {0}
value '{1}'.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value True to the UInt32 value 1.
```

```
//    The Int32 value '-12' is outside the range of the UInt32 type.
//    Converted the Int32 value 163 to the UInt32 value 163.
//    Converted the Int32 value 935 to the UInt32 value 935.
//    Converted the Char value x to the UInt32 value 120.
//    No conversion to a UInt32 exists for the DateTime value '5/12/2009
12:00:00 AM'.
//    Converted the String value 104 to the UInt32 value 104.
//    The String value 103.0 is not in a recognizable format.
//    The String value '-1' is outside the range of the UInt32 type.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the UInt32 value 100.
//    The Double value '1.63E+43' is outside the range of the UInt32
type.
```

Remarks

The return value is the result of invoking the IConvertible.ToUInt32 method of the underlying type of `value`.

ToUInt32(Byte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit unsigned integer to the equivalent 32-bit unsigned integer.

```C#
[System.CLSCompliant(false)]
public static uint ToUInt32 (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

UInt32

A 32-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a byte array to an unsigned integer.

```C#
byte[] bytes = { Byte.MinValue, 14, 122, Byte.MaxValue};
uint result;

foreach (byte byteValue in bytes)
{
   result = Convert.ToUInt32(byteValue);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     byteValue.GetType().Name, byteValue,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Byte value 0 to the UInt32 value 0.
//    Converted the Byte value 14 to the UInt32 value 14.
//    Converted the Byte value 122 to the UInt32 value 122.
//    Converted the Byte value 255 to the UInt32 value 255.
```

ToUInt32(Boolean)

> Important
>
> This API is not CLS-compliant.

Converts the specified Boolean value to the equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

UInt32

The number 1 if `value` is `true`; otherwise, 0.

Attributes CLSCompliantAttribute

Examples

The following example converts the Boolean values `true` and `false` to unsigned integers.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToUInt32(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToUInt32(trueFlag));
// The example displays the following output:
//       False converts to 0.
//       True converts to 1.
```

Convert.ToUInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified value to a 64-bit unsigned integer.

Overloads

Expand table

ToUInt64(String)	Converts the specified string representation of a number to an equivalent 64-bit unsigned integer.
ToUInt64(UInt16)	Converts the value of the specified 16-bit unsigned integer to the equivalent 64-bit unsigned integer.
ToUInt64(UInt32)	Converts the value of the specified 32-bit unsigned integer to an equivalent 64-bit unsigned integer.
ToUInt64(String, IFormatProvider)	Converts the specified string representation of a number to an equivalent 64-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt64(Object, IFormatProvider)	Converts the value of the specified object to a 64-bit unsigned integer, using the specified culture-specific formatting information.
ToUInt64(Single)	Converts the value of the specified single-precision floating-point number to an equivalent 64-bit unsigned integer.
ToUInt64(String, Int32)	Converts the string representation of a number in a specified base to an equivalent 64-bit unsigned integer.
ToUInt64(UInt64)	Returns the specified 64-bit unsigned integer; no actual conversion is performed.
ToUInt64(SByte)	Converts the value of the specified 8-bit signed integer to the equivalent 64-bit unsigned integer.
ToUInt64(Int16)	Converts the value of the specified 16-bit signed integer to the equivalent 64-bit unsigned integer.

ToUInt64(Int64)	Converts the value of the specified 64-bit signed integer to an equivalent 64-bit unsigned integer.
ToUInt64(Int32)	Converts the value of the specified 32-bit signed integer to an equivalent 64-bit unsigned integer.
ToUInt64(Double)	Converts the value of the specified double-precision floating-point number to an equivalent 64-bit unsigned integer.
ToUInt64(Decimal)	Converts the value of the specified decimal number to an equivalent 64-bit unsigned integer.
ToUInt64(DateTime)	Calling this method always throws InvalidCastException.
ToUInt64(Char)	Converts the value of the specified Unicode character to the equivalent 64-bit unsigned integer.
ToUInt64(Byte)	Converts the value of the specified 8-bit unsigned integer to the equivalent 64-bit unsigned integer.
ToUInt64(Boolean)	Converts the specified Boolean value to the equivalent 64-bit unsigned integer.
ToUInt64(Object)	Converts the value of the specified object to a 64-bit unsigned integer.

ToUInt64(String)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (string? value);
```

Parameters

`value` String

A string that contains the number to convert.

Returns

UInt64

A 64-bit signed integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example interprets the elements of a string array as numeric strings and attempts to convert them to unsigned long integers.

C#

```
string[] values = { "One", "1.34e28", "-26.87", "-18", "-6.00",
                    " 0", "137", "1601.9", Int32.MaxValue.ToString() };
ulong result;

foreach (string value in values)
{
   try {
      result = Convert.ToUInt64(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt64 type.",
value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value '{1}' is not in a recognizable
format.",
                        value.GetType().Name, value);
```

```
    }
}
// The example displays the following output:
//    The String value 'One' is not in a recognizable format.
//    The String value '1.34e28' is not in a recognizable format.
//    The String value '-26.87' is not in a recognizable format.
//    -18 is outside the range of the UInt64 type.
//    The String value '-6.00' is not in a recognizable format.
//    Converted the String value ' 0' to the UInt64 value 0.
//    Converted the String value '137' to the UInt64 value 137.
//    The String value '1601.9' is not in a recognizable format.
//    Converted the String value '2147483647' to the UInt64 value
2147483647.
```

Remarks

Using the ToInt64(String) method is equivalent to passing `value` to the Int64.Parse(String) method. `value` is interpreted by using the formatting conventions of the current culture.

If you prefer not to handle an exception if the conversion fails, you can call the UInt64.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToUInt64(UInt16)

Important

This API is not CLS-compliant.

Converts the value of the specified 16-bit unsigned integer to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (ushort value);
```

Parameters

value UInt16

The 16-bit unsigned integer to convert.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an array of unsigned 16-bit integers to an unsigned long integer.

C#

```
ushort[] numbers = { UInt16.MinValue, 121, 340, UInt16.MaxValue };
ulong result;

foreach (ushort number in numbers)
{
   try {
      result = Convert.ToUInt64(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt64 type.",
```

```
                        number.GetType().Name, number);
    }
}
// The example displays the following output:
//    Converted the UInt16 value 0 to the UInt64 value 0.
//    Converted the UInt16 value 121 to the UInt64 value 121.
//    Converted the UInt16 value 340 to the UInt64 value 340.
//    Converted the UInt16 value 65535 to the UInt64 value 65535.
```

ToUInt64(UInt32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit unsigned integer to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in an unsigned integer array to an unsigned long integer.

C#

```
uint[] numbers = { UInt32.MinValue, 121, 340, UInt32.MaxValue };
ulong result;

foreach (uint number in numbers)
{
   try {
      result = Convert.ToUInt64(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt64 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    Converted the UInt32 value 0 to the UInt64 value 0.
//    Converted the UInt32 value 121 to the UInt64 value 121.
//    Converted the UInt32 value 340 to the UInt64 value 340.
//    Converted the UInt32 value 4294967295 to the UInt64 value
4294967295.
```

ToUInt64(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the specified string representation of a number to an equivalent 64-bit unsigned integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (string? value, IFormatProvider? provider);
```

Parameters

`value` String

A string that contains the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` does not consist of an optional sign followed by a sequence of digits (0 through 9).

OverflowException

`value` represents a number that is less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example defines a custom NumberFormatInfo object that recognizes the string "pos" as the positive sign and the string "neg" as the negative sign. It then attempts to convert each element of a numeric string array to an unsigned long integer. The conversion uses both the custom provider and the NumberFormatInfo provider for the invariant culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Create a NumberFormatInfo object and set several properties.
      NumberFormatInfo provider = new NumberFormatInfo();
      provider.PositiveSign = "pos ";
      provider.NegativeSign = "neg ";

      // Define an array of numeric strings.
      string[] values = { "123456789012", "+123456789012",
                          "pos 123456789012", "123456789012.",
                          "123,456,789,012", "18446744073709551615",
                          "18446744073709551616", "neg 1", "-1" };
      //  Convert the strings using the format provider.
      foreach (string value in values)
      {
         Console.Write("{0,-20}  -->  ", value);
         try {
            Console.WriteLine("{0,20}", Convert.ToUInt64(value,
provider));
         }
         catch (FormatException) {
            Console.WriteLine("{0,20}", "Invalid Format");
         }
         catch (OverflowException) {
            Console.WriteLine("{0,20}", "Numeric Overflow");
         }
```

```
        }
    }
}
// The example displays the following output:
//    123456789012          -->          123456789012
//    +123456789012         -->        Invalid Format
//    pos 123456789012      -->          123456789012
//    123456789012.         -->        Invalid Format
//    123,456,789,012       -->        Invalid Format
//    18446744073709551615  --> 18446744073709551615
//    18446744073709551616  -->      Numeric Overflow
//    neg 1                 -->      Numeric Overflow
//    -1                    -->        Invalid Format
```

Remarks

The return value is the result of invoking UInt64.Parse on `value`.

`provider` is an IFormatProvider implementation that obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `value`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

If you prefer not to handle an exception if the conversion fails, you can call the UInt64.TryParse method instead. It returns a Boolean value that indicates whether the conversion succeeded or failed.

ToUInt64(Object, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to a 64-bit unsigned integer, using the specified culture-specific formatting information.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (object? value, IFormatProvider? provider);
```

Parameters

`value` Object

An object that implements the IConvertible interface.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example defines a `HexString` class that implements the IConvertible interface and that is designed to hold the string representation of both 64-bit signed and 64-bit unsigned values. The class includes a `Sign` property that indicates the sign of its hexadecimal value.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;

public enum SignBit { Negative=-1, Zero=0, Positive=1 };

public struct HexString : IConvertible
{
   private SignBit signBit;
   private string hexString;

   public SignBit Sign
   {
      set { signBit = value; }
      get { return signBit; }
   }

   public string Value
   {
      set
      {
         if (value.Trim().Length > 16)
            throw new ArgumentException("The hexadecimal representation
of a 64-bit integer cannot have more than 16 characters.");
         else if (! Regex.IsMatch(value, "([0-9,A-F]){1,8}",
RegexOptions.IgnoreCase))
            throw new ArgumentException("The hexadecimal representation
of a 64-bit integer contains invalid characters.");
         else
            hexString = value;
      }
      get { return hexString; }
   }

   // IConvertible implementations.
   public TypeCode GetTypeCode()
   {
      return TypeCode.Object;
   }
```

```
   public bool ToBoolean(IFormatProvider provider)
   {
      return signBit != SignBit.Zero;
   }

   public byte ToByte(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is out of range
of the Byte type.", Convert.ToInt64(hexString, 16)));
      else
         try {
            return Byte.Parse(hexString, NumberStyles.HexNumber);
         }
         catch (OverflowException e) {
            throw new OverflowException(String.Format("{0} is out of
range of the Byte type.", Convert.ToUInt64(hexString, 16)), e);
         }
   }

   public char ToChar(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is out of range
of the Char type.", Convert.ToInt64(hexString, 16)));

      try {
         ushort codePoint = UInt16.Parse(this.hexString,
NumberStyles.HexNumber);
         return Convert.ToChar(codePoint);
      }
      catch (OverflowException) {
         throw new OverflowException(String.Format("{0} is out of range
of the Char type.", Convert.ToUInt64(hexString, 16)));
      }
   }

   public DateTime ToDateTime(IFormatProvider provider)
   {
      throw new InvalidCastException("Hexadecimal to DateTime conversion
is not supported.");
   }

   public decimal ToDecimal(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
      {

            case TypeCode.String:
                return this.ToString(null);
            case TypeCode.UInt16:
                return this.ToUInt16(null);
            case TypeCode.UInt32:
                return this.ToUInt32(null);
            case TypeCode.UInt64:
                return this.ToUInt64(null);
            default:
                throw new InvalidCastException(String.Format("Conversion to
{0} is not supported.", conversionType.Name));
        }
    }

    public ushort ToUInt16(IFormatProvider provider)
    {
        if (signBit == SignBit.Negative)
            throw new OverflowException(String.Format("{0} is outside the
range of the UInt16 type.",
```

```
                                                        Int64.Parse(hexString,
NumberStyles.HexNumber)));
      else
         try {
            return Convert.ToUInt16(UInt64.Parse(hexString,
NumberStyles.HexNumber));
         }
         catch (OverflowException e) {
            throw new OverflowException(String.Format("{0} is out of
range of the UInt16 type.", Convert.ToUInt64(hexString, 16)), e);
         }
   }

   public uint ToUInt32(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt32 type.",
                                                        Int64.Parse(hexString,
NumberStyles.HexNumber)));
      else
         try {
            return Convert.ToUInt32(UInt64.Parse(hexString,
NumberStyles.HexNumber));
         }
         catch (OverflowException) {
            throw new OverflowException(String.Format("{0} is outside the
range of the UInt32 type.",

UInt64.Parse(hexString, NumberStyles.HexNumber)));
         }
   }

   public ulong ToUInt64(IFormatProvider provider)
   {
      if (signBit == SignBit.Negative)
         throw new OverflowException(String.Format("{0} is outside the
range of the UInt64 type.",
                                                        Int64.Parse(hexString,
NumberStyles.HexNumber)));
      else
         return Convert.ToUInt64(hexString, 16);
   }
}
```

The following example shows that a call to the ToUInt64(Object, IFormatProvider) method that passes a `HexString` object as a parameter, in turn, calls the IConvertible.ToUInt64 implementation of the `HexString` class.

```
C#
```

```
public class Example
{
   public static void Main()
   {
      ulong positiveValue = UInt64.MaxValue - 100000;
      long negativeValue = -1;

      HexString positiveString = new HexString();
      positiveString.Sign = (SignBit) Math.Sign((decimal)positiveValue);
      positiveString.Value = positiveValue.ToString("X");

      HexString negativeString = new HexString();
      negativeString.Sign = (SignBit) Math.Sign(negativeValue);
      negativeString.Value = negativeValue.ToString("X");

      try {
         Console.WriteLine("0x{0} converts to {1}.",
positiveString.Value, Convert.ToUInt64(positiveString));
      }
      catch (OverflowException) {
         Console.WriteLine("{0} is outside the range of the UInt64
type.",
                           Int64.Parse(positiveString.Value,
NumberStyles.HexNumber));
      }

      try {
         Console.WriteLine("0x{0} converts to {1}.",
negativeString.Value, Convert.ToUInt64(negativeString));
      }
      catch (OverflowException) {
         Console.WriteLine("{0} is outside the range of the UInt64
type.",
                           Int64.Parse(negativeString.Value,
NumberStyles.HexNumber));
      }
   }
}
// The example displays the following output:
//       0xFFFFFFFFFFFE795F converts to 18446744073709451615.
//       -1 is outside the range of the UInt64 type.
```

Remarks

The return value is the result of invoking the IConvertible.ToUInt64 method of the underlying type of `value`.

`provider` enables the user to specify culture-specific conversion information about the contents of `value`. For example, if `value` is a String that represents a number,

`provider` could supply culture-specific information about the notation used to represent that number.

The base types ignore `provider`; however, the parameter may be used if `value` is a user-defined type that implements the IConvertible interface.

ToUInt64(Single)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified single-precision floating-point number to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

UInt64

`value`, rounded to the nearest 64-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt64.MaxValue.

Examples

The following example attempts to convert each element in an array of Single values to an unsigned long integer. The output shows that fractional values are rounded before the conversion is performed.

C#

```
float[] values= { Single.MinValue, -1.38e10f, -1023.299f, -12.98f,
                  0f, 9.113e-16f, 103.919f, 17834.191f, Single.MaxValue
};
ulong result;

foreach (float value in values)
{
   try {
      result = Convert.ToUInt64(value);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt64 type.",
value);
   }
}
// The example displays the following output:
//    -3.402823E+38 is outside the range of the UInt64 type.
//    -1.38E+10 is outside the range of the UInt64 type.
//    -1023.299 is outside the range of the UInt64 type.
//    -12.98 is outside the range of the UInt64 type.
//    Converted the Single value 0 to the UInt64 value 0.
//    Converted the Single value 9.113E-16 to the UInt64 value 0.
//    Converted the Single value 103.919 to the UInt64 value 104.
```

```
//    Converted the Single value 17834.19 to the UInt64 value 17834.
//    3.402823E+38 is outside the range of the UInt64 type.
```

ToUInt64(String, Int32)

> Important
>
> This API is not CLS-compliant.

Converts the string representation of a number in a specified base to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (string? value, int fromBase);
```

Parameters

`value` String

A string that contains the number to convert.

`fromBase` Int32

The base of the number in `value`, which must be 2, 8, 10, or 16.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to the number in `value`, or 0 (zero) if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`fromBase` is not 2, 8, 10, or 16.

-or-

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

ArgumentOutOfRangeException

`value` is Empty.

FormatException

`value` contains a character that is not a valid digit in the base specified by `fromBase`. The exception message indicates that there are no digits to convert if the first character in `value` is invalid; otherwise, the message indicates that `value` contains invalid trailing characters.

OverflowException

`value`, which represents a non-base 10 unsigned number, is prefixed with a negative sign.

-or-

`value` represents a number that is less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example attempts to interpret each element in an array of numeric strings as a hexadecimal value and to convert it to an unsigned long integer.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] hexStrings = { "8000000000000000", "0FFFFFFFFFFFFFFF",
                              "F000000000000000", "00A3000000000000",
                              "D", "-13", "9AC61", "GAD",
                              "FFFFFFFFFFFFFFFF" };

      foreach (string hexString in hexStrings)
      {
         Console.Write("{0,-18}  -->  ", hexString);
         try {
            ulong number = Convert.ToUInt64(hexString, 16);
            Console.WriteLine("{0,26:N0}", number);
         }
         catch (FormatException) {
            Console.WriteLine("{0,26}", "Bad Format");
         }
         catch (OverflowException) {
            Console.WriteLine("{0,26}", "Numeric Overflow");
         }
         catch (ArgumentException) {
            Console.WriteLine("{0,26}", "Invalid in Base 16");
         }
      }
   }
}
// The example displays the following output:
//    8000000000000000    -->   9,223,372,036,854,775,808
//    0FFFFFFFFFFFFFFF    -->   1,152,921,504,606,846,975
//    F000000000000000    -->  17,293,822,569,102,704,640
//    00A3000000000000    -->      45,880,421,203,836,928
//    D                   -->                          13
//    -13                 -->          Invalid in Base 16
//    9AC61               -->                     633,953
//    GAD                 -->                  Bad Format
//    FFFFFFFFFFFFFFFF    -->            Numeric Overflow
```

Remarks

If `fromBase` is 16, you can prefix the number specified by the `value` parameter with "0x" or "0X".

Because the UInt64 data type supports unsigned values only, the ToUInt64(String, Int32) method assumes that `value` is expressed using unsigned binary representation. In other words, all 64 bits are used to represent the numeric value, and a sign bit is absent. As a result, it is possible to write code in which a signed long integer value that is out of the range of the UInt64 data type is converted to a UInt64 value without the method throwing an exception. The following example converts MinValue to its hexadecimal string representation, and then calls the ToUInt64(String, Int32) method. Instead of throwing an exception, the method displays the message, "0x8000000000000000 converts to 9223372036854775808."

C#

```
// Create a hexadecimal value out of range of the UInt64 type.
string value = Convert.ToString(Int64.MinValue, 16);
// Convert it back to a number.
try
{
   UInt64 number = Convert.ToUInt64(value, 16);
   Console.WriteLine("0x{0} converts to {1}.", value, number);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned long
integer.",
                     value);
}
```

When performing binary operations or numeric conversions, it is always the responsibility of the developer to verify that a method or operator is using the appropriate numeric representation to interpret a particular value. The following example illustrates one technique for ensuring that the method does not inappropriately use binary representation to interpret a value that uses two's complement representation when converting a hexadecimal string to a UInt64 value. The example determines whether a value represents a signed or an unsigned integer while it is converting that value to its string representation. When the example converts the value to a UInt64 value, it checks whether the original value was a signed integer. If so, and if its high-order bit is set (which indicates that the original value was negative), the method throws an exception.

C#

```
// Create a negative hexadecimal value out of range of the UInt64 type.
long sourceNumber = Int64.MinValue;
bool isSigned =
Math.Sign((long)sourceNumber.GetType().GetField("MinValue").GetValue(null
)) == -1;
```

```
string value = Convert.ToString(sourceNumber, 16);
UInt64 targetNumber;
try
{
   targetNumber = Convert.ToUInt64(value, 16);
   if (isSigned && ((targetNumber & 0x8000000000000000) != 0))
      throw new OverflowException();
   else
      Console.WriteLine("0x{0} converts to {1}.", value, targetNumber);
}
catch (OverflowException)
{
   Console.WriteLine("Unable to convert '0x{0}' to an unsigned long
integer.",
                     value);
}
// Displays the following to the console:
//    Unable to convert '0x8000000000000000' to an unsigned long integer.
```

ToUInt64(UInt64)

> Important
>
> This API is not CLS-compliant.

Returns the specified 64-bit unsigned integer; no actual conversion is performed.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to return.

Returns

UInt64

`value` is returned unchanged.

ToUInt64(SByte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit signed integer to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in a signed byte array to an unsigned long integer.

C#

```
sbyte[] numbers = { SByte.MinValue, -1, 0, 10, SByte.MaxValue };
ulong result;

foreach (sbyte number in numbers)
{
   try {
      result = Convert.ToUInt64(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt64 type.",
                        number.GetType().Name, number);
```

```
    }
}
// The example displays the following output:
//    The SByte value -128 is outside the range of the UInt64 type.
//    The SByte value -1 is outside the range of the UInt64 type.
//    Converted the SByte value 0 to the UInt64 value 0.
//    Converted the SByte value 10 to the UInt64 value 10.
//    Converted the SByte value 127 to the UInt64 value 127.
```

ToUInt64(Int16)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 16-bit signed integer to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in an array of 16-bit integers to an unsigned long integer.

C#

```

ToUInt64(Int32)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 32-bit signed integer to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero.

Examples

The following example attempts to convert each element in an array of integers to an unsigned long integer.

C#

```
int[] numbers = { Int32.MinValue, -1, 0, 121, 340, Int32.MaxValue };
ulong result;

foreach (int number in numbers)
{
   try {
      result = Convert.ToUInt64(number);
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        number.GetType().Name, number,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt64 type.",
                        number.GetType().Name, number);
   }
}
// The example displays the following output:
//    The Int32 value -2147483648 is outside the range of the UInt64
type.
//    The Int32 value -1 is outside the range of the UInt64 type.
//    Converted the Int32 value 0 to the UInt64 value 0.
//    Converted the Int32 value 121 to the UInt64 value 121.
//    Converted the Int32 value 340 to the UInt64 value 340.
//    Converted the Int32 value 2147483647 to the UInt64 value
2147483647.
```

ToUInt64(Double)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified double-precision floating-point number to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

UInt64

`value`, rounded to the nearest 64-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt64.MaxValue.

Examples

The following example attempts to convert each element in an array of Double values to an unsigned long integer.

C#

```
double[] values= { Double.MinValue, -1.38e10, -1023.299, -12.98,
                   0, 9.113e-16, 103.919, 17834.191, Double.MaxValue };
ulong result;

foreach (double value in values)
{
   try {
      result = Convert.ToUInt64(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt64 type.",
value);
   }
}
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the UInt64 type.
//    -13800000000 is outside the range of the UInt64 type.
//    -1023.299 is outside the range of the UInt64 type.
//    -12.98 is outside the range of the UInt64 type.
//    Converted the Double value '0' to the UInt64 value 0.
//    Converted the Double value '9.113E-16' to the UInt64 value 0.
//    Converted the Double value '103.919' to the UInt64 value 104.
//    Converted the Double value '17834.191' to the UInt64 value 17834.
//    1.79769313486232E+308 is outside the range of the UInt64 type.
```

ToUInt64(Decimal)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified decimal number to an equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

UInt64

`value`, rounded to the nearest 64-bit unsigned integer. If `value` is halfway between two whole numbers, the even number is returned; that is, 4.5 is converted to 4, and 5.5 is converted to 6.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than zero or greater than UInt64.MaxValue.

Examples

The following example attempts to convert each element in an array of Decimal values to an unsigned long integer.

C#

```
decimal[] values= { Decimal.MinValue, -1034.23m, -12m, 0m, 147m,
                    199.55m, 9214.16m, Decimal.MaxValue };
ulong result;

foreach (decimal value in values)
{
   try {
      result = Convert.ToUInt64(value);
      Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("{0} is outside the range of the UInt64 type.",
                        value);
   }
}
// The example displays the following output:
//    -79228162514264337593543950335 is outside the range of the UInt64
type.
//    -1034.23 is outside the range of the UInt64 type.
//    -12 is outside the range of the UInt64 type.
//    Converted the Decimal value '0' to the UInt64 value 0.
//    Converted the Decimal value '147' to the UInt64 value 147.
//    Converted the Decimal value '199.55' to the UInt64 value 200.
//    Converted the Decimal value '9214.16' to the UInt64 value 9214.
//    79228162514264337593543950335 is outside the range of the UInt64
type.
```

ToUInt64(DateTime)

> Important
>
> This API is not CLS-compliant.

Calling this method always throws InvalidCastException.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (DateTime value);
```

Parameters

`value` DateTime

The date and time value to convert.

Returns

UInt64

This conversion is not supported. No value is returned.

Attributes CLSCompliantAttribute

Exceptions

InvalidCastException

This conversion is not supported.

ToUInt64(Char)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified Unicode character to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a character array to an unsigned long integer.

C#

```
char[] chars = { 'a', 'z', '\u0007', '\u03FF',
                 '\u7FFF', '\uFFFE' };
ulong result;

foreach (char ch in chars)
{
   result = Convert.ToUInt64(ch);
   Console.WriteLine("Converted the {0} value '{1}' to the {2} value
{3}.",
                     ch.GetType().Name, ch,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Char value 'a' to the UInt64 value 97.
//    Converted the Char value 'z' to the UInt64 value 122.
//    Converted the Char value '' to the UInt64 value 7.
//    Converted the Char value '?' to the UInt64 value 1023.
//    Converted the Char value '?' to the UInt64 value 32767.
//    Converted the Char value '?' to the UInt64 value 65534.
```

ToUInt64(Byte)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified 8-bit unsigned integer to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (byte value);
```

Parameters

value Byte

The 8-bit unsigned integer to convert.

Returns

UInt64

A 64-bit signed integer that is equivalent to `value`.

Attributes CLSCompliantAttribute

Examples

The following example converts each element in a byte array to an unsigned long integer.

C#

```
byte[] bytes = { Byte.MinValue, 14, 122, Byte.MaxValue};
ulong result;

foreach (byte byteValue in bytes)
{
   result = Convert.ToUInt64(byteValue);
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     byteValue.GetType().Name, byteValue,
                     result.GetType().Name, result);
}
// The example displays the following output:
//    Converted the Byte value 0 to the UInt64 value 0.
//    Converted the Byte value 14 to the UInt64 value 14.
//    Converted the Byte value 122 to the UInt64 value 122.
//    Converted the Byte value 255 to the UInt64 value 255.
```

ToUInt64(Boolean)

> Important
>
> This API is not CLS-compliant.

Converts the specified Boolean value to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (bool value);
```

Parameters

`value` Boolean

The Boolean value to convert.

Returns

UInt64

The number 1 if `value` is `true`; otherwise, 0.

Attributes CLSCompliantAttribute

Examples

The following example converts Boolean `true` and `false` values to unsigned long integers.

C#

```
bool falseFlag = false;
bool trueFlag = true;

Console.WriteLine("{0} converts to {1}.", falseFlag,
                  Convert.ToUInt64(falseFlag));
Console.WriteLine("{0} converts to {1}.", trueFlag,
                  Convert.ToUInt64(trueFlag));
// The example displays the following output:
//       False converts to 0.
//       True converts to 1.
```

UWP	10.0

ToUInt64(Object)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified object to a 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (object? value);
```

Parameters

`value` Object

An object that implements the IConvertible interface, or `null`.

Returns

UInt64

A 64-bit unsigned integer that is equivalent to `value`, or zero if `value` is `null`.

Attributes CLSCompliantAttribute

Exceptions

FormatException

`value` is not in an appropriate format.

InvalidCastException

`value` does not implement the IConvertible interface.

-or-

The conversion is not supported.

OverflowException

`value` represents a number that is less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example attempts to convert each element in an object array to an unsigned long integer.

C#

```
object[] values = { true, -12, 163, 935, 'x', new DateTime(2009, 5, 12),
                    "104", "103.0", "-1",
                    "1.00e2", "One", 1.00e2, 16.3e42};
ulong result;

foreach (object value in values)
{
   try {
      result = Convert.ToUInt64(value);
```

```
      Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                        value.GetType().Name, value,
                        result.GetType().Name, result);
   }
   catch (OverflowException) {
      Console.WriteLine("The {0} value {1} is outside the range of the
UInt64 type.",
                        value.GetType().Name, value);
   }
   catch (FormatException) {
      Console.WriteLine("The {0} value {1} is not in a recognizable
format.",
                        value.GetType().Name, value);
   }
   catch (InvalidCastException) {
      Console.WriteLine("No conversion to a UInt64 exists for the {0}
value {1}.",
                        value.GetType().Name, value);
   }
}
// The example displays the following output:
//    Converted the Boolean value True to the UInt64 value 1.
//    The Int32 value -12 is outside the range of the UInt64 type.
//    Converted the Int32 value 163 to the UInt64 value 163.
//    Converted the Int32 value 935 to the UInt64 value 935.
//    Converted the Char value x to the UInt64 value 120.
//    No conversion to a UInt64 exists for the DateTime value 5/12/2009
12:00:00 AM.
//    Converted the String value 104 to the UInt64 value 104.
//    The String value 103.0 is not in a recognizable format.
//    The String value -1 is outside the range of the UInt64 type.
//    The String value 1.00e2 is not in a recognizable format.
//    The String value One is not in a recognizable format.
//    Converted the Double value 100 to the UInt64 value 100.
//    The Double value 1.63E+43 is outside the range of the UInt64 type.
```

Remarks

The return value is the result of invoking the IConvertible.ToUInt64 method of the underlying type of `value`.

Convert.TryFromBase64Chars Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the specified span containing a string representation that is encoded with base-64 digits into a span of 8-bit unsigned integers.

C#

```
public static bool TryFromBase64Chars (ReadOnlySpan<char> chars, Span<byte>
bytes, out int bytesWritten);
```

Parameters

chars ReadOnlySpan<Char>

A span containing the string representation that is encoded with base-64 digits.

bytes Span<Byte>

The span in which to write the converted 8-bit unsigned integers. If this method returns `false`, either the span remains unmodified or contains an incomplete conversion of `chars`, up to the last valid character.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `bytes`.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Convert.TryFromBase64String(String, Span<Byte>, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the specified string representation that is encoded with base-64 digits into a span of 8-bit unsigned integers.

C#

```
public static bool TryFromBase64String (string s, Span<byte> bytes, out int
bytesWritten);
```

Parameters

s String

The string representation that is encoded with base-64 digits.

bytes Span<Byte>

The span in which to write the converted 8-bit unsigned integers. When this method returns `false`, either the span remains unmodified or contains an incomplete conversion of `s`, up to the last valid character.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `bytes`.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Exceptions

ArgumentNullException

`s` is `null`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Convert.TryToBase64Chars Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the 8-bit unsigned integers inside the specified read-only span into their equivalent string representation that is encoded with base-64 digits. You can optionally specify whether to insert line breaks in the return value.

C#

```
public static bool TryToBase64Chars (ReadOnlySpan<byte> bytes, Span<char>
chars, out int charsWritten, Base64FormattingOptions options =
System.Base64FormattingOptions.None);
```

Parameters

bytes ReadOnlySpan<Byte>

A read-only span of 8-bit unsigned integers.

chars Span<Char>

The span in which to write the string representation in base 64 of the elements in `bytes`. If the length of `bytes` is 0, or when this method returns `false`, nothing is written into this parameter.

charsWritten Int32

When this method returns, contains the total number of characters written into `chars`.

options Base64FormattingOptions

One of the enumeration values that specify whether to insert line breaks in the return value. The default value is None.

Returns

Boolean

`true` if the conversion is successful; otherwise, `false`.

Exceptions

ArgumentException

`options` is not a valid Base64FormattingOptions value.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Converter<TInput,TOutput> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a method that converts an object from one type to another type.

C#

```
public delegate TOutput Converter<in TInput,out TOutput>(TInput input);
```

Type Parameters

`TInput`

The type of object that is to be converted.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TOutput`

The type the input object is to be converted to.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`input` TInput

The object to convert.

Return Value

TOutput

The `TOutput` that represents the converted `TInput`.

Examples

This section contains two code examples. The first demonstrates the Converter<TInput,TOutput> delegate with the ConvertAll method of the Array class, and the second demonstrates the delegate with the ConvertAll method of the List<T> generic class.

Example 1

The following code example defines a method named `PointFToPoint` that converts a PointF structure to a Point structure. The example then creates an array of PointF structures, creates a `Converter<PointF, Point>` delegate (`Converter(Of PointF, Point)` in Visual Basic) to represent the `PointFToPoint` method, and passes the delegate to the ConvertAll method. The ConvertAll method passes each element of the input list to the `PointFToPoint` method and puts the converted elements into a new list of Point structures. Both lists are displayed.

C#

```
using System;
using System.Drawing;
using System.Collections.Generic;

public class Example
{
    public static void Main()
    {
        // Create an array of PointF objects.
        PointF[] apf = {
            new PointF(27.8F, 32.62F),
            new PointF(99.3F, 147.273F),
            new PointF(7.5F, 1412.2F) };

        // Display each element in the PointF array.
        Console.WriteLine();
        foreach( PointF p in apf )
            Console.WriteLine(p);

        // Convert each PointF element to a Point object.
        Point[] ap = Array.ConvertAll(apf,
            new Converter<PointF, Point>(PointFToPoint));

        // Display each element in the Point array.
        Console.WriteLine();
        foreach( Point p in ap )
        {
            Console.WriteLine(p);
        }
    }
```

```
    public static Point PointFToPoint(PointF pf)
    {
        return new Point(((int) pf.X), ((int) pf.Y));
    }
}

/* This code example produces the following output:

{X=27.8, Y=32.62}
{X=99.3, Y=147.273}
{X=7.5, Y=1412.2}

{X=27,Y=32}
{X=99,Y=147}
{X=7,Y=1412}
 */
```

Example 2

The following code example defines a method named `PointFToPoint` that converts a PointF structure to a Point structure. The example then creates a List<T> of PointF structures, creates a `Converter\<PointF, Point>` delegate (`Converter(Of PointF, Point)` in Visual Basic) to represent the `PointFToPoint` method, and passes the delegate to the ConvertAll method. The ConvertAll method passes each element of the input list to the `PointFToPoint` method and puts the converted elements into a new list of Point structures. Both lists are displayed.

C#

```
using System;
using System.Drawing;
using System.Collections.Generic;

public class Example
{
    public static void Main()
    {
        List<PointF> lpf = new List<PointF>();

        lpf.Add(new PointF(27.8F, 32.62F));
        lpf.Add(new PointF(99.3F, 147.273F));
        lpf.Add(new PointF(7.5F, 1412.2F));

        Console.WriteLine();
        foreach( PointF p in lpf )
        {
            Console.WriteLine(p);
        }
```

```
        List<Point> lp = lpf.ConvertAll(
            new Converter<PointF, Point>(PointFToPoint));

        Console.WriteLine();
        foreach( Point p in lp )
        {
            Console.WriteLine(p);
        }
    }

    public static Point PointFToPoint(PointF pf)
    {
        return new Point(((int) pf.X), ((int) pf.Y));
    }
}

/* This code example produces the following output:

{X=27.8, Y=32.62}
{X=99.3, Y=147.273}
{X=7.5, Y=1412.2}

{X=27,Y=32}
{X=99,Y=147}
{X=7,Y=1412}
 */
```

Remarks

This delegate is used by the ConvertAll method of the Array class and the ConvertAll method of the List<T> class to convert each element of the collection from one type to another.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DataMisalignedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.InteropServices.dll

The exception that is thrown when a unit of data is read from or written to an address that is not a multiple of the data size. This class cannot be inherited.

C#

```
public sealed class DataMisalignedException : SystemException
```

Inheritance Object → Exception → SystemException → DataMisalignedException

Remarks

Some microprocessors, such as 64-bit processors, can issue hardware exceptions when data is read or written to a misaligned address (that is, when an address is not a multiple of the size of the data being accessed). DataMisalignedException is typically thrown when 16-bit, 32-bit, or 64-bit data is read from or written to an address that is not a multiple of two, four, or eight bytes.

The DataMisalignedException exposes the underlying hardware exception, which allows you to respond in an appropriate manner. For example, a routine in your application attempts to copy a sequence of bytes from one location to another in 64-bit units. However, the write operation starts at a misaligned address, which causes the common language runtime to throw a DataMisalignedException. Your routine responds to the exception by copying the data one byte at a time.

Constructors

Expand table

DataMisalignedException()	Initializes a new instance of the DataMisalignedException class.

DataMisaligned Exception(String)	Initializes a new instance of the DataMisalignedException class using the specified error message.
DataMisaligned Exception(String, Exception)	Initializes a new instance of the DataMisalignedException class using the specified error message and underlying exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.

	(Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

DataMisalignedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.InteropServices.dll

Initializes a new instance of the DataMisalignedException class.

Overloads

Expand table

DataMisalignedException()	Initializes a new instance of the DataMisalignedException class.
DataMisalignedException(String)	Initializes a new instance of the DataMisalignedException class using the specified error message.
DataMisalignedException(String, Exception)	Initializes a new instance of the DataMisalignedException class using the specified error message and underlying exception.

DataMisalignedException()

Initializes a new instance of the DataMisalignedException class.

C#

```
public DataMisalignedException ();
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DataMisalignedException(String)

Initializes a new instance of the DataMisalignedException class using the specified error message.

C#

```
public DataMisalignedException (string? message);
```

Parameters

`message` String

A String object that describes the error. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DataMisalignedException(String, Exception)

Initializes a new instance of the DataMisalignedException class using the specified error message and underlying exception.

```
C#

public DataMisalignedException (string? message, Exception?
innerException);
```

Parameters

`message` String

A String object that describes the error. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

`innerException` Exception

The exception that is the cause of the current DataMisalignedException. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Applies to

DateOnly Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents dates with values ranging from January 1, 0001 Anno Domini (Common Era) through December 31, 9999 A.D. (C.E.) in the Gregorian calendar.

C#

```
public readonly struct DateOnly : IComparable, IComparable<DateOnly>,
IEquatable<DateOnly>, IParsable<DateOnly>, ISpanFormattable,
ISpanParsable<DateOnly>, IUtf8SpanFormattable
```

Inheritance Object → ValueType → DateOnly

Implements IComparable , IComparable<DateOnly> , IEquatable<DateOnly> , IFormattable , ISpanFormattable , IParsable<DateOnly> , IParsable<TSelf> , ISpanParsable<DateOnly> , IUtf8SpanFormattable

Constructors

Expand table

DateOnly(Int32, Int32, Int32)	Creates a new instance of the DateOnly structure to the specified year, month, and day.
DateOnly(Int32, Int32, Int32, Calendar)	Creates a new instance of the DateOnly structure to the specified year, month, and day for the specified calendar.

Properties

Expand table

Day	Gets the day component of the date represented by this instance.

Day Number	Gets the number of days since January 1, 0001 in the Proleptic Gregorian calendar represented by this instance.
Day OfWeek	Gets the day of the week represented by this instance.
DayOfYear	Gets the day of the year represented by this instance.
MaxValue	Gets the latest possible date that can be created.
MinValue	Gets the earliest possible date that can be created.
Month	Gets the month component of the date represented by this instance.
Year	Gets the year component of the date represented by this instance.

Methods

Expand table

AddDays(Int32)	Adds the specified number of days to the value of this instance.
AddMonths(Int32)	Adds the specified number of months to the value of this instance.
AddYears(Int32)	Adds the specified number of years to the value of this instance.
CompareTo(DateOnly)	Compares the value of this instance to a specified DateOnly value and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateOnly value.
CompareTo(Object)	Compares the value of this instance to a specified object that contains a specified DateOnly value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateOnly value.
Deconstruct(Int32, Int32, Int32)	Deconstructs DateOnly by Year, Month, and Day.
Equals(DateOnly)	Returns a value indicating whether the value of this instance is equal to the value of the specified DateOnly instance.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

FromDateTime(DateTime)	Returns a DateOnly instance that is set to the date part of the specified `dateTime`.
FromDayNumber(Int32)	Creates a new instance of the DateOnly structure to the specified number of days.
GetHashCode()	Returns the hash code for this instance.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a memory span that contains string representation of a date to its DateOnly equivalent by using culture-specific format information and a formatting style.
Parse(String)	Converts a string that contains string representation of a date to its DateOnly equivalent by using the conventions of the current culture.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(String, IFormatProvider, DateTimeStyles)	Converts a string that contains string representation of a date to its DateOnly equivalent by using culture-specific format information and a formatting style.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[])	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String)	Converts the specified string representation of a date to its DateOnly equivalent using the specified format. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date to its DateOnly equivalent using the specified format, culture-

	specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(String, String[])	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ToDateTime(TimeOnly)	Returns a DateTime that is set to the date of this DateOnly instance and the time of specified input time.
ToDateTime(TimeOnly, DateTimeKind)	Returns a DateTime instance with the specified input kind that is set to the date of this DateOnly instance and the time of specified input time.
ToLongDateString()	Converts the value of the current DateOnly object to its equivalent long date string representation.
ToShortDateString()	Converts the value of the current DateOnly object to its equivalent short date string representation.
ToString()	Converts the value of the current DateOnly object to its equivalent string representation using the formatting conventions of the current culture. The DateOnly object will be formatted in short form.
ToString(IFormatProvider)	Converts the value of the current DateOnly object to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the value of the current DateOnly object to its equivalent string representation using the specified format and the formatting conventions of the current culture.
ToString(String, IFormatProvider)	Converts the value of the current DateOnly object to its equivalent string representation using the specified culture-specific format information.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current DateOnly instance into the provided span of characters.

TryParse(ReadOnlySpan<Char>, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateOnly)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. And returns a value that indicates whether the conversion succeeded.
TryParse(String, DateOnly)	Converts the specified string representation of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, DateOnly)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified string representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. And returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnly Span<Char>, ReadOnly Span<Char>, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnly Span<Char>, ReadOnly Span<Char>, IFormatProvider, Date TimeStyles, DateOnly)	Converts the specified span representation of a date to its DateOnlyequivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnly Span<Char>, String[], DateOnly)	Converts the specified char span of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnly Span<Char>, String[], IFormat Provider, DateTimeStyles, DateOnly)	Converts the specified char span of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, Date Only)	Converts the specified string representation of a date to its DateOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], DateOnly)	Converts the specified string of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified string of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

Operators

Expand table

Equality(DateOnly, DateOnly)	Determines whether two specified instances of DateOnly are equal.
GreaterThan(DateOnly, DateOnly)	Determines whether one specified DateOnly is later than another specified DateTime.
GreaterThanOrEqual(DateOnly, DateOnly)	Determines whether one specified DateOnly represents a date that is the same as or later than another specified DateOnly.
Inequality(DateOnly, DateOnly)	Determines whether two specified instances of DateOnly are not equal.
LessThan(DateOnly, DateOnly)	Determines whether one specified DateOnly is earlier than another specified DateOnly.
LessThanOrEqual(DateOnly, DateOnly)	Determines whether one specified DateOnly represents a date that is the same as or earlier than another specified DateOnly.

Applies to

DateOnly Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

DateOnly(Int32, Int32, Int32)	Creates a new instance of the DateOnly structure to the specified year, month, and day.
DateOnly(Int32, Int32, Int32, Calendar)	Creates a new instance of the DateOnly structure to the specified year, month, and day for the specified calendar.

DateOnly(Int32, Int32, Int32)

Creates a new instance of the DateOnly structure to the specified year, month, and day.

C#

```
public DateOnly (int year, int month, int day);
```

Parameters

year Int32

The year (1 through 9999).

month Int32

The month (1 through 12).

day Int32

The day (1 through the number of days in `month`).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly(Int32, Int32, Int32, Calendar)

Creates a new instance of the DateOnly structure to the specified year, month, and day for the specified calendar.

C#

```
public DateOnly (int year, int month, int day,
System.Globalization.Calendar calendar);
```

Parameters

`year` Int32

The year (1 through the number of years in calendar).

`month` Int32

The month (1 through the number of months in calendar).

`day` Int32

The day (1 through the number of days in `month`).

`calendar` Calendar

The calendar that is used to interpret year, month, and day. `month`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly.DayNumber Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of days since January 1, 0001 in the Proleptic Gregorian calendar represented by this instance.

C#

```
public int DayNumber { get; }
```

Property Value

Int32

The number of days since January 1, 0001 in the Proleptic Gregorian calendar represented by this instance.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.DayOfWeek Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the week represented by this instance.

C#

```
public DayOfWeek DayOfWeek { get; }
```

Property Value

DayOfWeek

A number that represents the day of the week represented by this instance.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.DayOfYear Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the year represented by this instance.

C#

```
public int DayOfYear { get; }
```

Property Value

Int32

A number that represents the day of the year represented by this instance.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the latest possible date that can be created.

C#

```
public static DateOnly MaxValue { get; }
```

Property Value

DateOnly

A DateOnly representing the latest possible date that can be created.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the earliest possible date that can be created.

C#

```
public static DateOnly MinValue { get; }
```

Property Value

DateOnly

A DateOnly representing the earliest possible date that can be created.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.Month Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the month component of the date represented by this instance.

C#

```
public int Month { get; }
```

Property Value

Int32

A number that represents the month component of the date.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.Year Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the year component of the date represented by this instance.

C#

```
public int Year { get; }
```

Property Value

Int32

A number that represents the year component of the date.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.AddDays(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds the specified number of days to the value of this instance.

C#

```
public DateOnly AddDays (int value);
```

Parameters

`value` Int32

The number of days to add. To subtract days, specify a negative number.

Returns

DateOnly

An instance whose value is the sum of the date represented by this instance and the number of days represented by value.

Exceptions

ArgumentOutOfRangeException

The resulting value is greater than DateOnly.MaxValue.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

DateOnly.AddMonths(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds the specified number of months to the value of this instance.

```
C#
public DateOnly AddMonths (int value);
```

Parameters

`value` Int32

A number of months. The months parameter can be negative or positive.

Returns

DateOnly

An object whose value is the sum of the date represented by this instance and months.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.AddYears(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds the specified number of years to the value of this instance.

```
C#
public DateOnly AddYears (int value);
```

Parameters

`value` Int32

A number of years. The value parameter can be negative or positive.

Returns

DateOnly

An object whose value is the sum of the date represented by this instance and the number of years represented by value.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(DateOnly)	Compares the value of this instance to a specified DateOnly value and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateOnly value.
CompareTo(Object)	Compares the value of this instance to a specified object that contains a specified DateOnly value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateOnly value.

CompareTo(DateOnly)

Compares the value of this instance to a specified DateOnly value and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateOnly value.

C#

```
public int CompareTo (DateOnly value);
```

Parameters

`value` DateOnly

The object to compare to the current instance.

Returns

Int32

Less than zero if this instance is earlier than value. Greater than zero if this instance is later than value. Zero if this instance is the same as value.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

CompareTo(Object)

Compares the value of this instance to a specified object that contains a specified DateOnly value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateOnly value.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

A boxed object to compare, or `null`.

Returns

Int32

Less than zero if this instance is earlier than value. Greater than zero if this instance is later than value. Zero if this instance is the same as value.

Implements

CompareTo(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly.Deconstruct(Int32, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Deconstructs DateOnly by Year, Month, and Day.

C#

```
public void Deconstruct (out int year, out int month, out int day);
```

Parameters

year Int32

When this method returns, represents the Year value of this DateOnly instance.

month Int32

When this method returns, represents the Month value of this DateOnly instance.

day Int32

When this method returns, represents the Day value of this DateOnly instance.

Applies to

Product	Versions
.NET	8, 9

DateOnly.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(DateOnly)	Returns a value indicating whether the value of this instance is equal to the value of the specified DateOnly instance.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(DateOnly)

Returns a value indicating whether the value of this instance is equal to the value of the specified DateOnly instance.

```
C#

public bool Equals (DateOnly value);
```

Parameters

`value` DateOnly

The object to compare to this instance.

Returns

Boolean

`true` if the value parameter equals the value of this instance; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

```
C#
public override bool Equals (object? value);
```

Parameters

`value` Object

The object to compare to this instance.

Returns

Boolean

`true` if value is an instance of DateOnly and equals the value of this instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly.FromDateTime(DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a DateOnly instance that is set to the date part of the specified `dateTime`.

```
C#
public static DateOnly FromDateTime (DateTime dateTime);
```

Parameters

`dateTime` DateTime

The DateTime instance.

Returns

DateOnly

The DateOnly instance composed of the date part of the specified input time `dateTime` instance.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.FromDayNumber(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new instance of the DateOnly structure to the specified number of days.

C#

```
public static DateOnly FromDayNumber (int dayNumber);
```

Parameters

dayNumber Int32

The number of days since January 1, 0001 in the Proleptic Gregorian calendar.

Returns

DateOnly

A DateOnly structure instance to the specified number of days.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String)	Converts a string that contains string representation of a date to its DateOnly equivalent by using the conventions of the current culture.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a memory span that contains string representation of a date to its DateOnly equivalent by using culture-specific format information and a formatting style.
Parse(String, IFormatProvider, DateTimeStyles)	Converts a string that contains string representation of a date to its DateOnly equivalent by using culture-specific format information and a formatting style.

Parse(String)

Converts a string that contains string representation of a date to its DateOnly equivalent by using the conventions of the current culture.

C#

```
public static DateOnly Parse (string s);
```

Parameters

`s` String

The string that contains the string to parse.

Returns

DateOnly

An object that is equivalent to the date contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#

public static DateOnly Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

DateOnly

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, IFormatProvider)

Parses a string into a value.

```
C#

public static DateOnly Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

DateOnly

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts a memory span that contains string representation of a date to its DateOnly equivalent by using culture-specific format information and a formatting style.

C#

```
public static DateOnly Parse (ReadOnlySpan<char> s, IFormatProvider?
provider = default, System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

The memory span that contains the string to parse.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by provider and styles.

Exceptions

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(String, IFormatProvider, DateTimeStyles)

Converts a string that contains string representation of a date to its DateOnly equivalent by using culture-specific format information and a formatting style.

C#

```
public static DateOnly Parse (string s, IFormatProvider? provider,
System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

`s` String

The string that contains the string to parse.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s` for the parse operation to succeed, and that defines how to interpret the parsed date. A typical value to specify is None.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by provider and styles.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.ParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[])	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String[])	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

ParseExact(String, String)	Converts the specified string representation of a date to its DateOnly equivalent using the specified format. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

ParseExact(String, String[], IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

C#

```
public static DateOnly ParseExact (string s, string[] formats,
IFormatProvider? provider, System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

s String

A string containing the characters that represent a date to convert.

formats String[]

An array of allowable formats of `s`.

provider IFormatProvider

An object that supplies culture-specific formatting information about `s`.

style DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format, provider, and style.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(String, String, IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

C#

```
public static DateOnly ParseExact (string s, string format,
IFormatProvider? provider, System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

s String

A string containing the characters that represent a date to convert.

`format` String

A string containing the characters that represent a format specifier that defines the required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of the enumeration values that provides additional information about `s`, about style elements that may be present in `s`, or about the conversion from `s` to a DateOnly value. A typical value to specify is None.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format, provider, and style.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)

Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. The

format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

```
C#

public static DateOnly ParseExact (ReadOnlySpan<char> s, string[]
formats, IFormatProvider? provider, System.Globalization.DateTimeStyles
style = System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent a date to convert.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format, provider, and style.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(ReadOnlySpan<Char>, String[])

Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

```
C#

public static DateOnly ParseExact (ReadOnlySpan<char> s, string[]
formats);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters that represent a date to convert.

formats String[]

An array of allowable formats of `s`.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format, provider, and style.

Exceptions

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(String, String[])

Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats. The format of the string representation must match at

least one of the specified formats exactly or an exception is thrown.

```C#
public static DateOnly ParseExact (string s, string[] formats);
```

Parameters

`s` String

A span containing the characters that represent a date to convert.

`formats` String[]

An array of allowable formats of `s`.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format, provider, and style.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(String, String)

Converts the specified string representation of a date to its DateOnly equivalent using the specified format. The format of the string representation must match the

specified format exactly or an exception is thrown.

```C#
public static DateOnly ParseExact (string s, string format);
```

Parameters

`s` String

A string containing the characters that represent a date to convert.

`format` String

A string that represent a format specifier that defines the required format of `s`.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date.

Remarks

The ParseExact(String, String) method parses the string representation of a date, which must be in the format defined by the `format` parameter. It also requires that the <Date> element of the string representation of a date appear in the order specified by `format`, and that `s` have no white space other than that permitted by `format`. The `format` parameter is a string that contains either a single standard format specifier, or one or more custom format specifiers that define the required format of `s`. For details about valid formatting codes, see Standard Date and Time Format Strings or Custom Date and Time Format Strings.

Note

If `format` is a custom format pattern that does not include date separators (such as "yyyyMMdd"), use the widest form of each custom format specifier. For example, if you want to specify months in the format pattern, specify the wider form, "MM", instead of the narrower form, "M".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts the specified span representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

C#

```
public static DateOnly ParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, IFormatProvider? provider = default,
System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters that represent a date to convert.

format ReadOnlySpan<Char>

A span containing the characters that represent a format specifier that defines the required format of `s`.

provider IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

DateOnly

An object that is equivalent to the date contained in `s`, as specified by format, provider, and style.

Exceptions

FormatException

`s` does not contain a valid string representation of a date.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly.ToDateTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToDateTime(TimeOnly)	Returns a DateTime that is set to the date of this DateOnly instance and the time of specified input time.
ToDateTime(TimeOnly, DateTimeKind)	Returns a DateTime instance with the specified input kind that is set to the date of this DateOnly instance and the time of specified input time.

ToDateTime(TimeOnly)

Returns a DateTime that is set to the date of this DateOnly instance and the time of specified input time.

C#

```
public DateTime ToDateTime (TimeOnly time);
```

Parameters

`time` TimeOnly

The time of the day.

Returns

DateTime

The DateTime instance composed of the date of the current DateOnly instance and the time specified by the input time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToDateTime(TimeOnly, DateTimeKind)

Returns a DateTime instance with the specified input kind that is set to the date of this DateOnly instance and the time of specified input time.

C#

```
public DateTime ToDateTime (TimeOnly time, DateTimeKind kind);
```

Parameters

`time` TimeOnly

The time of the day.

`kind` DateTimeKind

One of the enumeration values that indicates whether ticks specifies a local time, Coordinated Universal Time (UTC), or neither.

Returns

DateTime

The DateTime instance composed of the date of the current DateOnly instance and the time specified by the input time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly.ToLongDateString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateOnly object to its equivalent long date string representation.

C#

```
public string ToLongDateString ();
```

Returns

String

A string that contains the long date string representation of the current DateOnly object.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.ToShortDateString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateOnly object to its equivalent short date string representation.

C#

```
public string ToShortDateString ();
```

Returns

String

A string that contains the short date string representation of the current DateOnly object.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToString()	Converts the value of the current DateOnly object to its equivalent string representation using the formatting conventions of the current culture. The DateOnly object will be formatted in short form.
ToString(IFormatProvider)	Converts the value of the current DateOnly object to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the value of the current DateOnly object to its equivalent string representation using the specified format and the formatting conventions of the current culture.
ToString(String, IFormatProvider)	Converts the value of the current DateOnly object to its equivalent string representation using the specified culture-specific format information.

ToString()

Converts the value of the current DateOnly object to its equivalent string representation using the formatting conventions of the current culture. The DateOnly object will be formatted in short form.

C#

```
public override string ToString ();
```

Returns

String

A string that contains the short date string representation of the current DateOnly object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToString(IFormatProvider)

Converts the value of the current DateOnly object to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

A string representation of value of the current DateOnly object as specified by provider.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToString(String)

Converts the value of the current DateOnly object to its equivalent string representation using the specified format and the formatting conventions of the current culture.

```
C#
public string ToString (string? format);
```

Parameters

`format` String

A standard or custom date format string.

Returns

String

A string representation of value of the current DateOnly object as specified by format.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToString(String, IFormatProvider)

Converts the value of the current DateOnly object to its equivalent string representation using the specified culture-specific format information.

```
C#
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A standard or custom date format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

A string representation of value of the current DateOnly object as specified by format and provider.

Implements

ToString(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

DateOnly.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current DateOnly instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current DateOnly instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DateOnly.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(String, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified string representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. And returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. And returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, DateOnly)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, DateOnly)	Converts the specified string representation of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateOnly)	Tries to parse a span of characters into a value.

TryParse(String, IFormatProvider, DateTimeStyles, DateOnly)

Converts the specified string representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. And returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider,
System.Globalization.DateTimeStyles style, out DateOnly result);
```

Parameters

`s` String

A string containing the characters that represent a date to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` parameter is empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateOnly)

Converts the specified span representation of a date to its DateOnly equivalent using the specified array of formats, culture-specific format information, and style. And returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, System.Globalization.DateTimeStyles style, out DateOnly
result);
```

Parameters

`s` ReadOnlySpan<Char>

A string containing the characters that represent a date to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` parameter is empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(String, IFormatProvider, DateOnly)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
DateOnly result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` DateOnly

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, DateOnly)

Converts the specified span representation of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out DateOnly result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing the date to convert.

result DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` parameter is empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(String, DateOnly)

Converts the specified string representation of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (string? s, out DateOnly result);
```

Parameters

`s` String

A string containing the characters representing the date to convert.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` parameter is empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateOnly)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out DateOnly result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` DateOnly

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

DateOnly.TryParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified string of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, String[], DateOnly)	Converts the specified char span of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, DateOnly)	Converts the specified string representation of a date to its DateOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], DateOnly)	Converts the specified string of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified span representation of a date to its DateOnlyequivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified char span of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateOnly)	Converts the specified span representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateOnly)

Converts the specified string of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (string? s, string?[]? formats,
IFormatProvider? provider, System.Globalization.DateTimeStyles style, out
DateOnly result);
```

Parameters

`s` String

The string containing the date to parse.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed date. A typical value to specify is None.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, DateOnly)

Converts the specified span representation of a date to its DateOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, out DateOnly result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing a date to convert.

format ReadOnlySpan<Char>

The required format of `s`.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` is an empty string, or does not contain a date that correspond to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, String[], DateOnly)

Converts the specified char span of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s, string?[]?
formats, out DateOnly result);
```

Parameters

`s` ReadOnlySpan<Char>

The span containing the string to parse.

`formats` String[]

An array of allowable formats of `s`.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` parameter is an empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String, DateOnly)

Converts the specified string representation of a date to its DateOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (string? s, string? format, out DateOnly
result);
```

Parameters

`s` String

A string containing the characters representing a date to convert.

`format` String

The required format of `s`.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string, or does not contain a date that correspond to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String[], DateOnly)

Converts the specified string of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (string? s, string?[]? formats, out
DateOnly result);
```

Parameters

`s` String

The string containing date to parse.

`formats` String[]

An array of allowable formats of `s`.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion

failed. The conversion fails if `s` is an empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateOnly)

Converts the specified span representation of a date to its DateOnlyequivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, IFormatProvider? provider,
System.Globalization.DateTimeStyles style, out DateOnly result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing a date to convert.

format ReadOnlySpan<Char>

The required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of one or more enumeration values that indicate the permitted format of `s`.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if the `s` is an empty string, or does not contain a date that correspond to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateOnly)

Converts the specified char span of a date to its DateOnly equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s, string?[]?
formats, IFormatProvider? provider, System.Globalization.DateTimeStyles
style, out DateOnly result);
```

Parameters

`s` ReadOnlySpan<Char>

The span containing the string to parse.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed date. A typical value to specify is None.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string, or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateOnly)

Converts the specified span representation of a date to its DateOnly equivalent using the specified format, culture-specific format information, and style. The format of the

string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

```C#
public static bool TryParseExact (string? s, string? format,
IFormatProvider? provider, System.Globalization.DateTimeStyles style, out
DateOnly result);
```

Parameters

`s` String

A span containing the characters representing a date to convert.

`format` String

The required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of one or more enumeration values that indicate the permitted format of `s`.

`result` DateOnly

When this method returns, contains the DateOnly value equivalent to the date contained in `s`, if the conversion succeeded, or DateOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string, or does not contain a date that correspond to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

DateOnly.Equality(DateOnly, DateOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of DateOnly are equal.

```
C#
public static bool operator == (DateOnly left, DateOnly right);
```

Parameters

`left` DateOnly

The first object to compare.

`right` DateOnly

The second object to compare.

Returns

Boolean

`true` if left and right represent the same date; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.GreaterThan(DateOnly, DateOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateOnly is later than another specified DateTime.

```
C#
public static bool operator > (DateOnly left, DateOnly right);
```

Parameters

`left` DateOnly

The first object to compare.

`right` DateOnly

The second object to compare.

Returns

Boolean

`true` if left is later than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.GreaterThanOrEqual(DateOnly, DateOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateOnly represents a date that is the same as or later than another specified DateOnly.

C#

```
public static bool operator >= (DateOnly left, DateOnly right);
```

Parameters

`left` DateOnly

The first object to compare.

`right` DateOnly

The second object to compare.

Returns

Boolean

`true` if left is the same as or later than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.Inequality(DateOnly, DateOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of DateOnly are not equal.

```
C#
public static bool operator != (DateOnly left, DateOnly right);
```

Parameters

`left` DateOnly

The first object to compare.

`right` DateOnly

The second object to compare.

Returns

Boolean

`true` if left and right do not represent the same date; otherwise, `false`.

Applies to

DateOnly.LessThan(DateOnly, DateOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateOnly is earlier than another specified DateOnly.

```
C#
public static bool operator < (DateOnly left, DateOnly right);
```

Parameters

`left` DateOnly

The first object to compare.

`right` DateOnly

The second object to compare.

Returns

Boolean

`true` if left is earlier than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateOnly.LessThanOrEqual(DateOnly, DateOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateOnly represents a date that is the same as or earlier than another specified DateOnly.

```
C#
public static bool operator <= (DateOnly left, DateOnly right);
```

Parameters

`left` DateOnly

The first object to compare.

`right` DateOnly

The second object to compare.

Returns

Boolean

`true` if left is the same as or earlier than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

DateTime Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an instant in time, typically expressed as a date and time of day.

C#

```
public readonly struct DateTime : IComparable, IComparable<DateTime>,
IConvertible, IEquatable<DateTime>, IParsable<DateTime>, ISpanFormattable,
ISpanParsable<DateTime>, IUtf8SpanFormattable,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → ValueType → DateTime

Implements IComparable , IComparable<DateTime> , IConvertible , IEquatable<DateTime> , IFormattable , ISerializable , ISpanFormattable , IParsable<DateTime> , IParsable<TSelf> , ISpanParsable<DateTime> , IUtf8SpanFormattable

Remarks

For more information about this API, see Supplemental API remarks for DateTime.

Constructors

Expand table

DateTime(DateOnly, TimeOnly)	Initializes a new instance of the DateTime structure to the specified DateOnly and TimeOnly. The new instance will have the Unspecified kind.
DateTime(DateOnly, TimeOnly, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified DateOnly and TimeOnly and respecting the specified DateTimeKind.

DateTime(Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, and day.
DateTime(Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, and day for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, and second.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, and second for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and Coordinated Universal Time (UTC) or local time.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and millisecond.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and millisecond for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Date TimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32,	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond,

DateTimeKind)	and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int64)	Initializes a new instance of the DateTime structure to a specified number of ticks.
DateTime(Int64, DateTimeKind)	Initializes a new instance of the DateTime structure to a specified number of ticks and to Coordinated Universal Time (UTC) or local time.

Fields

Expand table

Max Value	Represents the largest possible value of DateTime. This field is read-only.
Min Value	Represents the smallest possible value of DateTime. This field is read-only.
Unix Epoch	The value of this constant is equivalent to 00:00:00.0000000 UTC, January 1, 1970, in the Gregorian calendar. UnixEpoch defines the point in time when Unix time is equal to 0.

Properties

Expand table

Date	Gets the date component of this instance.
Day	Gets the day of the month represented by this instance.
DayOfWeek	Gets the day of the week represented by this instance.
DayOfYear	Gets the day of the year represented by this instance.
Hour	Gets the hour component of the date represented by this instance.
Kind	Gets a value that indicates whether the time represented by this instance is based on local time, Coordinated Universal Time (UTC), or neither.
Microsecond	The microseconds component, expressed as a value between 0 and 999.
Millisecond	Gets the milliseconds component of the date represented by this instance.
Minute	Gets the minute component of the date represented by this instance.

Month	Gets the month component of the date represented by this instance.
Nanosecond	The nanoseconds component, expressed as a value between 0 and 900 (in increments of 100 nanoseconds).
Now	Gets a DateTime object that is set to the current date and time on this computer, expressed as the local time.
Second	Gets the seconds component of the date represented by this instance.
Ticks	Gets the number of ticks that represent the date and time of this instance.
TimeOfDay	Gets the time of day for this instance.
Today	Gets the current date.
UtcNow	Gets a DateTime object that is set to the current date and time on this computer, expressed as the Coordinated Universal Time (UTC).
Year	Gets the year component of the date represented by this instance.

Methods

Expand table

Add(TimeSpan)	Returns a new DateTime that adds the value of the specified TimeSpan to the value of this instance.
AddDays(Double)	Returns a new DateTime that adds the specified number of days to the value of this instance.
AddHours(Double)	Returns a new DateTime that adds the specified number of hours to the value of this instance.
AddMicroseconds(Double)	Returns a new DateTime that adds the specified number of microseconds to the value of this instance.
AddMilliseconds(Double)	Returns a new DateTime that adds the specified number of milliseconds to the value of this instance.
AddMinutes(Double)	Returns a new DateTime that adds the specified number of minutes to the value of this instance.
AddMonths(Int32)	Returns a new DateTime that adds the specified number of months to the value of this instance.
AddSeconds(Double)	Returns a new DateTime that adds the specified number of seconds to the value of this instance.

AddTicks(Int64)	Returns a new DateTime that adds the specified number of ticks to the value of this instance.
AddYears(Int32)	Returns a new DateTime that adds the specified number of years to the value of this instance.
Compare(DateTime, DateTime)	Compares two instances of DateTime and returns an integer that indicates whether the first instance is earlier than, the same as, or later than the second instance.
CompareTo(DateTime)	Compares the value of this instance to a specified DateTime value and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.
CompareTo(Object)	Compares the value of this instance to a specified object that contains a specified DateTime value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.
DaysInMonth(Int32, Int32)	Returns the number of days in the specified month and year.
Deconstruct(DateOnly, TimeOnly)	Deconstructs this DateTime instance by DateOnly and TimeOnly.
Deconstruct(Int32, Int32, Int32)	Deconstructs this DateOnly instance by Year, Month, and Day.
Equals(DateTime)	Returns a value indicating whether the value of this instance is equal to the value of the specified DateTime instance.
Equals(DateTime, DateTime)	Returns a value indicating whether two DateTime instances have the same date and time value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
FromBinary(Int64)	Deserializes a 64-bit binary value and recreates an original serialized DateTime object.
FromFileTime(Int64)	Converts the specified Windows file time to an equivalent local time.
FromFileTimeUtc(Int64)	Converts the specified Windows file time to an equivalent UTC time.
FromOADate(Double)	Returns a DateTime equivalent to the specified OLE Automation Date.

GetDateTimeFormats()	Converts the value of this instance to all the string representations supported by the standard date and time format specifiers.
GetDateTimeFormats(Char)	Converts the value of this instance to all the string representations supported by the specified standard date and time format specifier.
GetDateTimeFormats(Char, IFormatProvider)	Converts the value of this instance to all the string representations supported by the specified standard date and time format specifier and culture-specific formatting information.
GetDateTimeFormats(IFormatProvider)	Converts the value of this instance to all the string representations supported by the standard date and time format specifiers and the specified culture-specific formatting information.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type DateTime.
IsDaylightSavingTime()	Indicates whether this instance of DateTime is within the daylight saving time range for the current time zone.
IsLeapYear(Int32)	Returns an indication whether the specified year is a leap year.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a memory span that contains string representation of a date and time to its DateTime equivalent by using culture-specific format information and a formatting style.
Parse(String)	Converts the string representation of a date and time to its DateTime equivalent by using the conventions of the current culture.
Parse(String, IFormatProvider)	Converts the string representation of a date and time to its DateTime equivalent by using culture-specific format information.
Parse(String, IFormatProvider, DateTimeStyles)	Converts the string representation of a date and time to its DateTime equivalent by using culture-specific format information and a formatting style.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format

	of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String, IFormatProvider)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
SpecifyKind(DateTime, DateTimeKind)	Creates a new DateTime object that has the same number of ticks as the specified DateTime, but is designated as either local time, Coordinated Universal Time (UTC), or neither, as indicated by the specified DateTimeKind value.
Subtract(DateTime)	Returns a new TimeSpan that subtracts the specified date and time from the value of this instance.
Subtract(TimeSpan)	Returns a new DateTime that subtracts the specified duration from the value of this instance.
ToBinary()	Serializes the current DateTime object to a 64-bit binary value that subsequently can be used to recreate the DateTime object.
ToFileTime()	Converts the value of the current DateTime object to a Windows file time.
ToFileTimeUtc()	Converts the value of the current DateTime object to a Windows file time.
ToLocalTime()	Converts the value of the current DateTime object to local time.

ToLongDateString()	Converts the value of the current DateTime object to its equivalent long date string representation.
ToLongTimeString()	Converts the value of the current DateTime object to its equivalent long time string representation.
ToOADate()	Converts the value of this instance to the equivalent OLE Automation date.
ToShortDateString()	Converts the value of the current DateTime object to its equivalent short date string representation.
ToShortTimeString()	Converts the value of the current DateTime object to its equivalent short time string representation.
ToString()	Converts the value of the current DateTime object to its equivalent string representation using the formatting conventions of the current culture.
ToString(IFormatProvider)	Converts the value of the current DateTime object to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the value of the current DateTime object to its equivalent string representation using the specified format and the formatting conventions of the current culture.
ToString(String, IFormatProvider)	Converts the value of the current DateTime object to its equivalent string representation using the specified format and culture-specific format information.
ToUniversalTime()	Converts the value of the current DateTime object to Coordinated Universal Time (UTC).
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current datetime instance into the provided span of characters.
TryParse(ReadOnlySpan<Char>, DateTime)	Converts the specified char span of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTime)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTime)	Converts the span representation of a date and time to its DateTime equivalent using the specified culture-specific format information and formatting style, and returns a value that indicates whether the conversion succeeded.

TryParse(String, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, DateTime)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, DateTimeStyles, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified culture-specific format information and formatting style, and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTime)	Converts the specified span representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateTime)	Converts the specified char span of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly. The method returns a value that indicates whether the conversion succeeded.

Operators

Expand table

Addition(DateTime, TimeSpan)	Adds a specified time interval to a specified date and time, yielding a new date and time.
Equality(DateTime, DateTime)	Determines whether two specified instances of DateTime are equal.

GreaterThan(DateTime, DateTime)	Determines whether one specified DateTime is later than another specified DateTime.
GreaterThanOrEqual(DateTime, DateTime)	Determines whether one specified DateTime represents a date and time that is the same as or later than another specified DateTime.
Inequality(DateTime, DateTime)	Determines whether two specified instances of DateTime are not equal.
LessThan(DateTime, DateTime)	Determines whether one specified DateTime is earlier than another specified DateTime.
LessThanOrEqual(DateTime, DateTime)	Determines whether one specified DateTime represents a date and time that is the same as or earlier than another specified DateTime.
Subtraction(DateTime, DateTime)	Subtracts a specified date and time from another specified date and time and returns a time interval.
Subtraction(DateTime, TimeSpan)	Subtracts a specified time interval from a specified date and time and returns a new date and time.

Explicit Interface Implementations

Expand table

IConvertible.ToBoolean(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToByte(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToChar(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDateTime(IFormatProvider)	Returns the current DateTime object.
IConvertible.ToDecimal(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDouble(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToInt16(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToInt32(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.

IConvertible.ToInt64(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToSByte(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToSingle(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToType(Type, IFormat Provider)	Converts the current DateTime object to an object of a specified type.
IConvertible.ToUInt16(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToUInt32(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToUInt64(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
ISerializable.GetObjectData(Serialization Info, StreamingContext)	Populates a SerializationInfo object with the data needed to serialize the current DateTime object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

DateTime Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the DateTime structure.

Overloads

Expand table

DateTime(Int64)	Initializes a new instance of the DateTime structure to a specified number of ticks.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and millisecond for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time.

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and millisecond.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and Coordinated Universal Time (UTC) or local time.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, and second.
DateTime(Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, and day for the specified calendar.
DateTime(Int32, Int32, Int32)	Initializes a new instance of the DateTime structure to the specified year, month, and day.
DateTime(DateOnly, TimeOnly, DateTimeKind)	Initializes a new instance of the DateTime structure to the specified DateOnly and TimeOnly and respecting the specified DateTimeKind.
DateTime(Int64, DateTimeKind)	Initializes a new instance of the DateTime structure to a specified number of ticks and to Coordinated Universal Time (UTC) or local time.
DateTime(DateOnly, TimeOnly)	Initializes a new instance of the DateTime structure to the specified DateOnly and TimeOnly. The new instance will have the Unspecified kind.
DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Calendar)	Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, and second for the specified calendar.

DateTime(Int64)

Initializes a new instance of the DateTime structure to a specified number of ticks.

C#

```
public DateTime (long ticks);
```

Parameters

`ticks` Int64

A date and time expressed in the number of 100-nanosecond intervals that have elapsed since January 1, 0001 at 00:00:00.000 in the Gregorian calendar.

Exceptions

ArgumentOutOfRangeException

`ticks` is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example demonstrates one of the DateTime constructors.

C#

```
// This example demonstrates the DateTime(Int64) constructor.
using System;
using System.Globalization;

class Sample
{
    public static void Main()
    {
// Instead of using the implicit, default "G" date and time format
string, we
// use a custom format string that aligns the results and inserts leading
zeroes.
    string format = "{0}) The {1} date and time is {2:MM/dd/yyyy hh:mm:ss
tt}";

// Create a DateTime for the maximum date and time using ticks.
    DateTime dt1 = new DateTime(DateTime.MaxValue.Ticks);

// Create a DateTime for the minimum date and time using ticks.
    DateTime dt2 = new DateTime(DateTime.MinValue.Ticks);

// Create a custom DateTime for 7/28/1979 at 10:35:05 PM using a
// calendar based on the "en-US" culture, and ticks.
    long ticks = new DateTime(1979, 07, 28, 22, 35, 5,
    new CultureInfo("en-US", false).Calendar).Ticks;
    DateTime dt3 = new DateTime(ticks);

    Console.WriteLine(format, 1, "maximum", dt1);
    Console.WriteLine(format, 2, "minimum", dt2);
    Console.WriteLine(format, 3, "custom ", dt3);
    Console.WriteLine("\nThe custom date and time is created from {0:N0}
ticks.", ticks);
    }
}
/*
```

```
This example produces the following results:

1) The maximum date and time is 12/31/9999 11:59:59 PM
2) The minimum date and time is 01/01/0001 12:00:00 AM
3) The custom  date and time is 07/28/1979 10:35:05 PM

The custom date and time is created from 624,376,461,050,000,000 ticks.

*/
```

Remarks

The Kind property is initialized to Unspecified.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.

```
C#
```

```
public DateTime (int year, int month, int day, int hour, int minute, int
second, int millisecond, int microsecond, System.Globalization.Calendar
calendar);
```

Parameters

`year` Int32

The year (1 through the number of years in `calendar`).

`month` Int32

The month (1 through the number of months in `calendar`).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`microsecond` Int32

The microseconds (0 through 999).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

Exceptions

ArgumentNullException

`calendar` is `null`

ArgumentOutOfRangeException

`year` is not in the range supported by `calendar`.

-or-

`month` is less than 1 or greater than the number of months in `calendar`.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`microsecond` is less than 0 or greater than 999.

Remarks

The allowable values for `year`, `month`, and `day` parameters depend on the `calendar` parameter. An exception is thrown if the specified date and time cannot be expressed using `calendar`.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.

```
C#

public DateTime (int year, int month, int day, int hour, int minute, int
second, int millisecond, int microsecond, DateTimeKind kind);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`microsecond` Int32

The microseconds (0 through 999).

`kind` DateTimeKind

One of the enumeration values that indicates whether `year`, `month`, `day`, `hour`, `minute`, `second`, and `millisecond` specify a local time, Coordinated Universal Time (UTC), or neither.

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`microsecond` is less than 0 or greater than 999.

ArgumentException

`kind` is not one of the DateTimeKind values.

Remarks

This constructor interprets `year`, `month` and `day` as a year, month and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month and day in another calendar, call the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind) constructor.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.

C#

```
public DateTime (int year, int month, int day, int hour, int minute, int
second, int millisecond, System.Globalization.Calendar calendar,
DateTimeKind kind);
```

Parameters

`year` Int32

The year (1 through the number of years in `calendar`).

`month` Int32

The month (1 through the number of months in `calendar`).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

`kind` DateTimeKind

One of the enumeration values that indicates whether `year`, `month`, `day`, `hour`, `minute`, `second`, and `millisecond` specify a local time, Coordinated Universal Time (UTC), or neither.

Exceptions

ArgumentNullException

`calendar` is `null`.

ArgumentOutOfRangeException

`year` is not in the range supported by `calendar`.

-or-

`month` is less than 1 or greater than the number of months in `calendar`.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

ArgumentException
`kind` is not one of the DateTimeKind values.

Examples

The following example calls the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind) constructor twice to instantiate two DateTime values. The first call instantiates a DateTime value by using a PersianCalendar object. Because the Persian calendar cannot be designated as the default calendar for a culture, displaying a date in the Persian calendar requires individual calls to its PersianCalendar.GetMonth, PersianCalendar.GetDayOfMonth, and PersianCalendar.GetYear methods. The second call to the constructor instantiates a DateTime value by using a HijriCalendar object. The example changes the current culture to Arabic (Syria) and changes the current culture's default calendar to the Hijri calendar. Because Hijri is the current culture's default calendar, the Console.WriteLine method uses it to format the date. When the previous current culture (which is English (United States) in this case) is restored, the Console.WriteLine method uses the current culture's default Gregorian calendar to format the date.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;
using System.Threading;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("Using the Persian Calendar:");
      PersianCalendar persian = new PersianCalendar();
      DateTime date1 = new DateTime(1389, 5, 27, 16, 32, 18, 500,
```

```
                                    persian, DateTimeKind.Local);
      Console.WriteLine("{0:M/dd/yyyy h:mm:ss.fff tt} {1}", date1,
date1.Kind);
      Console.WriteLine("{0}/{1}/{2} {3}{8}{4:D2}{8}{5:D2}.{6:G3} {7}\n",
                                        persian.GetMonth(date1),
                                        persian.GetDayOfMonth(date1),
                                        persian.GetYear(date1),
                                        persian.GetHour(date1),
                                        persian.GetMinute(date1),
                                        persian.GetSecond(date1),
                                        persian.GetMilliseconds(date1),
                                        date1.Kind,

DateTimeFormatInfo.CurrentInfo.TimeSeparator);

      Console.WriteLine("Using the Hijri Calendar:");
      // Get current culture so it can later be restored.
      CultureInfo dftCulture = Thread.CurrentThread.CurrentCulture;

      // Define strings for use in composite formatting.
      string dFormat;
      string fmtString;
      // Define Hijri calendar.
      HijriCalendar hijri = new HijriCalendar();
      // Make ar-SY the current culture and Hijri the current calendar.
      Thread.CurrentThread.CurrentCulture = new CultureInfo("ar-SY");
      CultureInfo current = CultureInfo.CurrentCulture;
      current.DateTimeFormat.Calendar = hijri;
      dFormat = current.DateTimeFormat.ShortDatePattern;
      // Ensure year is displayed as four digits.
      dFormat = Regex.Replace(dFormat, "/yy$", "/yyyy") + " H:mm:ss.fff";
      fmtString = "{0} culture using the {1} calendar: {2:" + dFormat +
"} {3}";
      DateTime date2 = new DateTime(1431, 9, 9, 16, 32, 18, 500,
                                    hijri, DateTimeKind.Local);
      Console.WriteLine(fmtString, current, GetCalendarName(hijri),
                        date2, date2.Kind);

      // Restore previous culture.
      Thread.CurrentThread.CurrentCulture = dftCulture;
      dFormat = DateTimeFormatInfo.CurrentInfo.ShortDatePattern +"
H:mm:ss.fff";
      fmtString = "{0} culture using the {1} calendar: {2:" + dFormat +
"} {3}";
      Console.WriteLine(fmtString,
                        CultureInfo.CurrentCulture,

GetCalendarName(CultureInfo.CurrentCulture.Calendar),
                        date2, date2.Kind);
   }

   private static string GetCalendarName(Calendar cal)
   {
      return Regex.Match(cal.ToString(), "\\.
(\\w+)Calendar").Groups[1].Value;
```

```
    }
}
// The example displays the following output:
//    Using the Persian Calendar:
//    8/18/2010 4:32:18.500 PM Local
//    5/27/1389 16:32:18.500 Local
//
//    Using the Hijri Calendar:
//    ar-SY culture using the Hijri calendar: 09/09/1431 16:32:18.500
Local
//    en-US culture using the Gregorian calendar: 8/18/2010 16:32:18.500
Local
```

Remarks

The allowable values for `year`, `month`, and `day` parameters depend on the `calendar` parameter. An exception is thrown if the specified date and time cannot be expressed using `calendar`.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

The System.Globalization namespace provides several calendars including GregorianCalendar and JulianCalendar.

.NET Standard	2.0, 2.1

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.

C#

```
public DateTime (int year, int month, int day, int hour, int minute, int
second, int millisecond, int microsecond);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`microsecond` Int32

The microseconds (0 through 999).

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`microsecond` is less than 0 or greater than 999.

Remarks

This constructor interprets `year`, `month` and `day` as a year, month and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month and day in another calendar, call the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar) constructor.

The Kind property is initialized to Unspecified.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

Applies to

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

Examples

The following example calls the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar) constructor twice to instantiate two DateTime values. The first call instantiates a DateTime value by using a PersianCalendar object. Because the Persian calendar cannot be designated as the default calendar for a culture, displaying a date in the Persian calendar requires individual calls to its PersianCalendar.GetMonth, PersianCalendar.GetDayOfMonth, and PersianCalendar.GetYear methods. The second call to the constructor instantiates a DateTime value by using a HijriCalendar object. The example changes the current culture to Arabic (Syria) and changes the current culture's default calendar to the Hijri calendar. Because Hijri is the current culture's default calendar, the Console.WriteLine method uses it to format the date. When the previous current culture (which is English (United States) in this case) is restored, the Console.WriteLine method uses the current culture's default Gregorian calendar to format the date.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;
using System.Threading;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("Using the Persian Calendar:");
      PersianCalendar persian = new PersianCalendar();
      DateTime date1 = new DateTime(1389, 5, 27, 16, 32, 18, 500,
persian);
      Console.WriteLine(date1.ToString("M/dd/yyyy h:mm:ss.fff tt"));
      Console.WriteLine("{0}/{1}/{2} {3}{7}{4:D2}{7}{5:D2}.{6:G3}\n",
                                       persian.GetMonth(date1),
                                       persian.GetDayOfMonth(date1),
                                       persian.GetYear(date1),
                                       persian.GetHour(date1),
                                       persian.GetMinute(date1),
                                       persian.GetSecond(date1),
                                       persian.GetMilliseconds(date1),

DateTimeFormatInfo.CurrentInfo.TimeSeparator);

      Console.WriteLine("Using the Hijri Calendar:");
      // Get current culture so it can later be restored.
      CultureInfo dftCulture = Thread.CurrentThread.CurrentCulture;

      // Define strings for use in composite formatting.
      string dFormat;
      string fmtString;
      // Define Hijri calendar.
      HijriCalendar hijri = new HijriCalendar();
```

```
      // Make ar-SY the current culture and Hijri the current calendar.
      Thread.CurrentThread.CurrentCulture = new CultureInfo("ar-SY");
      CultureInfo current = CultureInfo.CurrentCulture;
      current.DateTimeFormat.Calendar = hijri;
      dFormat = current.DateTimeFormat.ShortDatePattern;
      // Ensure year is displayed as four digits.
      dFormat = Regex.Replace(dFormat, "/yy$", "/yyyy") + " H:mm:ss.fff";
      fmtString = "{0} culture using the {1} calendar: {2:" + dFormat +
"}";
      DateTime date2 = new DateTime(1431, 9, 9, 16, 32, 18, 500, hijri);
      Console.WriteLine(fmtString, current, GetCalendarName(hijri),
date2);

      // Restore previous culture.
      Thread.CurrentThread.CurrentCulture = dftCulture;
      dFormat = DateTimeFormatInfo.CurrentInfo.ShortDatePattern +"
H:mm:ss.fff";
      fmtString = "{0} culture using the {1} calendar: {2:" + dFormat +
"}";
      Console.WriteLine(fmtString,
                        CultureInfo.CurrentCulture,

GetCalendarName(CultureInfo.CurrentCulture.Calendar),
                        date2);
   }

   private static string GetCalendarName(Calendar cal)
   {
      return Regex.Match(cal.ToString(), "\\.
(\\w+)Calendar").Groups[1].Value;
   }
}
// The example displays the following output:
//       8/18/2010 4:32:18.500 PM
//       5/27/1389 16:32:18.500
//
//       Using the Hijri Calendar:
//       ar-SY culture using the Hijri calendar: 09/09/1431 16:32:18.500
//       en-US culture using the Gregorian calendar: 8/18/2010
16:32:18.500
```

Remarks

The Kind property is initialized to Unspecified.

The allowable values for `year`, `month`, and `day` depend on `calendar`. An exception is thrown if the specified date and time cannot be expressed using `calendar`.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

.NET Standard	2.0, 2.1

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time.

```
C#

public DateTime (int year, int month, int day, int hour, int minute, int
second, int millisecond, DateTimeKind kind);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`kind` DateTimeKind

One of the enumeration values that indicates whether `year`, `month`, `day`, `hour`, `minute`, `second`, and `millisecond` specify a local time, Coordinated Universal Time (UTC), or neither.

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

ArgumentException
`kind` is not one of the DateTimeKind values.

Examples

The following example uses the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind) constructor to instantiate a DateTime value.

C#

```
DateTime date1 = new DateTime(2010, 8, 18, 16, 32, 18, 500,
                              DateTimeKind.Local);
Console.WriteLine("{0:M/dd/yyyy h:mm:ss.fff tt} {1}", date1, date1.Kind);
// The example displays the following output, in this case for en-us
culture:
//      8/18/2010 4:32:18.500 PM Local
```

Remarks

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month, and day in another calendar, call the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind) constructor.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

Examples

The following example uses the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32) constructor to instantiate a DateTime value.

C#

```
DateTime date1 = new DateTime(2010, 8, 18, 16, 32, 18, 500);
Console.WriteLine(date1.ToString("M/dd/yyyy h:mm:ss.fff tt"));
// The example displays the following output, in this case for en-us
culture:
//      8/18/2010 4:32:18.500 PM
```

Remarks

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month, and day in another calendar, call the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar) constructor.

The Kind property is initialized to Unspecified.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

UWP	10.0

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, millisecond, and Coordinated Universal Time (UTC) or local time for the specified calendar.

```
C#

public DateTime (int year, int month, int day, int hour, int minute, int
second, int millisecond, int microsecond, System.Globalization.Calendar
calendar, DateTimeKind kind);
```

Parameters

`year` Int32

The year (1 through the number of years in `calendar`).

`month` Int32

The month (1 through the number of months in `calendar`).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`microsecond` Int32

The microseconds (0 through 999).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

`kind` DateTimeKind

One of the enumeration values that indicates whether `year`, `month`, `day`, `hour`, `minute`, `second`, and `millisecond` specify a local time, Coordinated Universal Time (UTC), or neither.

Exceptions

ArgumentNullException

`calendar` is `null`

ArgumentOutOfRangeException

`year` is not in the range supported by `calendar`.

-or-

`month` is less than 1 or greater than the number of months in `calendar`.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`microsecond` is less than 0 or greater than 999.

ArgumentException

`kind` is not one of the DateTimeKind values.

Remarks

The allowable values for `year`, `month`, and `day` parameters depend on the `calendar` parameter. An exception is thrown if the specified date and time cannot be expressed using `calendar`.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, second, and Coordinated Universal Time (UTC) or local time.

C#

```
public DateTime (int year, int month, int day, int hour, int minute, int
second, DateTimeKind kind);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`kind` DateTimeKind

One of the enumeration values that indicates whether `year`, `month`, `day`, `hour`, `minute` and `second` specify a local time, Coordinated Universal Time (UTC), or neither.

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

ArgumentException

`kind` is not one of the DateTimeKind values.

Examples

The following example uses the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, DateTimeKind) constructor to instantiate a DateTime value.

```
C#

DateTime date1 = new DateTime(2010, 8, 18, 16, 32, 0,
DateTimeKind.Local);
Console.WriteLine("{0} {1}", date1, date1.Kind);
// The example displays the following output, in this case for en-us
culture:
//      8/18/2010 4:32:00 PM Local
```

Remarks

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month, and day in another calendar, call the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, DateTimeKind) constructor.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

UWP	10.0

DateTime(Int32, Int32, Int32, Int32, Int32, Int32)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, and second.

```
C#

public DateTime (int year, int month, int day, int hour, int minute, int
second);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

Examples

The following example uses the DateTime constructor to instantiate a DateTime value.

```
C#

DateTime date1 = new DateTime(2010, 8, 18, 16, 32, 0);
Console.WriteLine(date1.ToString());
// The example displays the following output, in this case for en-us
culture:
//      8/18/2010 4:32:00 PM
```

Remarks

The Kind property is initialized to Unspecified.

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month, and day in another calendar, call the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Calendar) constructor.

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime(Int32, Int32, Int32, Calendar)

Initializes a new instance of the DateTime structure to the specified year, month, and day for the specified calendar.

C#

```
public DateTime (int year, int month, int day,
System.Globalization.Calendar calendar);
```

Parameters

`year` Int32

The year (1 through the number of years in `calendar`).

`month` Int32

The month (1 through the number of months in `calendar`).

`day` Int32

The day (1 through the number of days in `month`).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

Exceptions

ArgumentNullException

`calendar` is `null`.

ArgumentOutOfRangeException

`year` is not in the range supported by `calendar`.

-or-

`month` is less than 1 or greater than the number of months in `calendar`.

-or-

`day` is less than 1 or greater than the number of days in `month`.

Examples

The following example calls the DateTime(Int32, Int32, Int32, Calendar) constructor twice to instantiate two DateTime values. The first call instantiates a DateTime value by using a PersianCalendar object. Because the Persian calendar cannot be designated as the default calendar for a culture, displaying a date in the Persian calendar requires individual calls to its PersianCalendar.GetMonth, PersianCalendar.GetDayOfMonth, and PersianCalendar.GetYear methods. The second call to the constructor instantiates a DateTime value by using a HijriCalendar object. The example changes the current culture to Arabic (Syria) and changes the current culture's default calendar to the Hijri calendar. Because Hijri is the current culture's default calendar, the Console.WriteLine method uses it to format the date. When the previous current culture (which is English (United States) in this case) is restored, the Console.WriteLine method uses the current culture's default Gregorian calendar to format the date.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;
using System.Threading;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("Using the Persian Calendar:");
      PersianCalendar persian = new PersianCalendar();
      DateTime date1 = new DateTime(1389, 5, 27, persian);
      Console.WriteLine(date1.ToString());
      Console.WriteLine("{0}/{1}/{2}\n", persian.GetMonth(date1),
                                         persian.GetDayOfMonth(date1),
                                         persian.GetYear(date1));

      Console.WriteLine("Using the Hijri Calendar:");
      // Get current culture so it can later be restored.
      CultureInfo dftCulture = Thread.CurrentThread.CurrentCulture;

      // Define Hijri calendar.
```

```
        HijriCalendar hijri = new HijriCalendar();
        // Make ar-SY the current culture and Hijri the current calendar.
        Thread.CurrentThread.CurrentCulture = new CultureInfo("ar-SY");
        CultureInfo current = CultureInfo.CurrentCulture;
        current.DateTimeFormat.Calendar = hijri;
        string dFormat = current.DateTimeFormat.ShortDatePattern;
        // Ensure year is displayed as four digits.
        dFormat = Regex.Replace(dFormat, "/yy$", "/yyyy");
        current.DateTimeFormat.ShortDatePattern = dFormat;
        DateTime date2 = new DateTime(1431, 9, 9, hijri);
        Console.WriteLine("{0} culture using the {1} calendar: {2:d}",
current,
                          GetCalendarName(hijri), date2);

        // Restore previous culture.
        Thread.CurrentThread.CurrentCulture = dftCulture;
        Console.WriteLine("{0} culture using the {1} calendar: {2:d}",
                          CultureInfo.CurrentCulture,

GetCalendarName(CultureInfo.CurrentCulture.Calendar),
                          date2);
    }

    private static string GetCalendarName(Calendar cal)
    {
        return Regex.Match(cal.ToString(), "\\.
(\\w+)Calendar").Groups[1].Value;
    }
}
// The example displays the following output:
//       Using the Persian Calendar:
//       8/18/2010 12:00:00 AM
//       5/27/1389
//
//       Using the Hijri Calendar:
//       ar-SY culture using the Hijri calendar: 09/09/1431
//       en-US culture using the Gregorian calendar: 8/18/2010
```

Remarks

The time of day for the resulting DateTime is midnight (00:00:00). The Kind property is initialized to Unspecified.

The allowable values for `year`, `month`, and `day` depend on `calendar`. An exception is thrown if the specified date and time cannot be expressed using `calendar`.

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning

of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

The System.Globalization namespace provides several calendars including GregorianCalendar and JulianCalendar.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DateTime(Int32, Int32, Int32)

Initializes a new instance of the DateTime structure to the specified year, month, and day.

C#

```
public DateTime (int year, int month, int day);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

Examples

The following example uses the DateTime(Int32, Int32, Int32) constructor to instantiate a DateTime value. The example also illustrates that this overload creates a DateTime value whose time component equals midnight (or 0:00).

C#

```
DateTime date1 = new DateTime(2010, 8, 18);
Console.WriteLine(date1.ToString());
// The example displays the following output:
//       8/18/2010 12:00:00 AM
```

Remarks

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTime value by using the year, month, and day in another calendar, call the DateTime(Int32, Int32, Int32, Calendar) constructor.

The time of day for the resulting DateTime is midnight (00:00:00). The Kind property is initialized to DateTimeKind.Unspecified.

DateTime(DateOnly, TimeOnly, DateTimeKind)

Initializes a new instance of the DateTime structure to the specified DateOnly and TimeOnly and respecting the specified DateTimeKind.

C#

```
public DateTime (DateOnly date, TimeOnly time, DateTimeKind kind);
```

Parameters

`date` DateOnly

The date part.

`time` TimeOnly

The time part.

`kind` DateTimeKind

One of the enumeration values that indicates whether `date` and `time` specify a local time, Coordinated Universal Time (UTC), or neither.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

DateTime(Int64, DateTimeKind)

Initializes a new instance of the DateTime structure to a specified number of ticks and to Coordinated Universal Time (UTC) or local time.

```
C#
public DateTime (long ticks, DateTimeKind kind);
```

Parameters

`ticks` Int64

A date and time expressed in the number of 100-nanosecond intervals that have elapsed since January 1, 0001 at 00:00:00.000 in the Gregorian calendar.

`kind` DateTimeKind

One of the enumeration values that indicates whether `ticks` specifies a local time, Coordinated Universal Time (UTC), or neither.

Exceptions

ArgumentOutOfRangeException

`ticks` is less than DateTime.MinValue or greater than DateTime.MaxValue.

ArgumentException

`kind` is not one of the DateTimeKind values.

Remarks

For applications in which portability of date and time data or a limited degree of time zone awareness is important, you can use the corresponding DateTimeOffset constructor.

DateTime(DateOnly, TimeOnly)

Initializes a new instance of the DateTime structure to the specified DateOnly and TimeOnly. The new instance will have the Unspecified kind.

C#

```
public DateTime (DateOnly date, TimeOnly time);
```

Parameters

`date` DateOnly

The date part.

`time` TimeOnly

The time part.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Calendar)

Initializes a new instance of the DateTime structure to the specified year, month, day, hour, minute, and second for the specified calendar.

```
C#

public DateTime (int year, int month, int day, int hour, int minute, int
second, System.Globalization.Calendar calendar);
```

Parameters

`year` Int32

The year (1 through the number of years in `calendar`).

`month` Int32

The month (1 through the number of months in `calendar`).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

Exceptions

ArgumentNullException

`calendar` is `null`.

ArgumentOutOfRangeException

`year` is not in the range supported by `calendar`.

-or-

`month` is less than 1 or greater than the number of months in `calendar`.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

Examples

The following example calls the DateTime(Int32, Int32, Int32, Int32, Int32, Int32, Calendar) constructor twice to instantiate two DateTime values. The first call instantiates a DateTime value by using a PersianCalendar object. Because the Persian calendar cannot be designated as the default calendar for a culture, displaying a date in the Persian calendar requires individual calls to its PersianCalendar.GetMonth, PersianCalendar.GetDayOfMonth, and PersianCalendar.GetYear methods. The second call to the constructor instantiates a DateTime value by using a HijriCalendar object. The example changes the current culture to Arabic (Syria) and changes the current culture's default calendar to the Hijri calendar. Because Hijri is the current culture's default calendar, the Console.WriteLine method uses it to format the date. When the previous current culture (which is English (United States) in this case) is restored, the Console.WriteLine method uses the current culture's default Gregorian calendar to format the date.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;
using System.Threading;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("Using the Persian Calendar:");
```

```
      PersianCalendar persian = new PersianCalendar();
      DateTime date1 = new DateTime(1389, 5, 27, 16, 32, 0, persian);
      Console.WriteLine(date1.ToString());
      Console.WriteLine("{0}/{1}/{2} {3}{6}{4:D2}{6}{5:D2}\n",
                                        persian.GetMonth(date1),
                                        persian.GetDayOfMonth(date1),
                                        persian.GetYear(date1),
                                        persian.GetHour(date1),
                                        persian.GetMinute(date1),
                                        persian.GetSecond(date1),

DateTimeFormatInfo.CurrentInfo.TimeSeparator);

      Console.WriteLine("Using the Hijri Calendar:");
      // Get current culture so it can later be restored.
      CultureInfo dftCulture = Thread.CurrentThread.CurrentCulture;

      // Define Hijri calendar.
      HijriCalendar hijri = new HijriCalendar();
      // Make ar-SY the current culture and Hijri the current calendar.
      Thread.CurrentThread.CurrentCulture = new CultureInfo("ar-SY");
      CultureInfo current = CultureInfo.CurrentCulture;
      current.DateTimeFormat.Calendar = hijri;
      string dFormat = current.DateTimeFormat.ShortDatePattern;
      // Ensure year is displayed as four digits.
      dFormat = Regex.Replace(dFormat, "/yy$", "/yyyy");
      current.DateTimeFormat.ShortDatePattern = dFormat;
      DateTime date2 = new DateTime(1431, 9, 9, 16, 32, 18, hijri);
      Console.WriteLine("{0} culture using the {1} calendar: {2:g}",
current,
                        GetCalendarName(hijri), date2);

      // Restore previous culture.
      Thread.CurrentThread.CurrentCulture = dftCulture;
      Console.WriteLine("{0} culture using the {1} calendar: {2:g}",
                        CultureInfo.CurrentCulture,

GetCalendarName(CultureInfo.CurrentCulture.Calendar),
                        date2);
   }

   private static string GetCalendarName(Calendar cal)
   {
      return Regex.Match(cal.ToString(), "\\.
(\\w+)Calendar").Groups[1].Value;
   }
}
// The example displays the following output:
//       Using the Persian Calendar:
//       8/18/2010 4:32:00 PM
//       5/27/1389 16:32:00
//
//       Using the Hijri Calendar:
//       ar-SY culture using the Hijri calendar: 09/09/1431 04:32 م
//       en-US culture using the Gregorian calendar: 8/18/2010 4:32 PM
```

Remarks

The Kind property is initialized to Unspecified.

The allowable values for `year`, `month`, and `day` depend on `calendar`. An exception is thrown if the specified date and time cannot be expressed using `calendar`.

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

The System.Globalization namespace provides several calendars including GregorianCalendar and JulianCalendar.

DateTime.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of DateTime. This field is read-only.

C#

```
public static readonly DateTime MaxValue;
```

Field Value

DateTime

Examples

The following example instantiates a DateTime object by passing its constructor an Int64 value that represents a number of ticks. Before invoking the constructor, the example ensures that this value is greater than or equal to `DateTime.MinValue.Ticks` and less than or equal to `DateTime.MaxValue.Ticks`. If not, it throws an ArgumentOutOfRangeException.

C#

```
// Attempt to assign an out-of-range value to a DateTime constructor.
long numberOfTicks = Int64.MaxValue;
DateTime validDate;

// Validate the value.
if (numberOfTicks >= DateTime.MinValue.Ticks &&
    numberOfTicks <= DateTime.MaxValue.Ticks)
   validDate = new DateTime(numberOfTicks);
else if (numberOfTicks < DateTime.MinValue.Ticks)
   Console.WriteLine("{0:N0} is less than {1:N0} ticks.",
                     numberOfTicks,
                     DateTime.MinValue.Ticks);
else
   Console.WriteLine("{0:N0} is greater than {1:N0} ticks.",
                     numberOfTicks,
```

```
                        DateTime.MaxValue.Ticks);
// The example displays the following output:
//   9,223,372,036,854,775,807 is greater than 3,155,378,975,999,999,999
ticks.
```

Remarks

The value of this constant is equivalent to 23:59:59.9999999 UTC, December 31, 9999 in the Gregorian calendar, exactly one 100-nanosecond tick before 00:00:00 UTC, January 1, 10000.

Some calendars, such as the ThaiBuddhistCalendar, support an upper date range that is earlier than MaxValue. In these cases, trying to access MaxValue in variable assignments or formatting and parsing operations can throw an ArgumentOutOfRangeException. Rather than retrieving the value of DateTime.MaxValue, you can retrieve the value of the specified culture's latest valid date value from the Calendar.MaxSupportedDateTime property.

DateTime.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of DateTime. This field is read-only.

C#

```
public static readonly DateTime MinValue;
```

Field Value

DateTime

Examples

The following example instantiates a DateTime object by passing its constructor an Int64 value that represents a number of ticks. Before invoking the constructor, the example ensures that this value is greater than or equal to `DateTime.MinValue.Ticks` and less than or equal to `DateTime.MaxValue.Ticks`. If not, it throws an ArgumentOutOfRangeException.

C#

```
// Attempt to assign an out-of-range value to a DateTime constructor.
long numberOfTicks = Int64.MaxValue;
DateTime validDate;

// Validate the value.
if (numberOfTicks >= DateTime.MinValue.Ticks &&
    numberOfTicks <= DateTime.MaxValue.Ticks)
   validDate = new DateTime(numberOfTicks);
else if (numberOfTicks < DateTime.MinValue.Ticks)
   Console.WriteLine("{0:N0} is less than {1:N0} ticks.",
                     numberOfTicks,
                     DateTime.MinValue.Ticks);
else
   Console.WriteLine("{0:N0} is greater than {1:N0} ticks.",
                     numberOfTicks,
```

```
                        DateTime.MaxValue.Ticks);
// The example displays the following output:
//   9,223,372,036,854,775,807 is greater than 3,155,378,975,999,999,999
ticks.
```

Remarks

The value of this constant is equivalent to 00:00:00.0000000 UTC, January 1, 0001, in the Gregorian calendar.

MinValue defines the date and time that is assigned to an uninitialized DateTime variable. The following example illustrates this.

C#

```
// Define an uninitialized date.
DateTime date1 = new DateTime();
Console.Write(date1);
if (date1.Equals(DateTime.MinValue))
   Console.WriteLine("  (Equals Date.MinValue)");
// The example displays the following output:
//    1/1/0001 12:00:00 AM  (Equals Date.MinValue)
```

The MinValue and MaxValue properties can be used to ensure that a value lies within the supported range before passing it to a DateTime constructor. The code in the Example section illustrates this usage.

Applies to

DateTime.UnixEpoch Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The value of this constant is equivalent to 00:00:00.0000000 UTC, January 1, 1970, in the Gregorian calendar. UnixEpoch defines the point in time when Unix time is equal to 0.

C#

```
public static readonly DateTime UnixEpoch;
```

Field Value

DateTime

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

DateTime.Date Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the date component of this instance.

C#

```
public DateTime Date { get; }
```

Property Value

DateTime

A new object with the same date as this instance, and the time value set to 12:00:00 midnight (00:00:00).

Examples

The following example uses the Date property to extract the date component of a DateTime value with its time component set to zero (or 0:00:00, or midnight). It also illustrates that, depending on the format string used when displaying the DateTime value, the time component can continue to appear in formatted output.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime date1 = new DateTime(2008, 6, 1, 7, 47, 0);
      Console.WriteLine(date1.ToString());

      // Get date-only portion of date, without its time.
      DateTime dateOnly = date1.Date;
      // Display date using short date string.
      Console.WriteLine(dateOnly.ToString("d"));
```

```
        // Display date using 24-hour clock.
        Console.WriteLine(dateOnly.ToString("g"));
        Console.WriteLine(dateOnly.ToString("MM/dd/yyyy HH:mm"));
    }
}
// The example displays output like the following output:
//       6/1/2008 7:47:00 AM
//       6/1/2008
//       6/1/2008 12:00 AM
//       06/01/2008 00:00
```

Remarks

The value of the Kind property of the returned DateTime value is the same as that of the current instance.

Because the DateTime type represents both dates and times in a single type, it is important to avoid misinterpreting a date returned by the Date property as a date and time.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Day Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the month represented by this instance.

C#

```
public int Day { get; }
```

Property Value

Int32

The day component, expressed as a value between 1 and 31.

Examples

The following example demonstrates the Day property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

Remarks

The Day property always returns the day of the month in the Gregorian calendar, even if the current DateTime value was instantiated using some other calendar or if the current culture's default calendar is not the Gregorian calendar. To retrieve the day of the month of a particular date using some other calendar, call that calendar's Calendar.GetDayOfMonth method. The following example uses both the Day property and the HijriCalendar.GetDayOfMonth method to retrieve the day of the month for a DateTime value that is instantiated using the Hijri calendar.

C#

```
// Return day of 1/13/2009.
DateTime dateGregorian = new DateTime(2009, 1, 13);
Console.WriteLine(dateGregorian.Day);
// Displays 13 (Gregorian day).

// Create date of 1/13/2009 using Hijri calendar.
HijriCalendar hijri = new HijriCalendar();
DateTime dateHijri = new DateTime(1430, 1, 17, hijri);
// Return day of date created using Hijri calendar.
Console.WriteLine(dateHijri.Day);
// Displays 13 (Gregorian day).

// Display day of date in Hijri calendar.
Console.WriteLine(hijri.GetDayOfMonth(dateHijri));
// Displays 17 (Hijri day).
```

Similarly, the following example uses both the Day property and the HijriCalendar.GetDayOfMonth method to retrieve the day of the month when the current culture is ar-SA, which uses Hijri as its default calendar.

C#

```
CultureInfo originalCulture = Thread.CurrentThread.CurrentCulture;

// Change current culture to ar-SA.
CultureInfo ci = new CultureInfo("ar-SA");
Thread.CurrentThread.CurrentCulture = ci;

DateTime hijriDate = new DateTime(1430, 1, 17,
                          Thread.CurrentThread.CurrentCulture.Calendar);
// Display date (uses calendar of current culture by default).
```

```
Console.WriteLine(hijriDate.ToString("dd-MM-yyyy"));
// Displays 17-01-1430.

// Display day of 17th of Muharram
Console.WriteLine(hijriDate.Day);
// Displays 13 (corresponding day of January in Gregorian calendar).

// Display day of 17th of Muharram in Hijri calendar.
Console.WriteLine(Thread.CurrentThread.CurrentCulture.Calendar.GetDayOfMonth
(hijriDate));
// Displays 17.

Thread.CurrentThread.CurrentCulture = originalCulture;
```

Applies to

Product	Versions

DateTime.DayOfWeek Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the week represented by this instance.

C#

```
public DayOfWeek DayOfWeek { get; }
```

Property Value

DayOfWeek

An enumerated constant that indicates the day of the week of this DateTime value.

Examples

The following example demonstrates the DayOfWeek property and the System.DayOfWeek enumeration.

C#

```
// This example demonstrates the DateTime.DayOfWeek property
using System;

class Sample
{
    public static void Main()
    {
// Assume the current culture is en-US.
// Create a DateTime for the first of May, 2003.
    DateTime dt = new DateTime(2003, 5, 1);
    Console.WriteLine("Is Thursday the day of the week for {0:d}?: {1}",
                      dt, dt.DayOfWeek == DayOfWeek.Thursday);
    Console.WriteLine("The day of the week for {0:d} is {1}.", dt,
dt.DayOfWeek);
    }
}
/*
```

```
This example produces the following results:

Is Thursday the day of the week for 5/1/2003?: True
The day of the week for 5/1/2003 is Thursday.
*/
```

Remarks

The value of the constants in the DayOfWeek enumeration ranges from DayOfWeek.Sunday to DayOfWeek.Saturday. If cast to an integer, its value ranges from zero (which indicates DayOfWeek.Sunday) to six (which indicates DayOfWeek.Saturday).

The DayOfWeek property returns an enumerated constant; it does not reflect a system's regional and language settings. To retrieve a string representing a localized weekday name for a particular date, call one of the overloads of the ToString method that includes a `format` parameter and pass it either the `ddd` or `dddd` custom format strings. For details, see How to: Extract the Day of the Week from a Specific Date.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.DayOfYear Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the year represented by this instance.

C#

```
public int DayOfYear { get; }
```

Property Value

Int32

The day of the year, expressed as a value between 1 and 366.

Examples

The following example displays the day of the year of December 31 for the years 2010-2020 in the Gregorian calendar. Note that the example shows that December 31 is the 366th day of the year in leap years.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime dec31 = new DateTime(2010, 12, 31);
      for (int ctr = 0; ctr <= 10; ctr++) {
         DateTime dateToDisplay = dec31.AddYears(ctr);
         Console.WriteLine("{0:d}: day {1} of {2} {3}", dateToDisplay,
                           dateToDisplay.DayOfYear,
                           dateToDisplay.Year,
                           DateTime.IsLeapYear(dateToDisplay.Year) ?
                                              "(Leap Year)" : "");
      }
   }
```

```
}
// The example displays the following output:
//       12/31/2010: day 365 of 2010
//       12/31/2011: day 365 of 2011
//       12/31/2012: day 366 of 2012 (Leap Year)
//       12/31/2013: day 365 of 2013
//       12/31/2014: day 365 of 2014
//       12/31/2015: day 365 of 2015
//       12/31/2016: day 366 of 2016 (Leap Year)
//       12/31/2017: day 365 of 2017
//       12/31/2018: day 365 of 2018
//       12/31/2019: day 365 of 2019
//       12/31/2020: day 366 of 2020 (Leap Year)
```

Remarks

The DayOfYear property takes leap years into account when it calculates the day of the year. The property value always reflects the day of the year in the Gregorian calendar, regardless of the current culture's current calendar. To retrieve the day of the year in a different calendar, call the Calendar.GetDayOfYear method of that calendar.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Hour Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the hour component of the date represented by this instance.

C#

```
public int Hour { get; }
```

Property Value

Int32

The hour component, expressed as a value between 0 and 23.

Examples

The following example demonstrates the Hour property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

Remarks

The value of the Hour property is always expressed using a 24-hour clock. To retrieve a string that represents the hour of a date and time using a 12-hour clock, call the DateTime.ToString(String) or DateTime.ToString(String, IFormatProvider) method with the "h" custom format specifier. For example:

C#

```
DateTime date1 = new DateTime(2008, 4, 1, 18, 53, 0);
Console.WriteLine(date1.ToString("%h"));              // Displays 6
Console.WriteLine(date1.ToString("h tt"));            // Displays 6 PM
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Kind Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the time represented by this instance is based on local time, Coordinated Universal Time (UTC), or neither.

C#

```
public DateTimeKind Kind { get; }
```

Property Value

DateTimeKind

One of the enumeration values that indicates what the current time represents. The default is Unspecified.

Examples

The following example uses the SpecifyKind method to demonstrate how the Kind property influences the ToLocalTime and ToUniversalTime conversion methods.

C#

```
// This code example demonstrates the DateTime Kind, Now, and
// UtcNow properties, and the SpecifyKind(), ToLocalTime(),
// and ToUniversalTime() methods.

using System;

class Sample
{
    public static void Main()
    {
        // Get the date and time for the current moment, adjusted
        // to the local time zone.

        DateTime saveNow = DateTime.Now;
```

```
        // Get the date and time for the current moment expressed
        // as coordinated universal time (UTC).

        DateTime saveUtcNow = DateTime.UtcNow;
        DateTime myDt;

        // Display the value and Kind property of the current moment
        // expressed as UTC and local time.

        DisplayNow("UtcNow: ..........", saveUtcNow);
        DisplayNow("Now: ............", saveNow);
        Console.WriteLine();

        // Change the Kind property of the current moment to
        // DateTimeKind.Utc and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Utc);
        Display("Utc: ............", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Local and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Local);
        Display("Local: ...........", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Unspecified and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Unspecified);
        Display("Unspecified: .....", myDt);
    }

    // Display the value and Kind property of a DateTime structure, the
    // DateTime structure converted to local time, and the DateTime
    // structure converted to universal time.

    public static string datePatt = @"M/d/yyyy hh:mm:ss tt";
    public static void Display(string title, DateTime inputDt)
    {
        DateTime dispDt = inputDt;
        string dtString;

        // Display the original DateTime.

        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, dispDt.Kind);

        // Convert inputDt to local time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was universal time.
```

```
        dispDt = inputDt.ToLocalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToLocalTime:     {0}, Kind = {1}",
                          dtString, dispDt.Kind);

        // Convert inputDt to universal time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was local time.

        dispDt = inputDt.ToUniversalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToUniversalTime: {0}, Kind = {1}",
                          dtString, dispDt.Kind);
        Console.WriteLine();
    }

    // Display the value and Kind property for DateTime.Now and
DateTime.UtcNow.

    public static void DisplayNow(string title, DateTime inputDt)
    {
        string dtString = inputDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, inputDt.Kind);
    }
}

/*
This code example produces the following results:

UtcNow: ........... 5/6/2005 09:34:42 PM, Kind = Utc
Now: ............. 5/6/2005 02:34:42 PM, Kind = Local

Utc: ............. 5/6/2005 02:34:42 PM, Kind = Utc
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 02:34:42 PM, Kind = Utc

Local: ........... 5/6/2005 02:34:42 PM, Kind = Local
  ToLocalTime:     5/6/2005 02:34:42 PM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

Unspecified: ..... 5/6/2005 02:34:42 PM, Kind = Unspecified
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

*/
```

Remarks

You can explicitly set the Kind property of a new DateTime value to a particular DateTimeKind value by calling the SpecifyKind method.

The Kind property allows a DateTime value to clearly reflect either Coordinated Universal Time (UTC) or the local time. In contrast, the DateTimeOffset structure can unambiguously reflect any time in any time zone as a single point in time.

DateTime.Millisecond Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the milliseconds component of the date represented by this instance.

C#

```
public int Millisecond { get; }
```

Property Value

Int32

The milliseconds component, expressed as a value between 0 and 999.

Examples

The following example demonstrates the Millisecond property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

Remarks

You can display the string representation of the Millisecond property by using the "fff" format specifier. For example, the following code displays a string that contains the number of milliseconds in a date and time to the console.

C#

```
DateTime date1 = new DateTime(2008, 1, 1, 0, 30, 45, 125);
Console.WriteLine("Milliseconds: {0:fff}",
                  date1);           // displays Milliseconds: 125
```

You can also display the millisecond component together with the other components of a date and time value by using the "o" standard format specifier. For example:

C#

```
DateTime date2 = new DateTime(2008, 1, 1, 0, 30, 45, 125);
Console.WriteLine("Date: {0:o}",
                  date2);
// Displays the following output to the console:
//      Date: 2008-01-01T00:30:45.1250000
```

However, the "o" format specifier is intended less for displaying than for round-tripping or storing a DateTime value. You can also display milliseconds together with other date and time components by using a custom format string, as the following example shows.

C#

```
DateTime date3 = new DateTime(2008, 1, 1, 0, 30, 45, 125);
Console.WriteLine("Date with milliseconds: {0:MM/dd/yyy HH:mm:ss.fff}",
                  date3);
// Displays the following output to the console:
//       Date with milliseconds: 01/01/2008 00:30:45.125
```

DateTime.Minute Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minute component of the date represented by this instance.

C#

```
public int Minute { get; }
```

Property Value

Int32

The minute component, expressed as a value between 0 and 59.

Examples

The following example demonstrates the Minute property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

Applies to

DateTime.Month Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the month component of the date represented by this instance.

C#

```
public int Month { get; }
```

Property Value

Int32

The month component, expressed as a value between 1 and 12.

Examples

The following example demonstrates the Month property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

DateTime.Now Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTime object that is set to the current date and time on this computer, expressed as the local time.

C#

```
public static DateTime Now { get; }
```

Property Value

DateTime

An object whose value is the current local date and time.

Examples

The following example uses the Now and UtcNow properties to retrieve the current local date and time and the current universal coordinated (UTC) date and time. It then uses the formatting conventions of a number of cultures to display the strings, along with the values of their Kind properties.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      DateTime localDate = DateTime.Now;
      DateTime utcDate = DateTime.UtcNow;
      String[] cultureNames = { "en-US", "en-GB", "fr-FR",
                                "de-DE", "ru-RU" } ;

      foreach (var cultureName in cultureNames) {
```

```
            var culture = new CultureInfo(cultureName);
            Console.WriteLine("{0}:", culture.NativeName);
            Console.WriteLine("   Local date and time: {0}, {1:G}",
                              localDate.ToString(culture), localDate.Kind);
            Console.WriteLine("   UTC date and time: {0}, {1:G}\n",
                              utcDate.ToString(culture), utcDate.Kind);
        }
    }
}
// The example displays the following output:
//       English (United States):
//          Local date and time: 6/19/2015 10:35:50 AM, Local
//          UTC date and time: 6/19/2015 5:35:50 PM, Utc
//
//       English (United Kingdom):
//          Local date and time: 19/06/2015 10:35:50, Local
//          UTC date and time: 19/06/2015 17:35:50, Utc
//
//       français (France):
//          Local date and time: 19/06/2015 10:35:50, Local
//          UTC date and time: 19/06/2015 17:35:50, Utc
//
//       Deutsch (Deutschland):
//          Local date and time: 19.06.2015 10:35:50, Local
//          UTC date and time: 19.06.2015 17:35:50, Utc
//
//       русский (Россия):
//          Local date and time: 19.06.2015 10:35:50, Local
//          UTC date and time: 19.06.2015 17:35:50, Utc
```

Remarks

The Now property returns a DateTime value that represents the current date and time on the local computer. Note that there is a difference between a DateTime value, which represents the number of ticks that have elapsed since midnight of January 1, 0001, and the string representation of that DateTime value, which expresses a date and time value in a culture-specific-specific format. For information on formatting date and time values, see the ToString method. The following example displays the short date and time string in a number of culture-specific formats.

C#

```
using System;
using System.Globalization;

public class Example
{
    public static void Main()
    {
```

```
        DateTime localDate = DateTime.Now;
        String[] cultureNames = { "en-US", "en-GB", "fr-FR",
                                  "de-DE", "ru-RU" };

        foreach (var cultureName in cultureNames) {
           var culture = new CultureInfo(cultureName);
           Console.WriteLine("{0}: {1}", cultureName,
                             localDate.ToString(culture));
        }
    }
}
// The example displays the following output:
//       en-US: 6/19/2015 10:03:06 AM
//       en-GB: 19/06/2015 10:03:06
//       fr-FR: 19/06/2015 10:03:06
//       de-DE: 19.06.2015 10:03:06
//       ru-RU: 19.06.2015 10:03:06
```

The resolution of this property depends on the system timer, which depends on the underlying operating system. It tends to be between 0.5 and 15 milliseconds. As a result, repeated calls to the Now property in a short time interval, such as in a loop, may return the same value.

The Now property is frequently used to measure performance. However, because of its low resolution, it is not suitable for use as a benchmarking tool. A better alternative is to use the Stopwatch class.

Starting with the .NET Framework version 2.0, the return value is a DateTime whose Kind property returns DateTimeKind.Local.

> ⓘ **Note**
>
> You can also use the **DateTimeOffset.Now** property to retrieve the current local date and time. It allows a local time to be expressed unambiguously as a single point in time, which in turn makes that time value portable across computers.

DateTime.Second Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the seconds component of the date represented by this instance.

C#

```
public int Second { get; }
```

Property Value

Int32

The seconds component, expressed as a value between 0 and 59.

Examples

The following example demonstrates the Second property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Ticks Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of ticks that represent the date and time of this instance.

C#

```
public long Ticks { get; }
```

Property Value

Int64

The number of ticks that represent the date and time of this instance. The value is between `DateTime.MinValue.Ticks` and `DateTime.MaxValue.Ticks`.

Examples

The following example uses the Ticks property to display the number of ticks that have elapsed since the beginning of the twenty-first century and to instantiate a TimeSpan object. The TimeSpan object is then used to display the elapsed time using several other time intervals.

C#

```
DateTime centuryBegin = new DateTime(2001, 1, 1);
DateTime currentDate = DateTime.Now;

long elapsedTicks = currentDate.Ticks - centuryBegin.Ticks;
TimeSpan elapsedSpan = new TimeSpan(elapsedTicks);

Console.WriteLine("Elapsed from the beginning of the century to {0:f}:",
                  currentDate);
Console.WriteLine("   {0:N0} nanoseconds", elapsedTicks * 100);
Console.WriteLine("   {0:N0} ticks", elapsedTicks);
Console.WriteLine("   {0:N2} seconds", elapsedSpan.TotalSeconds);
Console.WriteLine("   {0:N2} minutes", elapsedSpan.TotalMinutes);
Console.WriteLine("   {0:N0} days, {1} hours, {2} minutes, {3} seconds",
```

```
                    elapsedSpan.Days, elapsedSpan.Hours,
                    elapsedSpan.Minutes, elapsedSpan.Seconds);

// This example displays an output similar to the following:
//
// Elapsed from the beginning of the century to Thursday, 14 November 2019
18:21:
//    595,448,498,171,000,000 nanoseconds
//    5,954,484,981,710,000 ticks
//    595,448,498.17 seconds
//    9,924,141.64 minutes
//    6,891 days, 18 hours, 21 minutes, 38 seconds
```

Remarks

A single tick represents one hundred nanoseconds or one ten-millionth of a second. There are 10,000 ticks in a millisecond (see TicksPerMillisecond) and 10 million ticks in a second.

The value of this property represents the number of 100-nanosecond intervals that have elapsed since 12:00:00 midnight, January 1, 0001 in the Gregorian calendar, which represents MinValue. It does not include the number of ticks that are attributable to leap seconds. If the DateTime object has its `Kind` property set to `Local`, its ticks represent the time elapsed time since 12:00:00 midnight, January 1, 0001 in the local time as specified by the current time zone setting. If the `DateTime` object has its `Kind` property set to `Utc`, its ticks represent the time elapsed time since 12:00:00 midnight, January 1, 0001 in the Coordinated Universal Time. If the `DateTime` object has its `Kind` property set to `Unspecified`, its ticks represent the time elapsed time since 12:00:00 midnight, January 1, 0001 in the unknown time zone.

In general, the ticks represent the time according to the time zone specified by the `Kind` property.

DateTime.TimeOfDay Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time of day for this instance.

C#

```
public TimeSpan TimeOfDay { get; }
```

Property Value

TimeSpan

A time interval that represents the fraction of the day that has elapsed since midnight.

Examples

The following example displays the value of the TimeOfDay property for an array of DateTime values. It also contrasts the return value with the string returned by the "t" standard format string in a composite formatting operation.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime[] dates = { DateTime.Now,
                           new DateTime(2013, 9, 14, 9, 28, 0),
                           new DateTime(2011, 5, 28, 10, 35, 0),
                           new DateTime(1979, 12, 25, 14, 30, 0) };
      foreach (var date in dates) {
         Console.WriteLine("Day: {0:d} Time: {1:g}", date.Date,
date.TimeOfDay);
         Console.WriteLine("Day: {0:d} Time: {0:t}\n", date);
      }
   }
```

```
}
// The example displays output like the following:
//    Day: 7/25/2012 Time: 10:08:12.9713744
//    Day: 7/25/2012 Time: 10:08 AM
//
//    Day: 9/14/2013 Time: 9:28:00
//    Day: 9/14/2013 Time: 9:28 AM
//
//    Day: 5/28/2011 Time: 10:35:00
//    Day: 5/28/2011 Time: 10:35 AM
//
//    Day: 12/25/1979 Time: 14:30:00
//    Day: 12/25/1979 Time: 2:30 PM
```

Remarks

Unlike the Date property. which returns a DateTime value that represents a date without its time component, the TimeOfDay property returns a TimeSpan value that represents a DateTime value's time component.

If you want to display the time of day or retrieve the string representation of the time of day of a DateTime value, you can instead call an overload of the ToString method that has a `format` parameter or use the composite formatting feature with the "t" or "T" standard format string.

Applies to

Product	Versions

DateTime.Today Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current date.

C#

```
public static DateTime Today { get; }
```

Property Value

DateTime

An object that is set to today's date, with the time component set to 00:00:00.

Examples

The following example uses the Date property to retrieve the current date. It also illustrates how a DateTime value can be formatted using some of the standard date and time format strings. Note that the output produced by the third call to the ToString(String) method uses the g format specifier to include the time component, which is zero.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get the current date.
      DateTime thisDay = DateTime.Today;
      // Display the date in the default (general) format.
      Console.WriteLine(thisDay.ToString());
      Console.WriteLine();
      // Display the date in a variety of formats.
      Console.WriteLine(thisDay.ToString("d"));
```

```
        Console.WriteLine(thisDay.ToString("D"));
        Console.WriteLine(thisDay.ToString("g"));
    }
}
// The example displays output similar to the following:
//    5/3/2012 12:00:00 AM
//
//    5/3/2012
//    Thursday, May 03, 2012
//    5/3/2012 12:00 AM
```

Remarks

Starting with the .NET Framework version 2.0, the return value is a DateTime whose Kind property returns Local.

Because it returns the current date without the current time, the Today property is suitable for use in applications that work with dates only. For details, see Choosing Between DateTime, DateTimeOffset, TimeSpan, and TimeZoneInfo. In contrast, the TimeOfDay property returns the current time without the current date, and the Now property returns both the current date and the current time.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.UtcNow Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTime object that is set to the current date and time on this computer, expressed as the Coordinated Universal Time (UTC).

C#

```
public static DateTime UtcNow { get; }
```

Property Value

DateTime

An object whose value is the current UTC date and time.

Examples

The following example uses the SpecifyKind method to demonstrate how the Kind property influences the ToLocalTime and ToUniversalTime conversion methods.

C#

```
// This code example demonstrates the DateTime Kind, Now, and
// UtcNow properties, and the SpecifyKind(), ToLocalTime(),
// and ToUniversalTime() methods.

using System;

class Sample
{
    public static void Main()
    {
        // Get the date and time for the current moment, adjusted
        // to the local time zone.

        DateTime saveNow = DateTime.Now;

        // Get the date and time for the current moment expressed
```

```
        // as coordinated universal time (UTC).

        DateTime saveUtcNow = DateTime.UtcNow;
        DateTime myDt;

        // Display the value and Kind property of the current moment
        // expressed as UTC and local time.

        DisplayNow("UtcNow: ..........", saveUtcNow);
        DisplayNow("Now: .............", saveNow);
        Console.WriteLine();

        // Change the Kind property of the current moment to
        // DateTimeKind.Utc and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Utc);
        Display("Utc: .............", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Local and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Local);
        Display("Local: ...........", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Unspecified and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Unspecified);
        Display("Unspecified: .....", myDt);
    }

    // Display the value and Kind property of a DateTime structure, the
    // DateTime structure converted to local time, and the DateTime
    // structure converted to universal time.

    public static string datePatt = @"M/d/yyyy hh:mm:ss tt";
    public static void Display(string title, DateTime inputDt)
    {
        DateTime dispDt = inputDt;
        string dtString;

        // Display the original DateTime.

        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, dispDt.Kind);

        // Convert inputDt to local time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was universal time.

        dispDt = inputDt.ToLocalTime();
```

```
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToLocalTime:     {0}, Kind = {1}",
                          dtString, dispDt.Kind);

        // Convert inputDt to universal time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was local time.

        dispDt = inputDt.ToUniversalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToUniversalTime: {0}, Kind = {1}",
                          dtString, dispDt.Kind);
        Console.WriteLine();
    }

    // Display the value and Kind property for DateTime.Now and
DateTime.UtcNow.

    public static void DisplayNow(string title, DateTime inputDt)
    {
        string dtString = inputDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, inputDt.Kind);
    }
}

/*
This code example produces the following results:

UtcNow: .......... 5/6/2005 09:34:42 PM, Kind = Utc
Now: ............. 5/6/2005 02:34:42 PM, Kind = Local

Utc: ............. 5/6/2005 02:34:42 PM, Kind = Utc
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 02:34:42 PM, Kind = Utc

Local: ........... 5/6/2005 02:34:42 PM, Kind = Local
  ToLocalTime:     5/6/2005 02:34:42 PM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

Unspecified: ..... 5/6/2005 02:34:42 PM, Kind = Unspecified
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

*/
```

Remarks

The resolution of this property depends on the system timer, which depends on the underlying operating system. It tends to be between 0.5 and 15 milliseconds.

Starting with the .NET Framework version 2.0, the return value is a DateTime whose Kind property returns DateTimeKind.Utc.

An alternative to using UtcNow is DateTimeOffset.UtcNow. While the former indicates that a date and time value is Coordinated Universal Time (UTC) by assigning DateTimeKind.Utc to its Kind property, the latter assigns the date and time value the UTC time's offset (equal to TimeSpan.Zero).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Year Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the year component of the date represented by this instance.

C#

```
public int Year { get; }
```

Property Value

Int32

The year, between 1 and 9999.

Examples

The following example demonstrates the Year property.

C#

```
System.DateTime moment = new System.DateTime(
                                1999, 1, 13, 3, 57, 32, 11);
// Year gets 1999.
int year = moment.Year;

// Month gets 1 (January).
int month = moment.Month;

// Day gets 13.
int day = moment.Day;

// Hour gets 3.
int hour = moment.Hour;

// Minute gets 57.
int minute = moment.Minute;

// Second gets 32.
int second = moment.Second;
```

```
// Millisecond gets 11.
int millisecond = moment.Millisecond;
```

Remarks

The Year property returns the year of the current instance in the Gregorian calendar. It does not return the year using the default calendar of the current culture. To retrieve the year using a particular calendar, you can call that calendar's `GetYear` method, as the following code shows.

C#

```
using System;
using System.Globalization;
using System.Threading;

public class YearMethodExample
{
    public static void Main()
    {
      // Initialize date variable and display year
      DateTime date1 = new DateTime(2008, 1, 1, 6, 32, 0);
      Console.WriteLine(date1.Year);                    // Displays 2008

      // Set culture to th-TH
      Thread.CurrentThread.CurrentCulture = new CultureInfo("th-TH");
      Console.WriteLine(date1.Year);                    // Displays 2008

      // display year using current culture's calendar
      Calendar thaiCalendar = CultureInfo.CurrentCulture.Calendar;
      Console.WriteLine(thaiCalendar.GetYear(date1));   // Displays 2551

      // display year using Persian calendar
      PersianCalendar persianCalendar = new PersianCalendar();
      Console.WriteLine(persianCalendar.GetYear(date1)); // Displays 1386
   }
}
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime.Add(TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the value of the specified TimeSpan to the value of this instance.

```
C#
public DateTime Add (TimeSpan value);
```

Parameters

`value` TimeSpan

A positive or negative time interval.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the time interval represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example demonstrates the Add method. It calculates the day of the week that is 36 days (864 hours) from this moment.

```
C#
```

```
// Calculate what day of the week is 36 days from this instant.
System.DateTime today = System.DateTime.Now;
System.TimeSpan duration = new System.TimeSpan(36, 0, 0, 0);
System.DateTime answer = today.Add(duration);
System.Console.WriteLine("{0:dddd}", answer);
```

Remarks

You can use the Add method to add more than one kind of time interval (days, hours, minutes, seconds, or milliseconds) in a single operation. This method's behavior is identical to that of the addition operator. The DateTime structure also supports specialized addition methods (such as AddDays, AddHours, and AddMinutes) for each time interval.

The Add method takes into account leap years and the number of days in a month when performing date arithmetic.

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation. The Kind property of the new DateTime instance is the same as that of the current instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime.AddDays(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of days to the value of this instance.

```
C#
public DateTime AddDays (double value);
```

Parameters

`value` Double

A number of whole and fractional days. The `value` parameter can be negative or positive.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of days represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example uses the AddDays method to determine the day of the week 36 days after the current date.

```
C#
```

```
using System;

class Class1
{
    static void Main()
    {
        DateTime today = DateTime.Now;
        DateTime answer = today.AddDays(36);
        Console.WriteLine("Today: {0:dddd}", today);
        Console.WriteLine("36 days from today: {0:dddd}", answer);
    }
}
// The example displays output like the following:
//       Today: Wednesday
//       36 days from today: Thursday
```

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

The fractional part of `value` is the fractional part of a day. For example, 4.5 is equivalent to 4 days, 12 hours, 0 minutes, 0 seconds, 0 milliseconds, and 0 ticks.

In .NET 6 and earlier versions, the `value` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `value` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

The AddDays method takes into account leap years and the number of days in a month when performing date arithmetic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.AddHours(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of hours to the value of this instance.

```
C#

public DateTime AddHours (double value);
```

Parameters

`value` Double

A number of whole and fractional hours. The `value` parameter can be negative or positive.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of hours represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example uses the AddHours method to add a number of whole and fractional values to a date and time. It also illustrates the loss of precision caused by passing the method a value that includes a fractional component.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double[] hours = {.08333, .16667, .25, .33333, .5, .66667, 1, 2,
                        29, 30, 31, 90, 365};
      DateTime dateValue = new DateTime(2009, 3, 1, 12, 0, 0);

      foreach (double hour in hours)
         Console.WriteLine("{0} + {1} hour(s) = {2}", dateValue, hour,
                           dateValue.AddHours(hour));
   }
}
// The example displays the following output on a system whose current
// culture is en-US:
//    3/1/2009 12:00:00 PM + 0.08333 hour(s) = 3/1/2009 12:04:59 PM
//    3/1/2009 12:00:00 PM + 0.16667 hour(s) = 3/1/2009 12:10:00 PM
//    3/1/2009 12:00:00 PM + 0.25 hour(s) = 3/1/2009 12:15:00 PM
//    3/1/2009 12:00:00 PM + 0.33333 hour(s) = 3/1/2009 12:19:59 PM
//    3/1/2009 12:00:00 PM + 0.5 hour(s) = 3/1/2009 12:30:00 PM
//    3/1/2009 12:00:00 PM + 0.66667 hour(s) = 3/1/2009 12:40:00 PM
//    3/1/2009 12:00:00 PM + 1 hour(s) = 3/1/2009 1:00:00 PM
//    3/1/2009 12:00:00 PM + 2 hour(s) = 3/1/2009 2:00:00 PM
//    3/1/2009 12:00:00 PM + 29 hour(s) = 3/2/2009 5:00:00 PM
//    3/1/2009 12:00:00 PM + 30 hour(s) = 3/2/2009 6:00:00 PM
//    3/1/2009 12:00:00 PM + 31 hour(s) = 3/2/2009 7:00:00 PM
//    3/1/2009 12:00:00 PM + 90 hour(s) = 3/5/2009 6:00:00 AM
//    3/1/2009 12:00:00 PM + 365 hour(s) = 3/16/2009 5:00:00 PM
```

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation. The Kind property of the returned DateTime object is the same as that of `value`.

The fractional part of `value` is the fractional part of an hour. For example, 4.5 is equivalent to 4 hours, 30 minutes, 0 seconds, 0 milliseconds, and 0 ticks.

In .NET 6 and earlier versions, the `value` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `value` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

Converting time intervals of less than an hour to a fraction can involve a loss of precision if the result is a non-terminating repeating decimal. (For example, one minute is 0.016667 of an hour.) If this is problematic, you can use the Add method, which enables you to specify more than one kind of time interval in a single method call and eliminates the need to convert time intervals to fractional parts of an hour.

DateTime.AddMicroseconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of microseconds to the value of this instance.

```
C#

public DateTime AddMicroseconds (double value);
```

Parameters

`value` Double

A number of whole and fractional microseconds. The `value` parameter can be negative or positive. Note that this value is rounded to the nearest integer.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of microseconds represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than MinValue or greater than MaxValue.

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

The fractional part of value is the fractional part of a microsecond. For example, 4.5 is equivalent to 4 microseconds and 50 ticks, where one microsecond = 10 ticks.

The value parameter is rounded to the nearest integer.

Applies to

Product	Versions
.NET	7, 8, 9

DateTime.AddMilliseconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of milliseconds to the value of this instance.

```
C#

public DateTime AddMilliseconds (double value);
```

Parameters

`value` Double

A number of whole and fractional milliseconds. The `value` parameter can be negative or positive. Note that this value is rounded to the nearest integer.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of milliseconds represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example uses the AddMilliseconds method to add one millisecond and 1.5 milliseconds to a DateTime value. It then displays each new value and displays the

difference between it and the original value. The difference is displayed both as a time span and as a number of ticks. The example makes it clear that one millisecond equals 10,000 ticks. It also shows that fractional milliseconds are rounded before performing the addition; the DateTime value that results from adding 1.5 milliseconds to the original date is 2 milliseconds greater than the original date.

C#

```
string dateFormat = "MM/dd/yyyy hh:mm:ss.fffffff";
DateTime date1 = new DateTime(2010, 9, 8, 16, 0, 0);
Console.WriteLine("Original date: {0} ({1:N0} ticks)\n",
                  date1.ToString(dateFormat), date1.Ticks);

DateTime date2 = date1.AddMilliseconds(1);
Console.WriteLine("Second date:   {0} ({1:N0} ticks)",
                  date2.ToString(dateFormat), date2.Ticks);
Console.WriteLine("Difference between dates: {0} ({1:N0} ticks)\n",
                  date2 - date1, date2.Ticks - date1.Ticks);

DateTime date3 = date1.AddMilliseconds(1.5);
Console.WriteLine("Third date:    {0} ({1:N0} ticks)",
                  date3.ToString(dateFormat), date3.Ticks);
Console.WriteLine("Difference between dates: {0} ({1:N0} ticks)",
                  date3 - date1, date3.Ticks - date1.Ticks);
// The example displays the following output:
//    Original date: 09/08/2010 04:00:00.0000000 (634,195,584,000,000,000
ticks)
//
//    Second date:   09/08/2010 04:00:00.0010000 (634,195,584,000,010,000
ticks)
//    Difference between dates: 00:00:00.0010000 (10,000 ticks)
//
//    Third date:    09/08/2010 04:00:00.0020000 (634,195,584,000,020,000
ticks)
//    Difference between dates: 00:00:00.0020000 (20,000 ticks)
```

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

The fractional part of `value` is the fractional part of a millisecond. For example, 4.5 is equivalent to 4 milliseconds and 5000 ticks, where one millisecond = 10000 ticks.

In .NET 6 and earlier versions, the `value` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `value`

parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.AddMinutes(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of minutes to the value of this instance.

```
C#

public DateTime AddMinutes (double value);
```

Parameters

`value` Double

A number of whole and fractional minutes. The `value` parameter can be negative or positive.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of minutes represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example uses the AddMinutes method to add a number of whole and fractional values to a date and time.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime dateValue = new DateTime(2013, 9, 15, 12, 0, 0);

      double[] minutes = { .01667, .08333, .16667, .25, .33333,
                           .5, .66667, 1, 2, 15, 30, 17, 45,
                           60, 180, 60 * 24 };

      foreach (double minute in minutes)
         Console.WriteLine("{0} + {1} minute(s) = {2}", dateValue, minute,
                           dateValue.AddMinutes(minute));
   }
}
// The example displays the following output on a system whose current
culture is en-US:
//    9/15/2013 12:00:00 PM + 0.01667 minute(s) = 9/15/2013 12:00:01 PM
//    9/15/2013 12:00:00 PM + 0.08333 minute(s) = 9/15/2013 12:00:05 PM
//    9/15/2013 12:00:00 PM + 0.16667 minute(s) = 9/15/2013 12:00:10 PM
//    9/15/2013 12:00:00 PM + 0.25 minute(s) = 9/15/2013 12:00:15 PM
//    9/15/2013 12:00:00 PM + 0.33333 minute(s) = 9/15/2013 12:00:20 PM
//    9/15/2013 12:00:00 PM + 0.5 minute(s) = 9/15/2013 12:00:30 PM
//    9/15/2013 12:00:00 PM + 0.66667 minute(s) = 9/15/2013 12:00:40 PM
//    9/15/2013 12:00:00 PM + 1 minute(s) = 9/15/2013 12:01:00 PM
//    9/15/2013 12:00:00 PM + 2 minute(s) = 9/15/2013 12:02:00 PM
//    9/15/2013 12:00:00 PM + 15 minute(s) = 9/15/2013 12:15:00 PM
//    9/15/2013 12:00:00 PM + 30 minute(s) = 9/15/2013 12:30:00 PM
//    9/15/2013 12:00:00 PM + 17 minute(s) = 9/15/2013 12:17:00 PM
//    9/15/2013 12:00:00 PM + 45 minute(s) = 9/15/2013 12:45:00 PM
//    9/15/2013 12:00:00 PM + 60 minute(s) = 9/15/2013 1:00:00 PM
//    9/15/2013 12:00:00 PM + 180 minute(s) = 9/15/2013 3:00:00 PM
//    9/15/2013 12:00:00 PM + 1440 minute(s) = 9/16/2013 12:00:00 PM
```

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

The fractional part of `value` is the fractional part of a minute. For example, 4.5 is equivalent to 4 minutes, 30 seconds, 0 milliseconds, and 0 ticks.

In .NET 6 and earlier versions, the `value` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `value` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

DateTime.AddMonths(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of months to the value of this instance.

```
C#
public DateTime AddMonths (int months);
```

Parameters

`months` Int32

A number of months. The `months` parameter can be negative or positive.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and `months`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

-or-

`months` is less than -120,000 or greater than 120,000.

Examples

The following example adds between zero and fifteen months to the last day of December, 2015. In this case, the AddMonths method returns the date of the last day of each month, and successfully handles leap years.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      var dat = new DateTime(2015, 12, 31);
      for (int ctr = 0; ctr <= 15; ctr++)
         Console.WriteLine(dat.AddMonths(ctr).ToString("d"));
   }
}
// The example displays the following output:
//       12/31/2015
//       1/31/2016
//       2/29/2016
//       3/31/2016
//       4/30/2016
//       5/31/2016
//       6/30/2016
//       7/31/2016
//       8/31/2016
//       9/30/2016
//       10/31/2016
//       11/30/2016
//       12/31/2016
//       1/31/2017
//       2/28/2017
//       3/31/2017
```

Remarks

This method does not change the value of this DateTime object. Instead, it returns a new DateTime object whose value is the result of this operation.

The AddMonths method calculates the resulting month and year, taking into account leap years and the number of days in a month, then adjusts the day part of the resulting DateTime object. If the resulting day is not a valid day in the resulting month, the last valid day of the resulting month is used. For example, March 31st + 1 month = April 30th, and March 31st - 1 month = February 28 for a non-leap year and February 29 for a leap year.

The time-of-day part of the resulting DateTime object remains the same as this instance.

DateTime.AddSeconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of seconds to the value of this instance.

```
C#

public DateTime AddSeconds (double value);
```

Parameters

`value` Double

A number of whole and fractional seconds. The `value` parameter can be negative or positive.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of seconds represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example uses the AddSeconds method to add 30 seconds and the number of seconds in one day to a DateTime value. It then displays each new value and displays the difference between it and the original value. The difference is displayed both as a time span and as a number of ticks.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string dateFormat = "MM/dd/yyyy hh:mm:ss";
      DateTime date1 = new DateTime(2014, 9, 8, 16, 0, 0);
      Console.WriteLine("Original date: {0} ({1:N0} ticks)\n",
                        date1.ToString(dateFormat), date1.Ticks);

      DateTime date2 = date1.AddSeconds(30);
      Console.WriteLine("Second date:   {0} ({1:N0} ticks)",
                        date2.ToString(dateFormat), date2.Ticks);
      Console.WriteLine("Difference between dates: {0} ({1:N0} ticks)\n",
                        date2 - date1, date2.Ticks - date1.Ticks);

      // Add 1 day's worth of seconds (60 secs. * 60 mins * 24 hrs.
      DateTime date3 = date1.AddSeconds(60 * 60 * 24);
      Console.WriteLine("Third date:    {0} ({1:N0} ticks)",
                        date3.ToString(dateFormat), date3.Ticks);
      Console.WriteLine("Difference between dates: {0} ({1:N0} ticks)",
                        date3 - date1, date3.Ticks - date1.Ticks);
   }
}
// The example displays the following output:
//    Original date: 09/08/2014 04:00:00 (635,457,888,000,000,000 ticks)
//
//    Second date:   09/08/2014 04:00:30 (635,457,888,300,000,000 ticks)
//    Difference between dates: 00:00:30 (300,000,000 ticks)
//
//    Third date:    09/09/2014 04:00:00 (635,458,752,000,000,000 ticks)
//    Difference between dates: 1.00:00:00 (864,000,000,000 ticks)
```

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

The fractional part of `value` is the fractional part of a second. For example, 4.5 is equivalent to 4 seconds, 500 milliseconds, and 0 ticks.

In .NET 6 and earlier versions, the `value` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `value` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

Applies to

DateTime.AddTicks(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of ticks to the value of this instance.

```
C#
public DateTime AddTicks (long value);
```

Parameters

`value` Int64

A number of 100-nanosecond ticks. The `value` parameter can be positive or negative.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the time represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Remarks

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.AddYears(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTime that adds the specified number of years to the value of this instance.

```
C#

public DateTime AddYears (int value);
```

Parameters

`value` Int32

A number of years. The `value` parameter can be negative or positive.

Returns

DateTime

An object whose value is the sum of the date and time represented by this instance and the number of years represented by `value`.

Exceptions

ArgumentOutOfRangeException

`value` or the resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Remarks

This method does not change the value of this DateTime object. Instead, it returns a new DateTime object whose value is the result of this operation.

The AddYears method calculates the resulting year taking into account leap years. The month and time-of-day part of the resulting DateTime object remains the same as this

instance.

If the current instance represents the leap day in a leap year, the return value depends on the target date:

- If `value` + DateTime.Year is also a leap year, the return value represents the leap day in that year. For example, if four years is added to February 29, 2012, the date returned is February 29, 2016.
- If `value` + DateTime.Year is not a leap year, the return value represents the day before the leap day in that year. For example, if one year is added to February 29, 2012, the date returned is February 28, 2013.

The following example illustrates using the AddYears method with a DateTime value that represents a leap year day. It displays the date for the fifteen years prior to and the fifteen years that follow February 29, 2000.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime baseDate = new DateTime(2000, 2, 29);
      Console.WriteLine("    Base Date:        {0:d}\n", baseDate);

      // Show dates of previous fifteen years.
      for (int ctr = -1; ctr >= -15; ctr--)
         Console.WriteLine("{0,2} year(s) ago:        {1:d}",
                           Math.Abs(ctr), baseDate.AddYears(ctr));
      Console.WriteLine();

      // Show dates of next fifteen years.
      for (int ctr = 1; ctr <= 15; ctr++)
         Console.WriteLine("{0,2} year(s) from now:   {1:d}",
                           ctr, baseDate.AddYears(ctr));
   }
}
// The example displays the following output:
//           Base Date:        2/29/2000
//
//        1 year(s) ago:        2/28/1999
//        2 year(s) ago:        2/28/1998
//        3 year(s) ago:        2/28/1997
//        4 year(s) ago:        2/29/1996
//        5 year(s) ago:        2/28/1995
//        6 year(s) ago:        2/28/1994
//        7 year(s) ago:        2/28/1993
//        8 year(s) ago:        2/29/1992
```

```
//        9 year(s) ago:        2/28/1991
//       10 year(s) ago:        2/28/1990
//       11 year(s) ago:        2/28/1989
//       12 year(s) ago:        2/29/1988
//       13 year(s) ago:        2/28/1987
//       14 year(s) ago:        2/28/1986
//       15 year(s) ago:        2/28/1985
//
//        1 year(s) from now:   2/28/2001
//        2 year(s) from now:   2/28/2002
//        3 year(s) from now:   2/28/2003
//        4 year(s) from now:   2/29/2004
//        5 year(s) from now:   2/28/2005
//        6 year(s) from now:   2/28/2006
//        7 year(s) from now:   2/28/2007
//        8 year(s) from now:   2/29/2008
//        9 year(s) from now:   2/28/2009
//       10 year(s) from now:   2/28/2010
//       11 year(s) from now:   2/28/2011
//       12 year(s) from now:   2/29/2012
//       13 year(s) from now:   2/28/2013
//       14 year(s) from now:   2/28/2014
//       15 year(s) from now:   2/28/2015
```

DateTime.Compare(DateTime, DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two instances of DateTime and returns an integer that indicates whether the first instance is earlier than, the same as, or later than the second instance.

C#

```
public static int Compare (DateTime t1, DateTime t2);
```

Parameters

t1 DateTime

The first object to compare.

t2 DateTime

The second object to compare.

Returns

Int32

A signed number indicating the relative values of `t1` and `t2`.

Expand table

Value Type	Condition
Less than zero	`t1` is earlier than `t2`.
Zero	`t1` is the same as `t2`.
Greater than zero	`t1` is later than `t2`.

Examples

The following example demonstrates the Compare method.

C#

```
DateTime date1 = new DateTime(2009, 8, 1, 0, 0, 0);
DateTime date2 = new DateTime(2009, 8, 1, 12, 0, 0);
int result = DateTime.Compare(date1, date2);
string relationship;

if (result < 0)
   relationship = "is earlier than";
else if (result == 0)
   relationship = "is the same time as";
else
   relationship = "is later than";

Console.WriteLine("{0} {1} {2}", date1, relationship, date2);

// The example displays the following output for en-us culture:
//    8/1/2009 12:00:00 AM is earlier than 8/1/2009 12:00:00 PM
```

Remarks

To determine the relationship of `t1` to `t2`, the Compare method compares the Ticks property of `t1` and `t2` but ignores their Kind property. Before comparing DateTime objects, ensure that the objects represent times in the same time zone.

Applies to

DateTime.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the value of this instance to a specified DateTime value and indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.

Overloads

Expand table

CompareTo(DateTime)	Compares the value of this instance to a specified DateTime value and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.
CompareTo(Object)	Compares the value of this instance to a specified object that contains a specified DateTime value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.

Remarks

The two overloads of the CompareTo method return a signed number that indicates the relative value of this instance and the `value` argument, as shown in the following table.

Expand table

Value	Description
Less than zero	This instance is earlier than `value`.
Zero	This instance is the same as `value`.
Greater than zero	This instance is later than `value`.

CompareTo(DateTime)

Compares the value of this instance to a specified DateTime value and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.

```
C#

public int CompareTo (DateTime value);
```

Parameters

`value` DateTime

The object to compare to the current instance.

Returns

Int32

A signed number indicating the relative values of this instance and the `value` parameter.

Expand table

Value	Description
Less than zero	This instance is earlier than `value`.
Zero	This instance is the same as `value`.
Greater than zero	This instance is later than `value`.

Implements

CompareTo(T)

Examples

The following example instantiates three DateTime objects, one that represents today's date, another that represents the date one year previously, and a third that represents the date one year in the future. It then calls the CompareTo(DateTime) method and displays the result of the comparison.

```
C#
```

```
using System;

public class DateTimeComparison
{
   private enum DateComparisonResult
   {
      Earlier = -1,
      Later = 1,
      TheSame = 0
   };

   public static void Main()
   {
      DateTime thisDate = DateTime.Today;

      // Define two DateTime objects for today's date
      // next year and last year
      DateTime thisDateNextYear, thisDateLastYear;

      // Call AddYears instance method to add/substract 1 year
      thisDateNextYear = thisDate.AddYears(1);
      thisDateLastYear = thisDate.AddYears(-1);

      // Compare dates
      //
      DateComparisonResult comparison;
      // Compare today to last year
      comparison = (DateComparisonResult)
thisDate.CompareTo(thisDateLastYear);
      Console.WriteLine("CompareTo method returns {0}: {1:d} is {2} than
{3:d}",
                        (int) comparison, thisDate,
comparison.ToString().ToLower(),
                        thisDateLastYear);

      // Compare today to next year
      comparison = (DateComparisonResult)
thisDate.CompareTo(thisDateNextYear);
      Console.WriteLine("CompareTo method returns {0}: {1:d} is {2} than
{3:d}",
                        (int) comparison, thisDate,
comparison.ToString().ToLower(),
                        thisDateNextYear);
   }
}
//
// If run on October 20, 2006, the example produces the following output:
//    CompareTo method returns 1: 10/20/2006 is later than 10/20/2005
//    CompareTo method returns -1: 10/20/2006 is earlier than 10/20/2007
```

Remarks

To determine the relationship of the current instance to `value`, the CompareTo method compares the Ticks property of the current instance and `value` but ignores their Kind property. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind properties.

This method implements the System.IComparable<T> interface and performs slightly better than the DateTime.CompareTo(Object) method overload because it does not have to convert the `value` parameter to an object.

See also

- Compare(DateTime, DateTime)
- Equals(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares the value of this instance to a specified object that contains a specified DateTime value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified DateTime value.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

A boxed object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Value	Description
Less than zero	This instance is earlier than `value`.
Zero	This instance is the same as `value`.
Greater than zero	This instance is later than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a DateTime.

Examples

The following example demonstrates the CompareTo method.

C#

```
System.DateTime theDay = new System.DateTime(System.DateTime.Today.Year,
7, 28);
int compareValue;

try
{
    compareValue = theDay.CompareTo(DateTime.Today);
}
catch (ArgumentException)
{
   Console.WriteLine("Value is not a DateTime");
   return;
```

```
}

if (compareValue < 0)
   System.Console.WriteLine("{0:d} is in the past.", theDay);
else if (compareValue == 0)
   System.Console.WriteLine("{0:d} is today!", theDay);
else // compareValue > 0
   System.Console.WriteLine("{0:d} has not come yet.", theDay);
```

Remarks

To determine the relationship of the current instance to `value`, the CompareTo method compares the Ticks property of the current instance and `value` but ignores their Kind property. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind properties.

Any instance of DateTime, regardless of its value, is considered greater than `null`.

DateTime.DaysInMonth(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the number of days in the specified month and year.

```
C#
public static int DaysInMonth (int year, int month);
```

Parameters

`year` Int32

The year.

`month` Int32

The month (a number ranging from 1 to 12).

Returns

Int32

The number of days in `month` for the specified `year`.

For example, if `month` equals 2 for February, the return value is 28 or 29 depending upon whether `year` is a leap year.

Exceptions

ArgumentOutOfRangeException

`month` is less than 1 or greater than 12.

-or-

`year` is less than 1 or greater than 9999.

Examples

The following example demonstrates how to use the DaysInMonth method to determine the number of days in July 2001, February 1998 (a non-leap year), and February 1996 (a leap year).

C#

```
using System;

class Example
{
    static void Main()
    {
        const int July = 7;
        const int Feb = 2;

        int daysInJuly = System.DateTime.DaysInMonth(2001, July);
        Console.WriteLine(daysInJuly);

        // daysInFeb gets 28 because the year 1998 was not a leap year.
        int daysInFeb = System.DateTime.DaysInMonth(1998, Feb);
        Console.WriteLine(daysInFeb);

        // daysInFebLeap gets 29 because the year 1996 was a leap year.
        int daysInFebLeap = System.DateTime.DaysInMonth(1996, Feb);
        Console.WriteLine(daysInFebLeap);
    }
}
// The example displays the following output:
//       31
//       28
//       29
```

The following example displays the number of days in each month of a year specified in an integer array.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      int[] years = { 2012, 2014 };
      DateTimeFormatInfo dtfi = DateTimeFormatInfo.CurrentInfo;
      Console.WriteLine("Days in the Month for the {0} culture " +
                        "using the {1} calendar\n",
                        CultureInfo.CurrentCulture.Name,
```

```
                        dtfi.Calendar.GetType().Name.Replace("Calendar",
""));
      Console.WriteLine("{0,-10}{1,-15}{2,4}\n", "Year", "Month", "Days");

      foreach (var year in years) {
         for (int ctr = 0; ctr <= dtfi.MonthNames.Length - 1; ctr++) {
            if (String.IsNullOrEmpty(dtfi.MonthNames[ctr]))
               continue;

            Console.WriteLine("{0,-10}{1,-15}{2,4}", year,
                              dtfi.MonthNames[ctr],
                              DateTime.DaysInMonth(year, ctr + 1));
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    Days in the Month for the en-US culture using the Gregorian calendar
//
//    Year      Month          Days
//
//    2012      January          31
//    2012      February         29
//    2012      March            31
//    2012      April            30
//    2012      May              31
//    2012      June             30
//    2012      July             31
//    2012      August           31
//    2012      September        30
//    2012      October          31
//    2012      November         30
//    2012      December         31
//
//    2014      January          31
//    2014      February         28
//    2014      March            31
//    2014      April            30
//    2014      May              31
//    2014      June             30
//    2014      July             31
//    2014      August           31
//    2014      September        30
//    2014      October          31
//    2014      November         30
//    2014      December         31
```

Remarks

The DaysInMonth method always interprets `month` and `year` as the month and year of the Gregorian calendar even if the Gregorian calendar is not the current culture's current

calendar. To get the number of days in a specified month of a particular calendar, call that calendar's GetDaysInMonth method.

DateTime.Deconstruct Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Deconstruct(DateOnly, TimeOnly)	Deconstructs this DateTime instance by DateOnly and TimeOnly.
Deconstruct(Int32, Int32, Int32)	Deconstructs this DateOnly instance by Year, Month, and Day.

Deconstruct(DateOnly, TimeOnly)

Deconstructs this DateTime instance by DateOnly and TimeOnly.

C#

```
public void Deconstruct (out DateOnly date, out TimeOnly time);
```

Parameters

`date` DateOnly

When this method returns, represents the DateOnly value of this DateTime instance.

`time` TimeOnly

When this method returns, represents the TimeOnly value of this DateTime instance.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Deconstruct(Int32, Int32, Int32)

Deconstructs this DateOnly instance by Year, Month, and Day.

```
C#
public void Deconstruct (out int year, out int month, out int day);
```

Parameters

`year` Int32

When this method returns, represents the Year value of this DateTime instance.

`month` Int32

When this method returns, represents the Month value of this DateTime instance.

`day` Int32

When this method returns, represents the Day value of this DateTime instance.

Applies to

DateTime.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two DateTime objects, or a DateTime instance and another object or DateTime, have the same value.

Overloads

Expand table

Equals(DateTime)	Returns a value indicating whether the value of this instance is equal to the value of the specified DateTime instance.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(DateTime, DateTime)	Returns a value indicating whether two DateTime instances have the same date and time value.

Equals(DateTime)

Returns a value indicating whether the value of this instance is equal to the value of the specified DateTime instance.

C#

```
public bool Equals (DateTime value);
```

Parameters

`value` DateTime

The object to compare to this instance.

Returns

Boolean

`true` if the `value` parameter equals the value of this instance; otherwise, `false`.

Implements

Equals(T)

Examples

The following example demonstrates the Equals method.

C#

```
using System;

public class Application
{
    public static void Main()
    {
        // Create some DateTime objects.
        DateTime one = DateTime.UtcNow;

        DateTime two = DateTime.Now;

        DateTime three = one;

        // Compare the DateTime objects and display the results.
        bool result = one.Equals(two);

        Console.WriteLine("The result of comparing DateTime object one
and two is: {0}.", result);

        result = one.Equals(three);

        Console.WriteLine("The result of comparing DateTime object one
and three is: {0}.", result);
    }
}

// This code example displays the following:
//
// The result of comparing DateTime object one and two is: False.
// The result of comparing DateTime object one and three is: True.
```

Remarks

The current instance and `value` are equal if their Ticks property values are equal. Their Kind property values are not considered in the test for equality.

This method implements the System.IEquatable<T> interface, and performs slightly better than the Equals method because the `value` parameter does not have to be converted to an object.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? value);
```

Parameters

`value` Object

The object to compare to this instance.

Returns

Boolean

`true` if `value` is an instance of DateTime and equals the value of this instance; otherwise, `false`.

Examples

The following example demonstrates the Equals method.

C#

```
using System;

public class Application
{
    public static void Main()
    {
        // Create some DateTime objects.
        DateTime one = DateTime.UtcNow;

        DateTime two = DateTime.Now;

        DateTime three = one;

        // Compare the DateTime objects and display the results.
        bool result = one.Equals(two);

        Console.WriteLine("The result of comparing DateTime object one
and two is: {0}.", result);

        result = one.Equals(three);

        Console.WriteLine("The result of comparing DateTime object one
and three is: {0}.", result);
    }
}

// This code example displays the following:
//
// The result of comparing DateTime object one and two is: False.
// The result of comparing DateTime object one and three is: True.
```

Remarks

The current instance and `value` are equal if their Ticks property values are equal. Their Kind property values are not considered in the test for equality.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(DateTime, DateTime)

Returns a value indicating whether two DateTime instances have the same date and time value.

C#

```
public static bool Equals (DateTime t1, DateTime t2);
```

Parameters

`t1` DateTime

The first object to compare.

`t2` DateTime

The second object to compare.

Returns

Boolean

`true` if the two values are equal; otherwise, `false`.

Examples

The following example demonstrates the Equals method.

```C#
System.DateTime today1 =
        new System.DateTime(System.DateTime.Today.Ticks);
System.DateTime today2 =
        new System.DateTime(System.DateTime.Today.Ticks);
System.DateTime tomorrow =
        new System.DateTime(
                    System.DateTime.Today.AddDays(1).Ticks);

// todayEqualsToday gets true.
bool todayEqualsToday = System.DateTime.Equals(today1, today2);

// todayEqualsTomorrow gets false.
bool todayEqualsTomorrow = System.DateTime.Equals(today1, tomorrow);
```

Remarks

`t1` and `t2` are equal if their Ticks property values are equal. Their Kind property values are not considered in the test for equality.

DateTime.FromBinary(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Deserializes a 64-bit binary value and recreates an original serialized DateTime object.

C#

```
public static DateTime FromBinary (long dateData);
```

Parameters

dateData Int64

A 64-bit signed integer that encodes the Kind property in a 2-bit field and the Ticks property in a 62-bit field.

Returns

DateTime

An object that is equivalent to the DateTime object that was serialized by the ToBinary() method.

Exceptions

ArgumentException

`dateData` is less than DateTime.MinValue or greater than DateTime.MaxValue.

Remarks

For more information about this API, see Supplemental API remarks for DateTime.FromBinary.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.FromFileTime(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified Windows file time to an equivalent local time.

C#

```
public static DateTime FromFileTime (long fileTime);
```

Parameters

`fileTime` Int64

A Windows file time expressed in ticks.

Returns

DateTime

An object that represents the local time equivalent of the date and time represented by the `fileTime` parameter.

Exceptions

ArgumentOutOfRangeException

`fileTime` is less than 0 or represents a time greater than DateTime.MaxValue.

Examples

The following example demonstrates the FromFileTime method.

C#

```
public System.TimeSpan FileAge(long fileCreationTime) {

    System.DateTime now = System.DateTime.Now;
    try {
```

```
        System.DateTime fCreationTime =
            System.DateTime.FromFileTime(fileCreationTime);
        System.TimeSpan fileAge = now.Subtract(fCreationTime);
        return fileAge;
    }
    catch (ArgumentOutOfRangeException) {
        // fileCreationTime is not valid, so re-throw the exception.
        throw;
    }
}
```

Remarks

A Windows file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 midnight, January 1, 1601 A.D. (C.E.) Coordinated Universal Time (UTC). Windows uses a file time to record when an application creates, accesses, or writes to a file.

The `fileTime` parameter specifies a file time expressed in 100-nanosecond ticks.

Starting with the .NET Framework version 2.0, the return value is a DateTime whose Kind property is DateTimeKind.Local.

Notes to Callers

Ordinarily, the FromFileTime(Int64) method restores a DateTime value that was saved by the ToFileTime() method. However, the two values may differ under the following conditions:

- If the serialization and deserialization of the DateTime value occur in different time zones. For example, if a DateTime value with a time of 12:30 P.M. in the U.S. Eastern Time zone is serialized, and then deserialized in the U.S. Pacific Time zone, the original value of 12:30 P.M. is adjusted to 9:30 A.M. to reflect the difference between the two time zones.

- If the DateTime value that is serialized represents an invalid time in the local time zone. In this case, the ToFileTime() method adjusts the restored DateTime value so that it represents a valid time in the local time zone.

  For example, the transition from standard time to daylight saving time occurs in the U.S. Pacific Time zone on March 14, 2010, at 2:00 A.M., when the time advances by one hour, to 3:00 A.M. This hour interval is an invalid time, that is, a time interval that does not exist in this time zone. The following example shows that

when a time that falls within this range is converted to a long integer value by the ToFileTime() method and is then restored by the FromFileTime(Int64) method, the original value is adjusted to become a valid time. You can determine whether a particular date and time value may be subject to modification by passing it to the IsInvalidTime(DateTime) method, as the example illustrates.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime date1 = new DateTime(2010, 3, 14, 2, 30, 00);
      Console.WriteLine("Invalid Time: {0}",
                        TimeZoneInfo.Local.IsInvalidTime(date1));
      long ft = date1.ToFileTime();
      DateTime date2 = DateTime.FromFileTime(ft);
      Console.WriteLine("{0} -> {1}", date1, date2);
   }
}
// The example displays the following output:
//       Invalid Time: True
//       3/14/2010 2:30:00 AM -> 3/14/2010 3:30:00 AM
```

Applies to

Product	Versions

DateTime.FromFileTimeUtc(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified Windows file time to an equivalent UTC time.

```
C#
public static DateTime FromFileTimeUtc (long fileTime);
```

Parameters

`fileTime` Int64

A Windows file time expressed in ticks.

Returns

DateTime

An object that represents the UTC time equivalent of the date and time represented by the `fileTime` parameter.

Exceptions

ArgumentOutOfRangeException

`fileTime` is less than 0 or represents a time greater than DateTime.MaxValue.

Remarks

A Windows file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 midnight, January 1, 1601 A.D. (C.E.) Coordinated Universal Time (UTC). Windows uses a file time to record when an application creates, accesses, or writes to a file.

The `fileTime` parameter specifies a file time expressed in 100-nanosecond ticks.

Starting with the .NET Framework version 2.0, the return value is a DateTime whose Kind property is Utc.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTime.FromOADate(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a DateTime equivalent to the specified OLE Automation Date.

```
C#
public static DateTime FromOADate (double d);
```

Parameters

d Double

An OLE Automation Date value.

Returns

DateTime

An object that represents the same date and time as `d`.

Exceptions

ArgumentException

The date is not a valid OLE Automation Date value.

Remarks

The `d` parameter is a double-precision floating-point number that represents a date as the number of days before or after the base date, midnight, 30 December 1899. The sign and integral part of `d` encode the date as a positive or negative day displacement from 30 December 1899, and the absolute value of the fractional part of `d` encodes the time of day as a fraction of a day displacement from midnight. `d` must be a value between negative 657435.0 through positive 2958465.99999999.

Note that because of the way dates are encoded, there are two ways of representing any time of day on 30 December 1899. For example, -0.5 and 0.5 both mean noon on 30 December 1899 because a day displacement of plus or minus zero days from the base date is still the base date, and a half day displacement from midnight is noon.

See ToOADate for more information on OLE Automation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DateTime.GetDateTimeFormats Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to all the string representations supported by the standard date and time format specifiers.

Overloads

Expand table

GetDateTimeFormats()	Converts the value of this instance to all the string representations supported by the standard date and time format specifiers.
GetDateTimeFormats(Char)	Converts the value of this instance to all the string representations supported by the specified standard date and time format specifier.
GetDateTimeFormats(IFormatProvider)	Converts the value of this instance to all the string representations supported by the standard date and time format specifiers and the specified culture-specific formatting information.
GetDateTimeFormats(Char, IFormatProvider)	Converts the value of this instance to all the string representations supported by the specified standard date and time format specifier and culture-specific formatting information.

Remarks

Important

You should not assume that multiple calls to the **GetDateTimeFormats** overloads will return identical data. Depending on the specific overload, the data returned by

this method can change if the current culture changes, the user overrides individual cultural settings, or an update occurs to the system's cultural data.

GetDateTimeFormats()

Converts the value of this instance to all the string representations supported by the standard date and time format specifiers.

C#

```
public string[] GetDateTimeFormats ();
```

Returns

String[]

A string array where each element is the representation of the value of this instance formatted with one of the standard date and time format specifiers.

Examples

The following example demonstrates the DateTime.GetDateTimeFormats() method. It displays the string representation of a date using all possible standard date and time formats in the computer's current culture, which in this case is en-US.

C#

```
DateTime july28 = new DateTime(2009, 7, 28, 5, 23, 15, 16);

string[] july28Formats = july28.GetDateTimeFormats();

// Print out july28 in all DateTime formats using the default culture.
foreach (string format in july28Formats) {
    Console.WriteLine(format);
}
```

The example displays the following output:

```
7/28/2009
7/28/09
07/28/09
```

Remarks

The string array returned by the DateTime.GetDateTimeFormats() method is equivalent to combining the string arrays returned by separate calls to the DateTime.GetDateTimeFormats(Char) method with the "d", "D", "f", "F", "g", "G", "m", "o", "r", "s", "t", "T", "u", "U", and "y" standard format strings. For more information about standard format specifiers, see Standard Date and Time Format Strings.

Each element of the return value is formatted using information from the current culture. For more information about culture-specific formatting information for the current culture, see CultureInfo.CurrentCulture.

> **Important**
>
> Because this method uses culture-sensitive data, you should not assume that multiple calls to the method will return identical data. The data returned by this method can change if the current culture changes, the user overrides individual cultural settings, or an update occurs to the system's cultural data.

UWP	10.0

GetDateTimeFormats(Char)

Converts the value of this instance to all the string representations supported by the specified standard date and time format specifier.

C#

```
public string[] GetDateTimeFormats (char format);
```

Parameters

`format` Char

A standard date and time format string.

Returns

String[]

A string array where each element is the representation of the value of this instance formatted with the `format` standard date and time format specifier.

Exceptions

FormatException

`format` is not a valid standard date and time format specifier character.

Examples

The following example demonstrates the GetDateTimeFormats(Char) method. It displays the string representation of a date using the long date format specifier ("D") for the current culture.

C#

```
  DateTime july28 = new DateTime(2009, 7, 28, 5, 23, 15);

  // Get the long date formats using the current culture.
  string [] longJuly28Formats =
              july28.GetDateTimeFormats('D');

  // Display july28 in all long date formats.
  foreach (string format in longJuly28Formats) {
      Console.WriteLine(format);
  }
// The example displays the following output:
//       Tuesday, July 28, 2009
//       July 28, 2009
//       Tuesday, 28 July, 2009
//       28 July, 2009
```

Remarks

The `format` parameter can be any of the standard date and time format specifiers. These include d, D, f, F, g, G, M (or m), O (or o), R (or r), s, t, T, u, U, and Y (or y). For more information, see Standard Date and Time Format Strings.

Each element of the return value is formatted using information from the current culture. For more information about culture-specific formatting information for the current culture, see CultureInfo.CurrentCulture.

> **Important**
>
> Because this method uses culture-sensitive data, you should not assume that multiple calls to the method will return identical data. The data returned by this method can change if the current culture changes, the user overrides individual cultural settings, or an update occurs to the system's cultural data.

GetDateTimeFormats(IFormatProvider)

Converts the value of this instance to all the string representations supported by the standard date and time format specifiers and the specified culture-specific formatting information.

C#

```
public string[] GetDateTimeFormats (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information about this instance.

Returns

String[]

A string array where each element is the representation of the value of this instance formatted with one of the standard date and time format specifiers.

Examples

The following example demonstrates the DateTime.GetDateTimeFormats(IFormatProvider) method. It displays the string

representation of a date using all possible standard date and time formats for the fr-FR culture.

```C#
DateTime july28 = new DateTime(2009, 7, 28, 5, 23, 15, 16);

IFormatProvider culture =
    new System.Globalization.CultureInfo("fr-FR", true);
// Get the short date formats using the "fr-FR" culture.
string [] frenchJuly28Formats =
            july28.GetDateTimeFormats(culture);

// Display july28 in various formats using "fr-FR" culture.
foreach (string format in frenchJuly28Formats) {
    Console.WriteLine(format);
}
```

The example displays the following output:

```

Remarks

The string array returned by the DateTime.GetDateTimeFormats(IFormatProvider) method is equivalent to combining the string arrays returned by separate calls to the DateTime.GetDateTimeFormats(Char, IFormatProvider) method with the "d", "D", "f", "F", "g", "G", "m", "o", "r", "s", "t", "T", "u", "U", and "y" standard format strings. For more information about standard format specifiers, see Standard Date and Time Format Strings.

Each element of the return value is formatted using culture-specific information supplied by `provider`.

> **Important**
>
> Because this method uses culture-sensitive data, you should not assume that multiple calls to the method will return identical data unless `provider` is a **CultureInfo** object that represents the invariant culture. The data returned by this method can change if the user overrides the individual cultural settings of `provider` or if an update occurs to the system's cultural data for `provider`.

UWP	10.0

GetDateTimeFormats(Char, IFormatProvider)

Converts the value of this instance to all the string representations supported by the specified standard date and time format specifier and culture-specific formatting information.

C#

```
public string[] GetDateTimeFormats (char format, IFormatProvider?
provider);
```

Parameters

`format` Char

A date and time format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about this instance.

Returns

String[]

A string array where each element is the representation of the value of this instance formatted with one of the standard date and time format specifiers.

Exceptions

FormatException

`format` is not a valid standard date and time format specifier character.

Examples

The following example demonstrates the GetDateTimeFormats(Char, IFormatProvider) method. It displays the string representations of a date using the short date format specifier ("d") for the fr-FR culture.

C#

```
  DateTime july28 = new DateTime(2009, 7, 28, 5, 23, 15);

  IFormatProvider culture =
      new System.Globalization.CultureInfo("fr-FR", true);
  // Get the short date formats using the "fr-FR" culture.
  string [] frenchJuly28Formats =
              july28.GetDateTimeFormats('d', culture);

  // Display july28 in short date formats using "fr-FR" culture.
  foreach (string format in frenchJuly28Formats) {
      Console.WriteLine(format);
  }
// The example displays the following output:
//       28/07/2009
//       28/07/09
//       28.07.09
//       28-07-09
//       2009-07-28
```

Remarks

The format parameter can be any of the standard date and time format specifiers. These include d, D, f, F, g, G, M (or m), O (or o), R (or r), s, t, T, u, U, and Y (or y). For more information, see Standard Date and Time Format Strings.

Each element of the return value is formatted using culture-specific information supplied by `provider`.

> **Important**
>
> Because this method uses culture-sensitive data, you should not assume that multiple calls to the method will return identical data unless `provider` is a **CultureInfo** object that represents the invariant culture. The data returned by

this method can change if the user overrides the individual cultural settings of `provider` or if an update occurs to the system's cultural data for `provider`.

DateTime.IsDaylightSavingTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether this instance of DateTime is within the daylight saving time range for the current time zone.

```
C#
public bool IsDaylightSavingTime ();
```

Returns

Boolean

`true` if the value of the Kind property is Local or Unspecified and the value of this instance of DateTime is within the daylight saving time range for the local time zone; `false` if Kind is Utc.

Remarks

This method determines whether the current DateTime value falls within the daylight saving time range of the local time zone, which is returned by the TimeZoneInfo.Local property. You can determine whether a time zone supports daylight saving time by retrieving the value of its TimeZoneInfo.SupportsDaylightSavingTime property. For time zones that observe daylight saving time, you can determine when the transition to and from daylight saving time occurs by retrieving the System.TimeZoneInfo.AdjustmentRule array returned by the time zone's TimeZoneInfo.GetAdjustmentRules property.

If the current DateTime value represents either an ambiguous or an invalid time in the local time zone, the method returns `false`.

On Windows XP systems, the IsDaylightSavingTime method recognizes only the current adjustment rule when determining whether the current instance is a daylight saving time. As a result, the method may not accurately report whether the current instance is a daylight saving time for periods before the current adjustment rule came into effect.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.IsLeapYear(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an indication whether the specified year is a leap year.

C#

```
public static bool IsLeapYear (int year);
```

Parameters

year Int32

A 4-digit year.

Returns

Boolean

`true` if `year` is a leap year; otherwise, `false`.

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

Examples

The following example uses the IsLeapYear method to determine which years between 1994 and 2014 are leap years. The example also illustrates the result when the AddYears method is used to add a year to a leap day.

C#

```
using System;

public class IsLeapYear
```

```
{
   public static void Main()
   {
      for (int year = 1994; year <= 2014; year++)
      {
         if (DateTime.IsLeapYear(year))
         {
            Console.WriteLine("{0} is a leap year.", year);
            DateTime leapDay = new DateTime(year, 2, 29);
            DateTime nextYear = leapDay.AddYears(1);
            Console.WriteLine("   One year from {0} is {1}.",
                              leapDay.ToString("d"),
                              nextYear.ToString("d"));
         }
      }
   }
}
// The example produces the following output:
//       1996 is a leap year.
//          One year from 2/29/1996 is 2/28/1997.
//       2000 is a leap year.
//          One year from 2/29/2000 is 2/28/2001.
//       2004 is a leap year.
//          One year from 2/29/2004 is 2/28/2005.
//       2008 is a leap year.
//          One year from 2/29/2008 is 2/28/2009.
//       2012 is a leap year.
//          One year from 2/29/2012 is 2/28/2013.
```

Remarks

`year` is specified as a 4-digit base 10 number; for example, 1996.

`year` is always interpreted as a year in the Gregorian calendar. To determine whether a particular year was a leap year in some other calendar, call that calendar object's `IsLeapYear` method.

DateTime.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a date and time to its DateTime equivalent.

Overloads

Expand table

Parse(String)	Converts the string representation of a date and time to its DateTime equivalent by using the conventions of the current culture.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a date and time to its DateTime equivalent by using culture-specific format information.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a memory span that contains string representation of a date and time to its DateTime equivalent by using culture-specific format information and a formatting style.
Parse(String, IFormatProvider, DateTimeStyles)	Converts the string representation of a date and time to its DateTime equivalent by using culture-specific format information and a formatting style.

Examples

Numerous examples that call the `DateTime.Parse` method are interspersed throughout the Remarks section of this article and in the documentation for the individual `DateTime.Parse` overloads.

Note

Some C# examples in this article run in the **Try.NET** inline code runner and playground. Select the **Run** button to run an example in an interactive window. Once you execute the code, you can modify it and run the modified code by selecting **Run** again. The modified code either runs in the interactive window or, if compilation fails, the interactive window displays all C# compiler error messages.

The **local time zone** of the **Try.NET** inline code runner and playground is Coordinated Universal Time, or UTC. This may affect the behavior and the output of examples that illustrate the **DateTime**, **DateTimeOffset**, and **TimeZoneInfo** types and their members.

You can also download a complete set of `DateTime.Parse` examples, which are included in a .NET Core project for C#.

Remarks

In this section:

- Which method do I call?
- The string to parse
- Parsing and cultural conventions
- Parsing and style elements
- The return value and DateTime.Kind

Which method do I call?

Expand table

To	Call
Parse a date and time string by using the conventions of the current culture.	Parse(String) overload
Parse a date and time string by using the conventions of a specific culture.	Parse(String, IFormatProvider) overload (see Parsing and Cultural Conventions)
Parse a date and time string with special style elements (such as white space or no white space).	Parse(String, IFormatProvider, DateTimeStyles) overload

To	Call
Parse a date and time string that must be in a particular format.	DateTime.ParseExact or DateTime.TryParseExact
Parse a date and time string and perform a conversion to UTC or local time.	Parse(String, IFormatProvider, DateTimeStyles) overload
Parse a date and time string without handling exceptions.	DateTime.TryParse method
Restore (round-trip) a date and time value created by a formatting operation.	Pass the "o" or "r" standard format string to the ToString(String) method, and call the Parse(String, IFormatProvider, DateTimeStyles) overload with DateTimeStyles.RoundtripKind
Parse a date and time string in a fixed format across machine (and possibly cultural) boundaries.	DateTime.ParseExact or DateTime.TryParseExact method

The string to parse

The Parse method tries to convert the string representation of a date and time value to its DateTime equivalent. It tries to parse the input string completely without throwing a FormatException exception.

> **ⓘ Important**
>
> If the parsing operation fails because of an unrecognized string format, the **Parse** method throws a **FormatException**, whereas the **TryParse** method returns `false`. Because exception handling can be expensive, you should use **Parse** when the parsing operation is expected to succeed because the input source is trusted. **TryParse** is preferable when parsing failures are likely, particularly because an input source is not trusted, or you have reasonable default values to substitute for strings that do not parse successfully.

The string to be parsed can take any of the following forms:

- A string with a date and a time component.
- A string with a date but no time component. If the time component is absent, the method assumes 12:00 midnight. If the date component has a two-digit year, it is converted to a year based on the Calendar.TwoDigitYearMax of the current

culture's current calendar or the specified culture's current calendar (if you use an overload with a non-null `provider` argument).

- A string with a date component that includes only the month and the year but no day component. The method assumes the first day of the month.
- A string with a date component that includes only the month and the day but no year component. The method assumes the current year.
- A string with a time but no date component. The method assumes the current date unless you call the Parse(String, IFormatProvider, DateTimeStyles) overload and include DateTimeStyles.NoCurrentDateDefault in the `styles` argument, in which case the method assumes a date of January 1, 0001.
- A string with a time component that includes only the hour and an AM/PM designator, with no date component. The method assumes the current date and a time with no minutes and no seconds. You can change this behavior by calling the Parse(String, IFormatProvider, DateTimeStyles) overload and include DateTimeStyles.NoCurrentDateDefault in the `styles` argument, in which case the method assumes a date of January 1, 0001.
- A string that includes time zone information and conforms to ISO 8601. In the following examples, the first string designates Coordinated Universal Time (UTC), and the second designates the time in a time zone that's seven hours earlier than UTC:

  "2008-11-01T19:35:00.0000000Z" "2008-11-01T19:35:00.0000000-07:00"
- A string that includes the GMT designator and conforms to the RFC 1123 time format; for example:

  "Sat, 01 Nov 2008 19:35:00 GMT"
- A string that includes the date and time along with time zone offset information; for example:

  "03/01/2009 05:42:00 -5:00"

The following example parses strings in each of these formats by using the formatting conventions of the current culture, which in this case is the en-US culture:

```C#
using System;

public class Example
```

```
{
   public static void Main()
   {
      (string dateAsString, string description)[]  dateInfo = { ("08/18/2018
07:22:16", "String with a date and time component"),

("08/18/2018", "String with a date component only"),
                                                                  ("8/2018",
"String with a month and year component only"),
                                                                  ("8/18",
"String with a month and day component only"),
                                                                  ("07:22:16",
"String with a time component only"),
                                                                  ("7 PM",
"String with an hour and AM/PM designator only"),
                                                                  ("2018-08-
18T07:22:16.0000000Z", "UTC string that conforms to ISO 8601"),
                                                                  ("2018-08-
18T07:22:16.0000000-07:00", "Non-UTC string that conforms to ISO 8601"),
                                                                  ("Sat, 18
Aug 2018 07:22:16 GMT", "String that conforms to RFC 1123"),
                                                                  ("08/18/2018
07:22:16 -5:00", "String with date, time, and time zone information" ) };

      Console.WriteLine($"Today is {DateTime.Now:d}\n");

      foreach (var item in dateInfo) {
         Console.WriteLine($"{item.description + ":",-52}
'{item.dateAsString}' --> {DateTime.Parse(item.dateAsString)}");
      }
   }
}
// The example displays output like the following:
//   Today is 2/22/2018
//
//   String with a date and time component:               '08/18/2018
07:22:16' --> 8/18/2018 7:22:16 AM
//   String with a date component only:                   '08/18/2018' -->
8/18/2018 12:00:00 AM
//   String with a month and year component only:         '8/2018' -->
8/1/2018 12:00:00 AM
//   String with a month and day component only:          '8/18' -->
8/18/2018 12:00:00 AM
//   String with a time component only:                   '07:22:16' -->
2/22/2018 7:22:16 AM
//   String with an hour and AM/PM designator only:       '7 PM' -->
2/22/2018 7:00:00 PM
//   UTC string that conforms to ISO 8601:                '2018-08-
18T07:22:16.0000000Z' --> 8/18/2018 12:22:16 AM
//   Non-UTC string that conforms to ISO 8601:            '2018-08-
18T07:22:16.0000000-07:00' --> 8/18/2018 7:22:16 AM
//   String that conforms to RFC 1123:                    'Sat, 18 Aug 2018
07:22:16 GMT' --> 8/18/2018 12:22:16 AM
//   String with date, time, and time zone information:   '08/18/2018
07:22:16 -5:00' --> 8/18/2018 5:22:16 AM
```

If the input string represents a leap day in a leap year in the calendar used by the parsing method (see Parsing and cultural conventions), the Parse method parses the string successfully. If the input string represents a leap day in a non-leap year, the method throws a FormatException.

Because the Parse method tries to parse the string representation of a date and time by using the formatting rules of the current or a specified culture, trying to parse a string across different cultures can fail. To parse a specific date and time format across different locales, use one of the overloads of the DateTime.ParseExact method and provide a format specifier.

Parsing and cultural conventions

All overloads of the Parse method are culture-sensitive unless the string to be parsed (which is represented by `s` in the following table) conforms to the ISO 8601 pattern. The parsing operation uses the formatting information in a DateTimeFormatInfo object that is derived as follows:

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

Expand table

If you call	And `provider` is	Formatting information is derived from
Parse(String)	-	The current culture (DateTimeFormatInfo.CurrentInfo property)

If you call	And `provider` is	Formatting information is derived from
Parse(String, IFormatProvider) or Parse(String, IFormatProvider, DateTimeStyles)	a DateTimeFormatInfo object	The specified DateTimeFormatInfo object
Parse(String, IFormatProvider) or Parse(String, IFormatProvider, DateTimeStyles)	`null`	The current culture (DateTimeFormatInfo.CurrentInfo property)
Parse(String, IFormatProvider) or Parse(String, IFormatProvider, DateTimeStyles)	a CultureInfo object	The CultureInfo.DateTimeFormat property
Parse(String, IFormatProvider) or Parse(String, IFormatProvider, DateTimeStyles)	Custom IFormatProvider implementation	The IFormatProvider.GetFormat method

When formatting information is derived from a DateTimeFormatInfo object, the DateTimeFormatInfo.Calendar property defines the calendar used in the parsing operation.

If you parse a date and time string by using a DateTimeFormatInfo object with customized settings that are different from those of a standard culture, use the ParseExact method instead of the Parse method to improve the chances for a successful conversion. A non-standard date and time string can be complicated and difficult to parse. The Parse method tries to parse a string with several implicit parse patterns, all of which might fail. In contrast, the ParseExact method requires you to explicitly designate one or more exact parse patterns that are likely to succeed. For more information, see the "DateTimeFormatInfo and Dynamic Data" section in the DateTimeFormatInfo topic.

> **ⓘ Important**
>
> Note that the formatting conventions for a particular culture are dynamic and can be subject to change. This means that parsing operations that depend on the formatting conventions of the default (current) culture or that specify an

IFormatProvider object that represents a culture other than the invariant culture can unexpectedly fail if any of the following occurs:

- The culture-specific data has changed between major or minor versions of the .NET Framework or as the result of an update to the existing version of the .NET Framework.
- The culture-specific data reflects user preferences, which can vary from machine to machine or session to session.
- The culture-specific data represents a replacement culture that overrides the settings of a standard culture or a custom culture.

To prevent the difficulties in parsing data and time strings that are associated with changes in cultural data, you can parse date and time strings by using the invariant culture, or you can call the **ParseExact** or **TryParseExact** method and specify the exact format of the string to be parsed. If you are serializing and deserializing date and time data, you can either use the formatting conventions of the invariant culture, or you can serialize and deserialize the **DateTime** value in a binary format.

For more information see the "Dynamic culture data" section in the **CultureInfo** topic and the "Persisting DateTime values" section in the **DateTime** topic.

Parsing and style elements

All Parse overloads ignore leading, inner, or trailing white-space characters in the input string (which is represented by `s` in the following table). The date and time can be bracketed with a pair of leading and trailing NUMBER SIGN characters ("#", U+0023), and can be trailed with one or more NULL characters (U+0000).

In addition, the Parse(String, IFormatProvider, DateTimeStyles) overload has a `styles` parameter that consists of one or more members of the DateTimeStyles enumeration. This parameter defines how `s` should be interpreted and how the parse operation should convert `s` to a date and time. The following table describes the effect of each DateTimeStyles member on the parse operation.

Expand table

DateTimeStyles member	Effect on conversion
AdjustToUniversal	Parses `s` and, if necessary, converts it to UTC, as follows:

DateTimeStyles member	Effect on conversion
	- If `s` includes a time zone offset, or if `s` contains no time zone information but `styles` includes the AssumeLocal flag, the method parses the string, calls ToUniversalTime to convert the returned DateTime value to UTC, and sets the Kind property to DateTimeKind.Utc. - If `s` indicates that it represents UTC, or if `s` does not contain time zone information but `styles` includes the AssumeUniversal flag, the method parses the string, performs no time zone conversion on the returned DateTime value, and sets the Kind property to DateTimeKind.Utc. - In all other cases, the flag has no effect.
AllowInnerWhite	This value is ignored. Inner white space is always permitted in the date and time elements of `s`.
AllowLeadingWhite	This value is ignored. Leading white space is always permitted in the date and time elements of `s`.
AllowTrailingWhite	This value is ignored. Trailing white space is always permitted in the date and time elements of `s`.
AllowWhiteSpaces	Specifies that `s` may contain leading, inner, and trailing white spaces. This is the default behavior. It cannot be overridden by supplying a more restrictive DateTimeStyles enumeration value such as None.
AssumeLocal	Specifies that if `s` lacks any time zone information, local time is assumed. Unless the AdjustToUniversal flag is present, the Kind property of the returned DateTime value is set to DateTimeKind.Local.
AssumeUniversal	Specifies that if `s` lacks any time zone information, UTC is assumed. Unless the AdjustToUniversal flag is present, the method converts the returned DateTime value from UTC to local time and sets its Kind property to DateTimeKind.Local.
None	Although valid, this value is ignored.
RoundtripKind	For strings that contain time zone information, tries to prevent the conversion of a date and time string to a DateTime value that represents a local time with its Kind property set to DateTimeKind.Local. Typically, such a string is created by calling the DateTime.ToString(String) method and by using the "o", "r", or "u" standard format specifier.

The return value and DateTime.Kind

The `DateTime.Parse` overloads return a DateTime value whose Kind property includes time zone information. It can indicate that the time is:

- Coordinated Universal Time (System.DateTimeKind.Utc).

- The time in the local time zone (System.DateTimeKind.Local).
- The time in an unknown time zone (System.DateTimeKind.Unspecified).

Generally, the Parse method returns a DateTime object whose Kind property is DateTimeKind.Unspecified. However, the Parse method may also perform time zone conversion and set the value of the Kind property differently, depending on the values of the `s` and `styles` parameters:

Expand table

If	Time zone conversion	Kind property
`s` contains time zone information.	The date and time is converted to the time in the local time zone.	DateTimeKind.Local
`s` contains time zone information, and `styles` includes the AdjustToUniversal flag.	The date and time is converted to Coordinated Universal Time (UTC).	DateTimeKind.Utc
`s` contains the Z or GMT time zone designator, and `styles` includes the RoundtripKind flag.	The date and time are interpreted as UTC.	DateTimeKind.Utc

The following example converts date strings that contain time zone information to the time in the local time zone:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] dateStrings = {"2008-05-01T07:34:42-5:00",
                              "2008-05-01 7:34:42Z",
                              "Thu, 01 May 2008 07:34:42 GMT"};
      foreach (string dateString in dateStrings)
      {
         DateTime convertedDate = DateTime.Parse(dateString);
         Console.WriteLine($"Converted {dateString} to {convertedDate.Kind}
time {convertedDate}");
      }
   }
}
// These calls to the DateTime.Parse method display the following output:
//  Converted 2008-05-01T07:34:42-5:00 to Local time 5/1/2008 5:34:42 AM
//  Converted 2008-05-01 7:34:42Z to Local time 5/1/2008 12:34:42 AM
```

```
//  Converted Thu, 01 May 2008 07:34:42 GMT to Local time 5/1/2008 12:34:42
AM
```

You can also preserve the value of a date and time's Kind property during a formatting and parsing operation by using the DateTimeStyles.RoundtripKind flag. The following example illustrates how the RoundtripKind flag affects the parsing operation on DateTime values that are converted to strings by using the "o", "r", or "u" format specifier.

C#

```
   string[] formattedDates = { "2008-09-15T09:30:41.7752486-07:00",
                               "2008-09-15T09:30:41.7752486Z",
                               "2008-09-15T09:30:41.7752486",
                               "2008-09-15T09:30:41.7752486-04:00",
                               "Mon, 15 Sep 2008 09:30:41 GMT" };
   foreach (string formattedDate in formattedDates)
   {
      Console.WriteLine(formattedDate);
      DateTime roundtripDate = DateTime.Parse(formattedDate, null,
                                              DateTimeStyles.RoundtripKind);
      Console.WriteLine($"   With RoundtripKind flag: {roundtripDate}
{roundtripDate.Kind} time.");

      DateTime noRoundtripDate = DateTime.Parse(formattedDate, null,
                                                DateTimeStyles.None);
      Console.WriteLine($"   Without RoundtripKind flag: {noRoundtripDate}
{noRoundtripDate.Kind} time.");
   }
// The example displays the following output:
//       2008-09-15T09:30:41.7752486-07:00
//          With RoundtripKind flag: 9/15/2008 9:30:41 AM Local time.
//          Without RoundtripKind flag: 9/15/2008 9:30:41 AM Local time.
//       2008-09-15T09:30:41.7752486Z
//          With RoundtripKind flag: 9/15/2008 9:30:41 AM Utc time.
//          Without RoundtripKind flag: 9/15/2008 2:30:41 AM Local time.
//       2008-09-15T09:30:41.7752486
//          With RoundtripKind flag: 9/15/2008 9:30:41 AM Unspecified time.
//          Without RoundtripKind flag: 9/15/2008 9:30:41 AM Unspecified
time.
//       2008-09-15T09:30:41.7752486-04:00
//          With RoundtripKind flag: 9/15/2008 6:30:41 AM Local time.
//          Without RoundtripKind flag: 9/15/2008 6:30:41 AM Local time.
//       Mon, 15 Sep 2008 09:30:41 GMT
//          With RoundtripKind flag: 9/15/2008 9:30:41 AM Utc time.
//          Without RoundtripKind flag: 9/15/2008 2:30:41 AM Local time.
```

Parse(String)

Converts the string representation of a date and time to its DateTime equivalent by using the conventions of the current culture.

```
C#

public static DateTime Parse (string s);
```

Parameters

s String

A string that contains a date and time to convert. See The string to parse for more information.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date and time.

Examples

The following example parses the string representation of several date and time values by:

- Using the default format provider, which provides the formatting conventions of the current culture of the computer used to produce the example output. The output from this example reflects the formatting conventions of the en-US culture.
- Using the default style value, which is AllowWhiteSpaces.

It handles the FormatException exception that is thrown when the method tries to parse the string representation of a date and time by using some other culture's

formatting conventions. It also shows how to successfully parse a date and time value that does not use the formatting conventions of the current culture.

C#

```
using System;
using System.Globalization;

public class DateTimeParser
{
   public static void Main()
   {
      // Assume the current culture is en-US.
      // The date is February 16, 2008, 12 hours, 15 minutes and 12
seconds.

      // Use standard en-US date and time value
      DateTime dateValue;
      string dateString = "2/16/2008 12:15:12 PM";
      try {
         dateValue = DateTime.Parse(dateString);
         Console.WriteLine("'{0}' converted to {1}.", dateString,
dateValue);
      }
      catch (FormatException) {
         Console.WriteLine("Unable to convert '{0}'.", dateString);
      }

      // Reverse month and day to conform to the fr-FR culture.
      // The date is February 16, 2008, 12 hours, 15 minutes and 12
seconds.
      dateString = "16/02/2008 12:15:12";
      try {
         dateValue = DateTime.Parse(dateString);
         Console.WriteLine("'{0}' converted to {1}.", dateString,
dateValue);
      }
      catch (FormatException) {
         Console.WriteLine("Unable to convert '{0}'.", dateString);
      }

      // Call another overload of Parse to successfully convert string
      // formatted according to conventions of fr-FR culture.
      try {
         dateValue = DateTime.Parse(dateString, new CultureInfo("fr-FR",
false));
         Console.WriteLine("'{0}' converted to {1}.", dateString,
dateValue);
      }
      catch (FormatException) {
         Console.WriteLine("Unable to convert '{0}'.", dateString);
      }

      // Parse string with date but no time component.
```

```
        dateString = "2/16/2008";
        try {
           dateValue = DateTime.Parse(dateString);
           Console.WriteLine("'{0}' converted to {1}.", dateString,
dateValue);
        }
        catch (FormatException) {
           Console.WriteLine("Unable to convert '{0}'.", dateString);
        }
    }
}
// The example displays the following output to the console:
//       '2/16/2008 12:15:12 PM' converted to 2/16/2008 12:15:12 PM.
//       Unable to convert '16/02/2008 12:15:12'.
//       '16/02/2008 12:15:12' converted to 2/16/2008 12:15:12 PM.
//       '2/16/2008' converted to 2/16/2008 12:00:00 AM.
```

Remarks

If `s` contains time zone information, this method returns a DateTime value whose Kind property is DateTimeKind.Local and converts the date and time in `s` to local time. Otherwise, it performs no time zone conversion and returns a DateTime value whose Kind property is DateTimeKind.Unspecified.

This overload attempts to parse `s` by using the formatting conventions of the current culture. The current culture is indicated by the CurrentCulture property. To parse a string using the formatting conventions of a specific culture, call the Parse(String, IFormatProvider) or the Parse(String, IFormatProvider, DateTimeStyles) overloads.

This overload attempts to parse `s` by using DateTimeStyles.AllowWhiteSpaces style.

UWP	10.0

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static DateTime Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

DateTime

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, IFormatProvider)

Converts the string representation of a date and time to its DateTime equivalent by using culture-specific format information.

```
C#

public static DateTime Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a date and time to convert. See The string to parse for more information.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`. See Parsing and cultural conventions

Returns

DateTime

An object that is equivalent to the date and time contained in `s` as specified by `provider`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date and time.

Examples

The following example parses an array of date strings by using the conventions of the en-US, fr-FR, and de-DE cultures. It demonstrates that the string representations of a single date can be interpreted differently across different cultures.

C#

```
using System;
using System.Globalization;

public class ParseDate
{
   public static void Main()
   {
      // Define cultures to be used to parse dates.
      CultureInfo[] cultures = {CultureInfo.CreateSpecificCulture("en-
US"),
                                CultureInfo.CreateSpecificCulture("fr-
FR"),
                                CultureInfo.CreateSpecificCulture("de-
DE")};
      // Define string representations of a date to be parsed.
      string[] dateStrings = {"01/10/2009 7:34 PM",
                              "10.01.2009 19:34",
                              "10-1-2009 19:34" };
      // Parse dates using each culture.
      foreach (CultureInfo culture in cultures)
      {
         DateTime dateValue;
         Console.WriteLine("Attempted conversions using {0} culture.",
                           culture.Name);
         foreach (string dateString in dateStrings)
         {
            try {
               dateValue = DateTime.Parse(dateString, culture);
               Console.WriteLine("   Converted '{0}' to {1}.",
                                 dateString, dateValue.ToString("f",
culture));
            }
            catch (FormatException) {
               Console.WriteLine("   Unable to convert '{0}' for culture
{1}.",
                                 dateString, culture.Name);
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output to the console:
//       Attempted conversions using en-US culture.
//          Converted '01/10/2009 7:34 PM' to Saturday, January 10, 2009
```

```
7:34 PM.
//          Converted '10.01.2009 19:34' to Thursday, October 01, 2009
7:34 PM.
//          Converted '10-1-2009 19:34' to Thursday, October 01, 2009
7:34 PM.
//
//       Attempted conversions using fr-FR culture.
//          Converted '01/10/2009 7:34 PM' to jeudi 1 octobre 2009 19:34.
//          Converted '10.01.2009 19:34' to samedi 10 janvier 2009 19:34.
//          Converted '10-1-2009 19:34' to samedi 10 janvier 2009 19:34.
//
//       Attempted conversions using de-DE culture.
//          Converted '01/10/2009 7:34 PM' to Donnerstag, 1. Oktober 2009
19:34.
//          Converted '10.01.2009 19:34' to Samstag, 10. Januar 2009
19:34.
//          Converted '10-1-2009 19:34' to Samstag, 10. Januar 2009
19:34.
```

Remarks

If `s` contains time zone information, this method returns a DateTime value whose Kind property is DateTimeKind.Local and converts the date and time in `s` to local time. Otherwise, it performs no time zone conversion and returns a DateTime value whose Kind property is DateTimeKind.Unspecified.

This overload attempts to parse `s` by using the DateTimeStyles.AllowWhiteSpaces style.

Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts a memory span that contains string representation of a date and time to its DateTime equivalent by using culture-specific format information and a formatting style.

C#

```
public static DateTime Parse (ReadOnlySpan<char> s, IFormatProvider?
provider = default, System.Globalization.DateTimeStyles styles =
System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

The memory span that contains the string to parse. See The string to parse for more information.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`. See Parsing and cultural conventions

`styles` DateTimeStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s` for the parse operation to succeed, and that defines how to interpret the parsed date in relation to the current time zone or the current date. A typical value to specify is None.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `provider` and `styles`.

Exceptions

FormatException

`s` does not contain a valid string representation of a date and time.

ArgumentException

`styles` contains an invalid combination of DateTimeStyles values. For example, both AssumeLocal and AssumeUniversal.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(String, IFormatProvider, DateTimeStyles)

Converts the string representation of a date and time to its DateTime equivalent by using culture-specific format information and a formatting style.

C#

```
public static DateTime Parse (string s, IFormatProvider? provider,
System.Globalization.DateTimeStyles styles);
```

Parameters

s String

A string that contains a date and time to convert. See The string to parse for more information.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`. See Parsing and cultural conventions

`styles` DateTimeStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s` for the parse operation to succeed, and that defines how to interpret the parsed date in relation to the current time zone or the current date. A typical value to specify is None.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `provider` and `styles`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a date and time.

ArgumentException

`styles` contains an invalid combination of DateTimeStyles values. For example, both AssumeLocal and AssumeUniversal.

Examples

The following example demonstrates the Parse(String, IFormatProvider, DateTimeStyles) method and displays the value of the Kind property of the resulting DateTime values.

C#

```
using System;
using System.Globalization;

public class ParseDateExample
{
   public static void Main()
```

```
    {
       string dateString;
       CultureInfo culture ;
       DateTimeStyles styles;
       DateTime result;

       // Parse a date and time with no styles.
       dateString = "03/01/2009 10:00 AM";
       culture = CultureInfo.CreateSpecificCulture("en-US");
       styles = DateTimeStyles.None;
       try {
          result = DateTime.Parse(dateString, culture, styles);
          Console.WriteLine("{0} converted to {1} {2}.",
                            dateString, result, result.Kind.ToString());
       }
       catch (FormatException) {
          Console.WriteLine("Unable to convert {0} to a date and time.",
                            dateString);
       }

       // Parse the same date and time with the AssumeLocal style.
       styles = DateTimeStyles.AssumeLocal;
       try {
          result = DateTime.Parse(dateString, culture, styles);
          Console.WriteLine("{0} converted to {1} {2}.",
                            dateString, result, result.Kind.ToString());
       }
       catch (FormatException) {
          Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);
       }

       // Parse a date and time that is assumed to be local.
       // This time is five hours behind UTC. The local system's time zone
is
       // eight hours behind UTC.
       dateString = "2009/03/01T10:00:00-5:00";
       styles = DateTimeStyles.AssumeLocal;
       try {
          result = DateTime.Parse(dateString, culture, styles);
          Console.WriteLine("{0} converted to {1} {2}.",
                            dateString, result, result.Kind.ToString());
       }
       catch (FormatException) {
          Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);
       }

       // Attempt to convert a string in improper ISO 8601 format.
       dateString = "03/01/2009T10:00:00-5:00";
       try {
          result = DateTime.Parse(dateString, culture, styles);
          Console.WriteLine("{0} converted to {1} {2}.",
                            dateString, result, result.Kind.ToString());
       }
```

```
      catch (FormatException) {
         Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);
      }

      // Assume a date and time string formatted for the fr-FR culture is
the local
      // time and convert it to UTC.
      dateString = "2008-03-01 10:00";
      culture = CultureInfo.CreateSpecificCulture("fr-FR");
      styles = DateTimeStyles.AdjustToUniversal |
DateTimeStyles.AssumeLocal;
      try {
         result = DateTime.Parse(dateString, culture, styles);
         Console.WriteLine("{0} converted to {1} {2}.",
                           dateString, result, result.Kind.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);
      }
   }
}
// The example displays the following output to the console:
//       03/01/2009 10:00 AM converted to 3/1/2009 10:00:00 AM
Unspecified.
//       03/01/2009 10:00 AM converted to 3/1/2009 10:00:00 AM Local.
//       2009/03/01T10:00:00-5:00 converted to 3/1/2009 7:00:00 AM Local.
//       Unable to convert 03/01/2009T10:00:00-5:00 to a date and time.
//       2008-03-01 10:00 converted to 3/1/2008 6:00:00 PM Utc.
```

Remarks

This method overload converts the date and time in `s` and sets the Kind property of the returned DateTime value as follows:

Expand table

If	Time zone conversion	Kind property
`s` contains no time zone information.	None.	DateTimeKind.Unspecified
`s` contains time zone information.	To the time in the local time zone	DateTimeKind.Local
`s` contains time zone information, and `styles` includes the DateTimeStyles.AdjustToUniversal flag.	To Coordinated Universal Time (UTC)	DateTimeKind.Utc

If	Time zone conversion	Kind property
`s` contains the Z or GMT time zone designator, and `styles` includes the DateTimeStyles.RoundtripKind.	None.	DateTimeKind.Utc

DateTime.ParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a date and time to its DateTime equivalent. The format of the string representation must match a specified format exactly or an exception is thrown.

Overloads

Expand table

ParseExact(String, String, IFormatProvider)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

Remarks

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

ParseExact(String, String, IFormatProvider)

Converts the specified string representation of a date and time to its DateTime equivalent using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

C#

```
public static DateTime ParseExact (string s, string format,
IFormatProvider? provider);
```

Parameters

s String

A string that contains a date and time to convert.

format String

A format specifier that defines the required format of `s`. For more information, see the Remarks section.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `format` and `provider`.

Exceptions

ArgumentNullException

`s` or `format` is `null`.

FormatException

`s` or `format` is an empty string.

-or-

`s` does not contain a date and time that corresponds to the pattern specified in `format`.

-or-

The hour component and the AM/PM designator in `s` do not agree.

Examples

The following example demonstrates the ParseExact method.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string dateString, format;
      DateTime result;
```

```
      CultureInfo provider = CultureInfo.InvariantCulture;

      // Parse date-only value with invariant culture.
      dateString = "06/15/2008";
      format = "d";
      try {
         result = DateTime.ParseExact(dateString, format, provider);
         Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("{0} is not in the correct format.",
dateString);
      }

      // Parse date-only value without leading zero in month using "d"
format.
      // Should throw a FormatException because standard short date
pattern of
      // invariant culture requires two-digit month.
      dateString = "6/15/2008";
      try {
         result = DateTime.ParseExact(dateString, format, provider);
         Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("{0} is not in the correct format.",
dateString);
      }

      // Parse date and time with custom specifier.
      dateString = "Sun 15 Jun 2008 8:30 AM -06:00";
      format = "ddd dd MMM yyyy h:mm tt zzz";
      try {
         result = DateTime.ParseExact(dateString, format, provider);
         Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("{0} is not in the correct format.",
dateString);
      }

      // Parse date and time with offset but without offset's minutes.
      // Should throw a FormatException because "zzz" specifier requires
leading
      // zero in hours.
      dateString = "Sun 15 Jun 2008 8:30 AM -06";
      try {
         result = DateTime.ParseExact(dateString, format, provider);
         Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
      }
      catch (FormatException) {
```

```
         Console.WriteLine("{0} is not in the correct format.",
dateString);
      }

      dateString = "15/06/2008 08:30";
      format = "g";
      provider = new CultureInfo("fr-FR");
      try {
         result = DateTime.ParseExact(dateString, format, provider);
         Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("{0} is not in the correct format.",
dateString);
      }

      // Parse a date that includes seconds and milliseconds
      // by using the French (France) and invariant cultures.
      dateString = "18/08/2015 06:30:15.006542";
      format = "dd/MM/yyyy HH:mm:ss.ffffff";
      try {
         result = DateTime.ParseExact(dateString, format, provider);
         Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
      }
      catch (FormatException) {
         Console.WriteLine("{0} is not in the correct format.",
dateString);
      }
   }
}
// The example displays the following output:
//       06/15/2008 converts to 6/15/2008 12:00:00 AM.
//       6/15/2008 is not in the correct format.
//       Sun 15 Jun 2008 8:30 AM -06:00 converts to 6/15/2008 7:30:00 AM.
//       Sun 15 Jun 2008 8:30 AM -06 is not in the correct format.
//       15/06/2008 08:30 converts to 6/15/2008 8:30:00 AM.
//       18/08/2015 06:30:15.006542 converts to 8/18/2015 6:30:15 AM.
```

Remarks

The DateTime.ParseExact(String, String, IFormatProvider) method parses the string representation of a date, which must be in the format defined by the `format` parameter. It also requires that the <Date> and <Time> elements of the string representation of a date and time appear in the order specified by `format`, and that `s` have no white space other than that permitted by `format`. If `format` defines a date with no time element and the parse operation succeeds, the resulting DateTime value has a time of midnight (00:00:00). If `format` defines a time with no date

element and the parse operation succeeds, the resulting DateTime value has a date of `DateTime.Now.Date`.

If `s` does not represent a time in a particular time zone and the parse operation succeeds, the Kind property of the returned DateTime value is DateTimeKind.Unspecified. If `s` does represent the time in a particular time zone and `format` allows time zone information to be present (for example, if `format` is equal to the "o", "r", or "u" standard format specifiers, or if it contains the "z", "zz", or "zzz" custom format specifiers), the Kind property of the returned DateTime value is DateTimeKind.Local.

The `format` parameter is a string that contains either a single standard format specifier, or one or more custom format specifiers that define the required format of `s`. For details about valid formatting codes, see Standard Date and Time Format Strings or Custom Date and Time Format Strings.

> **Note**
>
> If `format` is a custom format pattern that does not include date or time separators (such as "yyyyMMddHHmm"), use the invariant culture for the `provider` parameter and the widest form of each custom format specifier. For example, if you want to specify hours in the format pattern, specify the wider form, "HH", instead of the narrower form, "H".

The particular date and time symbols and strings (such as names of the days of the week in a particular language) used in `s` are defined by the `provider` parameter, as is the precise format of `s` if `format` is a standard format specifier string. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture used to interpret `s`. The DateTimeFormatInfo object returned by its DateTimeFormat property defines the symbols and formatting in `s`.
- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom IFormatProvider implementation whose GetFormat method returns either the CultureInfo object or the DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the CultureInfo object that corresponds to the current culture is used.

Notes to Callers

In the .NET Framework 4, the ParseExact method throws a FormatException if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

UWP	10.0

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts the specified span representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

C#

```
public static DateTime ParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, IFormatProvider? provider,
System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent a date and time to convert.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a format specifier that defines the required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of the enumeration values that provides additional information about `s`, about style elements that may be present in `s`, or about the conversion from `s` to a DateTime value. A typical value to specify is None.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `format`, `provider`, and `style`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)

Converts the specified span representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

```
C#

public static DateTime ParseExact (ReadOnlySpan<char> s, string[]
formats, IFormatProvider? provider, System.Globalization.DateTimeStyles
style = System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent a date and time to convert.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `formats`, `provider`, and `style`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ParseExact(String, String, IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

```
C#

public static DateTime ParseExact (string s, string format,
IFormatProvider? provider, System.Globalization.DateTimeStyles style);
```

Parameters

`s` String

A string containing a date and time to convert.

`format` String

A format specifier that defines the required format of `s`. For more information, see the Remarks section.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of the enumeration values that provides additional information about `s`, about style elements that may be present in `s`, or about the conversion from `s` to a DateTime value. A typical value to specify is None.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `format`, `provider`, and `style`.

Exceptions

ArgumentNullException

`s` or `format` is `null`.

FormatException

`s` or `format` is an empty string.

-or-

`s` does not contain a date and time that corresponds to the pattern specified in `format`.

-or-

The hour component and the AM/PM designator in `s` do not agree.

ArgumentException

`style` contains an invalid combination of DateTimeStyles values. For example, both AssumeLocal and AssumeUniversal.

Examples

The following example demonstrates the ParseExact(String, String, IFormatProvider) method. Note that the string " 5/01/2009 8:30 AM" cannot be parsed successfully when the `styles` parameter equals DateTimeStyles.None because leading spaces are not allowed by `format`. Additionally, the string "5/01/2009 09:00" cannot be parsed successfully with a `format` of "MM/dd/yyyyhh:mm" because the date string does not precede the month number with a leading zero, as `format` requires.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      CultureInfo enUS = new CultureInfo("en-US");
      string dateString;
```

```
      DateTime dateValue;

      // Parse date with no style flags.
      dateString = " 5/01/2009 8:30 AM";
      try {
         dateValue = DateTime.ParseExact(dateString, "g", enUS,
DateTimeStyles.None);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }
      // Allow a leading space in the date string.
      try {
         dateValue = DateTime.ParseExact(dateString, "g", enUS,
DateTimeStyles.AllowLeadingWhite);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }

      // Use custom formats with M and MM.
      dateString = "5/01/2009 09:00";
      try {
         dateValue = DateTime.ParseExact(dateString, "M/dd/yyyy hh:mm",
enUS, DateTimeStyles.None);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }
      // Allow a leading space in the date string.
      try {
         dateValue = DateTime.ParseExact(dateString, "MM/dd/yyyy hh:mm",
enUS, DateTimeStyles.None);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }

      // Parse a string with time zone information.
```

```
      dateString = "05/01/2009 01:30:42 PM -05:00";
      try {
         dateValue = DateTime.ParseExact(dateString, "MM/dd/yyyy hh:mm:ss
tt zzz", enUS, DateTimeStyles.None);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }
      // Allow a leading space in the date string.
      try {
         dateValue = DateTime.ParseExact(dateString, "MM/dd/yyyy hh:mm:ss
tt zzz", enUS,
                                         DateTimeStyles.AdjustToUniversal);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }

      // Parse a string representing UTC.
      dateString = "2008-06-11T16:11:20.0904778Z";
      try {
         dateValue = DateTime.ParseExact(dateString, "o",
CultureInfo.InvariantCulture,
                                         DateTimeStyles.None);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }
      try {
         dateValue = DateTime.ParseExact(dateString, "o",
CultureInfo.InvariantCulture,
                                         DateTimeStyles.RoundtripKind);
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
      }
   }
}
// The example displays the following output:
```

```
//    ' 5/01/2009 8:30 AM' is not in an acceptable format.
//    Converted ' 5/01/2009 8:30 AM' to 5/1/2009 8:30:00 AM
(Unspecified).
//    Converted '5/01/2009 09:00' to 5/1/2009 9:00:00 AM (Unspecified).
//    '5/01/2009 09:00' is not in an acceptable format.
//    Converted '05/01/2009 01:30:42 PM -05:00' to 5/1/2009 11:30:42 AM
(Local).
//    Converted '05/01/2009 01:30:42 PM -05:00' to 5/1/2009 6:30:42 PM
(Utc).
//    Converted '2008-06-11T16:11:20.0904778Z' to 6/11/2008 9:11:20 AM
(Local).
//    Converted '2008-06-11T16:11:20.0904778Z' to 6/11/2008 4:11:20 PM
(Utc).
```

Remarks

The DateTime.ParseExact(String, String, IFormatProvider, DateTimeStyles) method parses the string representation of a date, which must be in a format defined by the `format` parameter. It also requires that the date and time elements in `s` appear in the order specified by `format`. If `s` does not match the pattern of the `format` parameter, with any variations defined by the `style` parameter, the method throws a FormatException. In contrast, the DateTime.Parse(String, IFormatProvider, DateTimeStyles) method parses the string representation of a date in any one of the formats recognized by the format provider's DateTimeFormatInfo object. The DateTime.Parse(String, IFormatProvider, DateTimeStyles) method also allows the date and time elements in `s` to appear in any order.

If the `s` parameter contains only a time and no date, the current date is used unless the `style` parameter includes the DateTimeStyles.NoCurrentDateDefault flag, in which case the default date (`DateTime.Date.MinValue`) is used. If the `s` parameter contains only a date and no time, midnight (00:00:00) is used. The `style` parameter also determines whether the `s` parameter can contain leading, inner, or trailing white space characters.

If `s` contains no time zone information, the Kind property of the returned DateTime object is DateTimeKind.Unspecified. This behavior can be changed by using the DateTimeStyles.AssumeLocal flag, which returns a DateTime value whose Kind property is DateTimeKind.Local, or by using the DateTimeStyles.AssumeUniversal and DateTimeStyles.AdjustToUniversal flags, which returns a DateTime value whose Kind property is DateTimeKind.Utc. If `s` contains time zone information, the time is converted to local time, if necessary, and the Kind property of the returned DateTime object is set to DateTimeKind.Local. This behavior can be changed by using the

DateTimeStyles.RoundtripKind flag to not convert Coordinated Universal Time (UTC) to a local time and to set the Kind property to DateTimeKind.Utc.

The `format` parameter defines the required pattern of the `s` parameter. It can consist of either one or more custom format specifiers from the Custom Date and Time Format Strings table, or a single standard format specifier, which identifies a predefined pattern, from the Standard Date and Time Format Strings table.

If you do not use date or time separators in a custom format pattern, use the invariant culture for the `provider` parameter and the widest form of each custom format specifier. For example, if you want to specify hours in the pattern, specify the wider form, "HH", instead of the narrower form, "H".

> **Note**
>
> Rather than requiring that `s` conform to a single format for the parse operation to succeed, you can call the **DateTime.ParseExact(String, String[], IFormatProvider, DateTimeStyles)** method and specify multiple permitted formats. This makes the parse operation more likely to succeed.

The `styles` parameter includes one or more members of the DateTimeStyles enumeration that determine whether and where white space not defined by `format` can appear in `s` and that control the precise behavior of the parse operation. The following table describes how each member of the DateTimeStyles enumeration affects the operation of the ParseExact(String, String, IFormatProvider, DateTimeStyles) method.

Expand table

DateTimeStyles member	Description
AdjustToUniversal	Parses `s` and, if necessary, converts it to UTC. If `s` includes a time zone offset, or if `s` contains no time zone information but `styles` includes the DateTimeStyles.AssumeLocal flag, the method parses the string, calls ToUniversalTime to convert the returned DateTime value to UTC, and sets the Kind property to DateTimeKind.Utc. If `s` indicates that it represents UTC, or if `s` does not contain time zone information but `styles` includes the DateTimeStyles.AssumeUniversal flag, the method parses the string, performs no time zone conversion on the returned DateTime value, and sets the Kind property to DateTimeKind.Utc. In all other cases, the flag has no effect.

DateTimeStyles member	Description
AllowInnerWhite	Specifies that white space not defined by `format` can appear between any individual date or time element.
AllowLeadingWhite	Specifies that white space not defined by `format` can appear at the beginning of `s`.
AllowTrailingWhite	Specifies that white space not defined by `format` can appear at the end of `s`.
AllowWhiteSpaces	Specifies that `s` may contain leading, inner, and trailing white spaces not defined by `format`.
AssumeLocal	Specifies that if `s` lacks any time zone information, it is assumed to represent a local time. Unless the DateTimeStyles.AdjustToUniversal flag is present, the Kind property of the returned DateTime value is set to DateTimeKind.Local.
AssumeUniversal	Specifies that if `s` lacks any time zone information, it is assumed to represent UTC. Unless the DateTimeStyles.AdjustToUniversal flag is present, the method converts the returned DateTime value from UTC to local time and sets its Kind property to DateTimeKind.Local.
NoCurrentDateDefault	If `s` contains time without date information, the date of the return value is set to `DateTime.MinValue.Date`.
None	The `s` parameter is parsed using default values. No white space other than that present in `format` is allowed. If `s` lacks a date component, the date of the returned DateTime value is set to 1/1/0001. If `s` contains no time zone information, the Kind property of the returned DateTime object is set to DateTimeKind.Unspecified. If time zone information is present in `s`, the time is converted to local time and the Kind property of the returned DateTime object is set to DateTimeKind.Local.
RoundtripKind	For strings that contain time zone information, tries to prevent the conversion to a DateTime value date and time with its Kind property set to DateTimeKind.Local. This flag primarily prevents the conversion of UTC times to local times.

The particular date and time symbols and strings (such as the names of the days of the week in a particular language) used in `s` are defined by the `provider` parameter, as is the precise format of `s` if `format` is a standard format specifier string. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture used to interpret `s`. The DateTimeFormatInfo object returned by its DateTimeFormat property defines the symbols and formatting in `s`.
- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom IFormatProvider implementation whose GetFormat method returns either the CultureInfo object or the DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the CultureInfo object that corresponds to the current culture is used.

Notes to Callers

In the .NET Framework 4, the ParseExact method throws a FormatException if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

ParseExact(String, String[], IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

C#

```
public static DateTime ParseExact (string s, string[] formats,
IFormatProvider? provider, System.Globalization.DateTimeStyles style);
```

Parameters

`s` String

A string that contains a date and time to convert.

`formats` String[]

An array of allowable formats of `s`. For more information, see the Remarks section.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

DateTime

An object that is equivalent to the date and time contained in `s`, as specified by `formats`, `provider`, and `style`.

Exceptions

ArgumentNullException

`s` or `formats` is `null`.

FormatException

`s` is an empty string.

-or-

an element of `formats` is an empty string.

-or-

`s` does not contain a date and time that corresponds to any element of `formats`.

-or-

The hour component and the AM/PM designator in `s` do not agree.

ArgumentException

`style` contains an invalid combination of DateTimeStyles values. For example, both AssumeLocal and AssumeUniversal.

Examples

The following example uses the DateTime.ParseExact(String, String[], IFormatProvider, DateTimeStyles) method to ensure that a string in a number of possible formats can be successfully parsed .

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] formats= {"M/d/yyyy h:mm:ss tt", "M/d/yyyy h:mm tt",
                         "MM/dd/yyyy hh:mm:ss", "M/d/yyyy h:mm:ss",
                         "M/d/yyyy hh:mm tt", "M/d/yyyy hh tt",
                         "M/d/yyyy h:mm", "M/d/yyyy h:mm",
                         "MM/dd/yyyy hh:mm", "M/dd/yyyy hh:mm",
                         "MM/d/yyyy HH:mm:ss.ffffff" };
      string[] dateStrings = {"5/1/2009 6:32 PM", "05/01/2009 6:32:05
PM",
```

```
                                "5/1/2009 6:32:00", "05/01/2009 06:32",
                                "05/01/2009 06:32:00 PM", "05/01/2009
06:32:00",
                                "08/28/2015 16:17:39.125", "08/28/2015
16:17:39.125000" };
      DateTime dateValue;

      foreach (string dateString in dateStrings)
      {
         try {
            dateValue = DateTime.ParseExact(dateString, formats,
                                            new CultureInfo("en-US"),
                                            DateTimeStyles.None);
            Console.WriteLine("Converted '{0}' to {1}.", dateString,
dateValue);
         }
         catch (FormatException) {
            Console.WriteLine("Unable to convert '{0}' to a date.",
dateString);
         }
      }
   }
}
// The example displays the following output:
//       Converted '5/1/2009 6:32 PM' to 5/1/2009 6:32:00 PM.
//       Converted '05/01/2009 6:32:05 PM' to 5/1/2009 6:32:05 PM.
//       Converted '5/1/2009 6:32:00' to 5/1/2009 6:32:00 AM.
//       Converted '05/01/2009 06:32' to 5/1/2009 6:32:00 AM.
//       Converted '05/01/2009 06:32:00 PM' to 5/1/2009 6:32:00 PM.
//       Converted '05/01/2009 06:32:00' to 5/1/2009 6:32:00 AM.
//       Unable to convert '08/28/2015 16:17:39.125' to a date.
//       Converted '08/28/2015 16:17:39.125000' to 8/28/2015 4:17:39 PM.
```

Remarks

The DateTime.ParseExact(String, String[], IFormatProvider, DateTimeStyles) method parses the string representation of a date that matches any one of the patterns assigned to the `formats` parameter. If the string `s` does not match any one of these patterns with any of the variations defined by the `styles` parameter, the method throws a FormatException. Aside from comparing `s` to multiple formatting patterns, rather than to a single formatting pattern, this overload behaves identically to the DateTime.ParseExact(String, String, IFormatProvider, DateTimeStyles) method.

The `s` parameter contains the date and time to parse. If the `s` parameter contains only a time and no date, the current date is used unless the `style` parameter includes the DateTimeStyles.NoCurrentDateDefault flag, in which case the default date (`DateTime.Date.MinValue`) is used. If the `s` parameter contains only a date and no time, midnight (00:00:00) is used. The `style` parameter also determines whether

the `s` parameter can contain leading, inner, or trailing white space characters other than those permitted by one of the format strings in `formats`.

If `s` contains no time zone information, the Kind property of the returned DateTime object is DateTimeKind.Unspecified. This behavior can be changed by using the DateTimeStyles.AssumeLocal flag, which returns a DateTime value whose Kind property is DateTimeKind.Local, or by using the DateTimeStyles.AssumeUniversal and DateTimeStyles.AdjustToUniversal flags, which returns a DateTime value whose Kind property is DateTimeKind.Utc. If `s` contains time zone information, the time is converted to local time, if necessary, and the Kind property of the returned DateTime object is set to DateTimeKind.Local. This behavior can be changed by using the DateTimeStyles.RoundtripKind flag to not convert Coordinated Universal Time (UTC) to a local time and set the Kind property to DateTimeKind.Utc.

The `formats` parameter contains an array of patterns, one of which `s` must match exactly if the parse operation is to succeed. The patterns in the `formats` parameter consists of one or more custom format specifiers from the Custom Date and Time Format Strings table, or a single standard format specifier, which identifies a predefined pattern, from the Standard Date and Time Format Strings table.

If you do not use date or time separators in a custom format pattern, use the invariant culture for the `provider` parameter and the widest form of each custom format specifier. For example, if you want to specify hours in the pattern, specify the wider form, "HH", instead of the narrower form, "H".

The `styles` parameter includes one or more members of the DateTimeStyles enumeration that determine whether and where white space not defined by `format` can appear in `s` and that control the precise behavior of the parse operation. The following table describes how each member of the DateTimeStyles enumeration affects the operation of the ParseExact(String, String, IFormatProvider, DateTimeStyles) method.

Expand table

DateTimeStyles member	Description
AdjustToUniversal	Parses `s` and, if necessary, converts it to UTC. If `s` includes a time zone offset, or if `s` contains no time zone information but `styles` includes the DateTimeStyles.AssumeLocal flag, the method parses the string, calls ToUniversalTime to convert the returned DateTime value to UTC, and sets the Kind property to DateTimeKind.Utc. If `s` indicates that it represents UTC, or if `s` does not contain time zone

DateTimeStyles member	Description
	information but `styles` includes the DateTimeStyles.AssumeUniversal flag, the method parses the string, performs no time zone conversion on the returned DateTime value, and sets the Kind property to DateTimeKind.Utc. In all other cases, the flag has no effect.
AllowInnerWhite	Specifies that white space not defined by `format` can appear between any individual date or time element.
AllowLeadingWhite	Specifies that white space not defined by `format` can appear at the beginning of `s`.
AllowTrailingWhite	Specifies that white space not defined by `format` can appear at the end of `s`.
AllowWhiteSpaces	Specifies that `s` may contain leading, inner, and trailing white spaces not defined by `format`.
AssumeLocal	Specifies that if `s` lacks any time zone information, it is assumed to represent a local time. Unless the DateTimeStyles.AdjustToUniversal flag is present, the Kind property of the returned DateTime value is set to DateTimeKind.Local.
AssumeUniversal	Specifies that if `s` lacks any time zone information, it is assumed to represent UTC. Unless the DateTimeStyles.AdjustToUniversal flag is present, the method converts the returned DateTime value from UTC to local time and sets its Kind property to DateTimeKind.Local.
NoCurrentDateDefault	If `s` contains time without date information, the date of the return value is set to `DateTime.MinValue.Date`.
None	The `s` parameter is parsed using default values. No white space other than that present in `format` is allowed. If `s` lacks a date component, the date of the returned DateTime value is set to 1/1/0001. If `s` contains no time zone information, the Kind property of the returned DateTime object is set to DateTimeKind.Unspecified. If time zone information is present in `s`, the time is converted to local time and the Kind property of the returned DateTime object is set to DateTimeKind.Local.
RoundtripKind	For strings that contain time zone information, tries to prevent the conversion to a date and time with its Kind property set to DateTimeKind.Local. This flag primarily prevents the conversion of UTC times to local times.

The particular date and time symbols and strings (such as the names of the days of the week in a particular language) used in `s` are defined by the `provider` parameter,

as is the precise format of `s` if `format` is a standard format specifier string. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture used to interpret `s`. The DateTimeFormatInfo object returned by its DateTimeFormat property defines the symbols and formatting in `s`.
- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom IFormatProvider implementation whose GetFormat method returns either the CultureInfo object or the DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the CultureInfo object that corresponds to the current culture is used.

Notes to Callers

In the .NET Framework 4, the ParseExact method throws a FormatException if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

DateTime.SpecifyKind(DateTime, DateTimeKind) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new DateTime object that has the same number of ticks as the specified DateTime, but is designated as either local time, Coordinated Universal Time (UTC), or neither, as indicated by the specified DateTimeKind value.

C#

```
public static DateTime SpecifyKind (DateTime value, DateTimeKind kind);
```

Parameters

`value` DateTime

A date and time.

`kind` DateTimeKind

One of the enumeration values that indicates whether the new object represents local time, UTC, or neither.

Returns

DateTime

A new object that has the same number of ticks as the object represented by the `value` parameter and the DateTimeKind value specified by the `kind` parameter.

Examples

The following example uses the SpecifyKind method to demonstrate how the Kind property influences the ToLocalTime and ToUniversalTime conversion methods.

C#

```
// This code example demonstrates the DateTime Kind, Now, and
// UtcNow properties, and the SpecifyKind(), ToLocalTime(),
// and ToUniversalTime() methods.

using System;

class Sample
{
    public static void Main()
    {
        // Get the date and time for the current moment, adjusted
        // to the local time zone.

        DateTime saveNow = DateTime.Now;

        // Get the date and time for the current moment expressed
        // as coordinated universal time (UTC).

        DateTime saveUtcNow = DateTime.UtcNow;
        DateTime myDt;

        // Display the value and Kind property of the current moment
        // expressed as UTC and local time.

        DisplayNow("UtcNow: ..........", saveUtcNow);
        DisplayNow("Now: .............", saveNow);
        Console.WriteLine();

        // Change the Kind property of the current moment to
        // DateTimeKind.Utc and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Utc);
        Display("Utc: .............", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Local and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Local);
        Display("Local: ...........", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Unspecified and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Unspecified);
        Display("Unspecified: .....", myDt);
    }

    // Display the value and Kind property of a DateTime structure, the
    // DateTime structure converted to local time, and the DateTime
    // structure converted to universal time.

    public static string datePatt = @"M/d/yyyy hh:mm:ss tt";
    public static void Display(string title, DateTime inputDt)
    {
```

```
        DateTime dispDt = inputDt;
        string dtString;

        // Display the original DateTime.

        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, dispDt.Kind);

        // Convert inputDt to local time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was universal time.

        dispDt = inputDt.ToLocalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToLocalTime:     {0}, Kind = {1}",
                          dtString, dispDt.Kind);

        // Convert inputDt to universal time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was local time.

        dispDt = inputDt.ToUniversalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToUniversalTime: {0}, Kind = {1}",
                          dtString, dispDt.Kind);
        Console.WriteLine();
    }

    // Display the value and Kind property for DateTime.Now and
DateTime.UtcNow.

    public static void DisplayNow(string title, DateTime inputDt)
    {
        string dtString = inputDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, inputDt.Kind);
    }
}

/*
This code example produces the following results:

UtcNow: .......... 5/6/2005 09:34:42 PM, Kind = Utc
Now: ............. 5/6/2005 02:34:42 PM, Kind = Local

Utc: ............. 5/6/2005 02:34:42 PM, Kind = Utc
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
```

```
  ToUniversalTime: 5/6/2005 02:34:42 PM, Kind = Utc

Local: ........... 5/6/2005 02:34:42 PM, Kind = Local
  ToLocalTime:     5/6/2005 02:34:42 PM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

Unspecified: ..... 5/6/2005 02:34:42 PM, Kind = Unspecified
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

*/
```

Remarks

A DateTime object consists of a Kind field that indicates whether the time value is based on local time, Coordinated Universal Time (UTC), or neither, and a Ticks field that contains a time value measured in 100-nanosecond ticks. The SpecifyKind method creates a new DateTime object using the specified `kind` parameter and the original time value.

> **Important**
>
> The returned **DateTime** value does not represent the same instant in time as the `value` parameter, and **SpecifyKind** is not a time zone conversion method. Instead, it leaves the time specified by the `value` parameter unchanged, and sets the **Kind** property to `kind`. For information about time zone conversions, see **Converting Times Between Time Zones**.

The SpecifyKind method is useful in interoperability scenarios where you receive a DateTime object with an unspecified Kind field, but you can determine by independent means that the Ticks field represents local time or UTC.

DateTime.Subtract Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the value that results from subtracting the specified time or duration from the value of this instance.

Overloads

Expand table

Subtract(TimeSpan)	Returns a new DateTime that subtracts the specified duration from the value of this instance.
Subtract(DateTime)	Returns a new TimeSpan that subtracts the specified date and time from the value of this instance.

Subtract(TimeSpan)

Returns a new DateTime that subtracts the specified duration from the value of this instance.

C#

```
public DateTime Subtract (TimeSpan value);
```

Parameters

`value` TimeSpan

The time interval to subtract.

Returns

DateTime

An object that is equal to the date and time represented by this instance minus the time interval represented by `value`.

Exceptions

ArgumentOutOfRangeException

The result is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example demonstrates the Subtract method and the subtraction operator.

C#

```
System.DateTime date1 = new System.DateTime(1996, 6, 3, 22, 15, 0);
System.DateTime date2 = new System.DateTime(1996, 12, 6, 13, 2, 0);
System.DateTime date3 = new System.DateTime(1996, 10, 12, 8, 42, 0);

// diff1 gets 185 days, 14 hours, and 47 minutes.
System.TimeSpan diff1 = date2.Subtract(date1);

// date4 gets 4/9/1996 5:55:00 PM.
System.DateTime date4 = date3.Subtract(diff1);

// diff2 gets 55 days 4 hours and 20 minutes.
System.TimeSpan diff2 = date2 - date3;

// date5 gets 4/9/1996 5:55:00 PM.
System.DateTime date5 = date1 - diff2;
```

Remarks

The Subtract(TimeSpan) method returns the date that is a specified time interval difference from the current instance. To determine the time interval between two dates, call the Subtract(DateTime) method. To subtract a particular time interval from the current instance, call the method that adds that time interval to the current date, and supply a negative value as the method argument. For example, to subtract two months from the current date, call the AddMonths(Int32) method with a value of -2.

This method does not change the value of this DateTime. Instead, it returns a new DateTime whose value is the result of this operation.

Ordinarily, the DateTime.Subtract(TimeSpan) method subtracts a TimeSpan object that represents a positive time span and returns a DateTime value that is earlier than

the date and time of the current instance. However, if the TimeSpan object represents a negative time span, the DateTime.Subtract(TimeSpan) method returns a DateTime value that is later than the date and time of the current instance.

The DateTime.Subtract(TimeSpan) method allows you to subtract a time interval that consists of more than one unit of time (such as a given number of hours and a given number of minutes). To subtract a single unit of time (such as years, months, or days) from the DateTime instance, you can pass a negative numeric value as a parameter to any of the following methods:

- AddYears, to subtract a specific number of years from the current date and time instance.
- AddMonths, to subtract a specific number of months from the current date and time instance.
- AddDays, to subtract a specific number of days from the current date and time instance.
- AddHours, to subtract a specific number of hours from the current date and time instance.
- AddMinutes, to subtract a specific number of minutes from the current date and time instance.
- AddSeconds, to subtract a specific number of seconds from the current date and time instance.
- AddMilliseconds, to subtract a specific number of milliseconds from the current date and time instance.
- AddTicks, to subtract a specific number of ticks from the current date and time instance.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Subtract(DateTime)

Returns a new TimeSpan that subtracts the specified date and time from the value of this instance.

```
C#

public TimeSpan Subtract (DateTime value);
```

Parameters

`value` DateTime

The date and time value to subtract.

Returns

TimeSpan

A time interval that is equal to the date and time represented by this instance minus the date and time represented by `value`.

Exceptions

ArgumentOutOfRangeException

The result is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example demonstrates the Subtract method and the subtraction operator.

C#

```
System.DateTime date1 = new System.DateTime(1996, 6, 3, 22, 15, 0);
System.DateTime date2 = new System.DateTime(1996, 12, 6, 13, 2, 0);
System.DateTime date3 = new System.DateTime(1996, 10, 12, 8, 42, 0);

// diff1 gets 185 days, 14 hours, and 47 minutes.
System.TimeSpan diff1 = date2.Subtract(date1);

// date4 gets 4/9/1996 5:55:00 PM.
System.DateTime date4 = date3.Subtract(diff1);

// diff2 gets 55 days 4 hours and 20 minutes.
System.TimeSpan diff2 = date2 - date3;

// date5 gets 4/9/1996 5:55:00 PM.
System.DateTime date5 = date1 - diff2;
```

Remarks

The Subtract(DateTime) method determines the difference between two dates. To subtract a time interval from the current instance, call the Subtract(TimeSpan) method. To subtract a particular time interval from the current instance, call the method that adds that time interval to the current date, and supply a negative value as the method argument. For example, to subtract two months from the current date, call the AddMonths(Int32) method with a value of -2.

If the date and time of the current instance is earlier than `value`, the method returns a TimeSpan object that represents a negative time span. That is, the value of all of its non-zero properties (such as Days or Ticks) is negative.

The Subtract(DateTime) method does not consider the value of the Kind property of the two DateTime values when performing the subtraction. Before subtracting DateTime objects, ensure that the objects represent times in the same time zone. Otherwise, the result will include the difference between time zones.

> **Note**
>
> The **DateTimeOffset.Subtract(DateTimeOffset)** method does consider the difference between time zones when performing the subtraction.

DateTime.ToBinary Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serializes the current DateTime object to a 64-bit binary value that subsequently can be used to recreate the DateTime object.

```
C#
public long ToBinary ();
```

Returns

Int64

A 64-bit signed integer that encodes the Kind and Ticks properties.

Remarks

For more information about this API, see Supplemental API remarks for DateTime.ToBinary.

DateTime.ToFileTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to a Windows file time.

C#

```
public long ToFileTime ();
```

Returns

Int64

The value of the current DateTime object expressed as a Windows file time.

Exceptions

ArgumentOutOfRangeException

The resulting file time would represent a date and time before 12:00 midnight January 1, 1601 C.E. UTC.

Examples

The following example demonstrates the ToFileTime method.

C#

```
static void Main(string[] args)
{
    System.Console.WriteLine("Enter the file path:");
    string filePath = System.Console.ReadLine();

    if (System.IO.File.Exists(filePath)) {
        System.DateTime fileCreationDateTime =
            System.IO.File.GetCreationTime(filePath);

        long fileCreationFileTime = fileCreationDateTime.ToFileTime();
```

```
        System.Console.WriteLine("{0} in file time is {1}.",
                                 fileCreationDateTime,
                                 fileCreationFileTime);
    }
    else {
        System.Console.WriteLine("{0} is an invalid file", filePath);
    }
}
```

Remarks

A Windows file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 midnight, January 1, 1601 A.D. (C.E.) Coordinated Universal Time (UTC). Windows uses a file time to record when an application creates, accesses, or writes to a file.

The ToFileTime method uses the Kind property to determine whether the current DateTime object is a local time, a UTC time, or an unspecified kind of time which is treated as a local time.

Notes to Callers

Ordinarily, the FromFileTime(Int64) method restores a DateTime value that was saved by the ToFileTime() method. However, the two values may differ under the following conditions:

- If the serialization and deserialization of the DateTime value occur in different time zones. For example, if a DateTime value with a time of 12:30 P.M. in the U.S. Eastern Time zone is serialized, and then deserialized in the U.S. Pacific Time zone, the original value of 12:30 P.M. is adjusted to 9:30 A.M. to reflect the difference between the two time zones.

- If the DateTime value that is serialized represents an invalid time in the local time zone. In this case, the ToFileTime() method adjusts the restored DateTime value so that it represents a valid time in the local time zone.

  For example, the transition from standard time to daylight saving time occurs in the U.S. Pacific Time zone on March 14, 2010, at 2:00 A.M., when the time advances by one hour, to 3:00 A.M. This hour interval is an invalid time, that is, a time interval that does not exist in this time zone. The following example shows that when a time that falls within this range is converted to a long integer value by the ToFileTime() method and is then restored by the FromFileTime(Int64) method, the original value is adjusted to become a valid time. You can determine whether a

particular date and time value may be subject to modification by passing it to the IsInvalidTime(DateTime) method, as the example illustrates.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime date1 = new DateTime(2010, 3, 14, 2, 30, 00);
      Console.WriteLine("Invalid Time: {0}",
                        TimeZoneInfo.Local.IsInvalidTime(date1));
      long ft = date1.ToFileTime();
      DateTime date2 = DateTime.FromFileTime(ft);
      Console.WriteLine("{0} -> {1}", date1, date2);
   }
}
// The example displays the following output:
//       Invalid Time: True
//       3/14/2010 2:30:00 AM -> 3/14/2010 3:30:00 AM
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.ToFileTimeUtc Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to a Windows file time.

```
C#
public long ToFileTimeUtc ();
```

Returns

Int64

The value of the current DateTime object expressed as a Windows file time.

Exceptions

ArgumentOutOfRangeException

The resulting file time would represent a date and time before 12:00 midnight January 1, 1601 C.E. UTC.

Remarks

A Windows file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 midnight, January 1, 1601 A.D. (C.E.) Coordinated Universal Time (UTC). Windows uses a file time to record when an application creates, accesses, or writes to a file.

The ToFileTimeUtc method uses the Kind property to determine whether the current DateTime object is a local time, a UTC time, or an unspecified kind of time which is treated as a UTC time. If it is a local time, it converts the time to UTC before performing the conversion to a Windows file time.

Notes to Callers

The ToFileTimeUtc() method is sometimes used to convert a local time to UTC, and subsequently to restore it by calling the FromFileTimeUtc(Int64) method followed by the ToLocalTime() method. However, if the original time represents an invalid time in the local time zone, the two local time values will not be equal. For additional information, see the ToLocalTime() method.

Applies to

DateTime.ToLocalTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to local time.

C#

```
public DateTime ToLocalTime ();
```

Returns

DateTime

An object whose Kind property is Local, and whose value is the local time equivalent to the value of the current DateTime object, or DateTime.MaxValue if the converted value is too large to be represented by a DateTime object, or DateTime.MinValue if the converted value is too small to be represented as a DateTime object.

Examples

The following example demonstrates the ToLocalTime method. Note that the exact output depends on the current culture and the local time zone of the system on which it is run.

C#

```
using System;

class Example
{
    static void Main()
    {
        DateTime localDateTime, univDateTime;

        Console.WriteLine("Enter a date and time.");
        string strDateTime = Console.ReadLine();

        try {
```

```
            localDateTime = DateTime.Parse(strDateTime);
            univDateTime = localDateTime.ToUniversalTime();

            Console.WriteLine("{0} local time is {1} universal time.",
                              localDateTime,
                                  univDateTime);
        }
        catch (FormatException) {
            Console.WriteLine("Invalid format.");
            return;
        }

        Console.WriteLine("Enter a date and time in universal time.");
        strDateTime = Console.ReadLine();

        try {
            univDateTime = DateTime.Parse(strDateTime);
            localDateTime = univDateTime.ToLocalTime();

            Console.WriteLine("{0} universal time is {1} local time.",
                                univDateTime,
                                localDateTime);
        }
        catch (FormatException) {
            Console.WriteLine("Invalid format.");
            return;
        }
    }
}
// The example displays output like the following when run on a
// computer whose culture is en-US in the Pacific Standard Time zone:
//     Enter a date and time.
//     12/10/2015 6:18 AM
//     12/10/2015 6:18:00 AM local time is 12/10/2015 2:18:00 PM universal
time.
//     Enter a date and time in universal time.
//     12/20/2015 6:42:00
//     12/20/2015 6:42:00 AM universal time is 12/19/2015 10:42:00 PM local
time.
```

The following example uses the SpecifyKind method to demonstrate how the Kind property influences the ToLocalTime and ToUniversalTime conversion methods.

C#

```
// This code example demonstrates the DateTime Kind, Now, and
// UtcNow properties, and the SpecifyKind(), ToLocalTime(),
// and ToUniversalTime() methods.

using System;

class Sample
{
```

```
    public static void Main()
    {
        // Get the date and time for the current moment, adjusted
        // to the local time zone.

        DateTime saveNow = DateTime.Now;

        // Get the date and time for the current moment expressed
        // as coordinated universal time (UTC).

        DateTime saveUtcNow = DateTime.UtcNow;
        DateTime myDt;

        // Display the value and Kind property of the current moment
        // expressed as UTC and local time.

        DisplayNow("UtcNow: ..........", saveUtcNow);
        DisplayNow("Now: .............", saveNow);
        Console.WriteLine();

        // Change the Kind property of the current moment to
        // DateTimeKind.Utc and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Utc);
        Display("Utc: .............", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Local and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Local);
        Display("Local: ...........", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Unspecified and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Unspecified);
        Display("Unspecified: .....", myDt);
    }

    // Display the value and Kind property of a DateTime structure, the
    // DateTime structure converted to local time, and the DateTime
    // structure converted to universal time.

    public static string datePatt = @"M/d/yyyy hh:mm:ss tt";
    public static void Display(string title, DateTime inputDt)
    {
        DateTime dispDt = inputDt;
        string dtString;

        // Display the original DateTime.

        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, dispDt.Kind);
```

```
        // Convert inputDt to local time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was universal time.

        dispDt = inputDt.ToLocalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToLocalTime:     {0}, Kind = {1}",
                          dtString, dispDt.Kind);

        // Convert inputDt to universal time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was local time.

        dispDt = inputDt.ToUniversalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToUniversalTime: {0}, Kind = {1}",
                          dtString, dispDt.Kind);
        Console.WriteLine();
    }

    // Display the value and Kind property for DateTime.Now and
DateTime.UtcNow.

    public static void DisplayNow(string title, DateTime inputDt)
    {
        string dtString = inputDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, inputDt.Kind);
    }
}

/*
This code example produces the following results:

UtcNow: .......... 5/6/2005 09:34:42 PM, Kind = Utc
Now: ............. 5/6/2005 02:34:42 PM, Kind = Local

Utc: ............. 5/6/2005 02:34:42 PM, Kind = Utc
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 02:34:42 PM, Kind = Utc

Local: ........... 5/6/2005 02:34:42 PM, Kind = Local
  ToLocalTime:     5/6/2005 02:34:42 PM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

Unspecified: ..... 5/6/2005 02:34:42 PM, Kind = Unspecified
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc
```

```
*/
```

Remarks

The local time is equal to the Coordinated Universal Time (UTC) time plus the UTC offset. For more information about the UTC offset, see TimeZoneInfo.GetUtcOffset. The conversion also takes into account the daylight saving time rule that applies to the time represented by the current DateTime object.

> **Important**
>
> On Windows XP systems, the **ToLocalTime** method recognizes only the current adjustment rule when converting from UTC to local time. As a result, conversions for periods before the current adjustment rule came into effect may not accurately reflect the difference between UTC and local time.

Starting with the .NET Framework version 2.0, the value returned by the ToLocalTime method is determined by the Kind property of the current DateTime object. The following table describes the possible results.

Expand table

Kind	Results
Utc	This instance of DateTime is converted to local time.
Local	No conversion is performed.
Unspecified	This instance of DateTime is assumed to be a UTC time, and the conversion is performed as if Kind were Utc.

> **Note**
>
> The **ToLocalTime** method converts a **DateTime** value from UTC to local time. To convert the time in any designated time zone to local time, use the **TimeZoneInfo.ConvertTime** method.

The value returned by the conversion is a DateTime whose Kind property always returns Local. Consequently, a valid result is returned even if ToLocalTime is applied repeatedly to the same DateTime.

Notes to Callers

You can use the ToLocalTime() method to restore a local date and time value that was converted to UTC by the ToUniversalTime() or FromFileTimeUtc(Int64) method. However, if the original time represents an invalid time in the local time zone, it will not match the restored value. When the ToLocalTime() method converts a time from UTC to the local time zone, it also adjusts the time so that is valid in the local time zone.

For example, the transition from standard time to daylight saving time occurs in the U.S. Pacific Time zone on March 14, 2010, at 2:00 A.M., when the time advances by one hour, to 3:00 A.M. This hour interval is an invalid time, that is, a time interval that does not exist in this time zone. The following example shows that when a time that falls within this range is converted to UTC by the ToUniversalTime() method and is then restored by the ToLocalTime() method, the original value is adjusted to become a valid time. You can determine whether a particular date and time value may be subject to modification by passing it to the IsInvalidTime(DateTime) method, as the example illustrates.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime date1 = new DateTime(2010, 3, 14, 2, 30, 0,
DateTimeKind.Local);
      Console.WriteLine("Invalid time: {0}",
                        TimeZoneInfo.Local.IsInvalidTime(date1));
      DateTime utcDate1 = date1.ToUniversalTime();
      DateTime date2 = utcDate1.ToLocalTime();
      Console.WriteLine("{0} --> {1}", date1, date2);
   }
}
// The example displays the following output:
//       Invalid time: True
//       3/14/2010 2:30:00 AM --> 3/14/2010 3:30:00 AM
```

DateTime.ToLongDateString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to its equivalent long date string representation.

C#

```
public string ToLongDateString ();
```

Returns

String

A string that contains the long date string representation of the current DateTime object.

Examples

The following example demonstrates the ToLongDateString method.

C#

```
using System;
using System.Globalization;

class Sample
{
    public static void Main()
    {
        // Initialize a DateTime object.
        Console.WriteLine("Initialize the DateTime object to May 16, 2001
3:02:15 AM.\n");
        DateTime dateAndTime = new System.DateTime(2001, 5, 16, 3, 2, 15);

        // Display the name of the current culture.
        Console.WriteLine($"Current culture: \"
{CultureInfo.CurrentCulture.Name}\"\n");
        var dtfi = CultureInfo.CurrentCulture.DateTimeFormat;
```

```
        // Display the long date pattern and string.
        Console.WriteLine($"Long date pattern: \"{dtfi.LongDatePattern}\"");
        Console.WriteLine($"Long date string:  \"
{dateAndTime.ToLongDateString()}\"\n");

        // Display the long time pattern and string.
        Console.WriteLine($"Long time pattern: \"{dtfi.LongTimePattern}\"");
        Console.WriteLine($"Long time string:  \"
{dateAndTime.ToLongTimeString()}\"\n");

        // Display the short date pattern and string.
        Console.WriteLine($"Short date pattern: \"
{dtfi.ShortDatePattern}\"");
        Console.WriteLine($"Short date string:  \"
{dateAndTime.ToShortDateString()}\"\n");

        // Display the short time pattern and string.
        Console.WriteLine($"Short time pattern: \"
{dtfi.ShortTimePattern}\"");
        Console.WriteLine($"Short time string:  \"
{dateAndTime.ToShortTimeString()}\"\n");
    }
}
// The example displays output similar to the following:
//        Current culture: "en-US"
//
//        Long date pattern: "dddd, MMMM d, yyyy"
//        Long date string:  "Wednesday, May 16, 2001"
//
//        Long time pattern: "h:mm:ss tt"
//        Long time string:  "3:02:15 AM"
//
//        Short date pattern: "M/d/yyyy"
//        Short date string:  "5/16/2001"
//
//        Short time pattern: "h:mm tt"
//        Short time string:  "3:02 AM"
```

Remarks

The value of the current DateTime object is formatted using the pattern defined by the LongDatePattern property associated with the current culture. The return value is identical to the value returned by specifying the "D" standard DateTime format string with the ToString(String) method.

> ⓘ **Note**

The string returned by the **ToLongDateString** method is culture-sensitive. It reflects the pattern defined by the current culture's **DateTimeFormatInfo.LongDatePattern** property. For example, for the en-US culture, the standard long date pattern is commonly "dddd, MMMM dd, yyyy"; for the de-DE culture, it is "dddd, d. MMMM yyyy"; for the ja-JP culture, it is "yyyy'年'M'月'd'日'". Note that its value can vary depending on the .NET implementation and its version, the operating system and its version, and user customization.

For more information about the current thread culture, see the CultureInfo.CurrentCulture and Thread.CurrentCulture properties. For more information about format characters, format patterns, and the output they produce, see Standard date and time format strings and Custom date and time format strings. For more information about changing the format pattern associated with a format character, see the DateTimeFormatInfo class.

Applies to

DateTime.ToLongTimeString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to its equivalent long time string representation.

C#

```
public string ToLongTimeString ();
```

Returns

String

A string that contains the long time string representation of the current DateTime object.

Examples

The following example demonstrates the ToLongTimeString method.

C#

```
using System;
using System.Threading;
using System.Globalization;

public class Sample
{
   public static void Main()
   {
      // Create an array of culture names.
      String[] names = { "en-US", "en-GB", "fr-FR", "de-DE" };
      // Initialize a DateTime object.
      DateTime dateValue = new System.DateTime(2013, 5, 28, 10, 30, 15);

      // Iterate the array of culture names.
      foreach (var name in names) {
         // Change the culture of the current thread.
```

```
        Thread.CurrentThread.CurrentCulture =
CultureInfo.CreateSpecificCulture(name);
        // Display the name of the current culture and the date.
        Console.WriteLine("Current culture: {0}",
CultureInfo.CurrentCulture.Name);
        Console.WriteLine("Date: {0:G}", dateValue);

        // Display the long time pattern and the long time.
        Console.WriteLine("Long time pattern: '{0}'",
                          DateTimeFormatInfo.CurrentInfo.LongTimePattern);
        Console.WriteLine("Long time with format string:     {0:T}",
dateValue);
        Console.WriteLine("Long time with ToLongTimeString:  {0}\n",
                          dateValue.ToLongTimeString());
      }
   }
}
// The example displays the following output:
//       Current culture: en-US
//       Date: 5/28/2013 10:30:15 AM
//       Long time pattern: 'h:mm:ss tt'
//       Long time with format string:     10:30:15 AM
//       Long time with ToLongTimeString:  10:30:15 AM
//
//       Current culture: en-GB
//       Date: 28/05/2013 10:30:15
//       Long time pattern: 'HH:mm:ss'
//       Long time with format string:     10:30:15
//       Long time with ToLongTimeString:  10:30:15
//
//       Current culture: fr-FR
//       Date: 28/05/2013 10:30:15
//       Long time pattern: 'HH:mm:ss'
//       Long time with format string:     10:30:15
//       Long time with ToLongTimeString:  10:30:15
//
//       Current culture: de-DE
//       Date: 28.05.2013 10:30:15
//       Long time pattern: 'HH:mm:ss'
//       Long time with format string:     10:30:15
//       Long time with ToLongTimeString:  10:30:15
```

Remarks

The value of the current DateTime object is formatted using the pattern defined by the DateTimeFormatInfo.LongTimePattern property associated with the current culture. The return value is identical to the value returned by specifying the "T" standard date and time format string with the ToString(String) method.

ⓘ **Note**

The string returned by the **ToLongTimeString** method is culture-sensitive. It reflects the pattern defined by the current culture's **DateTimeFormatInfo.LongTimePattern** property. For example, for the en-US culture, the standard long time pattern is "h:mm:ss tt"; for the de-DE culture, it is "HH:mm:ss"; for the ja-JP culture, it is "H:mm:ss". Note that its value can vary depending on the .NET implementation and its version, the operating system and its version, and user customization.

For more information about the current thread culture, see the CultureInfo.CurrentCulture and Thread.CurrentCulture properties. For more information about format characters, format patterns, and the output they produce, see Standard date and time format strings and Custom date and time format strings. For more information about changing the format pattern associated with a format character, see the DateTimeFormatInfo class.

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to the equivalent OLE Automation date.

```
C#
public double ToOADate ();
```

Returns

Double

A double-precision floating-point number that contains an OLE Automation date equivalent to the value of this instance.

Exceptions

OverflowException

The value of this instance cannot be represented as an OLE Automation Date.

Remarks

An OLE Automation date is implemented as a floating-point number whose integral component is the number of days before or after midnight, 30 December 1899, and whose fractional component represents the time on that day divided by 24. For example, midnight, 31 December 1899 is represented by 1.0; 6 A.M., 1 January 1900 is represented by 2.25; midnight, 29 December 1899 is represented by -1.0; and 6 A.M., 29 December 1899 is represented by -1.25.

The base OLE Automation Date is midnight, 30 December 1899. The minimum OLE Automation date is midnight, 1 January 0100. The maximum OLE Automation Date is the same as DateTime.MaxValue, the last moment of 31 December 9999.

The ToOADate method throws an OverflowException if the current instance represents a date that is later than MaxValue and earlier than midnight on January1, 0100. However, if the value of the current instance is MinValue, the method returns 0.

For more information, see Automation.

DateTime.ToShortDateString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to its equivalent short date string representation.

C#

```
public string ToShortDateString ();
```

Returns

String

A string that contains the short date string representation of the current DateTime object.

Examples

The following example demonstrates the ToShortDateString method. It also shows that the result of calling the ToShortDateString method is identical to calling the DateTime.ToString(String) method with "d" as the format parameter.

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example
{
   public static void Main()
   {
      DateTime dateToDisplay = new DateTime(2009, 6, 1, 8, 42, 50);
      CultureInfo originalCulture = Thread.CurrentThread.CurrentCulture;
      // Change culture to en-US.
      Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
      Console.WriteLine("Displaying short date for {0} culture:",
```

```
                        Thread.CurrentThread.CurrentCulture.Name);
      Console.WriteLine("   {0} (Short Date String)",
                        dateToDisplay.ToShortDateString());
      // Display using 'd' standard format specifier to illustrate it is
      // identical to the string returned by ToShortDateString.
      Console.WriteLine("   {0} ('d' standard format specifier)",
                        dateToDisplay.ToString("d"));
      Console.WriteLine();

      // Change culture to fr-FR.
      Thread.CurrentThread.CurrentCulture = new CultureInfo("fr-FR");
      Console.WriteLine("Displaying short date for {0} culture:",
                        Thread.CurrentThread.CurrentCulture.Name);
