      Console.WriteLine("   {0}", dateToDisplay.ToShortDateString());
      Console.WriteLine();

      // Change culture to nl-NL.
      Thread.CurrentThread.CurrentCulture = new CultureInfo("nl-NL");
      Console.WriteLine("Displaying short date for {0} culture:",
                        Thread.CurrentThread.CurrentCulture.Name);
      Console.WriteLine("   {0}", dateToDisplay.ToShortDateString());

      // Restore original culture.
      Thread.CurrentThread.CurrentCulture = originalCulture;
   }
}
// The example displays the following output:
//       Displaying short date for en-US culture:
//          6/1/2009 (Short Date String)
//          6/1/2009 ('d' standard format specifier)
//
//       Displaying short date for fr-FR culture:
//          01/06/2009
//
//       Displaying short date for nl-NL culture:
//          1-6-2009
```

Remarks

The value of the current DateTime object is formatted using the pattern defined by the DateTimeFormatInfo.ShortDatePattern property associated with the current culture. The return value is identical to the value returned by specifying the "d" standard DateTime format string with the ToString(String) method.

> ⓘ **Note**
>
> The string returned by the **ToShortDateString** method is culture-sensitive. It reflects the pattern defined by the current culture's **DateTimeFormatInfo.ShortDatePattern** property. For example, for the en-US culture, the standard short date pattern is

"M/d/yyyy"; for the de-DE culture, it is "dd.MM.yyyy"; for the ja-JP culture, it is "yyyy/MM/dd". Note that its value can vary depending on the .NET implementation and its version, the operating system and its version, and user customization.

For more information about the current thread culture, see the CultureInfo.CurrentCulture and Thread.CurrentCulture properties. For more information about format characters, format patterns, and the output they produce, see Standard date and time format strings and Custom date and time format strings. For more information about changing the format pattern associated with a format character, see the DateTimeFormatInfo class.

DateTime.ToShortTimeString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to its equivalent short time string representation.

C#

```
public string ToShortTimeString ();
```

Returns

String

A string that contains the short time string representation of the current DateTime object.

Examples

The following example demonstrates the ToShortTimeString method.

C#

```
using System;
using System.Globalization;

class Sample
{
    public static void Main()
    {
        // Initialize a DateTime object.
        Console.WriteLine("Initialize the DateTime object to May 16, 2001
3:02:15 AM.\n");
        DateTime dateAndTime = new System.DateTime(2001, 5, 16, 3, 2, 15);

        // Display the name of the current culture.
        Console.WriteLine($"Current culture: \"
{CultureInfo.CurrentCulture.Name}\"\n");
        var dtfi = CultureInfo.CurrentCulture.DateTimeFormat;
```

```
        // Display the long date pattern and string.
        Console.WriteLine($"Long date pattern: \"{dtfi.LongDatePattern}\"");
        Console.WriteLine($"Long date string:  \"
{dateAndTime.ToLongDateString()}\"\n");

        // Display the long time pattern and string.
        Console.WriteLine($"Long time pattern: \"{dtfi.LongTimePattern}\"");
        Console.WriteLine($"Long time string:  \"
{dateAndTime.ToLongTimeString()}\"\n");

        // Display the short date pattern and string.
        Console.WriteLine($"Short date pattern: \"
{dtfi.ShortDatePattern}\"");
        Console.WriteLine($"Short date string:  \"
{dateAndTime.ToShortDateString()}\"\n");

        // Display the short time pattern and string.
        Console.WriteLine($"Short time pattern: \"
{dtfi.ShortTimePattern}\"");
        Console.WriteLine($"Short time string:  \"
{dateAndTime.ToShortTimeString()}\"\n");
    }
}
// The example displays output similar to the following:
//        Current culture: "en-US"
//
//        Long date pattern: "dddd, MMMM d, yyyy"
//        Long date string:  "Wednesday, May 16, 2001"
//
//        Long time pattern: "h:mm:ss tt"
//        Long time string:  "3:02:15 AM"
//
//        Short date pattern: "M/d/yyyy"
//        Short date string:  "5/16/2001"
//
//        Short time pattern: "h:mm tt"
//        Short time string:  "3:02 AM"
```

Remarks

The value of the current DateTime object is formatted using the pattern defined by the DateTimeFormatInfo.ShortTimePattern property associated with the current culture. The return value is identical to the value returned by specifying the "t" standard DateTime format string with the ToString(String) method.

> ⓘ **Note**

The string returned by the **ToShortTimeString** method is culture-sensitive. It reflects the pattern defined by the current culture's **DateTimeFormatInfo.ShortTimePattern** property. For example, for the en-US culture, the standard short time pattern is "h:mm tt"; for the de-DE culture, it is "HH:mm"; for the ja-JP culture, it is "H:mm". Note that its value can vary depending on the .NET implementation and its version, the operating system and its version, and user customization.

For more information about the current thread culture, see the CultureInfo.CurrentCulture and Thread.CurrentCulture properties. For more information about format characters, format patterns, and the output they produce, see Standard date and time format strings and Custom date and time format strings. For more information about changing the format pattern associated with a format character, see the DateTimeFormatInfo class.

DateTime.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to its equivalent string representation.

Overloads

Expand table

ToString(IFormatProvider)	Converts the value of the current DateTime object to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the value of the current DateTime object to its equivalent string representation using the specified format and the formatting conventions of the current culture.
ToString()	Converts the value of the current DateTime object to its equivalent string representation using the formatting conventions of the current culture.
ToString(String, IFormatProvider)	Converts the value of the current DateTime object to its equivalent string representation using the specified format and culture-specific format information.

ToString(IFormatProvider)

Converts the value of the current DateTime object to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

A string representation of value of the current DateTime object as specified by `provider`.

Implements

ToString(IFormatProvider)

Exceptions

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by `provider`.

Examples

The following example displays the string representation of a date and time using CultureInfo objects that represent five different cultures.

C#

```
using System;
using System.Globalization;

public class ToStringExample3
{
   public static void Main2()
   {
      CultureInfo[] cultures = new CultureInfo[]
{CultureInfo.InvariantCulture,
                                                    new CultureInfo("en-
us"),
                                                    new CultureInfo("fr-
fr"),
                                                    new CultureInfo("de-
DE"),
                                                    new CultureInfo("es-
ES"),
                                                    new CultureInfo("ja-
```

```
JP")};

      DateTime thisDate = new DateTime(2009, 5, 1, 9, 0, 0);

      foreach (CultureInfo culture in cultures)
      {
         string cultureName;
         if (string.IsNullOrEmpty(culture.Name))
            cultureName = culture.NativeName;
         else
            cultureName = culture.Name;

         Console.WriteLine("In {0}, {1}",
                           cultureName, thisDate.ToString(culture));
      }
      }
}
// The example produces the following output:
//    In Invariant Language (Invariant Country), 05/01/2009 09:00:00
//    In en-US, 5/1/2009 9:00:00 AM
//    In fr-FR, 01/05/2009 09:00:00
//    In de-DE, 01.05.2009 09:00:00
//    In es-ES, 01/05/2009 9:00:00
//    In ja-JP, 2009/05/01 9:00:00
```

Remarks

The value of the current DateTime object is formatted using the general date and time format specifier ('G'), which formats output using the short date pattern and the long time pattern.

The format of the short date and long time pattern is defined by the `provider` parameter. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom object that implements the IFormatProvider interface. Its GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the DateTimeFormatInfo object associated with the current culture is used. For more information, see CultureInfo.CurrentCulture.

Notes to Callers

The ToString(IFormatProvider) method returns the string representation of the date and time in the calendar used by the culture represented by the `provider` parameter. Its calendar is defined by the Calendar property. If the value of the current DateTime instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the JapaneseCalendar class.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      CultureInfo jaJP = new CultureInfo("ja-JP");
      jaJP.DateTimeFormat.Calendar = new JapaneseCalendar();
      DateTime date1 = new DateTime(1867, 1, 1);

      try {
         Console.WriteLine(date1.ToString(jaJP));
      }
      catch (ArgumentOutOfRangeException) {
         Console.WriteLine("{0:d} is earlier than {1:d} or later than
{2:d}",
                           date1,

jaJP.DateTimeFormat.Calendar.MinSupportedDateTime,

jaJP.DateTimeFormat.Calendar.MaxSupportedDateTime);
      }
   }
}
// The example displays the following output:
//    1/1/1867 is earlier than 9/8/1868 or later than 12/31/9999   }
```

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the value of the current DateTime object to its equivalent string representation using the specified format and the formatting conventions of the current culture.

```
C#
public string ToString (string? format);
```

Parameters

`format` String

A standard or custom date and time format string.

Returns

String

A string representation of value of the current DateTime object as specified by `format`.

Exceptions

FormatException

The length of `format` is 1, and it is not one of the format specifier characters defined for DateTimeFormatInfo.

-or-

`format` does not contain a valid custom format pattern.

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by the current culture.

Examples

The following example uses each of the standard date and time format strings and a selection of custom date and time format strings to display the string representation of a DateTime value. The thread current culture for the example is en-US.

C#

```
using System;

public class DateToStringExample2
{
   public static void Main()
   {
      DateTime dateValue = new DateTime(2008, 6, 15, 21, 15, 07);
      // Create an array of standard format strings.
      string[] standardFmts = {"d", "D", "f", "F", "g", "G", "m", "o",
                               "R", "s", "t", "T", "u", "U", "y"};
      // Output date and time using each standard format string.
      foreach (string standardFmt in standardFmts)
         Console.WriteLine("{0}: {1}", standardFmt,
                           dateValue.ToString(standardFmt));
      Console.WriteLine();

      // Create an array of some custom format strings.
      string[] customFmts = {"h:mm:ss.ff t", "d MMM yyyy", "HH:mm:ss.f",
                             "dd MMM HH:mm:ss", @"\Mon\t\h\: M",
"HH:mm:ss.ffffzzz" };
      // Output date and time using each custom format string.
      foreach (string customFmt in customFmts)
         Console.WriteLine("'{0}': {1}", customFmt,
                           dateValue.ToString(customFmt));
   }
}
// This example displays the following output to the console:
//       d: 6/15/2008
//       D: Sunday, June 15, 2008
//       f: Sunday, June 15, 2008 9:15 PM
//       F: Sunday, June 15, 2008 9:15:07 PM
//       g: 6/15/2008 9:15 PM
//       G: 6/15/2008 9:15:07 PM
//       m: June 15
//       o: 2008-06-15T21:15:07.0000000
//       R: Sun, 15 Jun 2008 21:15:07 GMT
```

```
//       s: 2008-06-15T21:15:07
//       t: 9:15 PM
//       T: 9:15:07 PM
//       u: 2008-06-15 21:15:07Z
//       U: Monday, June 16, 2008 4:15:07 AM
//       y: June, 2008
//
//       'h:mm:ss.ff t': 9:15:07.00 P
//       'd MMM yyyy': 15 Jun 2008
//       'HH:mm:ss.f': 21:15:07.0
//       'dd MMM HH:mm:ss': 15 Jun 21:15:07
//       '\Mon\t\h\: M': Month: 6
//       'HH:mm:ss.ffffzzz': 21:15:07.0000-07:00
```

Remarks

The ToString(String) method returns the string representation of a date and time value in a specific format that uses the formatting conventions of the current culture; for more information, see CultureInfo.CurrentCulture.

The `format` parameter should contain either a single format specifier character (see Standard Date and Time Format Strings) or a custom format pattern (see Custom Date and Time Format Strings) that defines the format of the returned string. If `format` is `null` or an empty string, the general format specifier, 'G', is used.

Some uses of this method include:

- Getting a string that displays the date and time in the current culture's short date and time format. To do this, you use the "G" format specifier.
- Getting a string that contains only the month and year. To do this, you use the "MM/yyyy" format string. The format string uses the current culture's date separator.
- Getting a string that contains the date and time in a specific format. For example, the "MM/dd/yyyyHH:mm" format string displays the date and time string in a fixed format such as "19//03//2013 18:06". The format string uses "/" as a fixed date separator regardless of culture-specific settings.
- Getting a date in a condensed format that could be used for serializing a date string. For example, the "yyyyMMdd" format string displays a four-digit year followed by a two-digit month and a two-digit day with no date separator.

The following example uses these three format strings to display a date and time value by using the conventions of the en-US and fr-FR cultures.

C#

```
using System;
using System.Globalization;

public class ToStringExample5
{
    public static void Main3()
    {
        string[] formats = { "G", "MM/yyyy", @"MM\/dd\/yyyy HH:mm",
"yyyyMMdd" };
        string[] cultureNames = { "en-US", "fr-FR" };
        DateTime date = new DateTime(2015, 8, 18, 13, 31, 17);
        foreach (var cultureName in cultureNames)
        {
            var culture = new CultureInfo(cultureName);
            CultureInfo.CurrentCulture = culture;
            Console.WriteLine(culture.NativeName);
            foreach (var format in formats)
                Console.WriteLine($"   {format}:
{date.ToString(format)}");
            Console.WriteLine();
        }
    }
}
// The example displays the following output:
//       English (United States)
//          G: 8/18/2015 1:31:17 PM
//          MM/yyyy: 08/2015
//          MM\/dd\/yyyy HH:mm: 08/18/2015 13:31
//          yyyyMMdd: 20150818
//
//       français (France)
//          G: 18/08/2015 13:31:17
//          MM/yyyy: 08/2015
//          MM\/dd\/yyyy HH:mm: 08/18/2015 13:31
//          yyyyMMdd: 20150818
```

Notes to Callers

The ToString(String) method returns the string representation of the date and time in the calendar used by the current culture. If the value of the current DateTime instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the HebrewCalendar class when the current culture is Hebrew (Israel).

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example3
{
    public static void Main()
    {
        DateTime date1 = new DateTime(1550, 7, 21);
        CultureInfo dft;
        CultureInfo heIL = new CultureInfo("he-IL");
        heIL.DateTimeFormat.Calendar = new HebrewCalendar();

        // Change current culture to he-IL.
        dft = Thread.CurrentThread.CurrentCulture;
        Thread.CurrentThread.CurrentCulture = heIL;

        // Display the date using the current culture's calendar.
        try
        {
            Console.WriteLine(date1.ToString("G"));
        }
        catch (ArgumentOutOfRangeException)
        {
            Console.WriteLine("{0} is earlier than {1} or later than
{2}",
                              date1.ToString("d",
CultureInfo.InvariantCulture),

heIL.DateTimeFormat.Calendar.MinSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture),

heIL.DateTimeFormat.Calendar.MaxSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture));
        }

        // Restore the default culture.
        Thread.CurrentThread.CurrentCulture = dft;
    }
}
// The example displays the following output:
//    07/21/1550 is earlier than 01/01/1583 or later than 09/29/2239
```

UWP	10.0

ToString()

Converts the value of the current DateTime object to its equivalent string representation using the formatting conventions of the current culture.

C#

```
public override string ToString ();
```

Returns

String

A string representation of the value of the current DateTime object.

Exceptions

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by the current culture.

Examples

The following example illustrates how the string representation of a DateTime value returned by the ToString() method depends on the thread current culture. It changes the current culture to en-US, fr-FR, and ja-JP, and in each case calls the ToString()

method to return the string representation of a date and time value using that culture.

C#

```
using System;
using System.Globalization;

public class ToStringExample1
{
    public static void Main()
    {
        CultureInfo currentCulture = CultureInfo.CurrentCulture;
        DateTime exampleDate = new DateTime(2021, 5, 1, 18, 32, 6);

        // Change the current culture to en-US and display the date.
        CultureInfo.CurrentCulture = CultureInfo.GetCultureInfo("en-US");
        Console.WriteLine(exampleDate.ToString());

        // Change the current culture to fr-FR and display the date.
        CultureInfo.CurrentCulture = CultureInfo.GetCultureInfo("fr-FR");
        Console.WriteLine(exampleDate.ToString());

        // Change the current culture to ja-JP and display the date.
        CultureInfo.CurrentCulture = CultureInfo.GetCultureInfo("ja-JP");
        Console.WriteLine(exampleDate.ToString());

        // Restore the original culture
        CultureInfo.CurrentCulture = currentCulture;
    }
}

// The example displays the following output to the console:
//       5/1/2021 6:32:06 PM
//       01/05/2021 18:32:06
//       2021/05/01 18:32:06
```

Remarks

The value of the current DateTime object is formatted using the general date and time format specifier ('G'). To format it using a specific date and time format specifier, call the ToString(String) method. To format it using the general date and time format specifier ('G') for a specific culture, call the ToString(IFormatProvider) method. To format it using a specific date and time format specifier and the conventions of a specific culture, call the ToString(String, IFormatProvider) method.

This method uses formatting information derived from the current culture. In particular, it combines the custom format strings returned by the ShortDatePattern and LongTimePattern properties of the DateTimeFormatInfo object returned by the

`Thread.CurrentThread.CurrentCulture.DateTimeFormat` property. For more information, see CultureInfo.CurrentCulture. Other overloads of the ToString method enable you to specify the culture whose formatting to use and to define the output pattern of the DateTime value.

Notes to Callers

The ToString() method returns the string representation of the date and time in the calendar used by the current culture. If the value of the current DateTime instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the HijriCalendar class when the current culture is Arabic (Syria).

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example2
{
    public static void Main()
    {
        DateTime date1 = new DateTime(550, 1, 1);
        CultureInfo dft;
        CultureInfo arSY = new CultureInfo("ar-SY");
        arSY.DateTimeFormat.Calendar = new HijriCalendar();

        // Change current culture to ar-SY.
        dft = Thread.CurrentThread.CurrentCulture;
        Thread.CurrentThread.CurrentCulture = arSY;

        // Display the date using the current culture's calendar.
        try
        {
            Console.WriteLine(date1.ToString());
        }
        catch (ArgumentOutOfRangeException)
        {
            Console.WriteLine("{0} is earlier than {1} or later than
{2}",
                              date1.ToString("d",
CultureInfo.InvariantCulture),

arSY.DateTimeFormat.Calendar.MinSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture),

arSY.DateTimeFormat.Calendar.MaxSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture));
```

```
        }

        // Restore the default culture.
        Thread.CurrentThread.CurrentCulture = dft;
    }
}
// The example displays the following output:
//    01/01/0550 is earlier than 07/18/0622 or later than 12/31/9999
```

UWP	10.0

ToString(String, IFormatProvider)

Converts the value of the current DateTime object to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A standard or custom date and time format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

A string representation of value of the current DateTime object as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

The length of `format` is 1, and it is not one of the format specifier characters defined for DateTimeFormatInfo.

-or-

`format` does not contain a valid custom format pattern.

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by `provider`.

Examples

The following example uses each of the standard date time format strings to display the string representation of a date and time for four different cultures.

C#

```
using System;
using System.Globalization;

public class ToStringExample4
{
   public static void Main1()
   {
      // Create an array of all supported standard date and time format
specifiers.
      string[] formats = {"d", "D", "f", "F", "g", "G", "m", "o", "r",
```

```
                              "s", "t", "T", "u", "U", "Y"};
      // Create an array of four cultures.
      CultureInfo[] cultures = {CultureInfo.GetCultureInfo("de-DE"),
                                CultureInfo.GetCultureInfo("en-US"),
                                CultureInfo.GetCultureInfo("es-ES"),
                                CultureInfo.GetCultureInfo("fr-FR")};
       // Define date to be displayed.
      DateTime dateToDisplay = new DateTime(2008, 10, 31, 17, 4, 32);

      // Iterate each standard format specifier.
      foreach (string formatSpecifier in formats)
      {
         foreach (CultureInfo culture in cultures)
            Console.WriteLine("{0} Format Specifier {1, 10} Culture {2,
40}",
                              formatSpecifier, culture.Name,
                              dateToDisplay.ToString(formatSpecifier,
culture));
         Console.WriteLine();
      }
   }
}

// The example displays the following output:

//    Y Format Specifier      fr-FR Culture
octobre 2008
```

The following example demonstrates different ways of formatting a DateTime value using the invariant DateTimeFormatInfo.

```
C#
```

```
using System;
using System.Globalization;

public class MainClass
{
    public static void Main(string[] args)
    {
        DateTime dt = DateTime.Now;
        String[] format = {
            "d", "D",
            "f", "F",
            "g", "G",
            "m",
            "r",
            "s",
            "t", "T",
            "u", "U",
            "y",
            "dddd, MMMM dd yyyy",
            "ddd, MMM d \"'\"yy",
            "dddd, MMMM dd",
            "M/yy",
            "dd-MM-yy",
        };
        string date;
        for (int i = 0; i < format.Length; i++)
        {
            date = dt.ToString(format[i],
DateTimeFormatInfo.InvariantInfo);
            Console.WriteLine(string.Concat(format[i], " :", date));
        }

        /** Output.
         *
         * d :08/17/2000
         * D :Thursday, August 17, 2000
         * f :Thursday, August 17, 2000 16:32
         * F :Thursday, August 17, 2000 16:32:32
         * g :08/17/2000 16:32
         * G :08/17/2000 16:32:32
         * m :August 17
         * r :Thu, 17 Aug 2000 23:32:32 GMT
         * s :2000-08-17T16:32:32
         * t :16:32
         * T :16:32:32
         * u :2000-08-17 23:32:32Z
         * U :Thursday, August 17, 2000 23:32:32
         * y :August, 2000
         * dddd, MMMM dd yyyy :Thursday, August 17 2000
         * ddd, MMM d "'"yy :Thu, Aug 17 '00
         * dddd, MMMM dd :Thursday, August 17
         * M/yy :8/00
         * dd-MM-yy :17-08-00
         */
```

```
    }
}
```

Remarks

The `format` parameter can contain either a single format specifier character (see Standard Date and Time Format Strings) or a custom format pattern (see Custom Date and Time Format Strings). If `format` is `null` or an empty string (""), the standard format specifier, "G", is used.

The `provider` parameter defines the pattern that corresponds to the standard format specifiers, as well as the symbols and names of date and time components. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom object that implements the IFormatProvider interface. Its GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the DateTimeFormatInfo associated with the current culture is used. For more information, see CultureInfo.CurrentCulture.

Notes to Callers

The ToString(String, IFormatProvider) method returns the string representation of the date and time in the calendar used by the `provider` parameter. Its calendar is defined by the Calendar property. If the value of the current DateTime instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the UmAlQuraCalendar class.

C#

```
using System;
using System.Globalization;
```

```
public class Example4
{
    public static void Main()
    {
        CultureInfo arSA = new CultureInfo("ar-SA");
        arSA.DateTimeFormat.Calendar = new UmAlQuraCalendar();
        DateTime date1 = new DateTime(1890, 9, 10);

        try
        {
            Console.WriteLine(date1.ToString("d", arSA));
        }
        catch (ArgumentOutOfRangeException)
        {
            Console.WriteLine("{0:d} is earlier than {1:d} or later than
{2:d}",
                              date1,

arSA.DateTimeFormat.Calendar.MinSupportedDateTime,

arSA.DateTimeFormat.Calendar.MaxSupportedDateTime);
        }
    }
}
// The example displays the following output:
//    9/10/1890 is earlier than 4/30/1900 or later than 5/13/2029
```

DateTime.ToUniversalTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTime object to Coordinated Universal Time (UTC).

C#

```
public DateTime ToUniversalTime ();
```

Returns

DateTime

An object whose Kind property is Utc, and whose value is the UTC equivalent to the value of the current DateTime object, or DateTime.MaxValue if the converted value is too large to be represented by a DateTime object, or DateTime.MinValue if the converted value is too small to be represented by a DateTime object.

Examples

The following example demonstrates the ToUniversalTime method.

C#

```
using System;

class Example
{
    static void Main()
    {
        DateTime localDateTime, univDateTime;

        Console.WriteLine("Enter a date and time.");
        string strDateTime = Console.ReadLine();

        try {
            localDateTime = DateTime.Parse(strDateTime);
            univDateTime = localDateTime.ToUniversalTime();
```

```
            Console.WriteLine("{0} local time is {1} universal time.",
                                localDateTime,
                                    univDateTime);
        }
        catch (FormatException) {
            Console.WriteLine("Invalid format.");
            return;
        }

        Console.WriteLine("Enter a date and time in universal time.");
        strDateTime = Console.ReadLine();

        try {
            univDateTime = DateTime.Parse(strDateTime);
            localDateTime = univDateTime.ToLocalTime();

            Console.WriteLine("{0} universal time is {1} local time.",
                                univDateTime,
                                localDateTime);
        }
        catch (FormatException) {
            Console.WriteLine("Invalid format.");
            return;
        }
    }
}
// The example displays output like the following when run on a
// computer whose culture is en-US in the Pacific Standard Time zone:
//     Enter a date and time.
//     12/10/2015 6:18 AM
//     12/10/2015 6:18:00 AM local time is 12/10/2015 2:18:00 PM universal
time.
//     Enter a date and time in universal time.
//     12/20/2015 6:42:00
//     12/20/2015 6:42:00 AM universal time is 12/19/2015 10:42:00 PM local
time.
```

The following example uses the SpecifyKind method to demonstrate how the Kind property influences the ToLocalTime and ToUniversalTime conversion methods.

C#

```
// This code example demonstrates the DateTime Kind, Now, and
// UtcNow properties, and the SpecifyKind(), ToLocalTime(),
// and ToUniversalTime() methods.

using System;

class Sample
{
    public static void Main()
    {
        // Get the date and time for the current moment, adjusted
```

```
        // to the local time zone.

        DateTime saveNow = DateTime.Now;

        // Get the date and time for the current moment expressed
        // as coordinated universal time (UTC).

        DateTime saveUtcNow = DateTime.UtcNow;
        DateTime myDt;

        // Display the value and Kind property of the current moment
        // expressed as UTC and local time.

        DisplayNow("UtcNow: ..........", saveUtcNow);
        DisplayNow("Now: ............", saveNow);
        Console.WriteLine();

        // Change the Kind property of the current moment to
        // DateTimeKind.Utc and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Utc);
        Display("Utc: ............", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Local and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Local);
        Display("Local: ...........", myDt);

        // Change the Kind property of the current moment to
        // DateTimeKind.Unspecified and display the result.

        myDt = DateTime.SpecifyKind(saveNow, DateTimeKind.Unspecified);
        Display("Unspecified: .....", myDt);
    }

    // Display the value and Kind property of a DateTime structure, the
    // DateTime structure converted to local time, and the DateTime
    // structure converted to universal time.

    public static string datePatt = @"M/d/yyyy hh:mm:ss tt";
    public static void Display(string title, DateTime inputDt)
    {
        DateTime dispDt = inputDt;
        string dtString;

        // Display the original DateTime.

        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, dispDt.Kind);

        // Convert inputDt to local time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is not
```

```
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was universal time.

        dispDt = inputDt.ToLocalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToLocalTime:     {0}, Kind = {1}",
                          dtString, dispDt.Kind);

        // Convert inputDt to universal time and display the result.
        // If inputDt.Kind is DateTimeKind.Utc, the conversion is not
performed.
        // If inputDt.Kind is DateTimeKind.Local, the conversion is
performed.
        // If inputDt.Kind is DateTimeKind.Unspecified, the conversion is
        // performed as if inputDt was local time.

        dispDt = inputDt.ToUniversalTime();
        dtString = dispDt.ToString(datePatt);
        Console.WriteLine("  ToUniversalTime: {0}, Kind = {1}",
                          dtString, dispDt.Kind);
        Console.WriteLine();
    }

    // Display the value and Kind property for DateTime.Now and
DateTime.UtcNow.

    public static void DisplayNow(string title, DateTime inputDt)
    {
        string dtString = inputDt.ToString(datePatt);
        Console.WriteLine("{0} {1}, Kind = {2}",
                          title, dtString, inputDt.Kind);
    }
}

/*
This code example produces the following results:

UtcNow: .......... 5/6/2005 09:34:42 PM, Kind = Utc
Now: ............. 5/6/2005 02:34:42 PM, Kind = Local

Utc: ............. 5/6/2005 02:34:42 PM, Kind = Utc
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 02:34:42 PM, Kind = Utc

Local: ........... 5/6/2005 02:34:42 PM, Kind = Local
  ToLocalTime:     5/6/2005 02:34:42 PM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

Unspecified: ..... 5/6/2005 02:34:42 PM, Kind = Unspecified
  ToLocalTime:     5/6/2005 07:34:42 AM, Kind = Local
  ToUniversalTime: 5/6/2005 09:34:42 PM, Kind = Utc

*/
```

Remarks

The Coordinated Universal Time (UTC) is equal to the local time minus the UTC offset. For more information about the UTC offset, see TimeZoneInfo.GetUtcOffset. The conversion also takes into account the daylight saving time rule that applies to the time represented by the current DateTime object.

> **Important**
>
> On Windows XP systems, the **ToUniversalTime** method recognizes only the current adjustment rule when converting from local time to UTC. As a result, conversions for periods before the current adjustment rule came into effect may not accurately reflect the difference between local time and UTC.

Starting with the .NET Framework version 2.0, the value returned by the ToUniversalTime method is determined by the Kind property of the current DateTime object. The following table describes the possible results.

Expand table

Kind	Results
Utc	No conversion is performed.
Local	The current DateTime object is converted to UTC.
Unspecified	The current DateTime object is assumed to be a local time, and the conversion is performed as if Kind were Local.

> **Note**
>
> The **ToUniversalTime** method converts a **DateTime** value from local time to UTC. To convert the time in a non-local time zone to UTC, use the **TimeZoneInfo.ConvertTimeToUtc(DateTime, TimeZoneInfo)** method. To convert a time whose offset from UTC is known, use the **ToUniversalTime** method.

If the date and time instance value is an ambiguous time, this method assumes that it is a standard time. (An ambiguous time is one that can map either to a standard time or to a daylight saving time in the local time zone) If the date and time instance value is an invalid time, this method simply subtracts the local time from the local time zone's UTC offset to return UTC. (An invalid time is one that does not exist because of the application of daylight saving time adjustment rules.)

Notes to Callers

The ToUniversalTime() method is sometimes used to convert a local time to UTC. The ToLocalTime() method is then called to restore the original local time. However, if the original time represents an invalid time in the local time zone, the two local time values will not be equal. For additional information and an example, see the ToLocalTime() method.

On Windows XP systems, the ToUniversalTime() method recognizes only the current adjustment rule for the local time zone, which it applies to all dates, including down-level dates (that is, dates that are earlier than the starting date of the current adjustment rule). Applications running on Windows XP that require historically accurate local date and time calculations must work around this behavior by using the FindSystemTimeZoneById(String) method to retrieve a TimeZoneInfo object that corresponds to the local time zone and calling its ConvertTimeToUtc(DateTime, TimeZoneInfo) method.

The following example illustrates the difference between the ToUniversalTime() and ConvertTimeToUtc(DateTime, TimeZoneInfo) methods on a Windows XP system in the U.S. Pacific Time zone. The first two method calls apply the current time zone adjustment rule (which went into effect in 2007) to a date in 2006. The current adjustment rule provides for the transition to daylight saving time on the second Sunday of March; the previous rule, which was in effect in 2006, provided for the transition to daylight saving time to occur on the first Sunday of April. Only the third method call accurately performs this historical date and time conversion.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTime date1 = new DateTime(2006, 3, 21, 2, 0, 0);

      Console.WriteLine(date1.ToUniversalTime());
      Console.WriteLine(TimeZoneInfo.ConvertTimeToUtc(date1));

      TimeZoneInfo tz = TimeZoneInfo.FindSystemTimeZoneById("Pacific
Standard Time");
      Console.WriteLine(TimeZoneInfo.ConvertTimeToUtc(date1, tz));
   }
}
// The example displays the following output on Windows XP systems:
//       3/21/2006 9:00:00 AM
```

```
//        3/21/2006 9:00:00 AM
//        3/21/2006 10:00:00 AM
```

DateTime.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current datetime instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current datetime instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

DateTime.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, DateTime)	Converts the specified char span of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTime)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, DateTime)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, DateTimeStyles, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified culture-specific format information and formatting style, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTime)	Converts the span representation of a date and time to its DateTime equivalent using the specified culture-specific format information and formatting style, and returns a value that indicates whether the conversion succeeded.

Remarks

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

TryParse(ReadOnlySpan<Char>, DateTime)

Converts the specified char span of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out DateTime result);
```

Parameters

`s` ReadOnlySpan<Char>

A string containing a date and time to convert.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if the `s` parameter is `null`, is an empty string (""), or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, DateTime)

Converts the specified string representation of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, out DateTime result);
```

Parameters

`s` String

A string containing a date and time to convert.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if the `s` parameter is `null`, is an empty string (""), or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

Examples

The following example passes a number of date and time strings to the DateTime.TryParse(String, DateTime) method.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] dateStrings = {"05/01/2009 14:57:32.8", "2009-05-01
14:57:32.8",
                              "2009-05-01T14:57:32.8375298-04:00",
"5/01/2008",
                              "5/01/2008 14:57:32.80 -07:00",
                              "1 May 2008 2:57:32.8 PM", "16-05-2009
1:00:32 PM",
                              "Fri, 15 May 2009 20:10:57 GMT" };
      DateTime dateValue;

      Console.WriteLine("Attempting to parse strings using {0} culture.",
                        CultureInfo.CurrentCulture.Name);
      foreach (string dateString in dateStrings)
      {
         if (DateTime.TryParse(dateString, out dateValue))
            Console.WriteLine("  Converted '{0}' to {1} ({2}).",
dateString,
                              dateValue, dateValue.Kind);
         else
            Console.WriteLine("  Unable to parse '{0}'.", dateString);
      }
   }
}
// The example displays output like the following:
//    Attempting to parse strings using en-US culture.
//      Converted '05/01/2009 14:57:32.8' to 5/1/2009 2:57:32 PM
(Unspecified).
//      Converted '2009-05-01 14:57:32.8' to 5/1/2009 2:57:32 PM
(Unspecified).
//      Converted '2009-05-01T14:57:32.8375298-04:00' to 5/1/2009
11:57:32 AM (Local).
//
//      Converted '5/01/2008' to 5/1/2008 12:00:00 AM (Unspecified).
//      Converted '5/01/2008 14:57:32.80 -07:00' to 5/1/2008 2:57:32 PM
(Local).
//      Converted '1 May 2008 2:57:32.8 PM' to 5/1/2008 2:57:32 PM
(Unspecified).
//      Unable to parse '16-05-2009 1:00:32 PM'.
//      Converted 'Fri, 15 May 2009 20:10:57 GMT' to 5/15/2009 1:10:57 PM
(Local).
```

Remarks

The DateTime.TryParse(String, DateTime) method is similar to the DateTime.Parse(String) method, except that the TryParse(String, DateTime) method does not throw an exception if the conversion fails.

The string `s` is parsed using formatting information in the current DateTimeFormatInfo object, which is supplied implicitly by the current culture.

This method tries to ignore unrecognized data, if possible, and fills in missing month, day, and year information with the current date. If `s` contains only a date and no time, this method assumes the time is 12:00 midnight. If `s` includes a date component with a two-digit year, it is converted to a year in the current culture's current calendar based on the value of the Calendar.TwoDigitYearMax property. Any leading, inner, or trailing white space character in `s` is ignored. The date and time can be bracketed with a pair of leading and trailing NUMBER SIGN characters ('#', U+0023), and can be trailed with one or more NULL characters (U+0000).

Because the DateTime.TryParse(String, DateTime) method tries to parse the string representation of a date and time using the formatting rules of the current culture, trying to parse a particular string across different cultures can either fail or return different results. If a specific date and time format will be parsed across different locales, use the DateTime.TryParse(String, IFormatProvider, DateTimeStyles, DateTime) method or one of the overloads of the TryParseExact method and provide a format specifier.

If `s` is the string representation of a leap day in a leap year in the current calendar, the method parses `s` successfully. If `s` is the string representation of a leap day in a non-leap year in the current culture's current calendar, the parse operation fails and the method returns `false`.

If `s` contains no time zone information, `result` contains a DateTime value whose Kind property is DateTimeKind.Unspecified when the method returns. If the string to be parsed contains time zone information, `result` contains a DateTime value whose Kind property is DateTimeKind.Local when the method returns.

Notes to Callers

Formatting is influenced by properties of the current DateTimeFormatInfo object, which by default are derived from the **Regional and Language Options** item in Control Panel. The TryParse method can unexpectedly fail and return `False` if the current DateSeparator and TimeSeparator properties are set to the same value.

UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTime)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out DateTime result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` DateTime

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, DateTime)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider, out
DateTime result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` DateTime

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, DateTimeStyles, DateTime)

Converts the specified string representation of a date and time to its DateTime equivalent using the specified culture-specific format information and formatting style, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider,
System.Globalization.DateTimeStyles styles, out DateTime result);
```

Parameters

`s` String

A string containing a date and time to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed date in relation to the current time zone or the current date. A typical value

to specify is None.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if the `s` parameter is `null`, is an empty string (""), or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`styles` is not a valid DateTimeStyles value.

-or-

`styles` contains an invalid combination of DateTimeStyles values (for example, both AssumeLocal and AssumeUniversal).

NotSupportedException

`provider` is a neutral culture and cannot be used in a parsing operation.

Examples

The following example illustrates the DateTime.TryParse(String, IFormatProvider, DateTimeStyles, DateTime) method.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string dateString;
      CultureInfo culture;
      DateTimeStyles styles;
```

```
      DateTime dateResult;

      // Parse a date and time with no styles.
      dateString = "03/01/2009 10:00 AM";
      culture = CultureInfo.CreateSpecificCulture("en-US");
      styles = DateTimeStyles.None;
      if (DateTime.TryParse(dateString, culture, styles, out dateResult))
         Console.WriteLine("{0} converted to {1} {2}.",
                           dateString, dateResult, dateResult.Kind);
      else
         Console.WriteLine("Unable to convert {0} to a date and time.",
                           dateString);

      // Parse the same date and time with the AssumeLocal style.
      styles = DateTimeStyles.AssumeLocal;
      if (DateTime.TryParse(dateString, culture, styles, out dateResult))
         Console.WriteLine("{0} converted to {1} {2}.",
                           dateString, dateResult, dateResult.Kind);
      else
         Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);

      // Parse a date and time that is assumed to be local.
      // This time is five hours behind UTC. The local system's time zone
is
      // eight hours behind UTC.
      dateString = "2009/03/01T10:00:00-5:00";
      styles = DateTimeStyles.AssumeLocal;
      if (DateTime.TryParse(dateString, culture, styles, out dateResult))
         Console.WriteLine("{0} converted to {1} {2}.",
                           dateString, dateResult, dateResult.Kind);
      else
         Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);

      // Attempt to convert a string in improper ISO 8601 format.
      dateString = "03/01/2009T10:00:00-5:00";
      if (DateTime.TryParse(dateString, culture, styles, out dateResult))
         Console.WriteLine("{0} converted to {1} {2}.",
                           dateString, dateResult, dateResult.Kind);
      else
         Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);

      // Assume a date and time string formatted for the fr-FR culture is
the local
      // time and convert it to UTC.
      dateString = "2008-03-01 10:00";
      culture = CultureInfo.CreateSpecificCulture("fr-FR");
      styles = DateTimeStyles.AdjustToUniversal |
DateTimeStyles.AssumeLocal;
      if (DateTime.TryParse(dateString, culture, styles, out dateResult))
         Console.WriteLine("{0} converted to {1} {2}.",
                           dateString, dateResult, dateResult.Kind);
      else
```

```
            Console.WriteLine("Unable to convert {0} to a date and time.",
dateString);
        }
    }
// The example displays the following output to the console:
//       03/01/2009 10:00 AM converted to 3/1/2009 10:00:00 AM
Unspecified.
//       03/01/2009 10:00 AM converted to 3/1/2009 10:00:00 AM Local.
//       2009/03/01T10:00:00-5:00 converted to 3/1/2009 7:00:00 AM Local.
//       Unable to convert 03/01/2009T10:00:00-5:00 to a date and time.
//       2008-03-01 10:00 converted to 3/1/2008 6:00:00 PM Utc.
```

Remarks

For more information about this API, see Supplemental API remarks for DateTime.TryParse.

Notes to Callers

Formatting is influenced by properties of the current DateTimeFormatInfo object, which is supplied by the `provider` parameter. The TryParse method can unexpectedly fail and return `False` if the current DateSeparator and TimeSeparator properties are set to the same value.

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTime)

Converts the span representation of a date and time to its DateTime equivalent using the specified culture-specific format information and formatting style, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, System.Globalization.DateTimeStyles styles, out DateTime
result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the date and time to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed date in relation to the current time zone or the current date. A typical value to specify is None.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if the `s` parameter is `null`, is an empty string (""), or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

DateTime.TryParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a date and time to its DateTime equivalent. The format of the string representation must match a specified format exactly. The method returns a value that indicates whether the conversion succeeded.

Overloads

Expand table

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTime)	Converts the specified span representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateTime)	Converts the specified char span of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTime)	Converts the specified string representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly. The method returns a value that indicates whether the conversion succeeded.

Remarks

> **Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTime)

Converts the specified span representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, IFormatProvider? provider,
System.Globalization.DateTimeStyles style, out DateTime result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing a date and time to convert.

format ReadOnlySpan<Char>

The required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of one or more enumeration values that indicate the permitted format of `s`.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if either the `s` or `format` parameter is `null`, is an empty string, or does not contain a date and time that correspond to the pattern specified in `format`. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateTime)

Converts the specified char span of a date and time to its DateTime equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s, string?[]?
formats, IFormatProvider? provider, System.Globalization.DateTimeStyles
style, out DateTime result);
```

Parameters

`s` ReadOnlySpan<Char>

The span containing the string to parse.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed date in relation to the current time zone or the current date. A typical value to specify is None.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if the `s` parameter is `null`, is Empty, or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime)

Converts the specified string representation of a date and time to its DateTime equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParseExact (string? s, string? format,
IFormatProvider? provider, System.Globalization.DateTimeStyles style, out
DateTime result);
```

Parameters

`s` String

A string containing a date and time to convert.

`format` String

The required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of one or more enumeration values that indicate the permitted format of `s`.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if either the `s` or `format` parameter is `null`, is an empty string, or does not contain a date and time that correspond to the pattern specified in `format`. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`styles` is not a valid DateTimeStyles value.

-or-

`styles` contains an invalid combination of DateTimeStyles values (for example, both AssumeLocal and AssumeUniversal).

Examples

The following example demonstrates the DateTime.TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime) method. Note that the string " 5/01/2009 8:30 AM" cannot be parsed successfully when the `styles` parameter equals DateTimeStyles.None because leading spaces are not allowed by `format`. Additionally, the string "5/01/2009 09:00" cannot be parsed successfully with a `format` of "MM/dd/yyyyhh:mm" because the date string does not precede the month number with a leading zero, as `format` requires.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      CultureInfo enUS = new CultureInfo("en-US");
      string dateString;
      DateTime dateValue;

      // Parse date with no style flags.
      dateString = " 5/01/2009 8:30 AM";
      if (DateTime.TryParseExact(dateString, "g", enUS,
                                 DateTimeStyles.None, out dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      // Allow a leading space in the date string.
      if (DateTime.TryParseExact(dateString, "g", enUS,
                                 DateTimeStyles.AllowLeadingWhite, out
dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
```

```
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      // Use custom formats with M and MM.
      dateString = "5/01/2009 09:00";
      if (DateTime.TryParseExact(dateString, "M/dd/yyyy hh:mm", enUS,
                                 DateTimeStyles.None, out dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      // Allow a leading space in the date string.
      if (DateTime.TryParseExact(dateString, "MM/dd/yyyy hh:mm", enUS,
                                 DateTimeStyles.None, out dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      // Parse a string with time zone information.
      dateString = "05/01/2009 01:30:42 PM -05:00";
      if (DateTime.TryParseExact(dateString, "MM/dd/yyyy hh:mm:ss tt
zzz", enUS,
                                 DateTimeStyles.None, out dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      // Allow a leading space in the date string.
      if (DateTime.TryParseExact(dateString, "MM/dd/yyyy hh:mm:ss tt
zzz", enUS,
                                 DateTimeStyles.AdjustToUniversal, out
dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                           dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      // Parse a string representing UTC.
      dateString = "2008-06-11T16:11:20.0904778Z";
      if (DateTime.TryParseExact(dateString, "o",
CultureInfo.InvariantCulture,
                                    DateTimeStyles.None, out dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
```

```
dateValue,
                            dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);

      if (DateTime.TryParseExact(dateString, "o",
CultureInfo.InvariantCulture,
                                  DateTimeStyles.RoundtripKind, out
dateValue))
         Console.WriteLine("Converted '{0}' to {1} ({2}).", dateString,
dateValue,
                            dateValue.Kind);
      else
         Console.WriteLine("'{0}' is not in an acceptable format.",
dateString);
   }
}
// The example displays the following output:
//    ' 5/01/2009 8:30 AM' is not in an acceptable format.
//    Converted ' 5/01/2009 8:30 AM' to 5/1/2009 8:30:00 AM
(Unspecified).
//    Converted '5/01/2009 09:00' to 5/1/2009 9:00:00 AM (Unspecified).
//    '5/01/2009 09:00' is not in an acceptable format.
//    Converted '05/01/2009 01:30:42 PM -05:00' to 5/1/2009 11:30:42 AM
(Local).
//    Converted '05/01/2009 01:30:42 PM -05:00' to 5/1/2009 6:30:42 PM
(Utc).
//    Converted '2008-06-11T16:11:20.0904778Z' to 6/11/2008 9:11:20 AM
(Local).
//    Converted '2008-06-11T16:11:20.0904778Z' to 6/11/2008 4:11:20 PM
(Utc).
```

Remarks

The DateTime.TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime) method parses the string representation of a date, which must be in the format defined by the `format` parameter. It is similar to the DateTime.ParseExact(String, String, IFormatProvider, DateTimeStyles) method, except that the TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime) method does not throw an exception if the conversion fails.

The `s` parameter contains the date and time to parse and must be in a format defined by the `format` parameter. If date, time, and time zone elements are present in `s`, they must also appear in the order specified by `format`. If `format` defines a date with no time element and the parse operation succeeds, the resulting DateTime value has a time of midnight (00:00:00). If `format` defines a time with no date element and the parse operation succeeds, the resulting DateTime value by default

has a date of `DateTime.Now.Date`, or it has a date of `DateTime.MinValue.Date` if `styles` includes the DateTimeStyles.NoCurrentDateDefault flag. The `style` parameter determines whether the `s` parameter can contain leading, inner, or trailing white space characters.

If `s` contains no time zone information, the Kind property of the returned DateTime object is DateTimeKind.Unspecified. This behavior can be changed by using the DateTimeStyles.AssumeLocal flag, which returns a DateTime value whose Kind property is DateTimeKind.Local, or by using the DateTimeStyles.AssumeUniversal and DateTimeStyles.AdjustToUniversal flags, which returns a DateTime value whose Kind property is DateTimeKind.Utc. If s contains time zone information, the time is converted to local time, if necessary, and the Kind property of the returned DateTime object is set to DateTimeKind.Local. This behavior can be changed by using the DateTimeStyles.RoundtripKind flag to not convert Coordinated Universal Time (UTC) to a local time and set the Kind property to DateTimeKind.Utc.

The `format` parameter contains a pattern that corresponds to the expected format of the `s` parameter. The pattern in the `format` parameter consists of one or more custom format specifiers from the Custom Date and Time Format Strings table, or a single standard format specifier, which identifies a predefined pattern, from the Standard Date and Time Format Strings table.

If you do not use date or time separators in a custom format pattern, use the invariant culture for the `provider` parameter and the widest form of each custom format specifier. For example, if you want to specify hours in the pattern, specify the wider form, "HH", instead of the narrower form, "H".

> **Note**
>
> Rather than requiring that `s` conform to a single format for the parse operation to succeed, you can call the **DateTime.TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTime)** method and specify multiple permitted formats. This makes the parse operation more likely to succeed.

The particular date and time symbols and strings (such as the names of the days of the week in a particular language) used in `s` are defined by the `provider` parameter, as is the precise format of `s` if `format` is a standard format specifier string. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture used to interpret `s`. The DateTimeFormatInfo object returned by its DateTimeFormat property defines

the symbols and formatting in `s`.

- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom IFormatProvider implementation whose GetFormat method returns either the CultureInfo object or the DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter includes one or more members of the DateTimeStyles enumeration that determine whether and where white space not defined by `format` can appear in `s` and that control the precise behavior of the parse operation. The following table describes how each member of the DateTimeStyles enumeration affects the operation of the TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime) method.

Expand table

DateTimeStyles member	Description
AdjustToUniversal	Parses `s` and, if necessary, converts it to UTC. If `s` includes a time zone offset, or if `s` contains no time zone information but `styles` includes the DateTimeStyles.AssumeLocal flag, the method parses the string, calls ToUniversalTime to convert the returned DateTime value to UTC, and sets the Kind property to DateTimeKind.Utc. If `s` indicates that it represents UTC, or if `s` does not contain time zone information but `styles` includes the DateTimeStyles.AssumeUniversal flag, the method parses the string, performs no time zone conversion on the returned DateTime value, and sets the Kind property to DateTimeKind.Utc. In all other cases, the flag has no effect.
AllowInnerWhite	Specifies that white space not defined by `format` can appear between any individual date or time element.
AllowLeadingWhite	Specifies that white space not defined by `format` can appear at the beginning of `s`.
AllowTrailingWhite	Specifies that white space not defined by `format` can appear at the end of `s`.
AllowWhiteSpaces	Specifies that `s` may contain leading, inner, and trailing white spaces not defined by `format`.

DateTimeStyles member	Description
AssumeLocal	Specifies that if `s` lacks any time zone information, it is assumed to represent a local time. Unless the DateTimeStyles.AdjustToUniversal flag is present, the Kind property of the returned DateTime value is set to DateTimeKind.Local.
AssumeUniversal	Specifies that if `s` lacks any time zone information, it is assumed to represent UTC. Unless the DateTimeStyles.AdjustToUniversal flag is present, the method converts the returned DateTime value from UTC to local time and sets its Kind property to DateTimeKind.Local.
NoCurrentDateDefault	If `s` contains time without date information, the date of the return value is set to `DateTime.MinValue.Date`.
None	The `s` parameter is parsed using default values. No white space other than that present in `format` is allowed. If `s` lacks a date component, the date of the returned DateTime value is set to 1/1/0001. If `s` contains no time zone information, the Kind property of the returned DateTime object is set to DateTimeKind.Unspecified. If time zone information is present in `s`, the time is converted to local time and the Kind property of the returned DateTime object is set to DateTimeKind.Local.
RoundtripKind	For strings that contain time zone information, tries to prevent the conversion to a DateTime value with its Kind property set to DateTimeKind.Local. This flag primarily prevents the conversion of UTC times to local times.

Notes to Callers

In the .NET Framework 4, the TryParseExact method returns `false` if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTime)

Converts the specified string representation of a date and time to its DateTime equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (string? s, string?[]? formats,
IFormatProvider? provider, System.Globalization.DateTimeStyles style, out
DateTime result);
```

Parameters

`s` String

A string that contains a date and time to convert.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

`result` DateTime

When this method returns, contains the DateTime value equivalent to the date and time contained in `s`, if the conversion succeeded, or DateTime.MinValue if the conversion failed. The conversion fails if `s` or `formats` is `null`, `s` or an element of `formats` is an empty string, or the format of `s` is not exactly as specified by at least one of the format patterns in `formats`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `s` parameter was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`styles` is not a valid DateTimeStyles value.

-or-

`styles` contains an invalid combination of DateTimeStyles values (for example, both AssumeLocal and AssumeUniversal).

Examples

The following example uses the DateTime.TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTime) method to ensure that a string in a number of possible formats can be successfully parsed .

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] formats= {"M/d/yyyy h:mm:ss tt", "M/d/yyyy h:mm tt",
                         "MM/dd/yyyy hh:mm:ss", "M/d/yyyy h:mm:ss",
```

```
                          "M/d/yyyy hh:mm tt", "M/d/yyyy hh tt",
                          "M/d/yyyy h:mm", "M/d/yyyy h:mm",
                          "MM/dd/yyyy hh:mm", "M/dd/yyyy hh:mm"};
      string[] dateStrings = {"5/1/2009 6:32 PM", "05/01/2009 6:32:05
PM",
                              "5/1/2009 6:32:00", "05/01/2009 06:32",
                              "05/01/2009 06:32:00 PM", "05/01/2009
06:32:00"};
      DateTime dateValue;

      foreach (string dateString in dateStrings)
      {
         if (DateTime.TryParseExact(dateString, formats,
                                    new CultureInfo("en-US"),
                                    DateTimeStyles.None,
                                    out dateValue))
            Console.WriteLine("Converted '{0}' to {1}.", dateString,
dateValue);
         else
            Console.WriteLine("Unable to convert '{0}' to a date.",
dateString);
      }
   }
}
// The example displays the following output:
//       Converted '5/1/2009 6:32 PM' to 5/1/2009 6:32:00 PM.
//       Converted '05/01/2009 6:32:05 PM' to 5/1/2009 6:32:05 PM.
//       Converted '5/1/2009 6:32:00' to 5/1/2009 6:32:00 AM.
//       Converted '05/01/2009 06:32' to 5/1/2009 6:32:00 AM.
//       Converted '05/01/2009 06:32:00 PM' to 5/1/2009 6:32:00 PM.
//       Converted '05/01/2009 06:32:00' to 5/1/2009 6:32:00 AM.
```

Remarks

The DateTime.TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTime) method parses the string representation of a date that matches any one of the patterns assigned to the `formats` parameter. It is like the DateTime.ParseExact(String, String[], IFormatProvider, DateTimeStyles) method, except the TryParseExact method does not throw an exception if the conversion fails.

The `s` parameter contains the date and time to parse. If the `s` parameter contains only a time and no date, the current date is used unless the `style` parameter includes the DateTimeStyles.NoCurrentDateDefault flag, in which case the default date (`DateTime.Date.MinValue`) is used. If the `s` parameter contains only a date and no time, midnight (00:00:00) is used. The `style` parameter also determines whether the `s` parameter can contain leading, inner, or trailing white space characters other than those permitted by one of the format strings in `formats`.

If `s` contains no time zone information, the Kind property of the returned DateTime object is DateTimeKind.Unspecified. This behavior can be changed by using the DateTimeStyles.AssumeLocal flag, which returns a DateTime value whose Kind property is DateTimeKind.Local, or by using the DateTimeStyles.AssumeUniversal and DateTimeStyles.AdjustToUniversal flags, which returns a DateTime value whose Kind property is DateTimeKind.Utc. If s contains time zone information, the time is converted to local time, if necessary, and the Kind property of the returned DateTime object is set to DateTimeKind.Local. This behavior can be changed by using the DateTimeStyles.RoundtripKind flag to not convert Coordinated Universal Time (UTC) to a local time and set the Kind property to DateTimeKind.Utc.

The `formats` parameter contains an array of patterns, one of which `s` must match exactly if the parse operation is to succeed. The patterns in the `formats` parameter consist of one or more custom format specifiers from the Custom Date and Time Format Strings table, or a single standard format specifier, which identifies a predefined pattern, from the Standard Date and Time Format Strings table.

If you do not use date or time separators in a custom format pattern, use the invariant culture for the `provider` parameter and the widest form of each custom format specifier. For example, if you want to specify hours in the pattern, specify the wider form, "HH", instead of the narrower form, "H".

The particular date and time symbols and strings (such as the names of the days of the week in a particular language) used in `s` are defined by the `provider` parameter, as is the precise format of `s` if `format` is a standard format specifier string. The `provider` parameter can be any of the following:

- A CultureInfo object that represents the culture used to interpret `s`. The DateTimeFormatInfo object returned by its DateTimeFormat property defines the symbols and formatting in `s`.
- A DateTimeFormatInfo object that defines the format of date and time data.
- A custom IFormatProvider implementation whose GetFormat method returns either the CultureInfo object or the DateTimeFormatInfo object that provides formatting information.

If `provider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter includes one or more members of the DateTimeStyles enumeration that determine whether and where white space not defined by `format`

can appear in `s` and that control the precise behavior of the parse operation. The following table describes how each member of the DateTimeStyles enumeration affects the operation of the TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTime) method.

Expand table

DateTimeStyles member	Description
AdjustToUniversal	Parses `s` and, if necessary, converts it to UTC. If `s` includes a time zone offset, or if `s` contains no time zone information but `styles` includes the DateTimeStyles.AssumeLocal flag, the method parses the string, calls ToUniversalTime to convert the returned DateTime value to UTC, and sets the Kind property to DateTimeKind.Utc. If `s` indicates that it represents UTC, or if `s` does not contain time zone information but `styles` includes the DateTimeStyles.AssumeUniversal flag, the method parses the string, performs no time zone conversion on the returned DateTime value, and sets the Kind property to DateTimeKind.Utc. In all other cases, the flag has no effect.
AllowInnerWhite	Specifies that white space not defined by `format` can appear between any individual date or time element.
AllowLeadingWhite	Specifies that white space not defined by `format` can appear at the beginning of `s`.
AllowTrailingWhite	Specifies that white space not defined by `format` can appear at the end of `s`.
AllowWhiteSpaces	Specifies that `s` may contain leading, inner, and trailing white spaces not defined by `format`.
AssumeLocal	Specifies that if `s` lacks any time zone information, it is assumed to represent a local time. Unless the DateTimeStyles.AdjustToUniversal flag is present, the Kind property of the returned DateTime value is set to DateTimeKind.Local.
AssumeUniversal	Specifies that if `s` lacks any time zone information, it is assumed to represent UTC. Unless the DateTimeStyles.AdjustToUniversal flag is present, the method converts the returned DateTime value from UTC to local time and sets its Kind property to DateTimeKind.Local.
NoCurrentDateDefault	If `s` contains time without date information, the date of the return value is set to `DateTime.MinValue.Date`.
None	The `s` parameter is parsed using default values. No white space other than that present in `format` is allowed. If `s` lacks a date

DateTimeStyles member	Description
	component, the date of the returned DateTime value is set to 1/1/0001. If `s` contains no time zone information, the Kind property of the returned DateTime object is set to DateTimeKind.Unspecified. If time zone information is present in `s`, the time is converted to local time and the Kind property of the returned DateTime object is set to DateTimeKind.Local.
RoundtripKind	For strings that contain time zone information, tries to prevent the conversion to a DateTime value with its Kind property set to DateTimeKind.Local. This flag primarily prevents the conversion of UTC times to local times.

Notes to Callers

In the .NET Framework 4, the TryParseExact method returns `false` if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

DateTime.Addition(DateTime, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds a specified time interval to a specified date and time, yielding a new date and time.

```
C#

public static DateTime operator + (DateTime d, TimeSpan t);
```

Parameters

`d` DateTime

The date and time value to add.

`t` TimeSpan

The time interval to add.

Returns

DateTime

An object that is the sum of the values of `d` and `t`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example demonstrates the addition operator.

C#

```
System.DateTime dTime = new System.DateTime(1980, 8, 5);

// tSpan is 17 days, 4 hours, 2 minutes and 1 second.
System.TimeSpan tSpan
    = new System.TimeSpan(17, 4, 2, 1);

// Result gets 8/22/1980 4:02:01 AM.
System.DateTime result = dTime + tSpan;
```

Remarks

The equivalent method for this operator is DateTime.Add(TimeSpan)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Equality(DateTime, DateTime) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of DateTime are equal.

```
C#

public static bool operator == (DateTime d1, DateTime d2);
```

Parameters

d1 DateTime

The first object to compare.

d2 DateTime

The second object to compare.

Returns

Boolean

`true` if `d1` and `d2` represent the same date and time; otherwise, `false`.

Examples

The following example demonstrates the equality operator.

```
C#

System.DateTime april19 = new DateTime(2001, 4, 19);
System.DateTime otherDate = new DateTime(1991, 6, 5);

// areEqual gets false.
bool areEqual = april19 == otherDate;
```

```
otherDate = new DateTime(2001, 4, 19);
// areEqual gets true.
areEqual = april19 == otherDate;
```

Remarks

The Equality operator determines whether two DateTime values are equal by comparing their number of ticks. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind property.

The equivalent method for this operator is DateTime.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime.GreaterThan(DateTime, DateTime) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTime is later than another specified DateTime.

```
C#
public static bool operator > (DateTime t1, DateTime t2);
```

Parameters

t1 DateTime

The first object to compare.

t2 DateTime

The second object to compare.

Returns

Boolean

`true` if `t1` is later than `t2`; otherwise, `false`.

Remarks

The GreaterThan operator determines the relationship between two DateTime values by comparing their number of ticks. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind property.

The equivalent method for this operator is DateTime.Compare(DateTime, DateTime)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTime.GreaterThanOrEqual(DateTime, DateTime) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTime represents a date and time that is the same as or later than another specified DateTime.

```
C#
public static bool operator >= (DateTime t1, DateTime t2);
```

Parameters

`t1` DateTime

The first object to compare.

`t2` DateTime

The second object to compare.

Returns

Boolean

`true` if `t1` is the same as or later than `t2`; otherwise, `false`.

Remarks

The GreaterThanOrEqual operator determines the relationship between two DateTime values by comparing their number of ticks. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind property.

The equivalent method for this operator is DateTime.Compare(DateTime, DateTime)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.Inequality(DateTime, DateTime) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of DateTime are not equal.

```C#
public static bool operator != (DateTime d1, DateTime d2);
```

Parameters

d1 DateTime

The first object to compare.

d2 DateTime

The second object to compare.

Returns

Boolean

`true` if `d1` and `d2` do not represent the same date and time; otherwise, `false`.

Remarks

The Inequality operator determines whether two DateTime values are not equal by comparing their number of ticks. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind property.

The equivalent method for this operator is DateTime.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.LessThan(DateTime, DateTime) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTime is earlier than another specified DateTime.

```
C#
public static bool operator < (DateTime t1, DateTime t2);
```

Parameters

t1 DateTime

The first object to compare.

t2 DateTime

The second object to compare.

Returns

Boolean

`true` if `t1` is earlier than `t2`; otherwise, `false`.

Remarks

The LessThan operator determines the relationship between two DateTime values by comparing their number of ticks. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind property.

The equivalent method for this operator is DateTime.Compare(DateTime, DateTime)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.LessThanOrEqual(DateTime, DateTime) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTime represents a date and time that is the same as or earlier than another specified DateTime.

C#

```
public static bool operator <= (DateTime t1, DateTime t2);
```

Parameters

`t1` DateTime

The first object to compare.

`t2` DateTime

The second object to compare.

Returns

Boolean

`true` if `t1` is the same as or earlier than `t2`; otherwise, `false`.

Remarks

The LessThanOrEqual operator determines the relationship between two DateTime values by comparing their number of ticks. Before comparing DateTime objects, make sure that the objects represent times in the same time zone. You can do this by comparing the values of their Kind property.

The equivalent method for this operator is DateTime.Compare(DateTime, DateTime)

Applies to

DateTime.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts a specified DateTime orTimeSpan from a specified DateTime.

Overloads

Expand table

Subtraction(DateTime, DateTime)	Subtracts a specified date and time from another specified date and time and returns a time interval.
Subtraction(DateTime, TimeSpan)	Subtracts a specified time interval from a specified date and time and returns a new date and time.

Subtraction(DateTime, DateTime)

Subtracts a specified date and time from another specified date and time and returns a time interval.

C#

```
public static TimeSpan operator - (DateTime d1, DateTime d2);
```

Parameters

d1 DateTime

The date and time value to subtract from (the minuend).

d2 DateTime

The date and time value to subtract (the subtrahend).

Returns

TimeSpan

The time interval between `d1` and `d2`; that is, `d1` minus `d2`.

Examples

The following example demonstrates the Subtract method and the subtraction operator.

C#

```
System.DateTime date1 = new System.DateTime(1996, 6, 3, 22, 15, 0);
System.DateTime date2 = new System.DateTime(1996, 12, 6, 13, 2, 0);
System.DateTime date3 = new System.DateTime(1996, 10, 12, 8, 42, 0);

// diff1 gets 185 days, 14 hours, and 47 minutes.
System.TimeSpan diff1 = date2.Subtract(date1);

// date4 gets 4/9/1996 5:55:00 PM.
System.DateTime date4 = date3.Subtract(diff1);

// diff2 gets 55 days 4 hours and 20 minutes.
System.TimeSpan diff2 = date2 - date3;

// date5 gets 4/9/1996 5:55:00 PM.
System.DateTime date5 = date1 - diff2;
```

Remarks

The Subtraction(DateTime, DateTime) method does not consider the value of the Kind property of the two DateTime values when performing the subtraction. Before subtracting DateTime objects, ensure that the objects represent times in the same time zone. Otherwise, the result will include the difference between time zones.

> **Note**
>
> The **DateTimeOffset.Subtraction(DateTimeOffset, DateTimeOffset)** method does consider the difference between time zones when performing the subtraction.

The equivalent method for this operator is DateTime.Subtract(DateTime)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Subtraction(DateTime, TimeSpan)

Subtracts a specified time interval from a specified date and time and returns a new date and time.

C#

```
public static DateTime operator - (DateTime d, TimeSpan t);
```

Parameters

`d` DateTime

The date and time value to subtract from.

`t` TimeSpan

The time interval to subtract.

Returns

DateTime

An object whose value is the value of `d` minus the value of `t`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTime is less than DateTime.MinValue or greater than DateTime.MaxValue.

Examples

The following example demonstrates the Subtract method and the subtraction operator.

C#

```
System.DateTime date1 = new System.DateTime(1996, 6, 3, 22, 15, 0);
System.DateTime date2 = new System.DateTime(1996, 12, 6, 13, 2, 0);
System.DateTime date3 = new System.DateTime(1996, 10, 12, 8, 42, 0);

// diff1 gets 185 days, 14 hours, and 47 minutes.
System.TimeSpan diff1 = date2.Subtract(date1);

// date4 gets 4/9/1996 5:55:00 PM.
System.DateTime date4 = date3.Subtract(diff1);

// diff2 gets 55 days 4 hours and 20 minutes.
System.TimeSpan diff2 = date2 - date3;

// date5 gets 4/9/1996 5:55:00 PM.
System.DateTime date5 = date1 - diff2;
```

Remarks

This method subtracts the ticks value of `t` from the ticks value of `d`.

The equivalent method for this operator is DateTime.Subtract(DateTime)

DateTime.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Boolean

The return value for this member is not used.

Implements

ToBoolean(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Byte

The return value for this member is not used.

Implements

ToByte(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Char

The return value for this member is not used.

Implements

ToChar(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the current DateTime object.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

DateTime

The current object.

Implements

ToDateTime(IFormatProvider)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Double

The return value for this member is not used.

Implements

ToDouble(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Int16

The return value for this member is not used.

Implements

ToInt16(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTime.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current DateTime object to an object of a specified type.

```
C#
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The desired type.

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Object

An object of the type specified by the `type` parameter, with a value equivalent to the current DateTime object.

Implements

ToType(Type, IFormatProvider)

Exceptions

ArgumentNullException

`type` is `null`.

InvalidCastException

This conversion is not supported for the DateTime type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTime.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data needed to serialize the current DateTime object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to populate with data.

`context` StreamingContext

The destination for this serialization. (This parameter is not used; specify `null`.)

Implements

GetObjectData(SerializationInfo, StreamingContext)

Exceptions

ArgumentNullException

`info` is `null`.

Remarks

This method populates the `info` parameter with the Ticks and Kind property values.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeKind Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies whether a DateTime object represents a local time, a Coordinated Universal Time (UTC), or is not specified as either local time or UTC.

```
C#

public enum DateTimeKind
```

Inheritance Object → ValueType → Enum → DateTimeKind

Fields

Expand table

Local	2	The time represented is local time.
Unspecified	0	The time represented is not specified as either local time or Coordinated Universal Time (UTC).
Utc	1	The time represented is UTC.

Remarks

A member of the DateTimeKind enumeration is returned by the DateTime.Kind property.

The members of the DateTimeKind enumeration are used in conversion operations between local time and Coordinated Universal Time (UTC), but not in comparison or arithmetic operations. For more information about time conversions, see Converting Times Between Time Zones.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a point in time, typically expressed as a date and time of day, relative to Coordinated Universal Time (UTC).

C#

```
public readonly struct DateTimeOffset : IComparable,
IComparable<DateTimeOffset>, IEquatable<DateTimeOffset>,
IParsable<DateTimeOffset>, ISpanFormattable, ISpanParsable<DateTimeOffset>,
IUtf8SpanFormattable, System.Runtime.Serialization.IDeserializationCallback,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → ValueType → DateTimeOffset

Implements IComparable , IComparable<DateTimeOffset> , IEquatable<DateTimeOffset> , IFormattable , IDeserializationCallback , ISerializable , ISpanFormattable , IParsable<DateTimeOffset> , IParsable<TSelf> , ISpanParsable<DateTimeOffset> , IUtf8SpanFormattable

Remarks

The DateTimeOffset structure includes a DateTime value, together with an Offset property that defines the difference between the current DateTimeOffset instance's date and time and Coordinated Universal Time (UTC). Because it exactly defines a date and time relative to UTC, the DateTimeOffset structure does not include a `Kind` member, as the DateTime structure does. It represents dates and times with values whose UTC ranges from 12:00:00 midnight, January 1, 0001 Anno Domini (Common Era), to 11:59:59 P.M., December 31, 9999 A.D. (C.E.).

Important

Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

The time component of a DateTimeOffset value is measured in 100-nanosecond units called ticks, and a particular date is the number of ticks since 12:00 midnight, January 1, 0001 A.D. (C.E.) in the GregorianCalendar calendar. A DateTimeOffset value is always expressed in the context of an explicit or default calendar. Ticks that are attributable to leap seconds are not included in the total number of ticks.

Although a DateTimeOffset value includes an offset, it is not a fully time zone-aware data structure. While an offset from UTC is one characteristic of a time zone, it does not unambiguously identify a time zone. Not only do multiple time zones share the same offset from UTC, but the offset of a single time zone changes if it observes daylight saving time. This means that, as soon as a DateTimeOffset value is disassociated from its time zone, it can no longer be unambiguously linked back to its original time zone.

Because DateTimeOffset is a structure, a DateTimeOffset object that has been declared but not otherwise initialized contains the default values for each of its member fields. This means that its DateTime property is set to DateTimeOffset.MinValue and its Offset property is set to TimeSpan.Zero.

You can create a new DateTimeOffset value by calling any of the overloads of its constructor, which are similar to the overloaded constructors for the DateTime structure. You can also create a new DateTimeOffset value by assigning it a DateTime value. This is an implicit conversion; it does not require a casting operator (in C#) or call to a conversion method (in Visual Basic). You can also initialize a DateTimeOffset value from the string representation of a date and time by calling a number of static string parsing methods, which include Parse, ParseExact, TryParse, and TryParseExact.

The members of the DateTimeOffset structure provide functionality in the following areas:

- Date and time arithmetic.

You can add or subtract either dates or time intervals from a particular DateTimeOffset value. Arithmetic operations with DateTimeOffset values, unlike those with DateTime values, adjust for differences in time offsets when returning a result. For example, the following code uses DateTime variables to subtract the current local time from the current UTC time. The code then uses DateTimeOffset variables to perform the same operation. The subtraction with DateTime values returns the local time zone's difference from UTC, while the subtraction with DateTimeOffset values returns TimeSpan.Zero.

C#

```
using System;

public class DateArithmetic
{
   public static void Main()
   {
      DateTime date1, date2;
      DateTimeOffset dateOffset1, dateOffset2;
      TimeSpan difference;

      // Find difference between Date.Now and Date.UtcNow
      date1 = DateTime.Now;
      date2 = DateTime.UtcNow;
      difference = date1 - date2;
      Console.WriteLine("{0} - {1} = {2}", date1, date2, difference);

      // Find difference between Now and UtcNow using DateTimeOffset
      dateOffset1 = DateTimeOffset.Now;
      dateOffset2 = DateTimeOffset.UtcNow;
      difference = dateOffset1 - dateOffset2;
      Console.WriteLine("{0} - {1} = {2}",
                        dateOffset1, dateOffset2, difference);
      // If run in the Pacific Standard time zone on 4/2/2007, the
example
      // displays the following output to the console:
      //    4/2/2007 7:23:57 PM - 4/3/2007 2:23:57 AM = -07:00:00
      //    4/2/2007 7:23:57 PM -07:00 - 4/3/2007 2:23:57 AM +00:00 =
00:00:00
   }
}
```

- Type conversion operations.

  You can convert DateTimeOffset values to DateTime values and vice versa.

- Time manipulation and extraction operations.

You can extract either the date or the time of a DateTimeOffset value. You can also retrieve the value of a particular DateTimeOffset component, such as its year or its month.

> **Note**
>
> If you are working with a ticks value that you want to convert to some other time interval, such as minutes or seconds, you should use the **TimeSpan.TicksPerDay**, **TimeSpan.TicksPerHour**, **TimeSpan.TicksPerMinute**, **TimeSpan.TicksPerSecond**, or **TimeSpan.TicksPerMillisecond** constant to perform the conversion. For example, to add the number of seconds represented by a specified number of ticks to the **Second** component of a **DateTimeOffset** value, you can use the expression `dateValue.Second + nTicks/Timespan.TicksPerSecond`.

- Date and time conversion.

  You can convert any DateTimeOffset value to another DateTimeOffset value that represents the same point in time in another time zone. However, a time zone's adjustment rules are applied only in the case of the ToLocalTime method, which converts a DateTimeOffset value to the date and time in the local system zone.

- Date and time comparison.

  You can determine whether any particular DateTimeOffset value is earlier than, the same as, or later than another DateTimeOffset value. Before the comparison is performed, all values are converted to UTC.

Constructors

Expand table

DateTimeOffset(DateOnly, TimeOnly, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified `date`, `time`, and `offset`.
DateTimeOffset(DateTime)	Initializes a new instance of the DateTimeOffset structure using the specified DateTime value.
DateTimeOffset(DateTime, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified DateTime value and offset.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, millisecond, and offset of a specified calendar.

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified `year`, `month`, `day`, `hour`, `minute`, `second`, `millisecond`, `microsecond` and `offset`.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Time Span)	Initializes a new instance of the DateTimeOffset structure using the specified `year`, `month`, `day`, `hour`, `minute`, `second`, `millisecond`, `microsecond` and `offset`.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, millisecond, and offset.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, and offset.
DateTimeOffset(Int64, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified number of ticks and offset.

Fields

Expand table

Max Value	Represents the greatest possible value of DateTimeOffset. This field is read-only.
Min Value	Represents the earliest possible DateTimeOffset value. This field is read-only.
Unix Epoch	The value of this constant is equivalent to 00:00:00.0000000 UTC, January 1, 1970, in the Gregorian calendar. UnixEpoch defines the point in time when Unix time is equal to 0.

Properties

Expand table

Date	Gets a DateTime value that represents the date component of the current DateTimeOffset object.
DateTime	Gets a DateTime value that represents the date and time of the current DateTimeOffset object.
Day	Gets the day of the month represented by the current DateTimeOffset object.
DayOfWeek	Gets the day of the week represented by the current DateTimeOffset object.

DayOfYear	Gets the day of the year represented by the current DateTimeOffset object.
Hour	Gets the hour component of the time represented by the current DateTimeOffset object.
LocalDateTime	Gets a DateTime value that represents the local date and time of the current DateTimeOffset object.
Microsecond	Gets the microsecond component of the time represented by the current DateTimeOffset object.
Millisecond	Gets the millisecond component of the time represented by the current DateTimeOffset object.
Minute	Gets the minute component of the time represented by the current DateTimeOffset object.
Month	Gets the month component of the date represented by the current DateTimeOffset object.
Nanosecond	Gets the nanosecond component of the time represented by the current DateTimeOffset object.
Now	Gets a DateTimeOffset object that is set to the current date and time on the current computer, with the offset set to the local time's offset from Coordinated Universal Time (UTC).
Offset	Gets the time's offset from Coordinated Universal Time (UTC).
Second	Gets the second component of the clock time represented by the current DateTimeOffset object.
Ticks	Gets the number of ticks that represents the date and time of the current DateTimeOffset object in clock time.
TimeOfDay	Gets the time of day for the current DateTimeOffset object.
TotalOffset Minutes	Gets the time's offset from Coordinated Universal Time (UTC) in minutes.
UtcDateTime	Gets a DateTime value that represents the Coordinated Universal Time (UTC) date and time of the current DateTimeOffset object.
UtcNow	Gets a DateTimeOffset object whose date and time are set to the current Coordinated Universal Time (UTC) date and time and whose offset is Zero.
UtcTicks	Gets the number of ticks that represents the date and time of the current DateTimeOffset object in Coordinated Universal Time (UTC).
Year	Gets the year component of the date represented by the current DateTimeOffset object.

Methods

Expand table

Add(TimeSpan)	Returns a new DateTimeOffset object that adds a specified time interval to the value of this instance.
AddDays(Double)	Returns a new DateTimeOffset object that adds a specified number of whole and fractional days to the value of this instance.
AddHours(Double)	Returns a new DateTimeOffset object that adds a specified number of whole and fractional hours to the value of this instance.
AddMicroseconds(Double)	Returns a new DateTimeOffset object that adds a specified number of microseconds to the value of this instance.
AddMilliseconds(Double)	Returns a new DateTimeOffset object that adds a specified number of milliseconds to the value of this instance.
AddMinutes(Double)	Returns a new DateTimeOffset object that adds a specified number of whole and fractional minutes to the value of this instance.
AddMonths(Int32)	Returns a new DateTimeOffset object that adds a specified number of months to the value of this instance.
AddSeconds(Double)	Returns a new DateTimeOffset object that adds a specified number of whole and fractional seconds to the value of this instance.
AddTicks(Int64)	Returns a new DateTimeOffset object that adds a specified number of ticks to the value of this instance.
AddYears(Int32)	Returns a new DateTimeOffset object that adds a specified number of years to the value of this instance.
Compare(DateTimeOffset, DateTime Offset)	Compares two DateTimeOffset objects and indicates whether the first is earlier than the second, equal to the second, or later than the second.
CompareTo(DateTimeOffset)	Compares the current DateTimeOffset object to a specified DateTimeOffset object and indicates whether the current object is earlier than, the same as, or later than the second DateTimeOffset object.

Deconstruct(DateOnly, TimeOnly, TimeSpan)	Deconstructs this DateTimeOffset instance by DateOnly, TimeOnly, and TimeSpan.
Equals(DateTimeOffset)	Determines whether the current DateTimeOffset object represents the same point in time as a specified DateTimeOffset object.
Equals(DateTimeOffset, DateTimeOffset)	Determines whether two specified DateTimeOffset objects represent the same point in time.
Equals(Object)	Determines whether a DateTimeOffset object represents the same point in time as a specified object.
EqualsExact(DateTimeOffset)	Determines whether the current DateTimeOffset object represents the same time and has the same offset as a specified DateTimeOffset object.
FromFileTime(Int64)	Converts the specified Windows file time to an equivalent local time.
FromUnixTimeMilliseconds(Int64)	Converts a Unix time expressed as the number of milliseconds that have elapsed since 1970-01-01T00:00:00Z to a DateTimeOffset value.
FromUnixTimeSeconds(Int64)	Converts a Unix time expressed as the number of seconds that have elapsed since 1970-01-01T00:00:00Z to a DateTimeOffset value.
GetHashCode()	Returns the hash code for the current DateTimeOffset object.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information and formatting style.
Parse(String)	Converts the specified string representation of a date, time, and offset to its DateTimeOffset equivalent.
Parse(String, IFormatProvider)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information.
Parse(String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information and formatting style.

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a character span that represents a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the date and time representation must match the specified format exactly.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts a character span that contains the string representation of a date and time to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the date and time representation must match one of the specified formats exactly.
ParseExact(String, String, IFormatProvider)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly.
ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the string representation must match one of the specified formats exactly.
Subtract(DateTimeOffset)	Subtracts a DateTimeOffset value that represents a specific date and time from the current DateTimeOffset object.
Subtract(TimeSpan)	Subtracts a specified time interval from the current DateTimeOffset object.
ToFileTime()	Converts the value of the current DateTimeOffset object to a Windows file time.
ToLocalTime()	Converts the current DateTimeOffset object to a DateTimeOffset object that represents the local time.
ToOffset(TimeSpan)	Converts the value of the current DateTimeOffset object to the date and time specified by an offset value.
ToString()	Converts the value of the current DateTimeOffset object to its equivalent string representation.

ToString(IFormatProvider)	Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified culture-specific formatting information.
ToString(String)	Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified format and culture-specific format information.
ToUniversalTime()	Converts the current DateTimeOffset object to a DateTimeOffset value that represents the Coordinated Universal Time (UTC).
ToUnixTimeMilliseconds()	Returns the number of milliseconds that have elapsed since 1970-01-01T00:00:00.000Z.
ToUnixTimeSeconds()	Returns the number of seconds that have elapsed since 1970-01-01T00:00:00Z.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current datetime offset instance into the provided span of characters.
TryParse(ReadOnlySpan<Char>, DateTimeOffset)	Tries to convert a specified span representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeOffset)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTimeOffset)	Tries to convert a specified span representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, DateTimeOffset)	Tries to converts a specified string representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, DateTimeOffset)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, DateTimeStyles, DateTimeOffset)	Tries to convert a specified string representation of a date and time to its DateTimeOffset equivalent, and

	returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the representation of a date and time in a character span to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the date and time representation must match the specified format exactly.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the representation of a date and time in a character span to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the date and time representation must match one of the specified formats exactly.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly.
TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match one of the specified formats exactly.

Operators

Expand table

Addition(DateTimeOffset, TimeSpan)	Adds a specified time interval to a DateTimeOffset object that has a specified date and time, and yields a DateTimeOffset object that has new a date and time.
Equality(DateTimeOffset, DateTimeOffset)	Determines whether two specified DateTimeOffset objects represent the same point in time.
GreaterThan(DateTimeOffset, DateTimeOffset)	Determines whether one specified DateTimeOffset object is greater than (or later than) a second specified DateTimeOffset object.
GreaterThanOrEqual(DateTimeOffset, DateTimeOffset)	Determines whether one specified DateTimeOffset object is greater than or equal to a second specified DateTimeOffset object.

Implicit(DateTime to DateTimeOffset)	Defines an implicit conversion of a DateTime object to a DateTimeOffset object.
Inequality(DateTimeOffset, DateTimeOffset)	Determines whether two specified DateTimeOffset objects refer to different points in time.
LessThan(DateTimeOffset, DateTimeOffset)	Determines whether one specified DateTimeOffset object is less than a second specified DateTimeOffset object.
LessThanOrEqual(DateTimeOffset, DateTimeOffset)	Determines whether one specified DateTimeOffset object is less than a second specified DateTimeOffset object.
Subtraction(DateTimeOffset, DateTimeOffset)	Subtracts one DateTimeOffset object from another and yields a time interval.
Subtraction(DateTimeOffset, TimeSpan)	Subtracts a specified time interval from a specified date and time, and yields a new date and time.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the value of the current DateTimeOffset object with another object of the same type.
IDeserializationCallback.OnDeserialization(Object)	Runs when the deserialization of an object has been completed.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo object with the data required to serialize the current DateTimeOffset object.

DateTimeOffset Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the DateTimeOffset structure.

Overloads

Expand table

DateTimeOffset(DateTime)	Initializes a new instance of the DateTimeOffset structure using the specified DateTime value.
DateTimeOffset(DateTime, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified DateTime value and offset.
DateTimeOffset(Int64, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified number of ticks and offset.
DateTimeOffset(DateOnly, TimeOnly, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified `date`, `time`, and `offset`.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, and offset.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, millisecond, and offset.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, millisecond, and offset of a specified calendar.
DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified `year`, `month`, `day`, `hour`, `minute`, `second`, `millisecond`, `microsecond` and `offset`.

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan)	Initializes a new instance of the DateTimeOffset structure using the specified `year`, `month`, `day`, `hour`, `minute`, `second`, `millisecond`, `microsecond` and `offset`.

DateTimeOffset(DateTime)

Initializes a new instance of the DateTimeOffset structure using the specified DateTime value.

```
C#

public DateTimeOffset (DateTime dateTime);
```

Parameters

`dateTime` DateTime

A date and time.

Exceptions

ArgumentOutOfRangeException

The Coordinated Universal Time (UTC) date and time that results from applying the offset is earlier than DateTimeOffset.MinValue.

-or-

The UTC date and time that results from applying the offset is later than DateTimeOffset.MaxValue.

Examples

The following example illustrates how the value of the DateTime.Kind property of the `dateTime` parameter affects the date and time value that is returned by this constructor.

```
C#

DateTime localNow = DateTime.Now;
DateTimeOffset localOffset = new DateTimeOffset(localNow);
Console.WriteLine(localOffset.ToString());

DateTime utcNow = DateTime.UtcNow;
```

```
DateTimeOffset utcOffset = new DateTimeOffset(utcNow);
Console.WriteLine(utcOffset.ToString());

DateTime unspecifiedNow = DateTime.SpecifyKind(DateTime.Now,
                                               DateTimeKind.Unspecified);
DateTimeOffset unspecifiedOffset = new DateTimeOffset(unspecifiedNow);
Console.WriteLine(unspecifiedOffset.ToString());
//
// The code produces the following output if run on Feb. 23, 2007, on
// a system 8 hours earlier than UTC:
//   2/23/2007 4:21:58 PM -08:00
//   2/24/2007 12:21:58 AM +00:00
//   2/23/2007 4:21:58 PM -08:00
```

Remarks

This constructor's behavior depends on the value of the DateTime.Kind property of the `dateTime` parameter:

- If the value of DateTime.Kind is DateTimeKind.Utc, the DateTime property of the new instance is set equal to `dateTime`, and the Offset property is set equal to Zero.
- If the value of DateTime.Kind is DateTimeKind.Local or DateTimeKind.Unspecified, the DateTime property of the new instance is set equal to `dateTime`, and the Offset property is set equal to the offset of the local system's current time zone.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

DateTimeOffset(DateTime, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified DateTime value and offset.

```
C#
public DateTimeOffset (DateTime dateTime, TimeSpan offset);
```

Parameters

`dateTime` DateTime

A date and time.

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`dateTime.Kind` equals Utc and `offset` does not equal zero.

-or-

`dateTime.Kind` equals Local and `offset` does not equal the offset of the system's local time zone.

-or-

`offset` is not specified in whole minutes.

ArgumentOutOfRangeException

`offset` is less than -14 hours or greater than 14 hours.

-or-

UtcDateTime is less than DateTimeOffset.MinValue or greater than DateTimeOffset.MaxValue.

Examples

The following example shows how to initialize a DateTimeOffset object with a date and time and the offset of the local time zone when that time zone is not known in advance.

```C#
DateTime localTime = new DateTime(2007, 07, 12, 06, 32, 00);
DateTimeOffset dateAndOffset = new DateTimeOffset(localTime,
                          TimeZoneInfo.Local.GetUtcOffset(localTime));
Console.WriteLine(dateAndOffset);
// The code produces the following output:
//    7/12/2007 6:32:00 AM -07:00
```

Remarks

This constructor's behavior depends in part on the value of the Kind property of the `dateTime` parameter:

- If the value of Kind is DateTimeKind.Utc, the value of the `offset` parameter must be 0 or an ArgumentException is thrown.
- If the value of Kind is DateTimeKind.Local, the value of the `offset` parameter must be equal to the local time zone's offset from Coordinated Universal Time (UTC) for that particular date or an ArgumentException is thrown.
- If the value of Kind is DateTimeKind.Unspecified, the `offset` parameter can have any valid value.

DateTimeOffset(Int64, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified number of ticks and offset.

```
C#

public DateTimeOffset (long ticks, TimeSpan offset);
```

Parameters

`ticks` Int64

A date and time expressed as the number of 100-nanosecond intervals that have elapsed since 12:00:00 midnight on January 1, 0001.

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`offset` is not specified in whole minutes.

ArgumentOutOfRangeException

The UtcDateTime property is earlier than DateTimeOffset.MinValue or later than DateTimeOffset.MaxValue.

-or-

`ticks` is less than `DateTimeOffset.MinValue.Ticks` or greater than `DateTimeOffset.MaxValue.Ticks`.

-or-

`Offset` s less than -14 hours or greater than 14 hours.

Examples

The following example initializes a DateTimeOffset object by using the number of ticks in an arbitrary date (in this case, July 16, 2007, at 1:32 PM) with an offset of -5.

C#

```
DateTime dateWithoutOffset = new DateTime(2007, 7, 16, 13, 32, 00);
DateTimeOffset timeFromTicks = new
DateTimeOffset(dateWithoutOffset.Ticks,
                                new TimeSpan(-5, 0, 0));
Console.WriteLine(timeFromTicks.ToString());
// The code produces the following output:
//    7/16/2007 1:32:00 PM -05:00
```

Remarks

Ordinarily, trying to call the DateTimeOffset constructor to instantiate a DateTimeOffset value with a local time and an offset other than that of the local time zone throws an ArgumentException. You can use this overload of the DateTimeOffset constructor to work around this limitation. The following example uses the local time's number of ticks to instantiate a DateTimeOffset value whose offset does not necessarily represent that of the local time:

C#

```
DateTime localTime = DateTime.Now;
DateTimeOffset nonLocalDateWithOffset = new
DateTimeOffset(localTime.Ticks,
                                  new TimeSpan(2, 0, 0));
Console.WriteLine(nonLocalDateWithOffset);
//
// The code produces the following output if run on Feb. 23, 2007:
//    2/23/2007 4:37:50 PM +02:00
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset(DateOnly, TimeOnly, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified `date`, `time`, and `offset`.

```
C#

public DateTimeOffset (DateOnly date, TimeOnly time, TimeSpan offset);
```

Parameters

`date` DateOnly

The date part.

`time` TimeOnly

The time part.

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, and offset.

C#

```
public DateTimeOffset (int year, int month, int day, int hour, int
minute, int second, TimeSpan offset);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`offset` does not represent whole minutes.

ArgumentOutOfRangeException

`year` is less than one or greater than 9999.

-or-

`month` is less than one or greater than 12.

-or-

`day` is less than one or greater than the number of days in `month`.

-or-

`hour` is less than zero or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`offset` is less than -14 hours or greater than 14 hours.

-or-

The UtcDateTime property is earlier than DateTimeOffset.MinValue or later than DateTimeOffset.MaxValue.

Examples

The following example instantiates a DateTimeOffset object by using the DateTimeOffset.DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan) constructor overload.

C#

```
DateTime specificDate = new DateTime(2008, 5, 1, 06, 32, 00);
DateTimeOffset offsetDate = new DateTimeOffset(specificDate.Year,
                                specificDate.Month,
                                specificDate.Day,
                                specificDate.Hour,
                                specificDate.Minute,
                                specificDate.Second,
                                new TimeSpan(-5, 0, 0));
Console.WriteLine("Current time: {0}", offsetDate);
```

```
    Console.WriteLine("Corresponding UTC time: {0}",
offsetDate.UtcDateTime);
// The code produces the following output:
//    Current time: 5/1/2008 6:32:00 AM -05:00
//    Corresponding UTC time: 5/1/2008 11:32:00 AM
```

Remarks

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTimeOffset value by using the year, month, and day in another calendar, call the DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan) constructor.

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, millisecond, and offset.

C#

```
public DateTimeOffset (int year, int month, int day, int hour, int
```

```
minute, int second, int millisecond, TimeSpan offset);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`offset` does not represent whole minutes.

ArgumentOutOfRangeException

`year` is less than one or greater than 9999.

-or-

`month` is less than one or greater than 12.

-or-

`day` is less than one or greater than the number of days in `month`.

-or-

`hour` is less than zero or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`offset` is less than -14 or greater than 14.

-or-

The UtcDateTime property is earlier than DateTimeOffset.MinValue or later than DateTimeOffset.MaxValue.

Examples

The following example instantiates a DateTimeOffset object by using the DateTimeOffset.DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan) constructor overload.

C#

```
string fmt = "dd MMM yyyy HH:mm:ss";
DateTime thisDate = new DateTime(2007, 06, 12, 19, 00, 14, 16);
DateTimeOffset offsetDate = new DateTimeOffset(thisDate.Year,
                                               thisDate.Month,
                                               thisDate.Day,
                                               thisDate.Hour,
                                               thisDate.Minute,
                                               thisDate.Second,
                                               thisDate.Millisecond,
                                               new TimeSpan(2, 0, 0));
Console.WriteLine("Current time: {0}:{1}", offsetDate.ToString(fmt),
offsetDate.Millisecond);
```

```
// The code produces the following output:
//    Current time: 12 Jun 2007 19:00:14:16
```

Remarks

This constructor interprets `year`, `month`, and `day` as a year, month, and day in the Gregorian calendar. To instantiate a DateTimeOffset value by using the year, month, and day in another calendar, call the DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan) constructor.

UWP	10.0

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified year, month, day, hour, minute, second, millisecond, and offset of a specified calendar.

C#

```
public DateTimeOffset (int year, int month, int day, int hour, int
minute, int second, int millisecond, System.Globalization.Calendar
calendar, TimeSpan offset);
```

Parameters

`year` Int32

The year.

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`offset` does not represent whole minutes.

ArgumentNullException

`calendar` cannot be `null`.

ArgumentOutOfRangeException

`year` is less than the `calendar` parameter's `MinSupportedDateTime.Year` or greater than `MaxSupportedDateTime.Year`.

-or-

`month` is either less than or greater than the number of months in `year` in the `calendar`.

-or-

`day` is less than one or greater than the number of days in `month`.

-or-

`hour` is less than zero or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`offset` is less than -14 hours or greater than 14 hours.

-or-

The `year`, `month`, and `day` parameters cannot be represented as a date and time value.

-or-

The UtcDateTime property is earlier than DateTimeOffset.MinValue or later than DateTimeOffset.MaxValue.

Examples

The following example uses instances of both the HebrewCalendar class and the HijriCalendar class to instantiate a DateTimeOffset value. That date is then displayed to the console using the respective calendars and the Gregorian calendar.

```
C#
```

```
CultureInfo fmt;
int year;
Calendar cal;
DateTimeOffset dateInCal;

// Instantiate DateTimeOffset with Hebrew calendar
year = 5770;
cal = new HebrewCalendar();
fmt = new CultureInfo("he-IL");
fmt.DateTimeFormat.Calendar = cal;
dateInCal = new DateTimeOffset(year, 7, 12,
                               15, 30, 0, 0,
                               cal,
                               new TimeSpan(2, 0, 0));
// Display the date in the Hebrew calendar
Console.WriteLine("Date in Hebrew Calendar: {0:g}",
                  dateInCal.ToString(fmt));
// Display the date in the Gregorian calendar
Console.WriteLine("Date in Gregorian Calendar: {0:g}", dateInCal);
Console.WriteLine();

// Instantiate DateTimeOffset with Hijri calendar
year = 1431;
cal = new HijriCalendar();
fmt = new CultureInfo("ar-SA");
fmt.DateTimeFormat.Calendar = cal;
dateInCal = new DateTimeOffset(year, 7, 12,
                               15, 30, 0, 0,
                               cal,
                               new TimeSpan(2, 0, 0));
// Display the date in the Hijri calendar
Console.WriteLine("Date in Hijri Calendar: {0:g}",
                  dateInCal.ToString(fmt));
// Display the date in the Gregorian calendar
Console.WriteLine("Date in Gregorian Calendar: {0:g}", dateInCal);
Console.WriteLine();
```

Remarks

The `year`, `month`, `day`, `hour`, `minute`, `second`, and `millisecond` parameters all reflect values expressed in the calendar specified by the `calendar` parameter. An exception is thrown if these values form a date and time that cannot be expressed by using this calendar.

> **ⓘ Important**
>
> Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning

of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified `year`, `month`, `day`, `hour`, `minute`, `second`, `millisecond`, `microsecond` and `offset`.

C#

```
public DateTimeOffset (int year, int month, int day, int hour, int
minute, int second, int millisecond, int microsecond, TimeSpan offset);
```

Parameters

year Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`microsecond` Int32

The microseconds (0 through 999).

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`offset` does not represent whole minutes.

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

-or-

`month` is less than 1 or greater than 12.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`microsecond` is less than 0 or greater than 999.

Remarks

This constructor interprets `year`, `month` and `day` as a year, month and day in the Gregorian calendar. To instantiate a DateTimeOffset value by using the year, month and day in another calendar, call the DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan) constructor.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan)

Initializes a new instance of the DateTimeOffset structure using the specified `year`, `month`, `day`, `hour`, `minute`, `second`, `millisecond`, `microsecond` and `offset`.

C#

```
public DateTimeOffset (int year, int month, int day, int hour, int
minute, int second, int millisecond, int microsecond,
```

```
System.Globalization.Calendar calendar, TimeSpan offset);
```

Parameters

`year` Int32

The year (1 through 9999).

`month` Int32

The month (1 through 12).

`day` Int32

The day (1 through the number of days in `month`).

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The milliseconds (0 through 999).

`microsecond` Int32

The microseconds (0 through 999).

`calendar` Calendar

The calendar that is used to interpret `year`, `month`, and `day`.

`offset` TimeSpan

The time's offset from Coordinated Universal Time (UTC).

Exceptions

ArgumentException

`offset` does not represent whole minutes.

ArgumentOutOfRangeException

`year` is not in the range supported by `calendar`.

-or-

`month` is less than 1 or greater than the number of months in `calendar`.

-or-

`day` is less than 1 or greater than the number of days in `month`.

-or-

`hour` is less than 0 or greater than 23.

-or-

`minute` is less than 0 or greater than 59.

-or-

`second` is less than 0 or greater than 59.

-or-

`millisecond` is less than 0 or greater than 999.

-or-

`microsecond` is less than 0 or greater than 999.

-or-

`offset` is less than -14 hours or greater than 14 hours.

-or-

The `year`, `month`, and `day` parameters cannot be represented as a date and time value.

-or-

The UtcDateTime property is earlier than MinValue or later than MaxValue.

Remarks

This constructor interprets `year`, `month` and `day` as a year, month and day in the Gregorian calendar. To instantiate a DateTimeOffset value by using the year, month and day in another calendar, call the DateTimeOffset(Int32, Int32, Int32, Int32, Int32, Int32, Int32, Int32, Calendar, TimeSpan) constructor.

DateTimeOffset.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the greatest possible value of DateTimeOffset. This field is read-only.

```
C#
public static readonly DateTimeOffset MaxValue;
```

Field Value

DateTimeOffset

Exceptions

ArgumentOutOfRangeException

DateTime.MaxValue is outside the range of the current or specified culture's default calendar.

Remarks

The value of this constant is 12/31/9999 11:59:59 PM +00:00.

The MaxValue property is used to determine whether the value of a new DateTimeOffset object or the DateTimeOffset value returned by an arithmetic operation is the same as or earlier than this maximum range value. If it is not, the method throws an ArgumentOutOfRangeException. Any DateTimeOffset value is converted to Coordinated Universal Time (UTC) before the method compares it with MaxValue. This means that a DateTimeOffset value whose date and time are close to the maximum range, but whose offset is negative, may throw an exception. For example, the value 12/31/9999 11:00 PM -02:00 is out of range because it is one hour later than MaxValue when it is converted to UTC.

Some calendars, such as the UmAlQuraCalendar, support an upper date range that is earlier than MaxValue. In these cases, trying to access MaxValue in variable assignments

or formatting and parsing operations can throw an ArgumentOutOfRangeException. Instead of retrieving the value of DateTime.MaxValue, you can retrieve the value of the specified culture's latest valid date value from the Calendar.MaxSupportedDateTime property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the earliest possible DateTimeOffset value. This field is read-only.

```
C#
public static readonly DateTimeOffset MinValue;
```

Field Value

DateTimeOffset

Remarks

The value of this constant is 1/1/0001 12:00:00 AM +00:00.

The MinValue property is used to determine whether the value of a new DateTimeOffset object or the DateTimeOffset value returned by an arithmetic operation is the same as or later than this minimum range value. If it is not, the method throws an ArgumentOutOfRangeException. Any DateTimeOffset value is converted to Coordinated Universal Time (UTC) before the method performs the comparison with MinValue. This means that a DateTimeOffset value whose date and time are close to the minimum range, but whose offset is positive, may throw an exception. For example, the value 1/1/0001 1:00:00 AM +02:00 is out of range because it is one hour earlier than MinValue when it is converted to UTC.

DateTimeOffset.UnixEpoch Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The value of this constant is equivalent to 00:00:00.0000000 UTC, January 1, 1970, in the Gregorian calendar. UnixEpoch defines the point in time when Unix time is equal to 0.

C#

```
public static readonly DateTimeOffset UnixEpoch;
```

Field Value

DateTimeOffset

Applies to

DateTimeOffset.Date Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTime value that represents the date component of the current DateTimeOffset object.

C#

```
public DateTime Date { get; }
```

Property Value

DateTime

A DateTime value that represents the date component of the current DateTimeOffset object.

Examples

The following example retrieves the value of the Date property for a specific date. It then displays that value to the console using some standard and custom date-only format specifiers.

C#

```
// Illustrate Date property and date formatting
DateTimeOffset thisDate = new DateTimeOffset(2008, 3, 17, 1, 32, 0, new
TimeSpan(-5, 0, 0));
string fmt;                       // format specifier

// Display date only using "D" format specifier
// For en-us culture, displays:
//   'D' format specifier: Monday, March 17, 2008
fmt = "D";
Console.WriteLine("'{0}' format specifier: {1}",
                  fmt, thisDate.Date.ToString(fmt));

// Display date only using "d" format specifier
```

```
// For en-us culture, displays:
//   'd' format specifier: 3/17/2008
fmt = "d";
Console.WriteLine("'{0}' format specifier: {1}",
                  fmt, thisDate.Date.ToString(fmt));

// Display date only using "Y" (or "y") format specifier
// For en-us culture, displays:
//   'Y' format specifier: March, 2008
fmt = "Y";
Console.WriteLine("'{0}' format specifier: {1}",
                  fmt, thisDate.Date.ToString(fmt));

// Display date only using custom format specifier
// For en-us culture, displays:
//   'dd MMM yyyy' format specifier: 17 Mar 2008
fmt = "dd MMM yyyy";
Console.WriteLine("'{0}' format specifier: {1}",
                  fmt, thisDate.Date.ToString(fmt));
```

Remarks

This property removes any significant part of the time component from a DateTimeOffset object and returns only its significant date component. For example, if the DateTimeOffset object has a date and time value of "1/12/07 4:01pm +7:30", the property returns a DateTime value of "1/12/07 12:00:00 AM". The DateTime value can then be displayed by using any of the standard or custom format specifiers that display dates only. (See the Example section for an illustration.)

The value of the DateTime.Kind property of the returned DateTime object is always DateTimeKind.Unspecified. It is not affected by the value of the Offset property.

To display a date without its time component, you can also use the "D" or "d" format specifiers; for an illustration, see the Example section.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.DateTime Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTime value that represents the date and time of the current DateTimeOffset object.

C#

```
public DateTime DateTime { get; }
```

Property Value

DateTime

The date and time of the current DateTimeOffset object.

Examples

The following example illustrates the use of the DateTime property to convert the time returned by the Now and UtcNow properties to DateTime values.

C#

```
DateTimeOffset offsetDate;
DateTime regularDate;

offsetDate = DateTimeOffset.Now;
regularDate = offsetDate.DateTime;
Console.WriteLine("{0} converts to {1}, Kind {2}.",
                  offsetDate.ToString(),
                  regularDate,
                  regularDate.Kind);

offsetDate = DateTimeOffset.UtcNow;
regularDate = offsetDate.DateTime;
Console.WriteLine("{0} converts to {1}, Kind {2}.",
                  offsetDate.ToString(),
                  regularDate,
                  regularDate.Kind);
```

```
// If run on 3/6/2007 at 17:11, produces the following output:
//
//   3/6/2007 5:11:22 PM -08:00 converts to 3/6/2007 5:11:22 PM, Kind
Unspecified.
//   3/7/2007 1:11:22 AM +00:00 converts to 3/7/2007 1:11:22 AM, Kind
Unspecified.
```

Remarks

The DateTime property is not affected by the value of the Offset property.

This property returns both the date and the time component of a DateTimeOffset object, which makes it useful for performing DateTimeOffset to DateTime conversion. For example, if the DateTimeOffset object has a date and time value of "1/12/07 4:01pm + 7:30", the property returns a date of "1/12/07 4:01pm".

The value of the DateTime.Kind property of the returned DateTime object is DateTimeKind.Unspecified.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Day Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the month represented by the current DateTimeOffset object.

C#

```
public int Day { get; }
```

Property Value

Int32

The day component of the current DateTimeOffset object, expressed as a value between 1 and 31.

Examples

The following example displays the day component of a DateTimeOffset object in three different ways:

- By retrieving the value of the Day property.
- By calling the ToString(String) method with the "d" format specifier.
- By calling the ToString(String) method with the "dd" format specifier.

C#

```
DateTimeOffset theTime = new DateTimeOffset(2007, 5, 1, 16, 35, 0,
                                            DateTimeOffset.Now.Offset);
Console.WriteLine("The day component of {0} is {1}.",
                  theTime, theTime.Day);

Console.WriteLine("The day component of {0} is{1}.",
                  theTime, theTime.ToString(" d"));

Console.WriteLine("The day component of {0} is {1}.",
                  theTime, theTime.ToString("dd"));
```

```
// The example produces the following output:
//    The day component of 5/1/2007 4:35:00 PM -08:00 is 1.
//    The day component of 5/1/2007 4:35:00 PM -08:00 is 1.
//    The day component of 5/1/2007 4:35:00 PM -08:00 is 01.
```

Remarks

The Day property is not affected by the value of the Offset property.

You can also create a string representation of a DateTimeOffset object's day component by calling the ToString method with the "d" or "dd" custom format specifiers.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.DayOfWeek Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the week represented by the current DateTimeOffset object.

C#

```
public DayOfWeek DayOfWeek { get; }
```

Property Value

DayOfWeek

One of the enumeration values that indicates the day of the week of the current DateTimeOffset object.

Examples

The following example displays the weekday name of the first day of each month of the year 2008.

C#

```
DateTimeOffset startOfMonth = new DateTimeOffset(2008, 1, 1, 0, 0, 0,
                                                 DateTimeOffset.Now.Offset);
int year = startOfMonth.Year;
do
{
   Console.WriteLine("{0:MMM d, yyyy} is a {1}.", startOfMonth,
startOfMonth.DayOfWeek);
   startOfMonth = startOfMonth.AddMonths(1);
}
while (startOfMonth.Year == year);
// This example writes the following output to the console:
//    Jan 1, 2008 is a Tuesday.
//    Feb 1, 2008 is a Friday.
//    Mar 1, 2008 is a Saturday.
//    Apr 1, 2008 is a Tuesday.
//    May 1, 2008 is a Thursday.
```

```
//    Jun 1, 2008 is a Sunday.
//    Jul 1, 2008 is a Tuesday.
//    Aug 1, 2008 is a Friday.
//    Sep 1, 2008 is a Monday.
//    Oct 1, 2008 is a Wednesday.
//    Nov 1, 2008 is a Saturday.
//    Dec 1, 2008 is a Monday.
```

Remarks

The value of the constants in the DayOfWeek enumeration ranges from DayOfWeek.Sunday to DayOfWeek.Saturday. If cast to an integer, its value ranges from zero (which indicates DayOfWeek.Sunday) to six (which indicates DayOfWeek.Saturday).

You can also display the weekday name of a particular date by using the "D" format specifier or the "dddd" custom format specifier. For example:

C#

```
DateTimeOffset displayDate = new DateTimeOffset(2008, 1, 1, 13, 18, 00,
                                                DateTimeOffset.Now.Offset);
Console.WriteLine("{0:D}", displayDate);  // Output: Tuesday, January 01,
2008
Console.WriteLine("{0:d} is a {0:dddd}.",
                  displayDate);           // Output: 1/1/2008 is a Tuesday.
```

Note that the string returned by calling the `ToString` method of the DayOfWeek enumeration member that is returned by this property is not localized. To extract a string that contains the weekday name of the current culture or of a specific culture, call the ToString method with the "dddd" custom format specifier. For example, the following code displays the weekday name for a date using the `fr-fr` culture.

C#

```
DateTimeOffset thisDate = new DateTimeOffset(2007, 6, 1, 6, 15, 0,
                                             DateTimeOffset.Now.Offset);
string weekdayName = thisDate.ToString("dddd",
                                       new CultureInfo("fr-fr"));
Console.WriteLine(weekdayName);                  // Displays vendredi
```

DateTimeOffset.DayOfYear Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the year represented by the current DateTimeOffset object.

C#

```
public int DayOfYear { get; }
```

Property Value

Int32

The day of the year of the current DateTimeOffset object, expressed as a value between 1 and 366.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Hour Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the hour component of the time represented by the current DateTimeOffset object.

C#

```
public int Hour { get; }
```

Property Value

Int32

The hour component of the current DateTimeOffset object. This property uses a 24-hour clock; the value ranges from 0 to 23.

Examples

The following example displays the hour component of a DateTimeOffset object in three different ways:

- By retrieving the value of the Hour property.
- By calling the ToString(String) method with the "H" format specifier.
- By calling the ToString(String) method with the "HH" format specifier.

C#

```
DateTimeOffset theTime = new DateTimeOffset(2008, 3, 1, 14, 15, 00,
                                            DateTimeOffset.Now.Offset);
Console.WriteLine("The hour component of {0} is {1}.",
                  theTime, theTime.Hour);

Console.WriteLine("The hour component of {0} is{1}.",
                  theTime, theTime.ToString(" H"));

Console.WriteLine("The hour component of {0} is {1}.",
                  theTime, theTime.ToString("HH"));
```

```
// The example produces the following output:
//    The hour component of 3/1/2008 2:15:00 PM -08:00 is 14.
//    The hour component of 3/1/2008 2:15:00 PM -08:00 is 14.
//    The hour component of 3/1/2008 2:15:00 PM -08:00 is 14.
```

Remarks

The Hour property is not affected by the value of the Offset property.

You can also create a string representation of a DateTimeOffset object's hour component by calling the ToString method with the "H", or "HH" custom format specifiers.

Applies to

Product	Versions

DateTimeOffset.LocalDateTime Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTime value that represents the local date and time of the current DateTimeOffset object.

C#

```
public DateTime LocalDateTime { get; }
```

Property Value

DateTime

The local date and time of the current DateTimeOffset object.

Examples

The following example illustrates several conversions of DateTimeOffset values to local times in the U.S. Pacific Standard Time zone. Note that the last three times are all ambiguous; the property maps all of them to a single date and time in the Pacific Standard Time zone.

C#

```
 DateTimeOffset dto;

 // Current time
 dto = DateTimeOffset.Now;
 Console.WriteLine(dto.LocalDateTime);
 // UTC time
 dto = DateTimeOffset.UtcNow;
 Console.WriteLine(dto.LocalDateTime);

// Transition to DST in local time zone occurs on 3/11/2007 at 2:00 AM
 dto = new DateTimeOffset(2007, 3, 11, 3, 30, 0, new TimeSpan(-7, 0, 0));
 Console.WriteLine(dto.LocalDateTime);
 dto = new DateTimeOffset(2007, 3, 11, 2, 30, 0, new TimeSpan(-7, 0, 0));
```

```
Console.WriteLine(dto.LocalDateTime);
// Invalid time in local time zone
dto = new DateTimeOffset(2007, 3, 11, 2, 30, 0, new TimeSpan(-8, 0, 0));
Console.WriteLine(TimeZoneInfo.Local.IsInvalidTime(dto.DateTime));
Console.WriteLine(dto.LocalDateTime);

// Transition from DST in local time zone occurs on 11/4/07 at 2:00 AM
// This is an ambiguous time
dto = new DateTimeOffset(2007, 11, 4, 1, 30, 0, new TimeSpan(-7, 0, 0));
Console.WriteLine(TimeZoneInfo.Local.IsAmbiguousTime(dto));
Console.WriteLine(dto.LocalDateTime);
dto = new DateTimeOffset(2007, 11, 4, 2, 30, 0, new TimeSpan(-7, 0, 0));
Console.WriteLine(TimeZoneInfo.Local.IsAmbiguousTime(dto));
Console.WriteLine(dto.LocalDateTime);
// This is also an ambiguous time
dto = new DateTimeOffset(2007, 11, 4, 1, 30, 0, new TimeSpan(-8, 0, 0));
Console.WriteLine(TimeZoneInfo.Local.IsAmbiguousTime(dto));
Console.WriteLine(dto.LocalDateTime);
// If run on 3/8/2007 at 4:56 PM, the code produces the following
// output:
//    3/8/2007 4:56:03 PM
//    3/8/2007 4:56:03 PM
//    3/11/2007 3:30:00 AM
//    3/11/2007 1:30:00 AM
//    True
//    3/11/2007 3:30:00 AM
//    True
//    11/4/2007 1:30:00 AM
//    11/4/2007 1:30:00 AM
//    True
//    11/4/2007 1:30:00 AM
```

Remarks

If necessary, the LocalDateTime property converts the current DateTimeOffset object's date and time to the local system's date and time. The conversion is a two-step operation:

1. The property converts the current DateTimeOffset object's time to Coordinated Universal Time (UTC).

2. The property then converts UTC to local time.

There are no invalid times and ambiguous times are mapped to the local zone's standard time. (However, the conversion can create an anomaly: if a DateTimeOffset value that is derived from the local computer reflects an ambiguous date and time, that value can be converted to UTC and then back to a local time that differs from the original time.) The property applies any adjustment rules in the local time zone when it performs this conversion.

This property returns both the date and the time component of a DateTimeOffset object, which makes it useful for DateTimeOffset to DateTime conversion. In addition to performing any necessary time conversion, this property differs from the DateTime property by setting the value of the Kind property of the returned DateTime object to DateTimeKind.Local.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Microsecond Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the microsecond component of the time represented by the current DateTimeOffset object.

```
C#
public int Microsecond { get; }
```

Property Value

Int32

Remarks

If you rely on properties such as Now or UtcNow to accurately track the number of elapsed microseconds, the precision of the time's microseconds component depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10000-15000 microseconds.

Applies to

Product	Versions
.NET	7, 8, 9

Provide product feedback

DateTimeOffset.Millisecond Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the millisecond component of the time represented by the current DateTimeOffset object.

C#

```
public int Millisecond { get; }
```

Property Value

Int32

The millisecond component of the current DateTimeOffset object, expressed as an integer between 0 and 999.

Examples

The following example displays the number of milliseconds of a DateTimeOffset object by using a custom format specifier and by directly accessing the Millisecond property.

C#

```
DateTimeOffset date1 = new DateTimeOffset(2008, 3, 5, 5, 45, 35, 649,
                                  new TimeSpan(-7, 0, 0));
Console.WriteLine("Milliseconds value of {0} is {1}.",
                  date1.ToString("MM/dd/yyyy hh:mm:ss.fff"),
                  date1.Millisecond);
// The example produces the following output:
//
// Milliseconds value of 03/05/2008 05:45:35.649 is 649.
```

Remarks

You can also create a string representation of a DateTimeOffset object's millisecond component by calling the ToString method with the "fff" custom format specifier.

If you rely on properties such as Now or UtcNow to accurately track the number of elapsed milliseconds, the precision of the time's millisecond component depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.

Applies to

Product	Versions

DateTimeOffset.Minute Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minute component of the time represented by the current DateTimeOffset object.

C#

```
public int Minute { get; }
```

Property Value

Int32

The minute component of the current DateTimeOffset object, expressed as an integer between 0 and 59.

Examples

The following example displays the minute component of a DateTimeOffset object in three different ways:

- By retrieving the value of the Minute property.
- By calling the ToString(String) method with the "m" format specifier.
- By calling the ToString(String) method with the "mm" format specifier.

C#

```
DateTimeOffset theTime = new DateTimeOffset(2008, 5, 1, 10, 3, 0,
                                            DateTimeOffset.Now.Offset);
Console.WriteLine("The minute component of {0} is {1}.",
                  theTime, theTime.Minute);

Console.WriteLine("The minute component of {0} is{1}.",
                  theTime, theTime.ToString(" m"));
```

```
Console.WriteLine("The minute component of {0} is {1}.",
                  theTime, theTime.ToString("mm"));
// The example produces the following output:
//    The minute component of 5/1/2008 10:03:00 AM -08:00 is 3.
//    The minute component of 5/1/2008 10:03:00 AM -08:00 is 3.
//    The minute component of 5/1/2008 10:03:00 AM -08:00 is 03.
```

Remarks

The Minute property is not affected by the value of the Offset property.

You can also create a string representation of a DateTimeOffset object's minute component by calling the ToString method with the "m", or "mm" custom format specifiers.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Month Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the month component of the date represented by the current DateTimeOffset object.

C#

```
public int Month { get; }
```

Property Value

Int32

The month component of the current DateTimeOffset object, expressed as an integer between 1 and 12.

Examples

The following example displays the month component of a DateTimeOffset value in three different ways:

- By retrieving the value of the Month property.
- By calling the ToString(String) method with the "M" format specifier.
- By calling the ToString(String) method with the "MM" format specifier.

C#

```
DateTimeOffset theTime = new DateTimeOffset(2008, 9, 7, 11, 25, 0,
                                            DateTimeOffset.Now.Offset);
Console.WriteLine("The month component of {0} is {1}.",
                  theTime, theTime.Month);

Console.WriteLine("The month component of {0} is{1}.",
                  theTime, theTime.ToString(" M"));
```

```
Console.WriteLine("The month component of {0} is {1}.",
                  theTime, theTime.ToString("MM"));
// The example produces the following output:
//    The month component of 9/7/2008 11:25:00 AM -08:00 is 9.
//    The month component of 9/7/2008 11:25:00 AM -08:00 is 9.
//    The month component of 9/7/2008 11:25:00 AM -08:00 is 09.
```

Remarks

The Month property is not affected by the value of the Offset property.

You can also create a string representation of a DateTimeOffset object's month component by calling the ToString method with the "M" or "MM" custom format specifiers.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Nanosecond Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the nanosecond component of the time represented by the current DateTimeOffset object.

C#

```
public int Nanosecond { get; }
```

Property Value

Int32

Remarks

If you rely on properties such as Now or UtcNow to accurately track the number of elapsed nanosecond, the precision of the time's nanosecond component depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10000000-15000000 nanoseconds.

Applies to

Product	Versions
.NET	7, 8, 9

DateTimeOffset.Now Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTimeOffset object that is set to the current date and time on the current computer, with the offset set to the local time's offset from Coordinated Universal Time (UTC).

C#

```
public static DateTimeOffset Now { get; }
```

Property Value

DateTimeOffset

A DateTimeOffset object whose date and time is the current local time and whose offset is the local time zone's offset from Coordinated Universal Time (UTC).

Examples

The following example uses the Now property to retrieve the current date and time and displays it by using each of the standard date and time format strings supported by the DateTimeOffset type.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] fmtStrings = { "d", "D", "f", "F", "g", "G", "M",
                              "R", "s", "t", "T", "u", "y" };

      DateTimeOffset value = DateTimeOffset.Now;
      // Display date in default format.
      Console.WriteLine(value);
```

```
      Console.WriteLine();

      // Display date using each of the specified formats.
      foreach (var fmtString in fmtStrings)
         Console.WriteLine("{0} --> {1}",
                           fmtString, value.ToString(fmtString));
   }
}
// The example displays output similar to the following:
//    11/19/2012 10:57:11 AM -08:00
//
//    d --> 11/19/2012
//    D --> Monday, November 19, 2012
//    f --> Monday, November 19, 2012 10:57 AM
//    F --> Monday, November 19, 2012 10:57:11 AM
//    g --> 11/19/2012 10:57 AM
//    G --> 11/19/2012 10:57:11 AM
//    M --> November 19
//    R --> Mon, 19 Nov 2012 18:57:11 GMT
//    s --> 2012-11-19T10:57:11
//    t --> 10:57 AM
//    T --> 10:57:11 AM
//    u --> 2012-11-19 18:57:11Z
//    y --> November, 2012
```

The following example uses the Now and Millisecond properties to determine the resolution of the system clock. It displays the time only when the value of its millisecond component has changed.

C#

```
DateTimeOffset dto;
int ctr = 0;
int ms = 0;
do {
   dto = DateTimeOffset.Now;
   if (dto.Millisecond != ms)
   {
      ms = dto.Millisecond;
      Console.WriteLine("{0}:{1:d3} ms. {2}",
                        dto.ToString("M/d/yyyy h:mm:ss"),
                        ms, dto.ToString("zzz"));
      ctr++;
   }
} while (ctr < 100);
```

Remarks

The precision of the current local time's millisecond component depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

DateTimeOffset.Offset Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time's offset from Coordinated Universal Time (UTC).

C#

```
public TimeSpan Offset { get; }
```

Property Value

TimeSpan

The difference between the current DateTimeOffset object's time value and Coordinated Universal Time (UTC).

Examples

The following example uses the Offset property to display the local time's difference from Coordinated Universal Time (UTC).

C#

```
DateTimeOffset localTime = DateTimeOffset.Now;
Console.WriteLine("The local time zone is {0} hours and {1} minutes {2} than
UTC.",
                  Math.Abs(localTime.Offset.Hours),
                  localTime.Offset.Minutes,
                  localTime.Offset.Hours < 0 ? "earlier" : "later");
// The example displays output similar to the following for a system in the
// U.S. Pacific Standard Time zone:
//       The local time zone is 8 hours and 0 minutes earlier than UTC.
```

Remarks

The value of the Hours property of the returned TimeSpan object can range from -14 hours to 14 hours.

The value of the Offset property is precise to the minute.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Second Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the second component of the clock time represented by the current DateTimeOffset object.

C#

```
public int Second { get; }
```

Property Value

Int32

The second component of the DateTimeOffset object, expressed as an integer value between 0 and 59.

Examples

The following example displays the second component of a DateTimeOffset object in three different ways:

- By retrieving the value of the Second property.
- By calling the ToString(String) method with the "s" format specifier.
- By calling the ToString(String) method with the "ss" format specifier.

C#

```
DateTimeOffset theTime = new DateTimeOffset(2008, 6, 12, 21, 16, 32,
                             DateTimeOffset.Now.Offset);
Console.WriteLine("The second component of {0} is {1}.",
                  theTime, theTime.Second);

Console.WriteLine("The second component of {0} is{1}.",
                  theTime, theTime.ToString(" s"));
```

```
Console.WriteLine("The second component of {0} is {1}.",
                  theTime, theTime.ToString("ss"));
// The example produces the following output:
//    The second component of 6/12/2008 9:16:32 PM -07:00 is 32.
//    The second component of 6/12/2008 9:16:32 PM -07:00 is 32.
//    The second component of 6/12/2008 9:16:32 PM -07:00 is 32.
```

Remarks

The Second property is not affected by the value of the Offset property.

You can also create a string representation of a DateTimeOffset object's second component by calling the ToString method with the "s", or "ss" custom format specifiers.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Ticks Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of ticks that represents the date and time of the current DateTimeOffset object in clock time.

C#

```
public long Ticks { get; }
```

Property Value

Int64

The number of ticks in the DateTimeOffset object's clock time.

Examples

The following example initializes a DateTimeOffset object by approximating the number of ticks in the date July 1, 2008 1:23:07. It then displays the date and the number of ticks represented by that date to the console.

C#

```
// Attempt to initialize date to number of ticks
// in July 1, 2008 1:23:07.
//
// There are 10,000,000 100-nanosecond intervals in a second
const long NSPerSecond = 10000000;
long ticks;
ticks = 7 * NSPerSecond;                        // Ticks in a 7 seconds
ticks += 23 * 60 * NSPerSecond;                 // Ticks in 23 minutes
ticks += 1 * 60 * 60 * NSPerSecond;             // Ticks in 1 hour
ticks += 60 * 60 * 24 * NSPerSecond;            // Ticks in 1 day
ticks += 181 * 60 * 60 * 24 * NSPerSecond;      // Ticks in 6 months
ticks += 2007 * 60 * 60 * 24 * 365L * NSPerSecond;   // Ticks in 2007 years
ticks += 486 * 60 * 60 * 24 * NSPerSecond;      // Adjustment for leap years
DateTimeOffset dto = new DateTimeOffset(
                         ticks,
```

```
                                DateTimeOffset.Now.Offset);
Console.WriteLine("There are {0:n0} ticks in {1}.",
                  dto.Ticks,
                  dto.ToString());
// The example displays the following output:
//       There are 633,504,721,870,000,000 ticks in 7/1/2008 1:23:07 AM
-08:00.
```

Remarks

The Ticks property is not affected by the value of the Offset property.

The value of the Ticks property represents the number of 100-nanosecond intervals that have elapsed since 12:00:00 midnight on January 1, 0001 (the value of MinValue). It does not include ticks that would be added by leap seconds. A nanosecond is one billionth of a second; there are ten million ticks in a second. The value of the Ticks property ranges from `DateTimeOffset.MinValue.Ticks` to `DateTimeOffset.MaxValue.Ticks`.

You can assign the number of ticks to a DateTimeOffset object by using the DateTimeOffset(Int64, TimeSpan) constructor overload.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.TimeOfDay Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time of day for the current DateTimeOffset object.

C#

```
public TimeSpan TimeOfDay { get; }
```

Property Value

TimeSpan

The time interval of the current date that has elapsed since midnight.

Examples

The following example uses the TimeOfDay property to extract the time and display it to the console.

C#

```
DateTimeOffset currentDate = new DateTimeOffset(2008, 5, 10, 5, 32, 16,
                                                DateTimeOffset.Now.Offset);
TimeSpan currentTime = currentDate.TimeOfDay;
Console.WriteLine("The current time is {0}.", currentTime.ToString());
// The example produces the following output:
//       The current time is 05:32:16.
```

Remarks

The TimeOfDay property is not affected by the value of the Offset property.

The TimeOfDay property returns the time component of a DateTimeOffset object in the form of a TimeSpan object. It is equivalent to the DateTime.TimeOfDay property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeOffset.UtcDateTime Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTime value that represents the Coordinated Universal Time (UTC) date and time of the current DateTimeOffset object.

C#

```
public DateTime UtcDateTime { get; }
```

Property Value

DateTime

The Coordinated Universal Time (UTC) date and time of the current DateTimeOffset object.

Examples

The following example shows how to use of the UtcDateTime property to display a DateTimeOffset value and its corresponding UTC time.

C#

```
DateTimeOffset offsetTime = new DateTimeOffset(2007, 11, 25, 11, 14, 00,
                            new TimeSpan(3, 0, 0));
Console.WriteLine("{0} is equivalent to {1} {2}",
                  offsetTime.ToString(),
                  offsetTime.UtcDateTime.ToString(),
                  offsetTime.UtcDateTime.Kind.ToString());
// The example displays the following output:
//       11/25/2007 11:14:00 AM +03:00 is equivalent to 11/25/2007 8:14:00
AM Utc
```

Remarks

The UtcDateTime property performs a dual conversion:

- It converts the date and time of the current DateTimeOffset object to Coordinated Universal Time (UTC). The conversion is performed by subtracting the value of the Offset property from the date and time of the current DateTimeOffset object.
- It converts the DateTimeOffset value to a DateTime value.

The Kind property of the returned DateTime value is set to DateTimeKind.Utc.

Retrieving the value of the UtcDateTime property is equivalent to calling the current DateTimeOffset object's `ToUniversalTime.DateTime` property, except that the Kind property of the latter DateTime value is DateTimeKind.Unspecified.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.UtcNow Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a DateTimeOffset object whose date and time are set to the current Coordinated Universal Time (UTC) date and time and whose offset is Zero.

C#

```
public static DateTimeOffset UtcNow { get; }
```

Property Value

DateTimeOffset

An object whose date and time is the current Coordinated Universal Time (UTC) and whose offset is Zero.

Examples

The following example illustrates the relationship between Coordinated Universal Time (UTC) and local time.

C#

```
DateTimeOffset localTime = DateTimeOffset.Now;
DateTimeOffset utcTime = DateTimeOffset.UtcNow;

Console.WriteLine("Local Time:          {0}", localTime.ToString("T"));
Console.WriteLine("Difference from UTC: {0}", localTime.Offset.ToString());
Console.WriteLine("UTC:                 {0}", utcTime.ToString("T"));
// If run on a particular date at 1:19 PM, the example produces
// the following output:
//    Local Time:          1:19:43 PM
//    Difference from UTC: -07:00:00
//    UTC:                 8:19:43 PM
```

Remarks

The UtcNow property computes the current Universal Coordinated Time (UTC) based on the local system's clock time and an offset defined by the local system's time zone.

The precision of the current UTC time's millisecond component depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.

DateTimeOffset.UtcTicks Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of ticks that represents the date and time of the current DateTimeOffset object in Coordinated Universal Time (UTC).

```
C#
public long UtcTicks { get; }
```

Property Value

Int64

The number of ticks in the DateTimeOffset object's Coordinated Universal Time (UTC).

Remarks

The value of the UtcTicks property represents the number of 100-nanosecond intervals that have elapsed since 12:00:00 midnight on January 1, 0001 (the value of MinValue). It does not include ticks that would be added by leap seconds. A nanosecond is one billionth of a second; there are ten million ticks in a second. The value of the UtcTicks property ranges from `DateTimeOffset.MinValue.Ticks` to `DateTimeOffset.MaxValue.Ticks`.

Applies to

Product	Versions

DateTimeOffset.Year Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the year component of the date represented by the current DateTimeOffset object.

C#

```
public int Year { get; }
```

Property Value

Int32

The year component of the current DateTimeOffset object, expressed as an integer value between 0 and 9999.

Examples

The following example displays the year component of a DateTimeOffset value in four different ways:

- By retrieving the value of the Year property.
- By calling the ToString(String) method with the "y" format specifier.
- By calling the ToString(String) method with the "yy" format specifier.
- By calling the ToString(String) method with the "yyyy" format specifier.

C#

```
DateTimeOffset theTime = new DateTimeOffset(2008, 2, 17, 9, 0, 0,
                             DateTimeOffset.Now.Offset);
Console.WriteLine("The year component of {0} is {1}.",
                  theTime, theTime.Year);

Console.WriteLine("The year component of {0} is{1}.",
                  theTime, theTime.ToString(" y"));
```

```
Console.WriteLine("The year component of {0} is {1}.",
                  theTime, theTime.ToString("yy"));

Console.WriteLine("The year component of {0} is {1}.",
                  theTime, theTime.ToString("yyyy"));
// The example produces the following output:
//    The year component of 2/17/2008 9:00:00 AM -07:00 is 2008.
//    The year component of 2/17/2008 9:00:00 AM -07:00 is 8.
//    The year component of 2/17/2008 9:00:00 AM -07:00 is 08.
//    The year component of 2/17/2008 9:00:00 AM -07:00 is 2008.
```

Remarks

The Year property is not affected by the value of the Offset property.

You can also create a string representation of a DateTimeOffset object's year component by calling the ToString method with the "y", "yy", or "yyyy" custom format specifiers.

DateTimeOffset.Add(TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified time interval to the value of this instance.

```
C#

public DateTimeOffset Add (TimeSpan timeSpan);
```

Parameters

`timeSpan` TimeSpan

A TimeSpan object that represents a positive or a negative time interval.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the time interval represented by `timeSpan`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Examples

The following example creates an array of TimeSpan objects that represent the flight times between destinations. The Add method then adds these times to a

DateTimeOffset object that represents a flight's initial takeoff time. The result reflects the scheduled arrival time at each destination.

C#

```
DateTimeOffset takeOff = new DateTimeOffset(2007, 6, 1, 7, 55, 0,
                             new TimeSpan(-5, 0, 0));
DateTimeOffset currentTime = takeOff;
TimeSpan[] flightTimes = new TimeSpan[]
                  {new TimeSpan(2, 25, 0), new TimeSpan(1, 48, 0)};
Console.WriteLine("Takeoff is scheduled for {0:d} at {0:T}.",
                  takeOff);
for (int ctr = flightTimes.GetLowerBound(0);
     ctr <= flightTimes.GetUpperBound(0); ctr++)
{
   currentTime = currentTime.Add(flightTimes[ctr]);
   Console.WriteLine("Destination #{0} at {1}.", ctr + 1, currentTime);
}
```

Remarks

You can use the Add method to add more than one kind of time interval (days, hours, minutes, seconds, or milliseconds) in a single operation. This method's behavior is identical to the addition operator. The DateTimeOffset structure also supports specialized addition methods (such as AddDays, AddHours, and AddMinutes) for each time interval.

> ⓘ **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `timeSpan` to its date and time.

The Add method does not affect the value of the current DateTimeOffset object's Offset property.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the Add method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

If the `timeSpan` parameter is `null`, this method returns the value of the original DateTimeOffset object unchanged.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.AddDays(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of whole and fractional days to the value of this instance.

```
C#

public DateTimeOffset AddDays (double days);
```

Parameters

days Double

A number of whole and fractional days. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of days represented by `days`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Examples

The following example uses the AddDays method to list the dates that fall on Monday, the start of the work week, in March 2008.

C#

```
DateTimeOffset workDay = new DateTimeOffset(2008, 3, 1, 9, 0, 0,
                    DateTimeOffset.Now.Offset);
int month = workDay.Month;
// Start with the first Monday of the month
if (workDay.DayOfWeek != DayOfWeek.Monday)
{
   if (workDay.DayOfWeek == DayOfWeek.Sunday)
      workDay = workDay.AddDays(1);
   else
      workDay = workDay.AddDays(8 - (int)workDay.DayOfWeek);
}
Console.WriteLine("Beginning of Work Week In {0:MMMM} {0:yyyy}:", workDay);
// Add one week to the current date
do
{
   Console.WriteLine("   {0:dddd}, {0:MMMM}{0: d}", workDay);
   workDay = workDay.AddDays(7);
} while (workDay.Month == month);
// The example produces the following output:
//    Beginning of Work Week In March 2008:
//       Monday, March 3
//       Monday, March 10
//       Monday, March 17
//       Monday, March 24
//       Monday, March 31
```

Remarks

The fractional part of the `days` parameter is the fractional part of a day. For example, 4.5 is equivalent to 4 days, 12 hours, 0 minutes, 0 seconds, 0 milliseconds.

In .NET 6 and earlier versions, the `days` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `days` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

> **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `days` to its date and time.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddDays method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

Converting time intervals of less than a day to a fraction can involve a loss of precision. If this is problematic, you can use the Add method, which enables you to specify more than one kind of time interval in a single method call and eliminates the need to convert time intervals to fractional parts of a day.

Applies to

DateTimeOffset.AddHours(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of whole and fractional hours to the value of this instance.

```
C#

public DateTimeOffset AddHours (double hours);
```

Parameters

hours Double

A number of whole and fractional hours. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of hours represented by `hours`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Examples

The following example uses the AddHours method to list the start times of work shifts for a particular week at an office that has two eight-hour shifts per day.

C#

```
const int SHIFT_LENGTH = 8;

DateTimeOffset startTime = new DateTimeOffset(2007, 8, 6, 0, 0, 0,
                      DateTimeOffset.Now.Offset);
DateTimeOffset startOfShift = startTime.AddHours(SHIFT_LENGTH);

Console.WriteLine("Shifts for the week of {0:D}", startOfShift);
do
{
   // Exclude third shift
   if (startOfShift.Hour > 6)
      Console.WriteLine("   {0:d} at {0:T}", startOfShift);

   startOfShift = startOfShift.AddHours(SHIFT_LENGTH);
} while (startOfShift.DayOfWeek != DayOfWeek.Saturday &
            startOfShift.DayOfWeek != DayOfWeek.Sunday);
// The example produces the following output:
//
//    Shifts for the week of Monday, August 06, 2007
//       8/6/2007 at 8:00:00 AM
//       8/6/2007 at 4:00:00 PM
//       8/7/2007 at 8:00:00 AM
//       8/7/2007 at 4:00:00 PM
//       8/8/2007 at 8:00:00 AM
//       8/8/2007 at 4:00:00 PM
//       8/9/2007 at 8:00:00 AM
//       8/9/2007 at 4:00:00 PM
//       8/10/2007 at 8:00:00 AM
//       8/10/2007 at 4:00:00 PM
```

Remarks

The fractional part of the `hours` parameter is the fractional part of an hour. For example, 4.5 is equivalent to 4 hours, 30 minutes, 0 seconds, 0 milliseconds.

In .NET 6 and earlier versions, the `hours` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `hours` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

Note

This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `hours` to its date and time.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddHours method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

Converting time intervals of less than an hour to a fraction can involve a loss of precision. (For example, one minute is 0.01666 of an hour.) If this is problematic, you can use the Add method, which enables you to specify more than one kind of time interval in a single method call and eliminates the need to convert time intervals to fractional parts of an hour.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.AddMicroseconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of microseconds to the value of this instance.

```
C#

public DateTimeOffset AddMicroseconds (double microseconds);
```

Parameters

`microseconds` Double

A number of whole and fractional microseconds. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of whole microseconds represented by `microseconds`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Remarks

The fractional part of value is the fractional part of a microsecond. For example, 4.5 is equivalent to 4 microseconds and 50 ticks, where one microseconds = 10 ticks. However, `microseconds` is rounded to the nearest microsecond; all values of .5 or greater are rounded up.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddMicroseconds(Double) method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

DateTimeOffset.Add Milliseconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of milliseconds to the value of this instance.

```
C#

public DateTimeOffset AddMilliseconds (double milliseconds);
```

Parameters

`milliseconds` Double

A number of whole and fractional milliseconds. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of whole milliseconds represented by `milliseconds`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Remarks

The fractional part of the `milliseconds` parameter is the fractional part of a millisecond. For example, 4.5 is equivalent to 4 milliseconds and 5000 ticks, where one millisecond equals 10,000 ticks. However, in .NET 6 and earlier versions, `milliseconds` is rounded to the nearest millisecond, and all values of .5 or greater are rounded up. In .NET 7 and later versions, the full Double precision of the `milliseconds` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

> **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `milliseconds` to its date and time.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddMilliseconds method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

DateTimeOffset.AddMinutes(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of whole and fractional minutes to the value of this instance.

```
C#

public DateTimeOffset AddMinutes (double minutes);
```

Parameters

`minutes` Double

A number of whole and fractional minutes. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of minutes represented by `minutes`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Remarks

The fractional part of the `minutes` parameter is the fractional part of a minute. For example, 4.5 is equivalent to 4 minutes, 30 seconds, 0 milliseconds.

In .NET 6 and earlier versions, the `minutes` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `minutes` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

> ⓘ **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `minutes` to its date and time.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddMinutes method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

Converting time intervals of less than a minute to a fraction can involve a loss of precision. (For example, one second is 0.01666 of a minute.) If this is problematic, you can use the Add method, which enables you to specify more than one kind of time interval in a single method call and eliminates the need to convert time intervals to fractional parts of a minute.

DateTimeOffset.AddMonths(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of months to the value of this instance.

```
C#

public DateTimeOffset AddMonths (int months);
```

Parameters

`months` Int32

A number of whole months. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of months represented by `months`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Examples

The following example uses the AddMonths method to display the start date of each quarter of the year 2007.

C#

```
DateTimeOffset quarterDate = new DateTimeOffset(2007, 1, 1, 0, 0, 0,
                                 DateTimeOffset.Now.Offset);
for (int ctr = 1; ctr <= 4; ctr++)
{
   Console.WriteLine("Quarter {0}: {1:MMMM d}", ctr, quarterDate);
   quarterDate = quarterDate.AddMonths(3);
}
// This example produces the following output:
//       Quarter 1: January 1
//       Quarter 2: April 1
//       Quarter 3: July 1
//       Quarter 4: October 1
```

Remarks

Unlike most of the other methods that add a single time interval unit (such as minutes or days) to a date and time value, AddMonths does not enable you to add fractional parts of a month. To add a time that consists of other time units in addition to months to a DateTimeOffset object, use the Add method.

> ⓘ **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `months` to its date and time.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeOffset.AddSeconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of whole and fractional seconds to the value of this instance.

```
C#

public DateTimeOffset AddSeconds (double seconds);
```

Parameters

`seconds` Double

A number of whole and fractional seconds. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of seconds represented by `seconds`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Remarks

The fractional part of the `seconds` parameter is the fractional part of a second. The value of fractional parts of a second are shown in the following table.

Expand table

Second value	Equivalent
.1 second	100 milliseconds
.01 second	10 milliseconds
.001 second	1 millisecond

In .NET 6 and earlier versions, the `seconds` parameter is rounded to the nearest millisecond. In .NET 7 and later versions, the full Double precision of the `seconds` parameter is used. However, due to the inherent imprecision of floating point math, the resulting precision will vary.

> **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `seconds` to its date and time.

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddSeconds method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.AddTicks(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of ticks to the value of this instance.

```
C#

public DateTimeOffset AddTicks (long ticks);
```

Parameters

`ticks` Int64

A number of 100-nanosecond ticks. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of ticks represented by `ticks`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Remarks

A tick represents 100 nanoseconds, or one-ten millionth of a second. Because a tick is a very small and precise time interval, any larger time unit can be expressed as a number of ticks without a loss of precision.

> **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `ticks` to its date and time.

The following table lists the number of ticks in a particular time interval.

Expand table

Time interval	Number of ticks
Second	10,000,000
Minute	600,000,000
Hour	36,000,000,000
Day	864,000,000,000
Week	6,048,000,000,000
Month	Depends on number of days in the month.
Non-leap year	315,360,000,000,000
Leap year	316,224,000,000,000

Because a DateTimeOffset object does not represent the date and time in a specific time zone, the AddTicks method does not consider a particular time zone's adjustment rules when it performs date and time arithmetic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.AddYears(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new DateTimeOffset object that adds a specified number of years to the value of this instance.

```
C#

public DateTimeOffset AddYears (int years);
```

Parameters

years Int32

A number of years. The number can be negative or positive.

Returns

DateTimeOffset

An object whose value is the sum of the date and time represented by the current DateTimeOffset object and the number of years represented by `years`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Examples

In the United States, driver's licenses cannot be issued to persons under 16 years of age. The following example displays the latest possible date on which a person must be born in order to legally be issued a driver's license.

C#

```
const int minimumAge = 16;
DateTimeOffset dateToday = DateTimeOffset.Now;
DateTimeOffset latestBirthday = dateToday.AddYears(-1 * minimumAge);
Console.WriteLine("To possess a driver's license, you must have been born on
or before {0:d}.",
                  latestBirthday);
```

Remarks

Unlike most of the other methods that add a single time interval unit (such as minutes or days) to a date and time value, AddYears does not enable you to add fractional parts of a year. To add a time that consists of other time units in addition to years to a DateTimeOffset object, use the Add method.

> **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by adding `years` to its date and time.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Compare(DateTimeOffset, DateTimeOffset) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two DateTimeOffset objects and indicates whether the first is earlier than the second, equal to the second, or later than the second.

C#

```
public static int Compare (DateTimeOffset first, DateTimeOffset second);
```

Parameters

`first` DateTimeOffset

The first object to compare.

`second` DateTimeOffset

The second object to compare.

Returns

Int32

A signed integer that indicates whether the value of the `first` parameter is earlier than, later than, or the same time as the value of the `second` parameter, as the following table shows.

Expand table

Return value	Meaning
Less than zero	`first` is earlier than `second`.
Zero	`first` is equal to `second`.

Return value	Meaning
Greater than zero	`first` is later than `second`.

Examples

The following example illustrates calls to the Compare method to compare DateTimeOffset objects.

C#

```
using System;

public class CompareTimes
{
   private enum TimeComparison
   {
      Earlier = -1,
      Same = 0,
      Later = 1
   };

   public static void Main()
   {
      DateTimeOffset firstTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                                 new TimeSpan(-7, 0, 0));

      DateTimeOffset secondTime = firstTime;
      Console.WriteLine("Comparing {0} and {1}: {2}",
                        firstTime, secondTime,
                        (TimeComparison) DateTimeOffset.Compare(firstTime,
secondTime));

      secondTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                       new TimeSpan(-6, 0, 0));
      Console.WriteLine("Comparing {0} and {1}: {2}",
                       firstTime, secondTime,
                       (TimeComparison) DateTimeOffset.Compare(firstTime,
secondTime));

      secondTime = new DateTimeOffset(2007, 9, 1, 8, 45, 0,
                       new TimeSpan(-5, 0, 0));
      Console.WriteLine("Comparing {0} and {1}: {2}",
                       firstTime, secondTime,
                       (TimeComparison) DateTimeOffset.Compare(firstTime,
secondTime));
      // The example displays the following output to the console:
      //       Comparing 9/1/2007 6:45:00 AM -07:00 and 9/1/2007 6:45:00 AM
-07:00: Same
      //       Comparing 9/1/2007 6:45:00 AM -07:00 and 9/1/2007 6:45:00 AM
-06:00: Later
      //       Comparing 9/1/2007 6:45:00 AM -07:00 and 9/1/2007 8:45:00 AM
```

```
-05:00: Same
    }
}
```

Remarks

In performing the comparison, the method converts both the `first` and the `second` parameters to Coordinated Universal Time (UTC) before it performs the comparison. The method is equivalent to the following:

```C#
return DateTime.Compare(first.UtcDateTime, second.UtcDateTime);
```

In other words, the Compare method determines whether two DateTimeOffset objects represent a single point in time. It directly compares neither dates and times nor offsets.

Applies to

Product	Versions

DateTimeOffset.CompareTo(DateTimeOffset) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current DateTimeOffset object to a specified DateTimeOffset object and indicates whether the current object is earlier than, the same as, or later than the second DateTimeOffset object.

C#

```
public int CompareTo (DateTimeOffset other);
```

Parameters

other DateTimeOffset

An object to compare with the current DateTimeOffset object.

Returns

Int32

A signed integer that indicates the relationship between the current DateTimeOffset object and `other`, as the following table shows.

Expand table

Return Value	Description
Less than zero	The current DateTimeOffset object is earlier than `other`.
Zero	The current DateTimeOffset object is the same as `other`.
Greater than zero.	The current DateTimeOffset object is later than `other`.

Implements

CompareTo(T)

Examples

The following example illustrates calls to the CompareTo method to compare DateTimeOffset objects.

C#

```
using System;

public class CompareTimes
{
   private enum TimeComparison
   {
      Earlier = -1,
      Same = 0,
      Later = 1
   };

   public static void Main()
   {
      DateTimeOffset firstTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                                 new TimeSpan(-7, 0, 0));

      DateTimeOffset secondTime = firstTime;
      Console.WriteLine("Comparing {0} and {1}: {2}",
                        firstTime, secondTime,
                        (TimeComparison) firstTime.CompareTo(secondTime));

      secondTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                       new TimeSpan(-6, 0, 0));
      Console.WriteLine("Comparing {0} and {1}: {2}",
                       firstTime, secondTime,
                       (TimeComparison) firstTime.CompareTo(secondTime));

      secondTime = new DateTimeOffset(2007, 9, 1, 8, 45, 0,
                       new TimeSpan(-5, 0, 0));
      Console.WriteLine("Comparing {0} and {1}: {2}",
                       firstTime, secondTime,
                       (TimeComparison) firstTime.CompareTo(secondTime));
      // The example displays the following output to the console:
      //       Comparing 9/1/2007 6:45:00 AM -07:00 and 9/1/2007 6:45:00 AM
-07:00: Same
      //       Comparing 9/1/2007 6:45:00 AM -07:00 and 9/1/2007 6:45:00 AM
-06:00: Later
      //       Comparing 9/1/2007 6:45:00 AM -07:00 and 9/1/2007 8:45:00 AM
-05:00: Same
   }
}
```

Remarks

This method compares DateTimeOffset objects by comparing their UtcDateTime values; that is, it determines whether the two objects represent a single point in time, and indicates whether the current object is earlier than, later than, or the same as the `other` parameter.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeOffset.Deconstruct(DateOnly, TimeOnly, TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Deconstructs this DateTimeOffset instance by DateOnly, TimeOnly, and TimeSpan.

C#

```
public void Deconstruct (out DateOnly date, out TimeOnly time, out TimeSpan
offset);
```

Parameters

`date` DateOnly

When this method returns, represents the DateOnly value of this DateTimeOffset instance.

`time` TimeOnly

When this method returns, represents the TimeOnly value of this DateTimeOffset instance.

`offset` TimeSpan

When this method returns, represents the Offset value of this DateTimeOffset instance.

Applies to

Product	Versions
.NET	8, 9

DateTimeOffset.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two DateTimeOffset objects are equal, or a DateTimeOffset object is equal to a specified object.

Overloads

Expand table

Equals(DateTimeOffset)	Determines whether the current DateTimeOffset object represents the same point in time as a specified DateTimeOffset object.
Equals(Object)	Determines whether a DateTimeOffset object represents the same point in time as a specified object.
Equals(DateTimeOffset, DateTimeOffset)	Determines whether two specified DateTimeOffset objects represent the same point in time.

Equals(DateTimeOffset)

Determines whether the current DateTimeOffset object represents the same point in time as a specified DateTimeOffset object.

C#

```
public bool Equals (DateTimeOffset other);
```

Parameters

`other` DateTimeOffset

An object to compare to the current DateTimeOffset object.

Returns

Boolean

`true` if both DateTimeOffset objects have the same UtcDateTime value; otherwise, `false`.

Implements

Equals(T)

Examples

The following example illustrates calls to the Equals(DateTimeOffset) method to test DateTimeOffset objects for equality with the current DateTimeOffset object.

C#

```
private static void CompareForEquality1()
{
   DateTimeOffset firstTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                              new TimeSpan(-7, 0, 0));

   DateTimeOffset secondTime = firstTime;
   Console.WriteLine("{0} = {1}: {2}",
                     firstTime, secondTime,
                     firstTime.Equals(secondTime));

   secondTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                    new TimeSpan(-6, 0, 0));
   Console.WriteLine("{0} = {1}: {2}",
                    firstTime, secondTime,
                    firstTime.Equals(secondTime));

   secondTime = new DateTimeOffset(2007, 9, 1, 8, 45, 0,
                    new TimeSpan(-5, 0, 0));
   Console.WriteLine("{0} = {1}: {2}",
                    firstTime, secondTime,
                    firstTime.Equals(secondTime));
   // The example displays the following output to the console:
   //      9/1/2007 6:45:00 AM -07:00 = 9/1/2007 6:45:00 AM -07:00: True
   //      9/1/2007 6:45:00 AM -07:00 = 9/1/2007 6:45:00 AM -06:00: False
   //      9/1/2007 6:45:00 AM -07:00 = 9/1/2007 8:45:00 AM -05:00: True
```

Remarks

Before it performs the comparison, this method converts the values of both DateTimeOffset objects to Coordinated Universal Time (UTC). The method is

equivalent to the following:

```
C#

return this.UtcDateTime == other.UtcDateTime;
```

In other words, the Equals(DateTimeOffset) method determines whether two DateTimeOffset objects represent a single point in time. It directly compares neither dates and times nor offsets. To determine whether two DateTimeOffset objects represent the same time and have the same offset value, use the EqualsExact method.

A DateTimeOffset object that is not `null` is considered to be later (or greater) than one that is `null`.

This overload of the Equals(DateTimeOffset) method implements the IEquatable<T>.Equals method. It offers slightly better performance than the DateTimeOffset.Equals(Object) overload because the `other` parameter does not have to be converted from an object.

See also

- EqualsExact(DateTimeOffset)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Determines whether a DateTimeOffset object represents the same point in time as a specified object.

```
C#

public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare to the current DateTimeOffset object.

Returns

Boolean

`true` if the `obj` parameter is a DateTimeOffset object and represents the same point in time as the current DateTimeOffset object; otherwise, `false`.

Examples

The following example indicates whether the current DateTimeOffset object is equal to several other DateTimeOffset objects, as well as to a null reference and a DateTime object.

```
C#

private static void CompareForEquality2()
{
   DateTimeOffset firstTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                              new TimeSpan(-7, 0, 0));

   object secondTime = firstTime;
   Console.WriteLine("{0} = {1}: {2}",
                     firstTime, secondTime,
                     firstTime.Equals(secondTime));

   secondTime = new DateTimeOffset(2007, 9, 1, 6, 45, 0,
                    new TimeSpan(-6, 0, 0));
   Console.WriteLine("{0} = {1}: {2}",
                    firstTime, secondTime,
                    firstTime.Equals(secondTime));

   secondTime = new DateTimeOffset(2007, 9, 1, 8, 45, 0,
                    new TimeSpan(-5, 0, 0));
   Console.WriteLine("{0} = {1}: {2}",
                    firstTime, secondTime,
```

```
                    firstTime.Equals(secondTime));

    secondTime = null;
    Console.WriteLine("{0} = {1}: {2}",
                    firstTime, secondTime,
                    firstTime.Equals(secondTime));

    secondTime = new DateTime(2007, 9, 1, 6, 45, 00);
    Console.WriteLine("{0} = {1}: {2}",
                    firstTime, secondTime,
                    firstTime.Equals(secondTime));
    // The example displays the following output to the console:
    //       9/1/2007 6:45:00 AM -07:00 = 9/1/2007 6:45:00 AM -07:00: True
    //       9/1/2007 6:45:00 AM -07:00 = 9/1/2007 6:45:00 AM -06:00:
  False
    //       9/1/2007 6:45:00 AM -07:00 = 9/1/2007 8:45:00 AM -05:00: True
    //       9/1/2007 6:45:00 AM -07:00 = : False
    //       9/1/2007 6:45:00 AM -07:00 = 9/1/2007 6:45:00 AM: False
```

Remarks

Before it performs the comparison, this method converts the values of both the current DateTimeOffset object and the `obj` parameter to Coordinated Universal Time (UTC). The method is equivalent to the following:

```
C#

return this.UtcDateTime == ((DateTimeOffset) obj).UtcDateTime;
```

In other words, the DateTimeOffset.Equals(Object) method determines whether the current DateTimeOffset object and a specified object represent a single point in time. It directly compares neither dates and times nor offsets. To determine whether two DateTimeOffset objects represent the same time and have the same offset value, use the EqualsExact method.

If `obj` is `null`, or if the run-time type of `obj` is not DateTimeOffset, the method returns `false`.

UWP	10.0

Equals(DateTimeOffset, DateTimeOffset)

Determines whether two specified DateTimeOffset objects represent the same point in time.

```
C#

public static bool Equals (DateTimeOffset first, DateTimeOffset second);
```

Parameters

`first` DateTimeOffset

The first object to compare.

`second` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if the two DateTimeOffset objects have the same UtcDateTime value; otherwise, `false`.

Examples

The following example illustrates calls to the Equals(DateTimeOffset, DateTimeOffset) method to test various pairs of DateTimeOffset objects for equality.

```
C#
```

```
DateTimeOffset firstTime = new DateTimeOffset(2007, 11, 15, 11, 35, 00,
                                    DateTimeOffset.Now.Offset);
DateTimeOffset secondTime = firstTime;
Console.WriteLine("{0} = {1}: {2}",
                  firstTime, secondTime,
                  DateTimeOffset.Equals(firstTime, secondTime));

// The value of firstTime remains unchanged
secondTime = new DateTimeOffset(firstTime.DateTime,
             TimeSpan.FromHours(firstTime.Offset.Hours + 1));
Console.WriteLine("{0} = {1}: {2}",
                  firstTime, secondTime,
                  DateTimeOffset.Equals(firstTime, secondTime));

// value of firstTime remains unchanged
secondTime = new DateTimeOffset(firstTime.DateTime +
TimeSpan.FromHours(1),
                                TimeSpan.FromHours(firstTime.Offset.Hours
+ 1));
Console.WriteLine("{0} = {1}: {2}",
                  firstTime, secondTime,
                  DateTimeOffset.Equals(firstTime, secondTime));
 // The example produces the following output:
 //       11/15/2007 11:35:00 AM -07:00 = 11/15/2007 11:35:00 AM -07:00:
True
 //       11/15/2007 11:35:00 AM -07:00 = 11/15/2007 11:35:00 AM -06:00:
False
 //       11/15/2007 11:35:00 AM -07:00 = 11/15/2007 12:35:00 PM -06:00:
True
```

Remarks

Before it performs the comparison, this method converts both DateTimeOffset objects to Coordinated Universal Time (UTC). The method is equivalent to the following:

C#

```
return first.UtcDateTime == second.UtcDateTime;
```

In other words, the Equals(DateTimeOffset, DateTimeOffset) method determines whether the two DateTimeOffset objects represent a single point in time. It directly compares neither dates and times nor offsets. To determine whether two DateTimeOffset objects represent the same time and have the same offset value, use the EqualsExact method.

DateTimeOffset.Equals Exact(DateTimeOffset) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the current DateTimeOffset object represents the same time and has the same offset as a specified DateTimeOffset object.

C#

```
public bool EqualsExact (DateTimeOffset other);
```

Parameters

other DateTimeOffset

The object to compare to the current DateTimeOffset object.

Returns

Boolean

`true` if the current DateTimeOffset object and `other` have the same date and time value and the same Offset value; otherwise, `false`.

Examples

The following example illustrates the use of the EqualsExact method to compare similar DateTimeOffset objects.

C#

```
DateTimeOffset instanceTime = new DateTimeOffset(2007, 10, 31, 0, 0, 0,
                                DateTimeOffset.Now.Offset);

DateTimeOffset otherTime = instanceTime;
Console.WriteLine("{0} = {1}: {2}",
                  instanceTime, otherTime,
```

```
                    instanceTime.EqualsExact(otherTime));

otherTime = new DateTimeOffset(instanceTime.DateTime,
            TimeSpan.FromHours(instanceTime.Offset.Hours + 1));
Console.WriteLine("{0} = {1}: {2}",
                    instanceTime, otherTime,
                    instanceTime.EqualsExact(otherTime));

otherTime = new DateTimeOffset(instanceTime.DateTime +
TimeSpan.FromHours(1),
                TimeSpan.FromHours(instanceTime.Offset.Hours + 1));
Console.WriteLine("{0} = {1}: {2}",
                    instanceTime, otherTime,
                    instanceTime.EqualsExact(otherTime));
// The example produces the following output:
//       10/31/2007 12:00:00 AM -07:00 = 10/31/2007 12:00:00 AM -07:00: True
//       10/31/2007 12:00:00 AM -07:00 = 10/31/2007 12:00:00 AM -06:00:
False
//       10/31/2007 12:00:00 AM -07:00 = 10/31/2007 1:00:00 AM -06:00: False
```

Remarks

Because multiple time zones share a single offset, a return value of `true` does not guarantee that the current and the `other` object represent times in the same time zone.

Unlike the EqualsExact method, the overloads of the Equals method determine only whether two DateTimeOffset values represent a single point in time. They do not indicate that two values have the same date and time as well as the same offset.

DateTimeOffset.FromFileTime(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified Windows file time to an equivalent local time.

```
C#
public static DateTimeOffset FromFileTime (long fileTime);
```

Parameters

`fileTime` Int64

A Windows file time, expressed in ticks.

Returns

DateTimeOffset

An object that represents the date and time of `fileTime` with the offset set to the local time offset.

Exceptions

ArgumentOutOfRangeException

`filetime` is less than zero.

-or-

`filetime` is greater than `DateTimeOffset.MaxValue.Ticks`.

Examples

The following example uses the Windows API to retrieve the Windows file times for the WordPad executable.

C#

```
using System;
using System.IO;
using System.Runtime.InteropServices;

public struct FileTime
{
   public uint dwLowDateTime;
   public uint dwHighDateTime;

   public static implicit operator long(FileTime fileTime)
   {
      long returnedLong;
      // Convert 4 high-order bytes to a byte array
      byte[] highBytes = BitConverter.GetBytes(fileTime.dwHighDateTime);
      // Resize the array to 8 bytes (for a Long)
      Array.Resize(ref highBytes, 8);

      // Assign high-order bytes to first 4 bytes of Long
      returnedLong = BitConverter.ToInt64(highBytes, 0);
      // Shift high-order bytes into position
      returnedLong = returnedLong << 32;
      // Or with low-order bytes
      returnedLong = returnedLong | fileTime.dwLowDateTime;
      // Return long
      return returnedLong;
   }
}

public class FileTimes
{
   private const int OPEN_EXISTING = 3;
   private const int INVALID_HANDLE_VALUE = -1;

   [DllImport("Kernel32.dll", CharSet = CharSet.Unicode)]
   private static extern int CreateFile(string lpFileName,
                                        int dwDesiredAccess,
                                        int dwShareMode,
                                        int lpSecurityAttributes,
                                        int dwCreationDisposition,
                                        int dwFlagsAndAttributes,
                                        int hTemplateFile);

   [DllImport("Kernel32.dll")]
   private static extern bool GetFileTime(int hFile,
                                          out FileTime lpCreationTime,
                                          out FileTime lpLastAccessTime,
                                          out FileTime lpLastWriteTime);

   [DllImport("Kernel32.dll")]
   private static extern bool CloseHandle(int hFile);

   public static void Main()
```

```
   {
      // Open file %windir%\write.exe
      string winDir = Environment.SystemDirectory;
      if (! (winDir.EndsWith(Path.DirectorySeparatorChar.ToString())))
         winDir += Path.DirectorySeparatorChar;
      winDir += "write.exe";

      // Get file time using Windows API
      //
      // Open file
      int hFile = CreateFile(winDir, 0, 0, 0, OPEN_EXISTING, 0, 0);
      if (hFile == INVALID_HANDLE_VALUE)
      {
         Console.WriteLine("Unable to access {0}.", winDir);
      }
      else
      {
         FileTime creationTime, accessTime, writeTime;
         if (GetFileTime(hFile, out creationTime, out accessTime, out
writeTime))
         {
            CloseHandle(hFile);
            long fileCreationTime = (long) creationTime;
            long fileAccessTime = accessTime;
            long fileWriteTime = (long) writeTime;

            Console.WriteLine("File {0} Retrieved Using the Windows API:",
winDir);
            Console.WriteLine("   Created:     {0:d}",
DateTimeOffset.FromFileTime(fileCreationTime).ToString());
            Console.WriteLine("   Last Access: {0:d}",
DateTimeOffset.FromFileTime(fileAccessTime).ToString());
            Console.WriteLine("   Last Write:  {0:d}",
DateTimeOffset.FromFileTime(fileWriteTime).ToString());
            Console.WriteLine();
         }
      }

      // Get date and time, convert to file time, then convert back
      FileInfo fileInfo = new FileInfo(winDir);
      DateTimeOffset infoCreationTime, infoAccessTime, infoWriteTime;
      long ftCreationTime, ftAccessTime, ftWriteTime;

      // Get dates and times of file creation, last access, and last write
      infoCreationTime = fileInfo.CreationTime;
      infoAccessTime = fileInfo.LastAccessTime;
      infoWriteTime = fileInfo.LastWriteTime;
      // Convert values to file times
      ftCreationTime = infoCreationTime.ToFileTime();
      ftAccessTime = infoAccessTime.ToFileTime();
      ftWriteTime = infoWriteTime.ToFileTime();

      // Convert file times back to DateTimeOffset values
      Console.WriteLine("File {0} Retrieved Using a FileInfo Object:",
winDir);
```

```
        Console.WriteLine("   Created:     {0:d}",
DateTimeOffset.FromFileTime(ftCreationTime).ToString());
        Console.WriteLine("   Last Access: {0:d}",
DateTimeOffset.FromFileTime(ftAccessTime).ToString());
        Console.WriteLine("   Last Write:  {0:d}",
DateTimeOffset.FromFileTime(ftWriteTime).ToString());
    }
}
// The example produces the following output:
//    File C:\WINDOWS\system32\write.exe Retrieved Using the Windows API:
//       Created:     10/13/2005 5:26:59 PM -07:00
//       Last Access: 3/20/2007 2:07:00 AM -07:00
//       Last Write:  8/4/2004 5:00:00 AM -07:00
//
//    File C:\WINDOWS\system32\write.exe Retrieved Using a FileInfo Object:
//       Created:     10/13/2005 5:26:59 PM -07:00
//       Last Access: 3/20/2007 2:07:00 AM -07:00
//       Last Write:  8/4/2004 5:00:00 AM -07:00
```

Remarks

A Windows file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 midnight, January 1, 1601 A.D. (C.E.) Coordinated Universal Time (UTC). Windows uses a file time to record when an application creates, accesses, or writes to a file.

A Windows file time is directly accessible through the Windows API by calling the `GetFileTime` function, which returns a `FILETIME` structure. The single function parameter is the handle of the file whose file time information is to be retrieved. The file handle is retrieved by calling the `CreateFile` function. The `FILETIME` structure's `dwHighDateTime` member contains the four high-order bytes of the file time, and its `dwLowDateTime` member contains the four low-order bytes. The example that follows illustrates how to retrieve Windows file time values and convert them to DateTimeOffset values.

Windows file time values can also be created from DateTime values by calling the DateTime.ToFileTime and DateTime.ToFileTimeUtc methods, and from DateTimeOffset values by calling the DateTimeOffset.ToFileTime method.

DateTimeOffset.FromUnixTimeMilliseconds(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a Unix time expressed as the number of milliseconds that have elapsed since 1970-01-01T00:00:00Z to a DateTimeOffset value.

C#

```
public static DateTimeOffset FromUnixTimeMilliseconds (long milliseconds);
```

Parameters

`milliseconds` Int64

A Unix time, expressed as the number of milliseconds that have elapsed since 1970-01-01T00:00:00Z (January 1, 1970, at 12:00 AM UTC). For Unix times before this date, its value is negative.

Returns

DateTimeOffset

A date and time value that represents the same moment in time as the Unix time.

Exceptions

ArgumentOutOfRangeException

`milliseconds` is less than -62,135,596,800,000.

-or-

`milliseconds` is greater than 253,402,300,799,999.

Remarks

The Offset property value of the returned DateTimeOffset instance is TimeSpan.Zero, which represents Coordinated Universal Time. You can convert it to the time in a specific time zone by calling the TimeZoneInfo.ConvertTime(DateTimeOffset, TimeZoneInfo) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.FromUnixTimeSeconds(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a Unix time expressed as the number of seconds that have elapsed since 1970-01-01T00:00:00Z to a DateTimeOffset value.

C#

```
public static DateTimeOffset FromUnixTimeSeconds (long seconds);
```

Parameters

seconds Int64

A Unix time, expressed as the number of seconds that have elapsed since 1970-01-01T00:00:00Z (January 1, 1970, at 12:00 AM UTC). For Unix times before this date, its value is negative.

Returns

DateTimeOffset

A date and time value that represents the same moment in time as the Unix time.

Exceptions

ArgumentOutOfRangeException

`seconds` is less than -62,135,596,800.

-or-

`seconds` is greater than 253,402,300,799.

Remarks

The Offset property value of the returned DateTimeOffset instance is TimeSpan.Zero, which represents Coordinated Universal Time. You can convert it to the time in a specific time zone by calling the TimeZoneInfo.ConvertTime(DateTimeOffset, TimeZoneInfo) method.

Applies to

DateTimeOffset.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current DateTimeOffset object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a date and time to its DateTimeOffset equivalent.

Overloads

Expand table

Parse(String)	Converts the specified string representation of a date, time, and offset to its DateTimeOffset equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, IFormatProvider)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information and formatting style.
Parse(String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information and formatting style.

Remarks

Important

Eras in the Japanese calendars are based on the emperor's reign and are therefore expected to change. For example, May 1, 2019 marked the beginning of the Reiwa era in the **JapaneseCalendar** and **JapaneseLunisolarCalendar**. Such a change of era affects all applications that use these calendars. For more information and to

determine whether your applications are affected, see **Handling a new era in the Japanese calendar in .NET**. For information on testing your applications on Windows systems to ensure their readiness for the era change, see **Prepare your application for the Japanese era change**. For features in .NET that support calendars with multiple eras and for best practices when working with calendars that support multiple eras, see **Working with eras**.

Parse(String)

Converts the specified string representation of a date, time, and offset to its DateTimeOffset equivalent.

```
C#

public static DateTimeOffset Parse (string input);
```

Parameters

`input` String

A string that contains a date and time to convert.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in `input`.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours.

ArgumentNullException

`input` is `null`.

FormatException

`input` does not contain a valid string representation of a date and time.

-or-

`input` contains the string representation of an offset value without a date or time.

Examples

The following example calls the Parse(String) method to parse several date and time strings. The example includes output from March 22, 2007, on a system whose culture is en-us.

C#

```
string dateString;
DateTimeOffset offsetDate;

// String with date only
dateString = "05/01/2008";
offsetDate = DateTimeOffset.Parse(dateString);
Console.WriteLine(offsetDate.ToString());

// String with time only
dateString = "11:36 PM";
offsetDate = DateTimeOffset.Parse(dateString);
Console.WriteLine(offsetDate.ToString());

// String with date and offset
dateString = "05/01/2008 +1:00";
offsetDate = DateTimeOffset.Parse(dateString);
Console.WriteLine(offsetDate.ToString());

// String with day abbreviation
dateString = "Thu May 01, 2008";
offsetDate = DateTimeOffset.Parse(dateString);
Console.WriteLine(offsetDate.ToString());
```

Remarks

Parse(String) parses a string with three elements that can appear in any order and are delimited by white space. These three elements are as shown in the following table.

Expand table

Element	Example
<Date>	"2/10/2007"
<Time>	"1:02:03 PM"
<Offset>	"-7:30"

Although each of these elements is optional, <Offset> cannot appear by itself. It must be provided together with either <Date> or <Time>. If <Date> is missing, its default value is the current day. If <Time> is missing, its default value is 12:00:00 AM. If <Date> is present but its year component consists of only two digits, it is converted to a year in the current culture's current calendar based on the value of the Calendar.TwoDigitYearMax property. If <Offset> is missing, its default value is the offset of the local time zone. <Offset> can represent either a negative or a positive offset from Coordinated Universal Time (UTC). In either case, <Offset> must include a sign symbol.

The `input` string is parsed by using the formatting information in a DateTimeFormatInfo object that is initialized for the current culture. To parse a string that contains designated formatting that does not necessarily correspond to the formatting of the current culture, use the ParseExact method and provide a format specifier.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#
```

```
public static DateTimeOffset Parse (ReadOnlySpan<char> s,
IFormatProvider? provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

DateTimeOffset

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, IFormatProvider)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information.

C#

```
public static DateTimeOffset Parse (string input, IFormatProvider?
formatProvider);
```

Parameters

`input` String

A string that contains a date and time to convert.

`formatProvider` IFormatProvider

An object that provides culture-specific format information about `input`.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in `input`, as specified by `formatProvider`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours.

ArgumentNullException

`input` is `null`.

FormatException

`input` does not contain a valid string representation of a date and time.

-or-

`input` contains the string representation of an offset value without a date or time.

Examples

The following example parses date and time strings that are formatted for the fr-fr culture and displays them using the local system's default en-us culture.

C#

```
DateTimeFormatInfo fmt = new CultureInfo("fr-fr").DateTimeFormat;
string dateString;
DateTimeOffset offsetDate;
```

```
dateString = "03-12-07";
offsetDate = DateTimeOffset.Parse(dateString, fmt);
Console.WriteLine("{0} returns {1}",
                  dateString,
                  offsetDate.ToString());

dateString = "15/09/07 08:45:00 +1:00";
offsetDate = DateTimeOffset.Parse(dateString, fmt);
Console.WriteLine("{0} returns {1}",
                  dateString,
                  offsetDate.ToString());

dateString = "mar. 1 janvier 2008 1:00:00 +1:00";
offsetDate = DateTimeOffset.Parse(dateString, fmt);
Console.WriteLine("{0} returns {1}",
                  dateString,
                  offsetDate.ToString());
// The example displays the following output to the console:
//    03-12-07 returns 12/3/2007 12:00:00 AM -08:00
//    15/09/07 08:45:00 +1:00 returns 9/15/2007 8:45:00 AM +01:00
//    mar. 1 janvier 2008 1:00:00 +1:00 returns 1/1/2008 1:00:00 AM
+01:00
```

Remarks

This method parses a string with three elements that can appear in any order and are delimited by white space. These three elements are shown in the following table.

Expand table

Element	Example
<Date>	"2/10/2007"
<Time>	"1:02:03 PM"
<Offset>	"-7:30"

Although each of these elements is optional, <Offset> cannot appear by itself. It must be provided together with either <Date> or <Time>. If <Date> is missing, its default value is the current day. If <Date> is present but its year component consists of only two digits, it is converted to a year in the `provider` parameter's current calendar based on the value of the Calendar.TwoDigitYearMax property. If <Time> is missing, its default value is 12:00:00 AM. If <Offset> is missing, its default value is the offset of the local time zone. <Offset> can represent either a negative or a positive offset from Coordinated Universal Time (UTC). In either case, <Offset> must include a sign symbol.

The format of these three elements is defined by the `formatProvider` parameter, which can be either of the following:

- A CultureInfo object that represents the culture whose formatting is used in the `input` parameter. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting used in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The positive or negative sign used in <Offset> must be either + or -. It is not defined by the PositiveSign or NegativeSign properties of the NumberFormatInfo object of the `formatProvider` parameter.

UWP	10.0

Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts the specified span representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information and formatting style.

```
C#

public static DateTimeOffset Parse (ReadOnlySpan<char> input,
IFormatProvider? formatProvider = default,
System.Globalization.DateTimeStyles styles =
System.Globalization.DateTimeStyles.None);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a date and time to convert.

`formatProvider` IFormatProvider

An object that provides culture-specific format information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`. A typical value to specify is None.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in `input` as specified by `formatProvider` and `styles`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(String, IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified culture-specific format information and formatting style.

```C#
public static DateTimeOffset Parse (string input, IFormatProvider?
formatProvider, System.Globalization.DateTimeStyles styles);
```

Parameters

`input` String

A string that contains a date and time to convert.

`formatProvider` IFormatProvider

An object that provides culture-specific format information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`. A typical value to specify is None.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in `input` as specified by `formatProvider` and `styles`.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours.

-or-

`styles` is not a valid DateTimeStyles value.

-or-

`styles` includes an unsupported DateTimeStyles value.

-or-

`styles` includes DateTimeStyles values that cannot be used together.

ArgumentNullException

`input` is `null`.

FormatException

`input` does not contain a valid string representation of a date and time.

-or-

`input` contains the string representation of an offset value without a date or time.

Examples

The following example illustrates the effect of passing the DateTimeStyles.AssumeLocal, DateTimeStyles.AssumeUniversal, and DateTimeStyles.AdjustToUniversal values to the `styles` parameter of the Parse(String, IFormatProvider, DateTimeStyles) method.

C#

```
string dateString;
DateTimeOffset offsetDate;

dateString = "05/01/2008 6:00:00";
// Assume time is local
offsetDate = DateTimeOffset.Parse(dateString, null,
DateTimeStyles.AssumeLocal);
Console.WriteLine(offsetDate.ToString());   // Displays 5/1/2008 6:00:00
AM -07:00

// Assume time is UTC
offsetDate = DateTimeOffset.Parse(dateString, null,
DateTimeStyles.AssumeUniversal);
Console.WriteLine(offsetDate.ToString());   // Displays 5/1/2008 6:00:00
AM +00:00

// Parse and convert to UTC
dateString = "05/01/2008 6:00:00AM +5:00";
offsetDate = DateTimeOffset.Parse(dateString, null,
DateTimeStyles.AdjustToUniversal);
Console.WriteLine(offsetDate.ToString());   // Displays 5/1/2008 1:00:00
AM +00:00
```

Remarks

This method parses a string with three elements that can appear in any order and are delimited by white space. These three elements are shown in the following table.

Expand table

Element	Example
<Date>	"2/10/2007"
<Time>	"1:02:03 PM"
<Offset>	"-7:30"

Although each of these elements is optional, <Offset> cannot appear by itself. It must be provided together with either <Date> or <Time>. If <Date> is missing, its default value is the current day. If <Date> is present but its year component consists of only two digits, it is converted to a year in the `provider` parameter's current calendar based on the value of the Calendar.TwoDigitYearMax property. If <Time> is missing, its default value is 12:00:00 AM. If <Offset> is missing, its default value is the offset of the local time zone, or TimeSpan.Zero if either the DateTimeStyles.AdjustToUniversal or DateTimeStyles.AssumeUniversal value is specified in the `styles` parameter. If <Offset> is present, it can represent either a negative or a positive offset from Coordinated Universal Time (UTC). In either case, <Offset> must include a sign symbol.

The format of these three elements is defined by the `formatProvider` parameter, which can be either of the following:

- A CultureInfo object that represents the culture whose formatting is used in the `input` parameter. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting used in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

Each element can also be enclosed by leading or trailing white space, and the <Date> and <Time> elements can include inner white space (such as 6: 00:00). Only the <Offset> component cannot include inner white space.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The positive or negative sign used in <Offset> must be either + or -. It is not defined by the PositiveSign or NegativeSign properties of the NumberFormatInfo object returned by the `formatProvider` parameter.

The following table shows the members of the System.Globalization.DateTimeStyles enumeration that are supported.

Expand table

DateTimeStyles member	Description
AdjustToUniversal	Parses the string represented by `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AllowInnerWhite	Although valid, this value is ignored. Inner white space is permitted in the <Date> and <Time> elements.
AllowLeadingWhite	Although valid, this value is ignored. Leading white space is permitted in front of each component in the parsed string.
AllowTrailingWhite	Although valid, this value is ignored. Trailing white space is permitted in front of each component in the parsed string.
AllowWhiteSpaces	This is the default behavior. It cannot be overridden by supplying a more restrictive DateTimeStyles enumeration value, such as DateTimeStyles.None.
AssumeLocal	Indicates that, if the `input` parameter lacks an <Offset> element, the offset of the local time zone should be provided. This is the default behavior of the Parse method.
AssumeUniversal	Indicates that, if the `input` parameter lacks an <Offset> element, the UTC offset (00:00) should be provided.
None	Although valid, this value is ignored and has no effect.
RoundtripKind	Because the DateTimeOffset structure does not include a `Kind` property, this value has no effect.

Only the DateTimeStyles.NoCurrentDateDefault value is not supported. An ArgumentException is thrown if this value is included in the `styles` parameter.

DateTimeOffset.ParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a date and time to its DateTimeOffset equivalent. The format of the string representation must match a specified format exactly.

Overloads

Expand table

ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the string representation must match one of the specified formats exactly.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly.
ParseExact(String, String, IFormatProvider)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a character span that represents a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the date and time representation must match the specified format exactly.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts a character span that contains the string representation of a date and time to its DateTimeOffset equivalent using the specified

formats, culture-specific format information, and style. The format of the date and time representation must match one of the specified formats exactly.

ParseExact(String, String[], IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the string representation must match one of the specified formats exactly.

```
C#

public static DateTimeOffset ParseExact (string input, string[] formats,
IFormatProvider? formatProvider, System.Globalization.DateTimeStyles
styles);
```

Parameters

`input` String

A string that contains a date and time to convert.

`formats` String[]

An array of format specifiers that define the expected formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in the `input` parameter, as specified by the `formats`, `formatProvider`, and `styles` parameters.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours.

-or-

`styles` includes an unsupported value.

-or-

The `styles` parameter contains DateTimeStyles values that cannot be used together.

ArgumentNullException

`input` is `null`.

FormatException

`input` is an empty string ("").

-or-

`input` does not contain a valid string representation of a date and time.

-or-

No element of `formats` contains a valid format specifier.

-or-

The hour component and the AM/PM designator in `input` do not agree.

Examples

The following example defines multiple input formats for the string representation of a date and time and offset value, and then passes the string that is entered by the user to the DateTimeOffset.ParseExact(String, String[], IFormatProvider, DateTimeStyles) method.

C#

```
TextReader conIn = Console.In;
TextWriter conOut = Console.Out;
int tries = 0;
string input = String.Empty;
string[] formats = new string[] {@"@M/dd/yyyy HH:m zzz", @"MM/dd/yyyy
HH:m zzz",
```

```
                                    @"M/d/yyyy HH:m zzz", @"MM/d/yyyy HH:m
zzz",
                                    @"M/dd/yy HH:m zzz", @"MM/dd/yy HH:m
zzz",
                                    @"M/d/yy HH:m zzz", @"MM/d/yy HH:m zzz",
                                    @"M/dd/yyyy H:m zzz", @"MM/dd/yyyy H:m
zzz",
                                    @"M/d/yyyy H:m zzz", @"MM/d/yyyy H:m
zzz",
                                    @"M/dd/yy H:m zzz", @"MM/dd/yy H:m zzz",
                                    @"M/d/yy H:m zzz", @"MM/d/yy H:m zzz",
                                    @"M/dd/yyyy HH:mm zzz", @"MM/dd/yyyy
HH:mm zzz",
                                    @"M/d/yyyy HH:mm zzz", @"MM/d/yyyy HH:mm
zzz",
                                    @"M/dd/yy HH:mm zzz", @"MM/dd/yy HH:mm
zzz",
                                    @"M/d/yy HH:mm zzz", @"MM/d/yy HH:mm
zzz",
                                    @"M/dd/yyyy H:mm zzz", @"MM/dd/yyyy H:mm
zzz",
                                    @"M/d/yyyy H:mm zzz", @"MM/d/yyyy H:mm
zzz",
                                    @"M/dd/yy H:mm zzz", @"MM/dd/yy H:mm
zzz",
                                    @"M/d/yy H:mm zzz", @"MM/d/yy H:mm
zzz"};
IFormatProvider provider = CultureInfo.InvariantCulture.DateTimeFormat;
DateTimeOffset result = new DateTimeOffset();

do {
   conOut.WriteLine("Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-
HH:MM),");
   conOut.Write("Then press Enter: ");
   input = conIn.ReadLine();
   conOut.WriteLine();
   try
   {
      result = DateTimeOffset.ParseExact(input, formats, provider,

DateTimeStyles.AllowWhiteSpaces);
      break;
   }
   catch (FormatException)
   {
      Console.WriteLine("Unable to parse {0}.", input);
      tries++;
   }
} while (tries < 3);
if (tries >= 3)
   Console.WriteLine("Exiting application without parsing {0}", input);
else
   Console.WriteLine("{0} was converted to {1}", input,
result.ToString());
// Some successful sample interactions with the user might appear as
```

```
follows:
//    Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-HH:MM),
//    Then press Enter: 12/08/2007 6:54 -6:00
//
//    12/08/2007 6:54 -6:00 was converted to 12/8/2007 6:54:00 AM -06:00
//
//    Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-HH:MM),
//    Then press Enter: 12/8/2007 06:54 -06:00
//
//    12/8/2007 06:54 -06:00 was converted to 12/8/2007 6:54:00 AM -06:00
//
//    Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-HH:MM),
//    Then press Enter: 12/5/07 6:54 -6:00
//
//    12/5/07 6:54 -6:00 was converted to 12/5/2007 6:54:00 AM -06:00
```

Remarks

The DateTimeOffset.ParseExact(String, String[], IFormatProvider, DateTimeStyles) method parses the string representation of a date that matches any one of the patterns assigned to the `formats` parameter. If the `input` string does not match any one of these patterns with any of the variations defined by the `styles` parameter, the method throws a FormatException. Aside from comparing `input` to multiple formatting patterns, this overload behaves identically to the DateTimeOffset.ParseExact(String, String, IFormatProvider, DateTimeStyles) method.

The `formats` parameter is a string array whose elements contain either a single standard format specifier or one or more custom format specifiers that define the possible pattern of the `input` parameter. When the method is called, `input` must match one of these patterns. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If the matched element in `formats` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the method throws a FormatException.

> **ⓘ Important**
>
> Using the `formats` parameter of this overload to specify multiple formats can help reduce the frustration many users experience when they enter dates and times. In particular, the ability to define multiple input patterns enables an application to handle date and time representations that can either include or

lack leading zeros in months, days, hours, minutes, and seconds. The example provides an illustration of this.

If the matched element in `formats` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If the matched element in `formats` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If the matched element in `formats` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter. The same is true for the precise format of `input`, if the matching element of `formats` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and formatting in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is permitted in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AssumeLocal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default value.
AssumeUniversal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).
AllowInnerWhite	Allows `input` to include inner white space not specified by `format`. Extra white space can appear between date and time components and within individual components (except the offset), and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by `formats`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by `formats`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by `formats`. All extra white-space characters not specified in the matched element in `formats` are ignored when parsing the string.
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in a particular element of `formats` for a match to occur. This is the default behavior.
RoundtripKind	Has no effect because the DateTimeOffset structure does not include a `Kind` property.

Notes to Callers

In the .NET Framework 4, the ParseExact method throws a FormatException if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

ParseExact(String, String, IFormatProvider, DateTimeStyles)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly.

C#

```
public static DateTimeOffset ParseExact (string input, string format,
IFormatProvider? formatProvider, System.Globalization.DateTimeStyles
styles);
```

Parameters

`input` String

A string that contains a date and time to convert.

`format` String

A format specifier that defines the expected format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in the `input` parameter, as specified by the `format`, `formatProvider`, and `styles` parameters.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours.

-or-

The `styles` parameter includes an unsupported value.

-or-

The `styles` parameter contains DateTimeStyles values that cannot be used together.

ArgumentNullException

`input` is `null`.

-or-

`format` is `null`.

FormatException

`input` is an empty string ("").

-or-

`input` does not contain a valid string representation of a date and time.

-or-

`format` is an empty string.

-or-

The hour component and the AM/PM designator in `input` do not agree.

Examples

The following example uses the DateTimeOffset.ParseExact(String, String, IFormatProvider, DateTimeStyles) method with standard and custom format specifiers, the invariant culture, and various DateTimeStyles values to parse several date and time strings.

C#

```
string dateString, format;
DateTimeOffset result;
CultureInfo provider = CultureInfo.InvariantCulture;

// Parse date-only value with invariant culture and assume time is UTC.
dateString = "06/15/2008";
format = "d";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider,
                                      DateTimeStyles.AssumeUniversal);
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("'{0}' is not in the correct format.", dateString);
}

// Parse date-only value with leading white space.
// Should throw a FormatException because only trailing white space is
// specified in method call.
dateString = " 06/15/2008";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider,
                                      DateTimeStyles.AllowTrailingWhite);
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("'{0}' is not in the correct format.", dateString);
}

// Parse date and time value, and allow all white space.
dateString = " 06/15/   2008  15:15    -05:00";
format = "MM/dd/yyyy H:mm zzz";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider,
                                      DateTimeStyles.AllowWhiteSpaces);
   Console.WriteLine("'{0}' converts to {1}.", dateString,
```

```
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("'{0}' is not in the correct format.", dateString);
}

// Parse date and time and convert to UTC.
dateString = "  06/15/2008 15:15:30 -05:00";
format = "MM/dd/yyyy H:mm:ss zzz";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider,
                                      DateTimeStyles.AllowWhiteSpaces |
                                      DateTimeStyles.AdjustToUniversal);
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("'{0}' is not in the correct format.", dateString);
}
// The example displays the following output:
//    '06/15/2008' converts to 6/15/2008 12:00:00 AM +00:00.
//    ' 06/15/2008' is not in the correct format.
//    ' 06/15/   2008  15:15    -05:00' converts to 6/15/2008 3:15:00 PM
-05:00.
//    '  06/15/2008 15:15:30 -05:00' converts to 6/15/2008 8:15:30 PM
+00:00.
```

The following example uses a variety of DateTimeStyles values to parse an array of strings that are expected to conform to ISO 8601. As the output from the example shows, strings that are in the proper format fail to parse if:

- they contain white space, and an appropriate DateTimeStyles flag (such as DateTimeStyles.AllowWhiteSpaces has not been supplied in the method call.
- they contain date and time elements that are out of range.

Strings that do not specify a UTC offset are assumed to have the offset of the local time zone (in this case, -07:00) unless the DateTimeStyles.AssumeUniversal flag is supplied in the method call. In that case, they are assumed to be Universal Coordinated Time.

C#

```
using System;
using System.Globalization;

public class Example
{
```

```
   public static void Main()
   {
      string[] dateStrings = { "2018-08-18T12:45:16.0000000Z",
                               "2018/08/18T12:45:16.0000000Z",
                               "2018-18-08T12:45:16.0000000Z",
                               "2018-08-18T12:45:16.0000000",
                               " 2018-08-18T12:45:16.0000000Z ",
                               "2018-08-18T12:45:16.0000000+02:00",
                               "2018-08-18T12:45:16.0000000-07:00" };

      ParseWithISO8601(dateStrings, DateTimeStyles.None);
      Console.WriteLine("\n-----\n");
      ParseWithISO8601(dateStrings, DateTimeStyles.AllowWhiteSpaces);
      Console.WriteLine("\n-----\n");
      ParseWithISO8601(dateStrings, DateTimeStyles.AdjustToUniversal);
      Console.WriteLine("\n-----\n");
      ParseWithISO8601(dateStrings, DateTimeStyles.AssumeLocal);
      Console.WriteLine("\n-----\n");
      ParseWithISO8601(dateStrings, DateTimeStyles.AssumeUniversal);   }

   private static void ParseWithISO8601(string[] dateStrings,
DateTimeStyles styles)
   {
      Console.WriteLine($"Parsing with {styles}:");
      foreach (var dateString in dateStrings)
      {
         try {
            var date = DateTimeOffset.ParseExact(dateString, "O", null,
styles);
            Console.WriteLine($"   {dateString,-35} --> {date:yyyy-MM-dd
HH:mm:ss.FF zzz}");
         }
         catch (FormatException)
         {
            Console.WriteLine($"   FormatException: Unable to convert

Remarks

The DateTimeOffset.ParseExact(String, String, IFormatProvider, DateTimeStyles) method parses the string representation of a date, which must be in the format defined by the `format` parameter. It also requires that the <Date>, <Time>, and <Offset> elements of the string representation of a date and time appear in the order specified by `format`. If the `input` string does not match the pattern of the `format` parameter, with any variations defined by the `styles` parameter, the method throws a FormatException. In contrast, the DateTimeOffset.Parse(String, IFormatProvider, DateTimeStyles) method parses the string representation of a date in any one of the formats recognized by the format provider's DateTimeFormatInfo object. Parse also allows the <Date>, <Time>, and <Offset> elements of the string representation of a date and time to appear in any order.

The `format` parameter is a string that contains either a single standard format specifier or one or more custom format specifiers that define the required pattern of the `input` parameter. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If `format` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the method throws a FormatException.

If `format` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If `format` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is

assigned the current date on the local system. If `format` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter. The same is true for the precise format of `input`, if `format` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and formatting in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is allowed in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AssumeLocal	If `format` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default value.
AssumeUniversal	If `format` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).

`DateTimeStyles` member	Behavior
AllowInnerWhite	Allows `input` to include inner white space not specified by `format`. Extra white space can appear between date and time components and within individual components, and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by `format`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by `format`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by `format`. All extra white-space characters not specified in `format` are ignored when parsing the string.
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in `format`. This is the default behavior.
RoundtripKind	Has no effect because the DateTimeOffset structure does not include a `Kind` property.

Notes to Callers

In the .NET Framework 4, the ParseExact method throws a FormatException if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

ParseExact(String, String, IFormatProvider)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

C#

```
public static DateTimeOffset ParseExact (string input, string format,
IFormatProvider? formatProvider);
```

Parameters

`input` String

A string that contains a date and time to convert.

`format` String

A format specifier that defines the expected format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in `input` as specified by `format` and `formatProvider`.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours.

ArgumentNullException

`input` is `null`.

-or-

`format` is `null`.

FormatException

`input` is an empty string ("").

-or-

`input` does not contain a valid string representation of a date and time.

-or-

`format` is an empty string.

-or-

The hour component and the AM/PM designator in `input` do not agree.

Examples

The following example uses the DateTimeOffset.ParseExact(String, String, IFormatProvider) method with standard and custom format specifiers and the invariant culture to parse several date and time strings.

C#

```
string dateString, format;
DateTimeOffset result;
CultureInfo provider = CultureInfo.InvariantCulture;

// Parse date-only value with invariant culture.
dateString = "06/15/2008";
format = "d";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider);
   Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("{0} is not in the correct format.", dateString);
}
```

```
// Parse date-only value without leading zero in month using "d" format.
// Should throw a FormatException because standard short date pattern of
// invariant culture requires two-digit month.
dateString = "6/15/2008";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider);
   Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("{0} is not in the correct format.", dateString);
}

// Parse date and time with custom specifier.
dateString = "Sun 15 Jun 2008 8:30 AM -06:00";
format = "ddd dd MMM yyyy h:mm tt zzz";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider);
   Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("{0} is not in the correct format.", dateString);
}

// Parse date and time with offset without offset//s minutes.
// Should throw a FormatException because "zzz" specifier requires
leading
// zero in hours.
dateString = "Sun 15 Jun 2008 8:30 AM -06";
try
{
   result = DateTimeOffset.ParseExact(dateString, format, provider);
   Console.WriteLine("{0} converts to {1}.", dateString,
result.ToString());
}
catch (FormatException)
{
   Console.WriteLine("{0} is not in the correct format.", dateString);
}
// The example displays the following output:
//    06/15/2008 converts to 6/15/2008 12:00:00 AM -07:00.
//    6/15/2008 is not in the correct format.
//    Sun 15 Jun 2008 8:30 AM -06:00 converts to 6/15/2008 8:30:00 AM
-06:00.
//    Sun 15 Jun 2008 8:30 AM -06 is not in the correct format.
```

The following example parses an array of strings that are expected to conform to ISO 8601. As the output from the example shows, strings with leading or trailing spaces

fail to parse successfully, as do strings with date and time elements that are out of range.

C#

```
using System;

public class Example2
{
   public static void Main()
   {
      string[] dateStrings = { "2018-08-18T12:45:16.0000000Z",
                               "2018/08/18T12:45:16.0000000Z",
                               "2018-18-08T12:45:16.0000000Z",
                               " 2018-08-18T12:45:16.0000000Z ",
                               "2018-08-18T12:45:16.0000000+02:00",
                               "2018-08-18T12:45:16.0000000-07:00" };

      foreach (var dateString in dateStrings)
      {
         try {
            var date = DateTimeOffset.ParseExact(dateString, "O", null);
            Console.WriteLine($"{dateString,-35} --> {date:yyyy-MM-dd
HH:mm:ss.FF zzz}");
         }
         catch (FormatException)
         {
            Console.WriteLine($"FormatException: Unable to convert
'{dateString}'");
         }
      }
   }
}
// The example displays the following output:
//      2018-08-18T12:45:16.0000000Z        --> 2018-08-18 12:45:16
+00:00
//      FormatException: Unable to convert '2018/08/18T12:45:16.0000000Z'
//      FormatException: Unable to convert '2018-18-08T12:45:16.0000000Z'
//      FormatException: Unable to convert ' 2018-08-18T12:45:16.0000000Z
'
//      2018-08-18T12:45:16.0000000+02:00   --> 2018-08-18 12:45:16
+02:00
//      2018-08-18T12:45:16.0000000-07:00   --> 2018-08-18 12:45:16
-07:00
```

Remarks

The ParseExact(String, String, IFormatProvider) method parses the string representation of a date, which must be in the format defined by the `format` parameter. It also requires that the <Date>, <Time>, and <Offset> elements of the

string representation of a date and time appear in the order specified by `format`. If the `input` string does not match this `format` parameter, the method throws a FormatException. In contrast, the DateTimeOffset.Parse(String, IFormatProvider) method parses the string representation of a date in any one of the formats recognized by the format provider's DateTimeFormatInfo object. Parse also allows the <Date>, <Time>, and <Offset> elements of the string representation of a date and time to appear in any order.

The `format` parameter is a string that contains either a single standard format specifier or one or more custom format specifiers that define the required format of the `input` parameter. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If `format` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the method throws a FormatException.

If `format` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If `format` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If `format` does not require that `input` contain an offset, the resulting DateTimeOffset object is assigned the time zone offset of the local system.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter, as is the precise format of `input` if `format` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by its DateTimeFormat property defines the symbols and formatting in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

Notes to Callers

In the .NET Framework 4, the ParseExact method throws a FormatException if the string to be parsed contains an hour component and an AM/PM designator that are

not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

UWP	10.0

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts a character span that represents a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the date and time representation must match the specified format exactly.

C#

```
public static DateTimeOffset ParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format, IFormatProvider? formatProvider,
System.Globalization.DateTimeStyles styles =
System.Globalization.DateTimeStyles.None);
```

Parameters

`input` ReadOnlySpan<Char>

A character span that represents a date and time.

`format` ReadOnlySpan<Char>

A character span that contains a format specifier that defines the expected format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in the `input` parameter, as specified by the `format`, `formatProvider`, and `styles` parameters.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours. -or- The `styles` parameter includes an unsupported value. -or- The `styles` parameter contains DateTimeStyles values that cannot be used together.

FormatException

`input` is an empty character span. -or- `input` does not contain a valid string representation of a date and time. -or- `format` is an empty character span. -or- The hour component and the AM/PM designator in `input` do not agree.

Remarks

This method parses a character span that represents a date, which must be in the format defined by the `format` parameter. It also requires that the <Date>, <Time>, and <Offset> elements of the string representation of a date and time appear in the order specified by `format`. If `input` does not match the `format` pattern, the method

throws a FormatException. In contrast, the DateTimeOffset.Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles) method parses the string representation of a date in any one of the formats recognized by the format provider's DateTimeFormatInfo object. Parse also allows the <Date>, <Time>, and <Offset> elements of the string representation of a date and time to appear in any order.

The `format` parameter is a character span that contains either a single-character standard format specifier or one or more custom format specifiers that define the required format of the `input` parameter. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If `format` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the method throws a FormatException.

If `format` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If `format` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If `format` does not require that `input` contain an offset, the resulting DateTimeOffset object is assigned the time zone offset of the local system.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter, as is the precise format of `input` if `format` is a standard format specifier. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by its DateTimeFormat property defines the symbols and formatting in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)

Converts a character span that contains the string representation of a date and time to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the date and time representation must match one of the specified formats exactly.

C#

```
public static DateTimeOffset ParseExact (ReadOnlySpan<char> input,
string[] formats, IFormatProvider? formatProvider,
System.Globalization.DateTimeStyles styles =
System.Globalization.DateTimeStyles.None);
```

Parameters

`input` ReadOnlySpan<Char>

A character span that contains a date and time to convert.

`formats` String[]

An array of format specifiers that define the expected formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`.

Returns

DateTimeOffset

An object that is equivalent to the date and time that is contained in the `input` parameter, as specified by the `formats`, `formatProvider`, and `styles` parameters.

Exceptions

ArgumentException

The offset is greater than 14 hours or less than -14 hours. -or- `styles` includes an unsupported value. -or- The `styles` parameter contains DateTimeStyles values that cannot be used together.

FormatException

`input` is an empty character span. -or- `input` does not contain a valid string representation of a date and time. -or- No element of `formats` contains a valid format specifier. -or- The hour component and the AM/PM designator in `input` do not agree.

Remarks

This method parses a character span representing a date that matches any one of the patterns assigned to the `formats` parameter. If `input` does not match any one of these patterns with any of the variations defined by the `styles` parameter, the method throws a FormatException. Aside from comparing `input` to multiple formatting patterns, this overload behaves identically to the DateTimeOffset.ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles) method.

The `formats` parameter is a string array whose elements contain either a single standard format specifier or one or more custom format specifiers that define the possible pattern of the `input` parameter. When the method is called, `input` must match one of these patterns. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If the matched element in `formats` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the method throws a FormatException.

> **ⓘ Important**
>
> Using the `formats` parameter of this overload to specify multiple formats can help reduce the frustration many users experience when they enter dates and times. In particular, the ability to define multiple input patterns enables an application to handle date and time representations that can either include or lack leading zeros in months, days, hours, minutes, and seconds.

If the matched element in `formats` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If the matched element in `formats` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If the matched element in `formats` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter. The same is true for the precise format of `input`, if the matching element of `formats` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and formatting in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is permitted in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.

`DateTimeStyles` member	Behavior
AssumeLocal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default value.
AssumeUniversal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).
AllowInnerWhite	Allows `input` to include inner white space not specified by `format`. Extra white space can appear between date and time components and within individual components (except the offset), and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by `formats`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by `formats`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by `formats`. All extra white-space characters not specified in the matched element in `formats` are ignored when parsing the string.
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in a particular element of `formats` for a match to occur. This is the default behavior.
RoundtripKind	Has no effect because the DateTimeOffset structure does not include a `Kind` property.

DateTimeOffset.Subtract Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts a specified time or duration from the current DateTimeOffset object.

Overloads

Expand table

Subtract(DateTimeOffset)	Subtracts a DateTimeOffset value that represents a specific date and time from the current DateTimeOffset object.
Subtract(TimeSpan)	Subtracts a specified time interval from the current DateTimeOffset object.

Subtract(DateTimeOffset)

Subtracts a DateTimeOffset value that represents a specific date and time from the current DateTimeOffset object.

C#

```
public TimeSpan Subtract (DateTimeOffset value);
```

Parameters

`value` DateTimeOffset

An object that represents the value to subtract.

Returns

TimeSpan

An object that specifies the interval between the two DateTimeOffset objects.

Examples

The following example illustrates subtraction that uses the Subtract(DateTimeOffset) method.

C#

```
DateTimeOffset firstDate = new DateTimeOffset(2018, 10, 25, 18, 0, 0,
                                              new TimeSpan(-7, 0, 0));
DateTimeOffset secondDate = new DateTimeOffset(2018, 10, 25, 18, 0, 0,
                                               new TimeSpan(-5, 0, 0));
DateTimeOffset thirdDate = new DateTimeOffset(2018, 9, 28, 9, 0, 0,
                                              new TimeSpan(-7, 0, 0));
TimeSpan difference;

difference = firstDate.Subtract(secondDate);
Console.WriteLine($"({firstDate}) - ({secondDate}): {difference.Days}
days, {difference.Hours}:{difference.Minutes:d2}");

difference = firstDate.Subtract(thirdDate);
Console.WriteLine($"({firstDate}) - ({thirdDate}): {difference.Days}
days, {difference.Hours}:{difference.Minutes:d2}");

// The example produces the following output:
//    (10/25/2018 6:00:00 PM -07:00) - (10/25/2018 6:00:00 PM -05:00): 0
days, 2:00
//    (10/25/2018 6:00:00 PM -07:00) - (9/28/2018 9:00:00 AM -07:00): 27
days, 9:00
```

Remarks

This method converts both DateTimeOffset objects to Coordinated Universal Time (UTC) before calculating the time interval that separates them. This removes any effect that different offsets from UTC may have on the comparison.

> **Note**
>
> For languages that support custom operators, you can also perform date and time subtraction by using the subtraction operator. For details, see the **Subtraction** method.

Because neither the current DateTimeOffset object nor the `value` parameter represent the date and time in a specific time zone, the Subtract(DateTimeOffset) method does not consider a particular time zone's adjustment rules when it subtracts dates and times.

UWP	10.0

Subtract(TimeSpan)

Subtracts a specified time interval from the current DateTimeOffset object.

C#

```
public DateTimeOffset Subtract (TimeSpan value);
```

Parameters

`value` TimeSpan

The time interval to subtract.

Returns

DateTimeOffset

An object that is equal to the date and time represented by the current DateTimeOffset object, minus the time interval represented by `value`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Examples

The following example illustrates subtraction that uses the Subtract method.

C#

```
DateTimeOffset offsetDate = new DateTimeOffset(2007, 12, 3, 11, 30, 0,
                                new TimeSpan(-8, 0, 0));
TimeSpan duration = new TimeSpan(7, 18, 0, 0);
Console.WriteLine(offsetDate.Subtract(duration).ToString());  // Displays
11/25/2007 5:30:00 PM -08:00
```

Remarks

You can use the Subtract method to subtract more than one kind of time interval (days, hours, minutes, seconds, or milliseconds) in a single operation. Its behavior is identical to the Subtraction(DateTimeOffset, TimeSpan) method, which defines the subtraction operator. The DateTimeOffset structure also supports specialized addition methods (such as AddDays, AddHours, and AddMinutes) that allow you to perform subtraction by assigning a negative value to the method parameter.

> **Note**
>
> This method returns a new **DateTimeOffset** object. It does not modify the value of the current object by subtracting `value` from its date and time.

The Subtract method does not affect the value of the DateTimeOffset object's Offset property. The returned DateTimeOffset object has the same offset as the original object.

Because the current DateTimeOffset object does not represent the date and time in a specific time zone, the Subtract(TimeSpan) method does not consider a particular time zone's adjustment rules when it performs the subtraction.

DateTimeOffset.ToFileTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTimeOffset object to a Windows file time.

C#

```
public long ToFileTime ();
```

Returns

Int64

The value of the current DateTimeOffset object, expressed as a Windows file time.

Exceptions

ArgumentOutOfRangeException

The resulting file time would represent a date and time before midnight on January 1, 1601 C.E. Coordinated Universal Time (UTC).

Remarks

A Windows file time is a 64-bit value that represents the number of 100-nanosecond intervals that have elapsed since 12:00 midnight, January 1, 1601 A.D. (C.E.) Coordinated Universal Time (UTC). Windows uses a file time to record when an application creates, accesses, or writes to a file.

The ToFileTime method converts the current DateTimeOffset object's date and time to UTC before it performs the conversion. In other words, calling the ToFileTime method is equivalent to the following method call:

C#

```
this.ToUtcDateTime().ToFileTime();
```

Applies to

Product	Versions

DateTimeOffset.ToLocalTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current DateTimeOffset object to a DateTimeOffset object that represents the local time.

C#

```
public DateTimeOffset ToLocalTime ();
```

Returns

DateTimeOffset

An object that represents the date and time of the current DateTimeOffset object converted to local time.

Examples

The following example uses the ToLocalTime method to convert a DateTimeOffset value to local time in the Pacific Standard Time zone. It also illustrates the method's support for the local time zone's adjustment rules.

C#

```
// Local time changes on 3/11/2007 at 2:00 AM
DateTimeOffset originalTime, localTime;

originalTime = new DateTimeOffset(2007, 3, 11, 3, 0, 0,
                                  new TimeSpan(-6, 0, 0));
localTime = originalTime.ToLocalTime();
Console.WriteLine("Converted {0} to {1}.", originalTime.ToString(),
                                           localTime.ToString());

originalTime = new DateTimeOffset(2007, 3, 11, 4, 0, 0,
                                  new TimeSpan(-6, 0, 0));
localTime = originalTime.ToLocalTime();
Console.WriteLine("Converted {0} to {1}.", originalTime.ToString(),
```

```
                                            localTime.ToString());

// Define a summer UTC time
originalTime = new DateTimeOffset(2007, 6, 15, 8, 0, 0,
                                  TimeSpan.Zero);
localTime = originalTime.ToLocalTime();
Console.WriteLine("Converted {0} to {1}.", originalTime.ToString(),
                                            localTime.ToString());

// Define a winter time
originalTime = new DateTimeOffset(2007, 11, 30, 14, 0, 0,
                                  new TimeSpan(3, 0, 0));
localTime = originalTime.ToLocalTime();
Console.WriteLine("Converted {0} to {1}.", originalTime.ToString(),
                                            localTime.ToString());
// The example produces the following output:
//    Converted 3/11/2007 3:00:00 AM -06:00 to 3/11/2007 1:00:00 AM -08:00.
//    Converted 3/11/2007 4:00:00 AM -06:00 to 3/11/2007 3:00:00 AM -07:00.
//    Converted 6/15/2007 8:00:00 AM +00:00 to 6/15/2007 1:00:00 AM -07:00.
//    Converted 11/30/2007 2:00:00 PM +03:00 to 11/30/2007 3:00:00 AM
-08:00.
```

Remarks

In performing the conversion to local time, the method first converts the current DateTimeOffset object's date and time to Coordinated Universal Time (UTC) by subtracting the offset from the time. It then converts the UTC date and time to local time by adding the local time zone offset. In doing this, it takes account of any adjustment rules for the local time zone.

Both the value of the current DateTimeOffset object and the value of the DateTimeOffset object returned by the method call represent the same point in time. That is, if both are passed to the DateTimeOffset.Equals(DateTimeOffset, DateTimeOffset) method, the method will return `true`.

If the conversion causes a time that is out of range of the DateTimeOffset type, the ToLocalTime method returns a DateTimeOffset object that has the date and time set to either MaxValue or MinValue and the offset set to the local time zone offset.

DateTimeOffset.ToOffset(TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTimeOffset object to the date and time specified by an offset value.

```
C#

public DateTimeOffset ToOffset (TimeSpan offset);
```

Parameters

`offset` TimeSpan

The offset to convert the DateTimeOffset value to.

Returns

DateTimeOffset

An object that is equal to the original DateTimeOffset object (that is, their ToUniversalTime() methods return identical points in time) but whose Offset property is set to `offset`.

Exceptions

ArgumentException

The resulting DateTimeOffset object has a DateTime value earlier than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset object has a DateTime value later than DateTimeOffset.MaxValue.

ArgumentOutOfRangeException

`offset` is less than -14 hours.

-or-

`offset` is greater than 14 hours.

Examples

The following example illustrates how to use the ToOffset method to convert a DateTimeOffset object to a DateTimeOffset object with a different offset.

C#

```
using System;

public class DateTimeOffsetConversion
{
   private static DateTimeOffset sourceTime;

   public static void Main()
   {
      DateTimeOffset targetTime;
      sourceTime = new DateTimeOffset(2007, 9, 1, 9, 30, 0,
                                      new TimeSpan(-5, 0, 0));

      // Convert to same time (return sourceTime unchanged)
      targetTime = sourceTime.ToOffset(new TimeSpan(-5, 0, 0));
      ShowDateAndTimeInfo(targetTime);

      // Convert to UTC (0 offset)
      targetTime = sourceTime.ToOffset(TimeSpan.Zero);
      ShowDateAndTimeInfo(targetTime);

      // Convert to 8 hours behind UTC
      targetTime = sourceTime.ToOffset(new TimeSpan(-8, 0, 0));
      ShowDateAndTimeInfo(targetTime);

      // Convert to 3 hours ahead of UTC
      targetTime = sourceTime.ToOffset(new TimeSpan(3, 0, 0));
      ShowDateAndTimeInfo(targetTime);
   }

   private static void ShowDateAndTimeInfo(DateTimeOffset newTime)
   {
      Console.WriteLine("{0} converts to {1}", sourceTime, newTime);
      Console.WriteLine("{0} and {1} are equal: {2}",
                        sourceTime, newTime, sourceTime.Equals(newTime));
      Console.WriteLine("{0} and {1} are identical: {2}",
                        sourceTime, newTime,
                        sourceTime.EqualsExact(newTime));
```

```
        Console.WriteLine();
    }
}
//
// The example displays the following output:
//    9/1/2007 9:30:00 AM -05:00 converts to 9/1/2007 9:30:00 AM -05:00
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 9:30:00 AM -05:00 are equal:
True
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 9:30:00 AM -05:00 are
identical: True
//
//    9/1/2007 9:30:00 AM -05:00 converts to 9/1/2007 2:30:00 PM +00:00
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 2:30:00 PM +00:00 are equal:
True
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 2:30:00 PM +00:00 are
identical: False
//
//    9/1/2007 9:30:00 AM -05:00 converts to 9/1/2007 6:30:00 AM -08:00
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 6:30:00 AM -08:00 are equal:
True
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 6:30:00 AM -08:00 are
identical: False
//
//    9/1/2007 9:30:00 AM -05:00 converts to 9/1/2007 5:30:00 PM +03:00
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 5:30:00 PM +03:00 are equal:
True
//    9/1/2007 9:30:00 AM -05:00 and 9/1/2007 5:30:00 PM +03:00 are
identical: False
```

Remarks

The ToOffset method is an alternative to calling the TimeZoneInfo.ConvertTime(DateTimeOffset, TimeZoneInfo) method. It can be useful for performing simple conversions from one time zone to another when the time zones' offsets from Coordinated Universal Time (UTC) are known. However, because neither the original DateTimeOffset object nor the new DateTimeOffset object returned by the method call are unambiguously related to a particular time zone, the method does not apply any time zone adjustment rules in the conversion.

DateTimeOffset.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current DateTimeOffset object to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the value of the current DateTimeOffset object to its equivalent string representation.
ToString(IFormatProvider)	Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified culture-specific formatting information.
ToString(String)	Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the value of the current DateTimeOffset object to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

A string representation of a DateTimeOffset object that includes the offset appended at the end of the string.

Exceptions

ArgumentOutOfRangeException
The date and time is outside the range of dates supported by the calendar used by the current culture.

Examples

The following example illustrates calls to the ToString() method and displays its output on a system whose current culture is en-us.

C#

```
DateTimeOffset thisDate;

// Show output for UTC time
thisDate = DateTimeOffset.UtcNow;
Console.WriteLine(thisDate.ToString());  // Displays 3/28/2007 7:13:50 PM
+00:00

// Show output for local time
thisDate = DateTimeOffset.Now;
Console.WriteLine(thisDate.ToString());  // Displays 3/28/2007 12:13:50
PM -07:00

// Show output for arbitrary time offset
thisDate = thisDate.ToOffset(new TimeSpan(-5, 0, 0));
Console.WriteLine(thisDate.ToString());  // Displays 3/28/2007 2:13:50 PM
-05:00
```

Remarks

The return value of this method is identical to that of the DateTime.ToString() method, except that it includes a space followed by the offset appended at the end of the string. In other words, it formats output using the short date pattern, the long time pattern, and the `zzz` custom format string, with each element separated from the previous element by a space. For example, if DateTime.ToString() returns a value of 1/12/2008 6:15:50 PM, ToString() returns a value of 1/12/2008 6:15:50 PM -08:00 for a time that is eight hours behind Coordinated Universal Time (UTC).

This method uses formatting information derived from the current culture. For more information, see CurrentCulture. Other overloads of the ToString method enable you

to specify the culture whose formatting to use, and to define the output pattern of the DateTimeOffset value.

Notes to Callers

The ToString() method returns the string representation of the date and time in the calendar used by the current culture. If the value of the current DateTimeOffset instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the HijriCalendar class when the current culture is Arabic (Syria).

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example
{
   public static void Main()
   {
      DateTimeOffset date1 = new DateTimeOffset(new DateTime(550, 1, 1),
                                                TimeSpan.Zero);
      CultureInfo dft;
      CultureInfo arSY = new CultureInfo("ar-SY");
      arSY.DateTimeFormat.Calendar = new HijriCalendar();

      // Change current culture to ar-SY.
      dft = Thread.CurrentThread.CurrentCulture;
      Thread.CurrentThread.CurrentCulture = arSY;

      // Display the date using the current culture's calendar.
      try {
         Console.WriteLine(date1.ToString());
      }
      catch (ArgumentOutOfRangeException) {
         Console.WriteLine("{0} is earlier than {1} or later than {2}",
                           date1.ToString("d",
CultureInfo.InvariantCulture),

arSY.DateTimeFormat.Calendar.MinSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture),

arSY.DateTimeFormat.Calendar.MaxSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture));
      }

      // Restore the default culture.
      Thread.CurrentThread.CurrentCulture = dft;
```

```
    }
}
// The example displays the following output:
//    01/01/0550 is earlier than 07/18/0622 or later than 12/31/9999
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified culture-specific formatting information.

C#

```
public string ToString (IFormatProvider? formatProvider);
```

Parameters

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

A string representation of the value of the current DateTimeOffset object, as specified by `formatProvider`.

Exceptions

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by `formatProvider`.

Examples

The following example displays a DateTimeOffset object using CultureInfo objects that represent the invariant culture, as well as four other cultures.

C#

```
CultureInfo[] cultures = new CultureInfo[] {CultureInfo.InvariantCulture,
                                            new CultureInfo("en-us"),
                                            new CultureInfo("fr-fr"),
                                            new CultureInfo("de-DE"),
                                            new CultureInfo("es-ES")};

DateTimeOffset thisDate = new DateTimeOffset(2007, 5, 1, 9, 0, 0,
                                             TimeSpan.Zero);

foreach (CultureInfo culture in cultures)
{
   string cultureName;
   if (string.IsNullOrEmpty(culture.Name))
      cultureName = culture.NativeName;
   else
      cultureName = culture.Name;

   Console.WriteLine("In {0}, {1}",
                     cultureName, thisDate.ToString(culture));
}
// The example produces the following output:
//    In Invariant Language (Invariant Country), 05/01/2007 09:00:00
+00:00
//    In en-US, 5/1/2007 9:00:00 AM +00:00
//    In fr-FR, 01/05/2007 09:00:00 +00:00
//    In de-DE, 01.05.2007 09:00:00 +00:00
//    In es-ES, 01/05/2007 9:00:00 +00:00
```

Remarks

The return value of this method is identical to that of its equivalent overload of the DateTime.ToString method, except that it includes a space followed by the offset appended at the end of the string. In other words, it formats output using the short date pattern, the long time pattern, and the `zzz` custom format string, with each element separated from the previous element by a space.

The format of these three elements is defined by the `formatProvider` parameter. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture whose formatting conventions are applied to the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatProvider` is `null`, the DateTimeFormatInfo object associated with the current culture is used (see CurrentCulture).

Notes to Callers

The ToString(IFormatProvider) method returns the string representation of the date and time in the calendar used by the culture represented by the `formatProvider` parameter. Its calendar is defined by the Calendar property. If the value of the current DateTimeOffset instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the JapaneseCalendar class.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      CultureInfo jaJP = new CultureInfo("ja-JP");
      jaJP.DateTimeFormat.Calendar = new JapaneseCalendar();
      DateTimeOffset date1 = new DateTimeOffset(new DateTime(1867, 1, 1),
                                                TimeSpan.Zero);

      try {
         Console.WriteLine(date1.ToString(jaJP));
      }
      catch (ArgumentOutOfRangeException) {
         Console.WriteLine("{0:d} is earlier than {1:d} or later than
{2:d}",
                           date1,

jaJP.DateTimeFormat.Calendar.MinSupportedDateTime,

jaJP.DateTimeFormat.Calendar.MaxSupportedDateTime);
```

```
        }
    }
}
// The example displays the following output:
//    1/1/1867 is earlier than 9/8/1868 or later than 12/31/9999
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A format string.

Returns

String

A string representation of the value of the current DateTimeOffset object, as specified by `format`.

Exceptions

FormatException

The length of `format` is one, and it is not one of the standard format specifier characters defined for DateTimeFormatInfo.

-or-

`format` does not contain a valid custom format pattern.

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by the current culture.

Examples

The following example displays a DateTimeOffset object to the console using each of the standard date and time format specifiers. The output is formatted by using the en-us culture.

C#

```
DateTimeOffset outputDate = new DateTimeOffset(2007, 10, 31, 21, 0, 0,
                                        new TimeSpan(-8, 0, 0));
string specifier;

// Output date using each standard date/time format specifier
specifier = "d";
// Displays   d: 10/31/2007
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "D";
// Displays   D: Wednesday, October 31, 2007
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "t";
// Displays   t: 9:00 PM
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "T";
// Displays   T: 9:00:00 PM
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "f";
// Displays   f: Wednesday, October 31, 2007 9:00 PM
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "F";
// Displays   F: Wednesday, October 31, 2007 9:00:00 PM
```

```
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "g";
// Displays   g: 10/31/2007 9:00 PM
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "G";
// Displays   G: 10/31/2007 9:00:00 PM
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "M";           // 'm' is identical
// Displays   M: October 31
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "R";           // 'r' is identical
// Displays   R: Thu, 01 Nov 2007 05:00:00 GMT
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "s";
// Displays   s: 2007-10-31T21:00:00
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

specifier = "u";
// Displays   u: 2007-11-01 05:00:00Z
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));

// Specifier is not supported
specifier = "U";
try
{
   Console.WriteLine("{0}: {1}", specifier,
outputDate.ToString(specifier));
}
catch (FormatException)
{
   Console.WriteLine("{0}: Not supported.", specifier);
}

specifier = "Y";         // 'y' is identical
// Displays   Y: October, 2007
Console.WriteLine("{0}: {1}", specifier, outputDate.ToString(specifier));
```

Remarks

The `format` parameter should contain either a single format specifier character (see Standard Date and Time Format Strings) or a custom format pattern (see Custom Date and Time Format Strings) that defines the format of the returned string. If `format` is a null or empty string ("""), the DateTimeOffset value is output using the default format.

The following table shows the exact operation of certain format specifiers when used with DateTimeOffset, which differs from their behavior when used with DateTime.

Expand table

Existing format specifier	New behavior
"K"	Designed to round-trip a date and time. With DateTimeOffset, maps to "zzz" (the offset is always displayed with hours and minutes). Note that "K" is a custom format specifier; it cannot appear as the single character in `format`.
"U"	Not supported.
"r"	Converts the DateTimeOffset object to Coordinated Universal Time (UTC) and outputs it using the custom format string `ddd, dd MMM yyyy HH:mm:ss GMT`.
"u"	Converts the DateTimeOffset object to UTC and outputs it using the format `yyyy-MM-dd HH:mm:ssZ`.

The remaining standard date and time format specifiers behave the same with the ToString(String) method as they do with the ToString method.

This method uses formatting information derived from the current culture. For more information, see CurrentCulture.

Notes to Callers

The ToString(String) method returns the string representation of the date and time in the calendar used by the current culture. If the value of the current DateTimeOffset instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the HebrewCalendar class when the current culture is Hebrew (Israel).

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example
{
   public static void Main()
   {
```

```
      DateTimeOffset date1 = new DateTimeOffset(new DateTime(1550, 7,
21),
                                                TimeSpan.Zero);
      CultureInfo dft;
      CultureInfo heIL = new CultureInfo("he-IL");
      heIL.DateTimeFormat.Calendar = new HebrewCalendar();

      // Change current culture to he-IL.
      dft = Thread.CurrentThread.CurrentCulture;
      Thread.CurrentThread.CurrentCulture = heIL;

      // Display the date using the current culture's calendar.
      try {
         Console.WriteLine(date1.ToString("G"));
      }
      catch (ArgumentOutOfRangeException) {
         Console.WriteLine("{0} is earlier than {1} or later than {2}",
                           date1.ToString("d",
CultureInfo.InvariantCulture),

heIL.DateTimeFormat.Calendar.MinSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture),

heIL.DateTimeFormat.Calendar.MaxSupportedDateTime.ToString("d",
CultureInfo.InvariantCulture));
      }

      // Restore the default culture.
      Thread.CurrentThread.CurrentCulture = dft;
   }
}
// The example displays the following output:
//    07/21/1550 is earlier than 01/01/1583 or later than 09/29/2239
```

UWP	10.0

ToString(String, IFormatProvider)

Converts the value of the current DateTimeOffset object to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? formatProvider);
```

Parameters

`format` String

A format string.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

A string representation of the value of the current DateTimeOffset object, as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

The length of `format` is one, and it is not one of the standard format specifier characters defined for DateTimeFormatInfo.

-or-

`format` does not contain a valid custom format pattern.

ArgumentOutOfRangeException

The date and time is outside the range of dates supported by the calendar used by `formatProvider`.

Examples

The following example uses the ToString(String, IFormatProvider) method to display a DateTimeOffset object using a custom format string for several different cultures.

C#

```
DateTimeOffset outputDate = new DateTimeOffset(2007, 11, 1, 9, 0, 0,
                                       new TimeSpan(-7, 0, 0));
string format = "dddd, MMM dd yyyy HH:mm:ss zzz";

// Output date and time using custom format specification
Console.WriteLine(outputDate.ToString(format, null as
DateTimeFormatInfo));
Console.WriteLine(outputDate.ToString(format,
CultureInfo.InvariantCulture));
Console.WriteLine(outputDate.ToString(format,
                                        new CultureInfo("fr-FR")));
Console.WriteLine(outputDate.ToString(format,
                                        new CultureInfo("es-ES")));
// The example displays the following output to the console:
//    Thursday, Nov 01 2007 09:00:00 -07:00
//    Thursday, Nov 01 2007 09:00:00 -07:00
//    jeudi, nov. 01 2007 09:00:00 -07:00
//    jueves, nov 01 2007 09:00:00 -07:00
```

Remarks

The `format` parameter should contain either a single format specifier character (see Standard Date and Time Format Strings) or a custom format pattern (see Custom Date and Time Format Strings). If `format` is a null or empty string ("), the DateTimeOffset object is output using the default format.

The following table shows the exact operation of certain format specifiers when used with DateTimeOffset, which differs from their behavior when used with DateTime.

Expand table

Existing format specifier	New behavior
"K"	Designed to round-trip a date and time. With DateTimeOffset, maps to "zzz" (the offset is always displayed with hours and minutes). Note that "K" is a custom format specifier; it cannot appear as the single character in `format`.
"U"	Not supported.
"r"	Converts the DateTimeOffset object to Coordinated Universal Time (UTC) and outputs it using the custom format string `ddd, dd MMM yyyy HH:mm:ss GMT`.
"u"	Converts the DateTimeOffset value to UTC and outputs it using the format `yyyy-MM-dd HH:mm:ssZ`.

The remaining standard date and time format specifiers behave the same with the ToString(String) method as they do with the ToString method.

The pattern that corresponds to standard format specifiers, as well as the symbols and names of date and time components, is defined by the `formatProvider` parameter. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture whose formatting is used in `input`. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting used in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatProvider` is `null`, the DateTimeFormatInfo object associated with the current culture is used (see CurrentCulture).

Notes to Callers

The ToString(String, IFormatProvider) method returns the string representation of the date and time in the calendar used by the `formatProvider` parameter. Its calendar is defined by the Calendar property. If the value of the current DateTimeOffset instance is earlier than MinSupportedDateTime or later than MaxSupportedDateTime, the method throws an ArgumentOutOfRangeException. The following example provides an illustration. It attempts to format a date that is outside the range of the UmAlQuraCalendar class.

```
C#
```

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      CultureInfo arSA = new CultureInfo("ar-SA");
      arSA.DateTimeFormat.Calendar = new UmAlQuraCalendar();
      DateTimeOffset date1 = new DateTimeOffset(new DateTime(1890, 9,
10),
                                                TimeSpan.Zero);

      try {
         Console.WriteLine(date1.ToString("d", arSA));
      }
      catch (ArgumentOutOfRangeException) {
         Console.WriteLine("{0:d} is earlier than {1:d} or later than
{2:d}",
                           date1,

arSA.DateTimeFormat.Calendar.MinSupportedDateTime,

arSA.DateTimeFormat.Calendar.MaxSupportedDateTime);
      }
   }
}
// The example displays the following output:
//    9/10/1890 is earlier than 4/30/1900 or later than 5/13/2029
```

DateTimeOffset.ToUniversalTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current DateTimeOffset object to a DateTimeOffset value that represents the Coordinated Universal Time (UTC).

C#

```
public DateTimeOffset ToUniversalTime ();
```

Returns

DateTimeOffset

An object that represents the date and time of the current DateTimeOffset object converted to Coordinated Universal Time (UTC).

Examples

The following example calls the ToUniversalTime method to convert a local time and several other times to Coordinated Universal Time (UTC).

C#

```
DateTimeOffset localTime, otherTime, universalTime;

// Define local time in local time zone
localTime = new DateTimeOffset(new DateTime(2007, 6, 15, 12, 0, 0));
Console.WriteLine("Local time: {0}", localTime);
Console.WriteLine();

// Convert local time to offset 0 and assign to otherTime
otherTime = localTime.ToOffset(TimeSpan.Zero);
Console.WriteLine("Other time: {0}", otherTime);
Console.WriteLine("{0} = {1}: {2}",
                  localTime, otherTime,
```

```
                    localTime.Equals(otherTime));
Console.WriteLine("{0} exactly equals {1}: {2}",
                    localTime, otherTime,
                    localTime.EqualsExact(otherTime));
Console.WriteLine();

// Convert other time to UTC
universalTime = localTime.ToUniversalTime();
Console.WriteLine("Universal time: {0}", universalTime);
Console.WriteLine("{0} = {1}: {2}",
                    otherTime, universalTime,
                    universalTime.Equals(otherTime));
Console.WriteLine("{0} exactly equals {1}: {2}",
                    otherTime, universalTime,
                    universalTime.EqualsExact(otherTime));
Console.WriteLine();
// The example produces the following output to the console:
//    Local time: 6/15/2007 12:00:00 PM -07:00
//
//    Other time: 6/15/2007 7:00:00 PM +00:00
//    6/15/2007 12:00:00 PM -07:00 = 6/15/2007 7:00:00 PM +00:00: True
//    6/15/2007 12:00:00 PM -07:00 exactly equals 6/15/2007 7:00:00 PM
+00:00: False
//
//    Universal time: 6/15/2007 7:00:00 PM +00:00
//    6/15/2007 7:00:00 PM +00:00 = 6/15/2007 7:00:00 PM +00:00: True
//    6/15/2007 7:00:00 PM +00:00 exactly equals 6/15/2007 7:00:00 PM
+00:00: True
```

Remarks

This method returns a DateTimeOffset object whose Offset property is set to zero.

Both the value of the current DateTimeOffset object and the value of the DateTimeOffset object returned by the method call represent the same point in time. That is, if both are passed to the DateTimeOffset.Equals(DateTimeOffset, DateTimeOffset) method, the method will return `true`.

DateTimeOffset.ToUnixTimeMilliseconds Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the number of milliseconds that have elapsed since 1970-01-01T00:00:00.000Z.

C#

```
public long ToUnixTimeMilliseconds ();
```

Returns

Int64

The number of milliseconds that have elapsed since 1970-01-01T00:00:00.000Z.

Remarks

Unix time represents the number of seconds that have elapsed since 1970-01-01T00:00:00Z (January 1, 1970, at 12:00 AM UTC). It does not take leap seconds into account. This method returns the number of milliseconds in Unix time.

This method first converts the current instance to UTC before returning the number of milliseconds in its Unix time. For date and time values before 1970-01-01T00:00:00Z, this method returns a negative value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.ToUnixTimeSeconds Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the number of seconds that have elapsed since 1970-01-01T00:00:00Z.

C#

```
public long ToUnixTimeSeconds ();
```

Returns

Int64

The number of seconds that have elapsed since 1970-01-01T00:00:00Z.

Examples

The following example calls the ToUnixTimeSeconds method to return the Unix time of values that are equal to, shortly before, and shortly after 1970-01-01T00:00:00Z.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      DateTimeOffset dto = new DateTimeOffset(1970, 1, 1, 0, 0, 0,
TimeSpan.Zero);
      Console.WriteLine("{0} --> Unix Seconds: {1}", dto,
dto.ToUnixTimeSeconds());

      dto = new DateTimeOffset(1969, 12, 31, 23, 59, 0, TimeSpan.Zero);
      Console.WriteLine("{0} --> Unix Seconds: {1}", dto,
dto.ToUnixTimeSeconds());
```

```
        dto = new DateTimeOffset(1970, 1, 1, 0, 1, 0, TimeSpan.Zero);
        Console.WriteLine("{0} --> Unix Seconds: {1}", dto,
dto.ToUnixTimeSeconds());
    }
}
// The example displays the following output:
//    1/1/1970 12:00:00 AM +00:00 --> Unix Seconds: 0
//    12/31/1969 11:59:00 PM +00:00 --> Unix Seconds: -60
//    1/1/1970 12:01:00 AM +00:00 --> Unix Seconds: 60
```

Remarks

Unix time represents the number of seconds that have elapsed since 1970-01-01T00:00:00Z (January 1, 1970, at 12:00 AM UTC). It does not take leap seconds into account.

This method first converts the current instance to UTC before returning its Unix time. For date and time values before 1970-01-01T00:00:00Z, this method returns a negative value.

DateTimeOffset.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current datetime offset instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? formatProvider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`formatProvider` IFormatProvider

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current datetime offset instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? formatProvider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the charactes that represent a standard or custom format string that defines the acceptable format for `destination`.

`formatProvider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

DateTimeOffset.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified string representation of a date and time to its DateTimeOffset equivalent.

Overloads

Expand table

TryParse(String, IFormatProvider, DateTimeStyles, DateTimeOffset)	Tries to convert a specified string representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTimeOffset)	Tries to convert a specified span representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, DateTimeOffset)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeOffset)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, DateTimeOffset)	Tries to convert a specified span representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, DateTimeOffset)	Tries to converts a specified string representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.

TryParse(String, IFormatProvider, DateTimeStyles, DateTimeOffset)

Tries to convert a specified string representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (string? input, IFormatProvider?
formatProvider, System.Globalization.DateTimeStyles styles, out
DateTimeOffset result);
```

Parameters

`input` String

A string that contains a date and time to convert.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset value equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue, if the conversion failed. The conversion fails if the `input` parameter is `null` or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Exceptions

ArgumentException

`styles` includes an undefined DateTimeStyles value.

-or-

NoCurrentDateDefault is not supported.

-or-

`styles` includes mutually exclusive DateTimeStyles values.

Examples

The following example calls the TryParse(String, IFormatProvider, DateTimeStyles, DateTimeOffset) method with a variety of DateTimeStyles values to parse some strings with various date and time formats.

C#

```
string dateString;
DateTimeOffset parsedDate;

dateString = "05/01/2008 6:00:00";
// Assume time is local
if (DateTimeOffset.TryParse(dateString, null as IFormatProvider,
                            DateTimeStyles.AssumeLocal,
                            out parsedDate))
   Console.WriteLine("'{0}' was converted to {1}.",
                     dateString, parsedDate.ToString());
else
   Console.WriteLine("Unable to parse '{0}'.", dateString);

// Assume time is UTC
if (DateTimeOffset.TryParse(dateString, null as IFormatProvider,
                            DateTimeStyles.AssumeUniversal,
                            out parsedDate))
   Console.WriteLine("'{0}' was converted to {1}.",
                     dateString, parsedDate.ToString());
else
   Console.WriteLine("Unable to parse '{0}'.", dateString);

// Parse and convert to UTC
dateString = "05/01/2008 6:00:00AM +5:00";
if (DateTimeOffset.TryParse(dateString, null as IFormatProvider,
                           DateTimeStyles.AdjustToUniversal,
                           out parsedDate))
   Console.WriteLine("'{0}' was converted to {1}.",
                     dateString, parsedDate.ToString());
else
   Console.WriteLine("Unable to parse '{0}'.", dateString);
// The example displays the following output to the console:
//    '05/01/2008 6:00:00' was converted to 5/1/2008 6:00:00 AM -07:00.
```

```
//    '05/01/2008 6:00:00' was converted to 5/1/2008 6:00:00 AM +00:00.
//    '05/01/2008 6:00:00AM +5:00' was converted to 5/1/2008 1:00:00 AM
+00:00.
```

Remarks

This overload of the TryParse(String, IFormatProvider, DateTimeStyles, DateTimeOffset) method is like the DateTimeOffset.Parse(String, IFormatProvider, DateTimeStyles) method, except that it does not throw an exception if the conversion fails. The method parses a string with three elements that can appear in any order and are delimited by white space. These three elements are shown in the following table.

Expand table

Element	Example
<Date>	"2/10/2007"
<Time>	"1:02:03 PM"
<Offset>	"-7:30"

Although each of these elements is optional, <Offset> cannot appear by itself. It must be provided together with either <Date> or <Time>. If <Date> is missing, its default value is the current day. If <Date> is present but its year component consists of only two digits, it is converted to a year in the `provider` parameter's current calendar based on the value of the Calendar.TwoDigitYearMax property. If <Time> is missing, its default value is 12:00:00 AM. If <Offset> is missing, its default value is the offset of the local time zone, or Zero if either the DateTimeStyles.AdjustToUniversal or DateTimeStyles.AssumeUniversal value is specified in `styles`. If <Offset> is present, it can represent either a negative or a positive offset from Coordinated Universal Time (UTC). In either case, <Offset> must include a sign symbol or the method returns `false`.

The `input` string is parsed by using the culture-specific formatting information in a DateTimeFormatInfo object supplied by the `formatProvider` parameter. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture whose formatting is used in `input`. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the format that is used in `input`.

- A DateTimeFormatInfo object that defines the format of date and time data.

In addition, each element can be delimited by leading or trailing white space, and the <Date> and <Time> components can include inner white space (such as 6: 00:00). Only the <Offset> component cannot include inner white space.

If `provider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The positive or negative sign used in <Offset> must be either + or -. It is not defined by the PositiveSign or NegativeSign properties of the NumberFormatInfo object returned by the `formatprovider` parameter's NumberFormat property.

The following members of the DateTimeStyles enumeration are supported:

Expand table

DateTimeStyles Member	Comments
AdjustToUniversal	Parses the string represented by `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the returned object's ToUniversalTime() method.
AllowInnerWhite	Although valid, this value is ignored. Inner white space is allowed in the <Date> and <Time> components.
AllowLeadingWhite	Although valid, this value is ignored. Leading white space is allowed in front of each component in the parsed string.
AllowTrailingWhite	Although valid, this value is ignored. Trailing white space is allowed in front of each component in the parsed string.
AllowWhiteSpaces	This is the default behavior. It cannot be overridden by supplying a more restrictive DateTimeStyles enumeration value, such as DateTimeStyles.None.
AssumeLocal	Indicates that, if the `input` parameter lacks an <Offset> element, the offset of the local time zone should be provided. This is the default behavior of the TryParse(String, IFormatProvider, DateTimeStyles, DateTimeOffset) method.
AssumeUniversal	Indicates that, if the `input` parameter lacks an <Offset> element, the UTC offset (00:00) should be provided.
None	Although valid, this value is ignored and has no effect.
RoundtripKind	Because the DateTimeOffset structure does not include a `Kind` property, this value has no effect.

Only the DateTimeStyles.NoCurrentDateDefault value is not supported. An ArgumentException is thrown if this value is included in the `styles` parameter.

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTimeOffset)

Tries to convert a specified span representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> input, IFormatProvider?
formatProvider, System.Globalization.DateTimeStyles styles, out
DateTimeOffset result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters representing the date and time to convert.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset value equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue, if the conversion failed. The conversion fails if the `input` parameter is `null` or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

TryParse(String, IFormatProvider, DateTimeOffset)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider, out
DateTimeOffset result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` DateTimeOffset

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeOffset)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out DateTimeOffset result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` DateTimeOffset

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, DateTimeOffset)

Tries to convert a specified span representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> input, out DateTimeOffset
result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters representing the date and time to convert.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue, if the conversion failed. The conversion fails if the `input` parameter is `null` or does not contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, DateTimeOffset)

Tries to converts a specified string representation of a date and time to its DateTimeOffset equivalent, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? input, out DateTimeOffset result);
```

Parameters

`input` String

A string that contains a date and time to convert.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue, if the conversion failed. The conversion fails if the `input` parameter is `null` or does not

contain a valid string representation of a date and time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Examples

The following example calls the TryParse(String, DateTimeOffset) method to parse several strings with various date and time formats.

C#

```
DateTimeOffset parsedDate;
string dateString;

// String with date only
dateString = "05/01/2008";
if (DateTimeOffset.TryParse(dateString, out parsedDate))
   Console.WriteLine("{0} was converted to {1}.",
                     dateString, parsedDate);

// String with time only
dateString = "11:36 PM";
if (DateTimeOffset.TryParse(dateString, out parsedDate))
   Console.WriteLine("{0} was converted to {1}.",
                     dateString, parsedDate);

// String with date and offset
dateString = "05/01/2008 +7:00";
if (DateTimeOffset.TryParse(dateString, out parsedDate))
   Console.WriteLine("{0} was converted to {1}.",
                     dateString, parsedDate);

// String with day abbreviation
dateString = "Thu May 01, 2008";
if (DateTimeOffset.TryParse(dateString, out parsedDate))
   Console.WriteLine("{0} was converted to {1}.",
                     dateString, parsedDate);

// String with date, time with AM/PM designator, and offset
dateString = "5/1/2008 10:00 AM -07:00";
if (DateTimeOffset.TryParse(dateString, out parsedDate))
   Console.WriteLine("{0} was converted to {1}.",
                     dateString, parsedDate);
// if (run on 3/29/07, the example displays the following output
// to the console:
//    05/01/2008 was converted to 5/1/2008 12:00:00 AM -07:00.
```

```
//    11:36 PM was converted to 3/29/2007 11:36:00 PM -07:00.
//    05/01/2008 +7:00 was converted to 5/1/2008 12:00:00 AM +07:00.
//    Thu May 01, 2008 was converted to 5/1/2008 12:00:00 AM -07:00.
//    5/1/2008 10:00 AM -07:00 was converted to 5/1/2008 10:00:00 AM
-07:00.
```

Remarks

This overload of the TryParse(String, DateTimeOffset) method is like the DateTimeOffset.Parse(String) method, except that it does not throw an exception if the conversion fails. It parses a string with three elements that can appear in any order and are delimited by white space. These three elements are shown in the following table.

Expand table

Element	Example
<Date>	"2/10/2007"
<Time>	"1:02:03 PM"
<Offset>	"-7:30"

Although each of these elements is optional, <Offset> cannot appear by itself. It must be provided together with either <Date> or <Time>. If <Date> is missing, its default value is the current day. If <Date> is present but its year component consists of only two digits, it is converted to a year in the current culture's current calendar based on the value of the Calendar.TwoDigitYearMax property. If <Time> is missing, its default value is 12:00:00 AM. If <Offset> is missing, its default value is the offset of the local time zone. If <Offset> is present, it can represent either a negative or a positive offset from Coordinated Universal Time (UTC). In either case, <Offset> must include a sign symbol or the method returns `false`.

The `input` string is parsed by using the formatting information in a DateTimeFormatInfo object initialized for the current culture. To parse a string that contains designated formatting that does not necessarily correspond to that of the current culture, use the TryParseExact method and provide a format specifier.

DateTimeOffset.TryParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a date and time to its DateTimeOffset equivalent. The format of the string representation must match a specified format exactly.

Overloads

Expand table

TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match one of the specified formats exactly.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the representation of a date and time in a character span to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the date and time representation must match the specified format exactly.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the representation of a date and time in a character span to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the date and time representation must match one of the specified formats exactly.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTimeOffset)	Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly.

TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTimeOffset)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match one of the specified formats exactly.

C#

```
public static bool TryParseExact (string? input, string?[]? formats,
IFormatProvider? formatProvider, System.Globalization.DateTimeStyles
styles, out DateTimeOffset result);
```

Parameters

`input` String

A string that contains a date and time to convert.

`formats` String[]

An array that defines the expected formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of input. A typical value to specify is `None`.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue, if the conversion failed. The conversion fails if the `input` does not contain a valid string representation of a date and time, or does not contain the date and time in the expected format defined by `format`, or if `formats` is `null`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Exceptions

ArgumentException

`styles` includes an undefined DateTimeStyles value.

-or-

NoCurrentDateDefault is not supported.

-or-

`styles` includes mutually exclusive DateTimeStyles values.

Examples

The following example defines multiple input formats for the string representation of a date and time and offset value, and then passes the string that is entered by the user to the TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTimeOffset) method.

C#

```
TextReader conIn = Console.In;
TextWriter conOut = Console.Out;
int tries = 0;
string input = String.Empty;

string[] formats = new string[] {"M/dd/yyyy HH:m zzz", "MM/dd/yyyy HH:m
zzz",
                                 "M/d/yyyy HH:m zzz", "MM/d/yyyy HH:m
zzz",
                                 "M/dd/yy HH:m zzz", "MM/dd/yy HH:m zzz",
                                 "M/d/yy HH:m zzz", "MM/d/yy HH:m zzz",
                                 "M/dd/yyyy H:m zzz", "MM/dd/yyyy H:m
zzz",
                                 "M/d/yyyy H:m zzz", "MM/d/yyyy H:m zzz",
                                 "M/dd/yy H:m zzz", "MM/dd/yy H:m zzz",
                                 "M/d/yy H:m zzz", "MM/d/yy H:m zzz",
                                 "M/dd/yyyy HH:mm zzz", "MM/dd/yyyy HH:mm
zzz",
                                 "M/d/yyyy HH:mm zzz", "MM/d/yyyy HH:mm
zzz",
                                 "M/dd/yy HH:mm zzz", "MM/dd/yy HH:mm
zzz",
                                 "M/d/yy HH:mm zzz", "MM/d/yy HH:mm zzz",
                                 "M/dd/yyyy H:mm zzz", "MM/dd/yyyy H:mm
zzz",
```

```
                                    "M/d/yyyy H:mm zzz", "MM/d/yyyy H:mm
zzz",
                                    "M/dd/yy H:mm zzz", "MM/dd/yy H:mm zzz",
                                    "M/d/yy H:mm zzz", "MM/d/yy H:mm zzz"};
IFormatProvider provider = CultureInfo.InvariantCulture.DateTimeFormat;
DateTimeOffset result;

do {
   conOut.WriteLine("Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-
HH:MM),");
   conOut.Write("Then press Enter: ");
   input = conIn.ReadLine();
   conOut.WriteLine();
   if (DateTimeOffset.TryParseExact(input, formats, provider,
                                    DateTimeStyles.AllowWhiteSpaces,
                                    out result))
   {
      break;
   }
   else
   {
      Console.WriteLine("Unable to parse {0}.", input);
      tries++;
   }
} while (tries < 3);
if (tries >= 3)
   Console.WriteLine("Exiting application without parsing {0}", input);
else
   Console.WriteLine("{0} was converted to {1}", input,
result.ToString());
// Some successful sample interactions with the user might appear as
follows:
//    Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-HH:MM),
//    Then press Enter: 12/08/2007 6:54 -6:00
//
//    12/08/2007 6:54 -6:00 was converted to 12/8/2007 6:54:00 AM -06:00
//
//    Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-HH:MM),
//    Then press Enter: 12/8/2007 06:54 -06:00
//
//    12/8/2007 06:54 -06:00 was converted to 12/8/2007 6:54:00 AM -06:00
//
//    Enter a date, time, and offset (MM/DD/YYYY HH:MM +/-HH:MM),
//    Then press Enter: 12/5/07 6:54 -6:00
//
//    12/5/07 6:54 -6:00 was converted to 12/5/2007 6:54:00 AM -06:00
```

Remarks

The TryParseExact(String, String[], IFormatProvider, DateTimeStyles, DateTimeOffset) method parses the string representation of a date that matches any one of the patterns assigned to the `formats` array. If the `input` string does not match any one

of these patterns with any variations defined by the `styles` parameter, the parsing operation fails and the method returns `false`. Aside from comparing `input` to multiple strings that contain format specifiers, this overload behaves identically to the DateTimeOffset.ParseExact(String, String[], IFormatProvider, DateTimeStyles) method.

The `formats` parameter is a string array whose elements contain either a single standard format specifier or one or more custom format specifiers that define the possible pattern of `input`. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If the matched element in `formats` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the parse operation fails and the method returns `false`.

> **ⓘ Important**
>
> Using the `formats` parameter of this overload to specify multiple formats can help reduce the frustration many users experience when they enter dates and times. In particular, the ability to define multiple input patterns enables an application to handle date and time representations that can either include or lack leading zeros in months, days, hours, minutes, and seconds. The example provides an illustration of this.

If the matched element in `formats` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If the matched element in `formats` requires that input contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If the matched element in `formats` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter. The same is true for the precise pattern of `input` if the matching element of `formats` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and formatting in `input`.

- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is permitted in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AssumeLocal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default value.
AssumeUniversal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).
AllowInnerWhite	Allows `input` to include inner white space not specified by the elements in `formats`. Extra white space can appear between date and time components and within individual components (except for the offset) and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by the elements in `formats`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by the elements in `formats`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by the elements in `formats`. All extra white-space characters not

`DateTimeStyles` member	Behavior
	specified in the matched element in `formats` are ignored when parsing the string.
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in a particular element in `formats` for a successful match to occur. This is the default behavior.
RoundtripKind	Has no effect because the DateTimeOffset structure does not include a `Kind` property.

Notes to Callers

In the .NET Framework 4, the TryParseExact returns `false` if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, DateTimeOffset)

Converts the representation of a date and time in a character span to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the date and time representation must match the specified format exactly.

```C#
public static bool TryParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format, IFormatProvider? formatProvider,
System.Globalization.DateTimeStyles styles, out DateTimeOffset result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a date and time to convert.

`format` ReadOnlySpan<Char>

A format specifier that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`. A typical value to specify is None.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue if the conversion failed. The conversion fails if the

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Exceptions

ArgumentException

`styles` includes an undefined DateTimeStyles value. -or- NoCurrentDateDefault is not supported. -or- `styles` includes mutually exclusive DateTimeStyles values.

Remarks

This overload is like the DateTimeOffset.ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles) method, except that this method does not throw an exception if the conversion fails. It parses the representation of a date and time that must exactly match the pattern specified by the `format` parameter. If `input` does not match this pattern, with some possible variations in white space defined by the `styles` parameter, the parsing operation fails and the method returns `false`.

The `format` parameter is a character span that contains either a single standard format specifier or one or more custom format specifiers that define the required pattern of `input`. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If `format` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the parsing operation fails and the method returns `false`.

If `format` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If `format` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If `format` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter. The same is true for the precise pattern of `input` if `format` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and standard formats allowed in `input`.

- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is allowed in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a date and time representation, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AssumeLocal	If `format` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default behavior.
AssumeUniversal	If `format` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).
AllowInnerWhite	Allows `input` to include inner white space not specified by format. Extra white space can appear between date and time components and within individual components, other than the offset, and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by `format`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by `format`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by `format`. All extra white-space characters not specified in `format` are ignored when parsing the string.
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in `format`. This is the default behavior.
RoundtripKind	Has no effect, because the DateTimeOffset structure does not include a `Kind` property.

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, DateTimeOffset)

Converts the representation of a date and time in a character span to its DateTimeOffset equivalent using the specified formats, culture-specific format information, and style. The format of the date and time representation must match one of the specified formats exactly.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> input, string?[]?
formats, IFormatProvider? formatProvider,
System.Globalization.DateTimeStyles styles, out DateTimeOffset result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a date and time to convert.

`formats` String[]

A array of standard or custom format strings that define the acceptable formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `input`. A typical value to specify is None.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue if the conversion failed. The conversion fails if the

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Exceptions

ArgumentException

`styles` includes an undefined DateTimeStyles value. -or- NoCurrentDateDefault is not supported. -or- `styles` includes mutually exclusive DateTimeStyles values.

Remarks

This method parses the string representation of a date that matches any one of the patterns assigned to the `formats` array. If `input` does not match any one of these patterns with any variations defined by the `styles` parameter, the parsing operation fails and the method returns `false`. Aside from comparing `input` to multiple strings that contain format specifiers, this overload behaves identically to the DateTimeOffset.ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles) method.

The `formats` parameter is a string array whose elements contain either a single standard format specifier or one or more custom format specifiers that define the possible pattern of `input`. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If the matched element in `formats` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the parse operation fails and the method returns `false`.

> **ⓘ Important**
>
> Using the `formats` parameter of this overload to specify multiple formats can help reduce the frustration many users experience when they enter dates and times. In particular, the ability to define multiple input patterns enables an application to handle date and time representations that can either include or

lack leading zeros in months, days, hours, minutes, and seconds. The example provides an illustration of this.

If the matched element in `formats` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If the matched element in `formats` requires that input contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If the matched element in `formats` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes DateTimeStyles.AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes DateTimeStyles.AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols used in `input` are defined by the `formatProvider` parameter. The same is true for the precise pattern of `input` if the matching element of `formats` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and formatting in `input`.
- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is permitted in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AssumeLocal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default value.
AssumeUniversal	If the matched element in `formats` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).
AllowInnerWhite	Allows `input` to include inner white space not specified by the elements in `formats`. Extra white space can appear between date and time components and within individual components (except for the offset) and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by the elements in `formats`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by the elements in `formats`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by the elements in `formats`. All extra white-space characters not specified in the matched element in `formats` are ignored when parsing the string.
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in a particular element in `formats` for a successful match to occur. This is the default behavior.
RoundtripKind	Has no effect because the DateTimeOffset structure does not include a `Kind` property.

Applies to

▼ .NET 9 and other versions

TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTimeOffset)

Converts the specified string representation of a date and time to its DateTimeOffset equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly.

C#

```
public static bool TryParseExact (string? input, string? format,
IFormatProvider? formatProvider, System.Globalization.DateTimeStyles
styles, out DateTimeOffset result);
```

Parameters

`input` String

A string that contains a date and time to convert.

`format` String

A format specifier that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information about `input`.

`styles` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of input. A typical value to specify is `None`.

`result` DateTimeOffset

When the method returns, contains the DateTimeOffset equivalent to the date and time of `input`, if the conversion succeeded, or DateTimeOffset.MinValue, if the conversion failed. The conversion fails if the `input` parameter is `null`, or does not contain a valid string representation of a date and time in the expected format defined by `format` and `provider`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `input` parameter is successfully converted; otherwise, `false`.

Exceptions

ArgumentException

`styles` includes an undefined DateTimeStyles value.

-or-

NoCurrentDateDefault is not supported.

-or-

`styles` includes mutually exclusive DateTimeStyles values.

Examples

The following example uses the TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTimeOffset) method with standard and custom format specifiers, the invariant culture, and various DateTimeStyles values to parse several date and time strings.

C#

```
string dateString, format;
DateTimeOffset result;
IFormatProvider provider = CultureInfo.InvariantCulture;

// Parse date-only value with invariant culture and assume time is UTC.
dateString = "06/15/2008";
format = "d";
if (DateTimeOffset.TryParseExact(dateString, format, provider,
                                 DateTimeStyles.AssumeUniversal,
                                 out result))
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
else
   Console.WriteLine("'{0}' is not in the correct format.", dateString);

// Parse date-only value with leading white space.
// Should return False because only trailing white space is
// specified in method call.
dateString = " 06/15/2008";
if (DateTimeOffset.TryParseExact(dateString, format, provider,
                                 DateTimeStyles.AllowTrailingWhite,
                                 out result))
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
else
   Console.WriteLine("'{0}' is not in the correct format.", dateString);

// Parse date and time value, and allow all white space.
```

```
dateString = " 06/15/   2008  15:15    -05:00";
format = "MM/dd/yyyy H:mm zzz";
if (DateTimeOffset.TryParseExact(dateString, format, provider,
                                 DateTimeStyles.AllowWhiteSpaces,
                                 out result))
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
else
   Console.WriteLine("'{0}' is not in the correct format.", dateString);

// Parse date and time and convert to UTC.
dateString = "  06/15/2008 15:15:30 -05:00";
format = "MM/dd/yyyy H:mm:ss zzz";
if (DateTimeOffset.TryParseExact(dateString, format, provider,
                                 DateTimeStyles.AllowWhiteSpaces |
                                 DateTimeStyles.AdjustToUniversal,
                                 out result))
   Console.WriteLine("'{0}' converts to {1}.", dateString,
result.ToString());
else
   Console.WriteLine("'{0}' is not in the correct format.", dateString);
// The example displays the following output:
//    '06/15/2008' converts to 6/15/2008 12:00:00 AM +00:00.
//    ' 06/15/2008' is not in the correct format.
//    ' 06/15/   2008  15:15    -05:00' converts to 6/15/2008 3:15:00 PM
-05:00.
//    '  06/15/2008 15:15:30 -05:00' converts to 6/15/2008 8:15:30 PM
+00:00.
```

The following example uses a variety of DateTimeStyles values to parse an array of strings that are expected to conform to ISO 8601. As the output from the example shows, strings that are in the proper format fail to parse if:

- they contain white space, and an appropriate DateTimeStyles flag (such as DateTimeStyles.AllowWhiteSpaces has not been supplied in the method call.
- they contain date and time elements that are out of range.

Strings that do not specify a UTC offset are assumed to have the offset of the local time zone (in this case, -07:00, which reflects the offset of the Pacific Daylight Time zone) unless the DateTimeStyles.AssumeUniversal flag is supplied in the method call. In that case, they are assumed to be Universal Coordinated Time.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
```

```
    {
        string[] dateStrings = { "2018-08-18T12:45:16.0000000Z",
                                 "2018/08/18T12:45:16.0000000Z",
                                 "2018-18-08T12:45:16.0000000Z",
                                 "2018-08-18T12:45:16.0000000",
                                 " 2018-08-18T12:45:16.0000000Z ",
                                 "2018-08-18T12:45:16.0000000+02:00",
                                 "2018-08-18T12:45:16.0000000-07:00" };

        ParseWithISO8601(dateStrings, DateTimeStyles.None);
        Console.WriteLine("\n-----\n");
        ParseWithISO8601(dateStrings, DateTimeStyles.AllowWhiteSpaces);

Remarks

This overload of the TryParseExact(String, String, IFormatProvider, DateTimeStyles, DateTimeOffset) method is like the DateTimeOffset.ParseExact(String, String, IFormatProvider, DateTimeStyles) method, except that this method does not throw an exception if the conversion fails. It parses the string representation of a date and time that must exactly match the pattern specified by the `format` parameter. If the `input` string does not match this pattern, with some possible variations in white space defined by the `styles` parameter, the parsing operation fails and the method returns `false`.

The `format` parameter is a string that contains either a single standard format specifier or one or more custom format specifiers that define the required pattern of `input`. For details about valid formatting codes, see Standard Date and Time Format Strings and Custom Date and Time Format Strings. If `format` includes the `z`, `zz`, or `zzz` custom format specifiers to indicate that an offset must be present in `input`, that offset must include either a negative sign or a positive sign. If the sign is missing, the parsing operation fails and the method returns `false`.

If `format` requires that `input` contain a date but not a time, the resulting DateTimeOffset object is assigned a time of midnight (0:00:00). If `format` requires that `input` contain a time but not a date, the resulting DateTimeOffset object is assigned the current date on the local system. If `format` does not require that `input` contain an offset, the offset of the resulting DateTimeOffset object depends on the value of the `styles` parameter. If `styles` includes AssumeLocal, the offset of the local time zone is assigned to the DateTimeOffset object. If `styles` includes AssumeUniversal, the Coordinated Universal Time (UTC) offset, or +00:00, is assigned to the DateTimeOffset object. If neither value is specified, the offset of the local time zone is used.

The particular date and time symbols and strings used in `input` are defined by the `formatProvider` parameter. The same is true for the precise pattern of `input` if `format` is a standard format specifier string. The `formatProvider` parameter can be either of the following:

- A CultureInfo object that represents the culture based on which `input` is interpreted. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the symbols and standard formats allowed in `input`.

- A DateTimeFormatInfo object that defines the format of date and time data.

If `formatprovider` is `null`, the CultureInfo object that corresponds to the current culture is used.

The `styles` parameter defines whether white space is allowed in the input string, indicates how strings without an explicit offset component are parsed, and supports UTC conversion as part of the parsing operation. All members of the DateTimeStyles enumeration are supported except NoCurrentDateDefault. The following table lists the effect of each supported member.

Expand table

`DateTimeStyles` member	Behavior
AdjustToUniversal	Parses `input` and, if necessary, converts it to UTC. It is equivalent to parsing a string, and then calling the DateTimeOffset.ToUniversalTime method of the returned DateTimeOffset object.
AssumeLocal	If `format` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the offset of the local time zone. This is the default behavior.
AssumeUniversal	If `format` does not require that `input` contain an offset value, the returned DateTimeOffset object is given the UTC offset (+00:00).
AllowInnerWhite	Allows `input` to include inner white space not specified by format. Extra white space can appear between date and time components and within individual components, other than the offset, and is ignored when parsing the string.
AllowLeadingWhite	Allows `input` to include leading spaces not specified by `format`. These are ignored when parsing the string.
AllowTrailingWhite	Allows `input` to include trailing spaces not specified by `format`. These are ignored when parsing the string.
AllowWhiteSpaces	Allows `input` to include leading, trailing, and inner spaces not specified by `format`. All extra white-space characters not specified in `format` are ignored when parsing the string.

`DateTimeStyles` member	Behavior
None	Indicates that additional white space is not permitted in `input`. White space must appear exactly as specified in `format`. This is the default behavior.
RoundtripKind	Has no effect, because the DateTimeOffset structure does not include a `Kind` property.

Notes to Callers

In the .NET Framework 4, the TryParseExact returns `false` if the string to be parsed contains an hour component and an AM/PM designator that are not in agreement. In the .NET Framework 3.5 and earlier versions, the AM/PM designator is ignored.

DateTimeOffset.Addition(DateTimeOffset, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds a specified time interval to a DateTimeOffset object that has a specified date and time, and yields a DateTimeOffset object that has new a date and time.

C#

```
public static DateTimeOffset operator + (DateTimeOffset dateTimeOffset,
TimeSpan timeSpan);
```

Parameters

`dateTimeOffset` DateTimeOffset

The object to add the time interval to.

`timeSpan` TimeSpan

The time interval to add.

Returns

DateTimeOffset

An object whose value is the sum of the values of `dateTimeTz` and `timeSpan`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue.

-or-

The resulting DateTimeOffset value is greater than DateTimeOffset.MaxValue.

Remarks

The Addition method defines the addition operation for DateTimeOffset values. It enables code such as the following:

C#

```
DateTimeOffset date1 = new DateTimeOffset(2008, 1, 1, 13, 32, 45,
                       new TimeSpan(-5, 0, 0));
TimeSpan interval1 = new TimeSpan(202, 3, 30, 0);
TimeSpan interval2 = new TimeSpan(5, 0, 0, 0);
DateTimeOffset date2;

Console.WriteLine(date1);         // Displays 1/1/2008 1:32:45 PM -05:00
date2 = date1 + interval1;
Console.WriteLine(date2);         // Displays 7/21/2008 5:02:45 PM -05:00
date2 += interval2;
Console.WriteLine(date2);         // Displays 7/26/2008 5:02:45 PM -05:00
```

Languages that do not support custom operators and operator overloading can call the Add method instead.

The equivalent method for this operator is DateTimeOffset.Add(TimeSpan).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.Equality(DateTimeOffset, DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified DateTimeOffset objects represent the same point in time.

```
C#
public static bool operator == (DateTimeOffset left, DateTimeOffset right);
```

Parameters

`left` DateTimeOffset

The first object to compare.

`right` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if both DateTimeOffset objects have the same UtcDateTime value; otherwise, `false`.

Remarks

The Equality method defines the operation of the equality operator for DateTimeOffset objects. It enables code such as the following:

```
C#
```

```
DateTimeOffset date1 = new DateTimeOffset(2007, 6, 3, 14, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date2 = new DateTimeOffset(2007, 6, 3, 15, 45, 0,
             new TimeSpan(-6, 0, 0));
DateTimeOffset date3 = new DateTimeOffset(date1.DateTime,
             new TimeSpan(-6, 0, 0));
Console.WriteLine(date1 == date2);        // Displays True
Console.WriteLine(date1 == date3);        // Displays False
```

Before evaluating the `left` and `right` operands for equality, the operator converts both values to Coordinated Universal Time (UTC). The operation is equivalent to the following:

C#

```
return first.UtcDateTime == second.UtcDateTime;
```

In other words, the Equality method determines whether the two DateTimeOffset objects represent a single point in time. It directly compares neither dates and times nor offsets. To determine whether two DateTimeOffset objects represent the same time and have the same offset value, use the EqualsExact method.

The equivalent method for this operator is DateTimeOffset.Equals(DateTimeOffset, DateTimeOffset)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.GreaterThan(DateTimeOffset, DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTimeOffset object is greater than (or later than) a second specified DateTimeOffset object.

C#

```
public static bool operator > (DateTimeOffset left, DateTimeOffset right);
```

Parameters

`left` DateTimeOffset

The first object to compare.

`right` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if the UtcDateTime value of `left` is later than the UtcDateTime value of `right`; otherwise, `false`.

Remarks

The GreaterThan method defines the operation of the greater than operator for DateTimeOffset objects. It enables code such as the following:

C#

```
DateTimeOffset date1 = new DateTimeOffset(2007, 6, 3, 14, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date2 = new DateTimeOffset(2007, 6, 3, 15, 45, 0,
             new TimeSpan(-6, 0, 0));
DateTimeOffset date3 = new DateTimeOffset(date1.DateTime,
             new TimeSpan(-6, 0, 0));
Console.WriteLine(date1 > date2);        // Displays False
Console.WriteLine(date1 > date3);        // Displays True
```

Languages that do not support custom operators can call the Compare method instead. They can also call the GreaterThan method directly, as the following example shows.

VB

```
Dim date1 As New DateTimeOffset(#6/3/2007 2:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date2 As New DateTimeOffset(#6/3/2007 3:45PM#, _
             New TimeSpan(-6, 0, 0))
Dim date3 As New DateTimeOffset(date1.DateTime, _
             New TimeSpan(-6, 0, 0))
Console.WriteLine(DateTimeOffset.op_GreaterThan(date1, date2))  ' Displays
False
Console.WriteLine(DateTimeOffset.op_GreaterThan(date1, date3))  ' Displays
True
```

Before evaluating the `left` and `right` operands, the operator converts both values to Coordinated Universal Time (UTC). The operation is equivalent to the following:

C#

```
return left.UtcDateTime > right.UtcDateTime;
```

The equivalent method for this operator is DateTimeOffset.Compare(DateTimeOffset, DateTimeOffset)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.GreaterThanOrEqual(DateTimeOffset, DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTimeOffset object is greater than or equal to a second specified DateTimeOffset object.

```
C#

public static bool operator >= (DateTimeOffset left, DateTimeOffset right);
```

Parameters

`left` DateTimeOffset

The first object to compare.

`right` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if the UtcDateTime value of `left` is the same as or later than the UtcDateTime value of `right`; otherwise, `false`.

Remarks

The GreaterThan method defines the operation of the greater than or equal to operator for DateTimeOffset objects. It enables code such as the following:

```
C#
```

```
DateTimeOffset date1 = new DateTimeOffset(2007, 6, 3, 14, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date2 = new DateTimeOffset(2007, 6, 3, 15, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date3 = new DateTimeOffset(date1.DateTime,
             new TimeSpan(-6, 0, 0));
DateTimeOffset date4 = date1;
Console.WriteLine(date1 >= date2);        // Displays False
Console.WriteLine(date1 >= date3);        // Displays True
Console.WriteLine(date1 >= date4);        // Displays True
```

Languages that do not support custom operators can call the Compare method instead. Some languages can also call the GreaterThanOrEqual method directly, as the following example shows.

VB

```
Dim date1 As New DateTimeOffset(#6/3/2007 2:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date2 As New DateTimeOffset(#6/3/2007 3:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date3 As New DateTimeOffset(date1.DateTime, _
             New TimeSpan(-6, 0, 0))
Dim date4 As DateTimeOffset = date1
Console.WriteLine( _
    DateTimeOffset.op_GreaterThanOrEqual(date1, date2))   ' Displays False
Console.WriteLine( _
    DateTimeOffset.op_GreaterThanOrEqual(date1, date3))   ' Displays True
Console.WriteLine( _
    DateTimeOffset.op_GreaterThanOrEqual(date1, date4))   ' Displays True
```

Before evaluating the `left` and `right` operands, the operator converts both values to Coordinated Universal Time (UTC). The operation is equivalent to the following:

C#

```
return left.UtcDateTime >= right.UtcDateTime;
```

The equivalent method for this operator is DateTimeOffset.Compare(DateTimeOffset, DateTimeOffset)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeOffset.Implicit(DateTime to DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines an implicit conversion of a DateTime object to a DateTimeOffset object.

C#

```
public static implicit operator DateTimeOffset (DateTime dateTime);
```

Parameters

dateTime DateTime

The object to convert.

Returns

DateTimeOffset

The converted object.

Exceptions

ArgumentOutOfRangeException

The Coordinated Universal Time (UTC) date and time that results from applying the offset is earlier than DateTimeOffset.MinValue.

-or-

The UTC date and time that results from applying the offset is later than DateTimeOffset.MaxValue.

Remarks

The Implicit method enables the compiler to automatically convert a DateTime object to a DateTimeOffset object without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). It defines a widening conversion that does not involve data loss and does not throw an OverflowException. The Implicit method makes code such as the following possible:

C#

```
DateTimeOffset timeWithOffset;
timeWithOffset = new DateTime(2008, 7, 3, 18, 45, 0);
Console.WriteLine(timeWithOffset.ToString());

timeWithOffset = DateTime.UtcNow;
Console.WriteLine(timeWithOffset.ToString());

timeWithOffset = DateTime.SpecifyKind(DateTime.Now,
                                      DateTimeKind.Unspecified);
Console.WriteLine(timeWithOffset.ToString());

timeWithOffset = new DateTime(2008, 7, 1, 2, 30, 0) +
                        new TimeSpan(1, 0, 0, 0);
Console.WriteLine(timeWithOffset.ToString());

timeWithOffset = new DateTime(2008, 1, 1, 2, 30, 0);
Console.WriteLine(timeWithOffset.ToString());
// The example produces the following output if run on 3/20/2007
// at 6:25 PM on a computer in the U.S. Pacific Daylight Time zone:
//       7/3/2008 6:45:00 PM -07:00
//       3/21/2007 1:25:52 AM +00:00
//       3/20/2007 6:25:52 PM -07:00
//       7/2/2008 2:30:00 AM -07:00
//       1/1/2008 2:30:00 AM -08:00
//
// The last example shows automatic adaption to the U.S. Pacific Time
// for winter dates.
```

This method is equivalent to the DateTimeOffset constructor. The offset of the resulting DateTimeOffset object depends on the value of the DateTime.Kind property of the `dateTime` parameter:

- If the value of the DateTime.Kind property is DateTimeKind.Utc, the date and time of the DateTimeOffset object is set equal to `dateTime`, and its Offset property is set equal to 0.
- If the value of the DateTime.Kind property is DateTimeKind.Local or DateTimeKind.Unspecified, the date and time of the DateTimeOffset object is set equal to `dateTime`, and its Offset property is set equal to the offset of the local system's current time zone.

The equivalent method for this operator is DateTimeOffset.DateTimeOffset(DateTime)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.Inequality(DateTimeOffset, DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified DateTimeOffset objects refer to different points in time.

```
C#
public static bool operator != (DateTimeOffset left, DateTimeOffset right);
```

Parameters

`left` DateTimeOffset

The first object to compare.

`right` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if `left` and `right` do not have the same UtcDateTime value; otherwise, `false`.

Remarks

The Inequality method defines the operation of the inequality operator for DateTimeOffset objects. It always returns the opposite result from Equality. The Inequality method enables code such as the following:

```
C#
```

```
DateTimeOffset date1 = new DateTimeOffset(2007, 6, 3, 14, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date2 = new DateTimeOffset(2007, 6, 3, 15, 45, 0,
             new TimeSpan(-6, 0, 0));
DateTimeOffset date3 = new DateTimeOffset(date1.DateTime,
             new TimeSpan(-6, 0, 0));
Console.WriteLine(date1 != date2);        // Displays False
Console.WriteLine(date1 != date3);        // Displays True
```

Before evaluating the `left` and `right` operands for equality, the operator converts both values to Coordinated Universal Time (UTC). The operation is equivalent to the following:

C#

```
return first.UtcDateTime == second.UtcDateTime;
```

In other words, the Inequality method determines whether the two DateTimeOffset objects represent different points in time. It directly compares neither dates and times nor offsets.

Languages that do not support custom operators can call the Compare method instead. In addition, some languages can also call the Inequality method directly, as the following example shows.

VB

```
Dim date1 As New DateTimeOffset(#6/3/2007 2:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date2 As New DateTimeOffset(#6/3/2007 3:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date3 As New DateTimeOffset(date1.DateTime, _
             New TimeSpan(-6, 0, 0))
Dim date4 As DateTimeOffset = date1
Console.WriteLine( _
    DateTimeOffset.op_Inequality(date1, date2))   ' Displays True
Console.WriteLine( _
    DateTimeOffset.op_Inequality(date1, date3))   ' Displays True
Console.WriteLine( _
    DateTimeOffset.op_Inequality(date1, date4))   ' Displays False
```

The equivalent method for this operator is DateTimeOffset.Compare(DateTimeOffset, DateTimeOffset)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DateTimeOffset.LessThan(DateTimeOffset, DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTimeOffset object is less than a second specified DateTimeOffset object.

```
C#
public static bool operator < (DateTimeOffset left, DateTimeOffset right);
```

Parameters

`left` DateTimeOffset

The first object to compare.

`right` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if the UtcDateTime value of `left` is earlier than the UtcDateTime value of `right`; otherwise, `false`.

Remarks

The LessThan method defines the operation of the less than operator for DateTimeOffset objects. It enables code such as the following:

```
C#
```

```
DateTimeOffset date1 = new DateTimeOffset(2007, 6, 3, 14, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date2 = new DateTimeOffset(2007, 6, 3, 15, 45, 0,
             new TimeSpan(-6, 0, 0));
DateTimeOffset date3 = new DateTimeOffset(date1.DateTime,
             new TimeSpan(-8, 0, 0));
Console.WriteLine(date1 < date2);        // Displays False
Console.WriteLine(date1 < date3);        // Displays True
```

Before evaluating the `left` and `right` operands, the operator converts both operands to Coordinated Universal Time (UTC). The operation is equivalent to the following:

C#

```
return left.UtcDateTime < right.UtcDateTime;
```

Languages that do not support custom operators can call the Compare method instead. In addition, some languages can also call the LessThan method directly, as the following example shows.

VB

```
Dim date1 As New DateTimeOffset(#6/3/2007 2:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date2 As New DateTimeOffset(#6/3/2007 3:45PM#, _
             New TimeSpan(-6, 0, 0))
Dim date3 As New DateTimeOffset(date1.DateTime, _
             New TimeSpan(-8, 0, 0))
Console.WriteLine(DateTimeOffset.op_LessThan(date1, date2))  ' Displays
False
Console.WriteLine(DateTimeOffset.op_LessThan(date1, date3))  ' Displays True
```

The equivalent method for this operator is DateTimeOffset.Compare(DateTimeOffset, DateTimeOffset)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeOffset.LessThanOrEqual(DateTimeOffset, DateTimeOffset) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified DateTimeOffset object is less than a second specified DateTimeOffset object.

C#

```
public static bool operator <= (DateTimeOffset left, DateTimeOffset right);
```

Parameters

`left` DateTimeOffset

The first object to compare.

`right` DateTimeOffset

The second object to compare.

Returns

Boolean

`true` if the UtcDateTime value of `left` is earlier than the UtcDateTime value of `right`; otherwise, `false`.

Remarks

The LessThanOrEqual method defines the operation of the less than or equal to operator for DateTimeOffset objects. It enables code such as the following:

C#

```
DateTimeOffset date1 = new DateTimeOffset(2007, 6, 3, 14, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date2 = new DateTimeOffset(2007, 6, 3, 15, 45, 0,
             new TimeSpan(-7, 0, 0));
DateTimeOffset date3 = new DateTimeOffset(date1.DateTime,
             new TimeSpan(-6, 0, 0));
DateTimeOffset date4 = date1;
Console.WriteLine(date1 <= date2);        // Displays True
Console.WriteLine(date1 <= date3);        // Displays False
Console.WriteLine(date1 <= date4);        // Displays True
```

Languages that do not support custom operators can call the Compare method instead. Some languages can also call the LessThanOrEqual method directly, as the following example shows.

VB

```
Dim date1 As New DateTimeOffset(#6/3/2007 2:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date2 As New DateTimeOffset(#6/3/2007 3:45PM#, _
             New TimeSpan(-7, 0, 0))
Dim date3 As New DateTimeOffset(date1.DateTime, _
             New TimeSpan(-6, 0, 0))
Dim date4 As DateTimeOffset = date1
Console.WriteLine(DateTimeOffset.op_LessThanOrEqual(date1, date2))   '
Displays True
Console.WriteLine(DateTimeOffset.op_LessThanOrEqual(date1, date3)) '
Displays False
Console.WriteLine(DateTimeOffset.op_LessThanOrEqual(date1, date4)) '
Displays True
```

Before evaluating the `left` and `right` operands, the operator converts both values to Coordinated Universal Time (UTC). The operation is equivalent to the following:

C#

```
return left.UtcDateTime <= right.UtcDateTime;
```

The equivalent method for this operator is DateTimeOffset.Compare(DateTimeOffset, DateTimeOffset)

Applies to

DateTimeOffset.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts a specified DateTimeOffset or TimeSpan object from a DateTimeOffset object.

Overloads

Expand table

Subtraction(DateTimeOffset, DateTimeOffset)	Subtracts one DateTimeOffset object from another and yields a time interval.
Subtraction(DateTimeOffset, TimeSpan)	Subtracts a specified time interval from a specified date and time, and yields a new date and time.

Subtraction(DateTimeOffset, DateTimeOffset)

Subtracts one DateTimeOffset object from another and yields a time interval.

C#

```
public static TimeSpan operator - (DateTimeOffset left, DateTimeOffset
right);
```

Parameters

`left` DateTimeOffset

The minuend.

`right` DateTimeOffset

The subtrahend.

Returns

TimeSpan

An object that represents the difference between `left` and `right`.

Remarks

The Subtraction method defines the subtraction operation for DateTimeOffset objects. It enables code such as the following:

C#

```
DateTimeOffset firstDate = new DateTimeOffset(2008, 3, 25, 18, 0, 0,
                                              new TimeSpan(-7, 0, 0));
DateTimeOffset secondDate = new DateTimeOffset(2008, 3, 25, 18, 0, 0,
                                               new TimeSpan(-5, 0, 0));
DateTimeOffset thirdDate = new DateTimeOffset(2008, 2, 28, 9, 0, 0,
                                              new TimeSpan(-7, 0, 0));
TimeSpan difference;

difference = firstDate - secondDate;
Console.WriteLine("({0}) - ({1}): {2} days, {3}:{4:d2}",
                  firstDate.ToString(),
                  secondDate.ToString(),
                  difference.Days,
                  difference.Hours,
                  difference.Minutes);

difference = firstDate - thirdDate;
Console.WriteLine("({0}) - ({1}): {2} days, {3}:{4:d2}",
                  firstDate.ToString(),
                  secondDate.ToString(),
                  difference.Days,
                  difference.Hours,
                  difference.Minutes);
// The example produces the following output:
//    (3/25/2008 6:00:00 PM -07:00) - (3/25/2008 6:00:00 PM -05:00): 0
days, 2:00
//    (3/25/2008 6:00:00 PM -07:00) - (3/25/2008 6:00:00 PM -05:00): 26
days, 9:00
```

Languages that do not support custom operators and operator overloading can call the DateTimeOffset.Subtract(DateTimeOffset) method instead.

The equivalent method for this operator is DateTimeOffset.Subtract(TimeSpan).

See also

- Subtract(DateTimeOffset)

- Performing Arithmetic Operations with Dates and Times

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Subtraction(DateTimeOffset, TimeSpan)

Subtracts a specified time interval from a specified date and time, and yields a new date and time.

C#

```
public static DateTimeOffset operator - (DateTimeOffset dateTimeOffset,
TimeSpan timeSpan);
```

Parameters

`dateTimeOffset` DateTimeOffset

The date and time object to subtract from.

`timeSpan` TimeSpan

The time interval to subtract.

Returns

DateTimeOffset

An object that is equal to the value of `dateTimeOffset` minus `timeSpan`.

Exceptions

ArgumentOutOfRangeException

The resulting DateTimeOffset value is less than DateTimeOffset.MinValue or greater than DateTimeOffset.MaxValue.

Remarks

The Subtraction method defines the subtraction operation for DateTimeOffset objects. It enables code such as the following:

```
C#

DateTimeOffset offsetDate = new DateTimeOffset(2007, 12, 3, 11, 30, 0,
                                new TimeSpan(-8, 0, 0));
TimeSpan duration = new TimeSpan(7, 18, 0, 0);
Console.WriteLine(offsetDate - duration);  // Displays 11/25/2007 5:30:00
PM -08:00
```

Languages that do not support custom operators and operator overloading can call the DateTimeOffset.Subtract(TimeSpan) method instead.

The equivalent method for this operator is DateTimeOffset.Subtract(TimeSpan).

DateTimeOffset.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the value of the current DateTimeOffset object with another object of the same type.

```
C#

int IComparable.CompareTo (object obj);
```

Parameters

obj Object

The object to compare with the current DateTimeOffset object.

Returns

Int32

A 32-bit signed integer that indicates whether the current DateTimeOffset object is less than, equal to, or greater than `obj`. The return values of the method are interpreted as follows:

Expand table

Return Value	Description
Less than zero	The current DateTimeOffset object is less than (earlier than) `obj`.
Zero	The current DateTimeOffset object is equal to (the same point in time as) `obj`.
Greater than zero	The current DateTimeOffset object is greater than (later than) `obj`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DateTimeOffset.IDeserialization Callback.OnDeserialization(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Runs when the deserialization of an object has been completed.

```
C#
void IDeserializationCallback.OnDeserialization (object sender);
```

Parameters

sender Object

The object that initiated the callback. The functionality for this parameter is not currently implemented.

Implements

OnDeserialization(Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DateTimeOffset.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data required to serialize the current DateTimeOffset object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to populate with data.

`context` StreamingContext

The destination for this serialization (see StreamingContext).

Implements

GetObjectData(SerializationInfo, StreamingContext)

Exceptions

ArgumentNullException

The `info` parameter is `null`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

DayOfWeek Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the day of the week.

C#

```
public enum DayOfWeek
```

Inheritance Object → ValueType → Enum → DayOfWeek

Fields

Expand table

Friday	5	Indicates Friday.
Monday	1	Indicates Monday.
Saturday	6	Indicates Saturday.
Sunday	0	Indicates Sunday.
Thursday	4	Indicates Thursday.
Tuesday	2	Indicates Tuesday.
Wednesday	3	Indicates Wednesday.

Examples

The following example demonstrates the DateTime.DayOfWeek property and the DayOfWeek enumeration.

C#

```
// This example demonstrates the DateTime.DayOfWeek property
using System;

class Sample
{
    public static void Main()
    {
// Assume the current culture is en-US.
// Create a DateTime for the first of May, 2003.
    DateTime dt = new DateTime(2003, 5, 1);
    Console.WriteLine("Is Thursday the day of the week for {0:d}?: {1}",
                      dt, dt.DayOfWeek == DayOfWeek.Thursday);
    Console.WriteLine("The day of the week for {0:d} is {1}.", dt,
dt.DayOfWeek);
    }
}
/*
This example produces the following results:

Is Thursday the day of the week for 5/1/2003?: True
The day of the week for 5/1/2003 is Thursday.
*/
```

Remarks

The DayOfWeek enumeration represents the day of the week in calendars that have seven days per week. The value of the constants in this enumeration ranges from Sunday to Saturday. If cast to an integer, its value ranges from zero (which indicates Sunday) to six (which indicates Saturday).

This enumeration is useful when it is desirable to have a strongly typed specification of the day of the week. For example, this enumeration is the type of the property value for the DateTime.DayOfWeek and DateTimeOffset.DayOfWeek properties.

The members of the DayOfWeek enumeration are not localized. To return the localized name of the day of the week, call the DateTime.ToString(String) or the DateTime.ToString(String, IFormatProvider) method with either the "ddd" or "dddd" format strings. The former format string produces the abbreviated weekday name; the latter produces the full weekday name.

Applies to

Product	Versions

DBNull Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a nonexistent value. This class cannot be inherited.

C#

```
public sealed class DBNull : IConvertible,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → DBNull

Implements IConvertible , ISerializable

Examples

The following example calls the `DBNull.Value.Equals` method to determine whether a database field in a contacts database has a valid value. If it does, the field value is appended to the string output in a label.

C#

```
private void OutputLabels(DataTable dt)
{
   string label;

   // Iterate rows of table
   foreach (DataRow row in dt.Rows)
   {
      int labelLen;
      label = String.Empty;
      label += AddFieldValue(label, row, "Title");
      label += AddFieldValue(label, row, "FirstName");
      label += AddFieldValue(label, row, "MiddleInitial");
      label += AddFieldValue(label, row, "LastName");
      label += AddFieldValue(label, row, "Suffix");
      label += "\n";
      label += AddFieldValue(label, row, "Address1");
      label += AddFieldValue(label, row, "AptNo");
```

```
        label += "\n";
        labelLen = label.Length;
        label += AddFieldValue(label, row, "Address2");
        if (label.Length != labelLen)
           label += "\n";
        label += AddFieldValue(label, row, "City");
        label += AddFieldValue(label, row, "State");
        label += AddFieldValue(label, row, "Zip");
        Console.WriteLine(label);
        Console.WriteLine();
    }
}

private string AddFieldValue(string label, DataRow row,
                             string fieldName)
{
    if (! DBNull.Value.Equals(row[fieldName]))
        return (string) row[fieldName] + " ";
    else
        return String.Empty;
}
```

Remarks

The DBNull class represents a nonexistent value. In a database, for example, a column in a row of a table might not contain any data whatsoever. That is, the column is considered to not exist at all instead of merely not having a value. A DBNull object represents the nonexistent column. Additionally, COM interop uses the DBNull class to distinguish between a VT_NULL variant, which indicates a nonexistent value, and a VT_EMPTY variant, which indicates an unspecified value.

The DBNull type is a singleton class, which means only one DBNull object exists. The DBNull.Value member represents the sole DBNull object. DBNull.Value can be used to explicitly assign a nonexistent value to a database field, although most ADO.NET data providers automatically assign values of DBNull when a field does not have a valid value. You can determine whether a value retrieved from a database field is a DBNull value by passing the value of that field to the `DBNull.Value.Equals` method. However, some languages and database objects supply methods that make it easier to determine whether the value of a database field is DBNull.Value. These include the Visual Basic `IsDBNull` function, the Convert.IsDBNull method, the DataTableReader.IsDBNull method, and the IDataRecord.IsDBNull method.

Do not confuse the notion of `null` in an object-oriented programming language with a DBNull object. In an object-oriented programming language, `null` means the absence

of a reference to an object. DBNull represents an uninitialized variant or nonexistent database column.

Fields

Expand table

Value	Represents the sole instance of the DBNull class.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Implements the ISerializable interface and returns the data needed to serialize the DBNull object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
GetTypeCode()	Gets the TypeCode value for DBNull.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns an empty string (Empty).
ToString(IFormatProvider)	Returns an empty string using the specified IFormatProvider.

Explicit Interface Implementations

Expand table

IConvertible.ToBoolean(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.

IConvertible.ToByte(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToChar(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToDouble(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToInt16(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToInt32(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToInt64(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToSByte(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToSingle(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToType(Type, IFormatProvider)	Converts the current DBNull object to the specified type.
IConvertible.ToUInt16(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToUInt32(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.
IConvertible.ToUInt64(IFormatProvider)	This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.

Applies to

DBNull.Value Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the sole instance of the DBNull class.

C#

```
public static readonly DBNull Value;
```

Field Value

DBNull

Examples

The following example calls the `DBNull.Value.Equals` method to determine whether a database field in a contacts database has a valid value. If it does, the field value is appended to the string output in a label.

C#

```
private void OutputLabels(DataTable dt)
{
   string label;

   // Iterate rows of table
   foreach (DataRow row in dt.Rows)
   {
      int labelLen;
      label = String.Empty;
      label += AddFieldValue(label, row, "Title");
      label += AddFieldValue(label, row, "FirstName");
      label += AddFieldValue(label, row, "MiddleInitial");
      label += AddFieldValue(label, row, "LastName");
      label += AddFieldValue(label, row, "Suffix");
      label += "\n";
      label += AddFieldValue(label, row, "Address1");
      label += AddFieldValue(label, row, "AptNo");
      label += "\n";
```

```
        labelLen = label.Length;
        label += AddFieldValue(label, row, "Address2");
        if (label.Length != labelLen)
           label += "\n";
        label += AddFieldValue(label, row, "City");
        label += AddFieldValue(label, row, "State");
        label += AddFieldValue(label, row, "Zip");
        Console.WriteLine(label);
        Console.WriteLine();
    }
}

private string AddFieldValue(string label, DataRow row,
                             string fieldName)
{
    if (! DBNull.Value.Equals(row[fieldName]))
        return (string) row[fieldName] + " ";
    else
        return String.Empty;
}
```

Remarks

DBNull is a singleton class, which means only this instance of this class can exist.

If a database field has missing data, you can use the DBNull.Value property to explicitly assign a DBNull object value to the field. However, most data providers do this automatically.

To evaluate database fields to determine whether their values are DBNull, you can pass the field value to the `DBNull.Value.Equals` method. However, this method is rarely used because there are a number of other ways to evaluate a database field for missing data. These include the Visual Basic `IsDBNull` function, the Convert.IsDBNull method, the DataTableReader.IsDBNull method, the IDataRecord.IsDBNull method, and several other methods.

Applies to

DBNull.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Implements the ISerializable interface and returns the data needed to serialize the DBNull object.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public void GetObjectData (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

A SerializationInfo object containing information required to serialize the DBNull object.

`context` StreamingContext

A StreamingContext object containing the source and destination of the serialized stream associated with the DBNull object.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DBNull.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the TypeCode value for DBNull.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The TypeCode value for DBNull, which is DBNull.

Implements

GetTypeCode()

Applies to

Product	Versions

DBNull.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an empty string.

Overloads

Expand table

ToString()	Returns an empty string (Empty).
ToString(IFormatProvider)	Returns an empty string using the specified IFormatProvider.

ToString()

Returns an empty string (Empty).

C#

```
public override string ToString ();
```

Returns

String

An empty string (Empty).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Returns an empty string using the specified IFormatProvider.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

The IFormatProvider to be used to format the return value.

-or-

`null` to obtain the format information from the current locale setting of the operating system.

Returns

String

An empty string (Empty).

Implements

ToString(IFormatProvider)

DBNull.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.

```
C#

bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Boolean

None. The return value for this member is not used.

Implements

ToBoolean(IFormatProvider)

Exceptions

InvalidCastException

This conversion is not supported for the DBNull type.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DBNull.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.

```
C#

byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Byte

None. The return value for this member is not used.

Implements

ToByte(IFormatProvider)

Exceptions

InvalidCastException

This conversion is not supported for the DBNull type.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.

```
C#

char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

Char

None. The return value for this member is not used.

Implements

ToChar(IFormatProvider)

Exceptions

InvalidCastException

This conversion is not supported for the DBNull type.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DBNull.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current DBNull object to the specified type.

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to convert the current DBNull object to.

provider IFormatProvider

An object that implements the IFormatProvider interface and is used to augment the conversion. If `null` is specified, format information is obtained from the current culture.

Returns

Object

The boxed equivalent of the current DBNull object, if that conversion is supported; otherwise, an exception is thrown and no value is returned.

Implements

ToType(Type, IFormatProvider)

Exceptions

InvalidCastException

This conversion is not supported for the DBNull type.

ArgumentNullException

`type` is `null`.

Remarks

Three conversions are supported: If the `type` parameter specifies Object or DBNull, the return value is the current DBNull object itself. If the `type` parameter specifies String, the return value is the string returned by the ToString method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DBNull.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

This conversion is not supported. Attempting to make this conversion throws an InvalidCastException.

```
C#
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that implements the IFormatProvider interface. (This parameter is not used; specify `null`.)

Returns

UInt16

None. The return value for this member is not used.

Implements

ToUInt16(IFormatProvider)

Exceptions

InvalidCastException

This conversion is not supported for the DBNull type.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Remarks

For more information about this API, see Supplemental API remarks for Decimal.

Constructors

Expand table

Decimal(Double)	Initializes a new instance of Decimal to the value of the specified double-precision floating-point number.
Decimal(Int32)	Initializes a new instance of Decimal to the value of the specified 32-bit signed integer.
Decimal(Int32, Int32, Int32, Boolean, Byte)	Initializes a new instance of Decimal from parameters specifying the instance's constituent parts.
Decimal(Int32[])	Initializes a new instance of Decimal to a decimal value represented in binary and contained in a specified array.
Decimal(Int64)	Initializes a new instance of Decimal to the value of the specified 64-bit signed integer.
Decimal(ReadOnlySpan<Int32>)	Initializes a new instance of Decimal to a decimal value represented in binary and contained in the specified span.
Decimal(Single)	Initializes a new instance of Decimal to the value of the specified single-precision floating-point number.
Decimal(UInt32)	Initializes a new instance of Decimal to the value of the specified 32-bit unsigned integer.
Decimal(UInt64)	Initializes a new instance of Decimal to the value of the specified 64-bit unsigned integer.

Fields

Expand table

MaxValue	Represents the largest possible value of Decimal. This field is constant and read-only.
MinusOne	Represents the number negative one (-1).
MinValue	Represents the smallest possible value of Decimal. This field is constant and read-only.
One	Represents the number one (1).
Zero	Represents the number zero (0).

Properties

Expand table

Scale	Gets the scaling factor of the decimal, which is a number from 0 to 28 that represents the number of decimal digits.

Methods

Expand table

Abs(Decimal)	Computes the absolute of a value.
Add(Decimal, Decimal)	Adds two specified Decimal values.
Ceiling(Decimal)	Returns the smallest integral value that is greater than or equal to the specified decimal number.
Clamp(Decimal, Decimal, Decimal)	Clamps a value to an inclusive minimum and maximum value.
Compare(Decimal, Decimal)	Compares two specified Decimal values.
CompareTo(Decimal)	Compares this instance to a specified Decimal object and returns a comparison of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns a comparison of their relative values.
CopySign(Decimal, Decimal)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
Divide(Decimal, Decimal)	Divides two specified Decimal values.
Equals(Decimal)	Returns a value indicating whether this instance and a specified Decimal object represent the same value.

Equals(Decimal, Decimal)	Returns a value indicating whether two specified instances of Decimal represent the same value.
Equals(Object)	Returns a value indicating whether this instance and a specified Object represent the same type and value.
Floor(Decimal)	Rounds a specified Decimal number to the closest integer toward negative infinity.
FromOACurrency(Int64)	Converts the specified 64-bit signed integer, which contains an OLE Automation Currency value, to the equivalent Decimal value.
GetBits(Decimal)	Converts the value of a specified instance of Decimal to its equivalent binary representation.
GetBits(Decimal, Span<Int32>)	Converts the value of a specified instance of Decimal to its equivalent binary representation.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type Decimal.
IsCanonical(Decimal)	Determines if a value is in its canonical representation.
IsEvenInteger(Decimal)	Determines if a value represents an even integral number.
IsInteger(Decimal)	Determines if a value represents an integral number.
IsNegative(Decimal)	Determines if a value is negative.
IsOddInteger(Decimal)	Determines if a value represents an odd integral number.
IsPositive(Decimal)	Determines if a value is positive.
Max(Decimal, Decimal)	Compares two values to compute which is greater.
MaxMagnitude(Decimal, Decimal)	Compares two values to compute which is greater.
Min(Decimal, Decimal)	Compares two values to compute which is lesser.
MinMagnitude(Decimal, Decimal)	Compares two values to compute which is lesser.
Multiply(Decimal, Decimal)	Multiplies two specified Decimal values.
Negate(Decimal)	Returns the result of multiplying the specified Decimal value by negative one.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.

Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format.
Parse(String)	Converts the string representation of a number to its Decimal equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number to its Decimal equivalent using the specified culture-specific format information.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its Decimal equivalent.
Parse(String, NumberStyles, IFormat Provider)	Converts the string representation of a number to its Decimal equivalent using the specified style and culture-specific format.
Remainder(Decimal, Decimal)	Computes the remainder after dividing two Decimal values.
Round(Decimal)	Rounds a decimal value to the nearest integer.
Round(Decimal, Int32)	Rounds a Decimal value to a specified number of decimal places.
Round(Decimal, Int32, Midpoint Rounding)	Rounds a decimal value to the specified precision using the specified rounding strategy.
Round(Decimal, MidpointRounding)	Rounds a decimal value to an integer using the specified rounding strategy.
Sign(Decimal)	Computes the sign of a value.
Subtract(Decimal, Decimal)	Subtracts one specified Decimal value from another.
ToByte(Decimal)	Converts the value of the specified Decimal to the equivalent 8-bit unsigned integer.
ToDouble(Decimal)	Converts the value of the specified Decimal to the equivalent double-precision floating-point number.
ToInt16(Decimal)	Converts the value of the specified Decimal to the equivalent 16-bit signed integer.
ToInt32(Decimal)	Converts the value of the specified Decimal to the equivalent 32-bit signed integer.

ToInt64(Decimal)	Converts the value of the specified Decimal to the equivalent 64-bit signed integer.
ToOACurrency(Decimal)	Converts the specified Decimal value to the equivalent OLE Automation Currency value, which is contained in a 64-bit signed integer.
ToSByte(Decimal)	Converts the value of the specified Decimal to the equivalent 8-bit signed integer.
ToSingle(Decimal)	Converts the value of the specified Decimal to the equivalent single-precision floating-point number.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToUInt16(Decimal)	Converts the value of the specified Decimal to the equivalent 16-bit unsigned integer.
ToUInt32(Decimal)	Converts the value of the specified Decimal to the equivalent 32-bit unsigned integer.
ToUInt64(Decimal)	Converts the value of the specified Decimal to the equivalent 64-bit unsigned integer.
Truncate(Decimal)	Returns the integral digits of the specified Decimal; any fractional digits are discarded.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current decimal instance into the provided span of characters.
TryGetBits(Decimal, Span<Int32>, Int32)	Tries to convert the value of a specified instance of Decimal to its equivalent binary representation.
TryParse(ReadOnlySpan<Byte>, Decimal)	Tries to convert a UTF-8 character span containing the string representation of a number to its signed decimal equivalent.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Decimal)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Decimal)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Decimal)	Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Decimal)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Decimal)	Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Decimal)	Converts the string representation of a number to its Decimal equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, Decimal)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, Decimal)	Converts the string representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.

Operators

Expand table

Addition(Decimal, Decimal)	Adds two specified Decimal values.
Decrement(Decimal)	Decrements the Decimal operand by one.
Division(Decimal, Decimal)	Divides two specified Decimal values.
Equality(Decimal, Decimal)	Returns a value that indicates whether two Decimal values are equal.
Explicit(Decimal to Byte)	Defines an explicit conversion of a Decimal to an 8-bit unsigned integer.

Explicit(Decimal to Char)	Defines an explicit conversion of a Decimal to a Unicode character.
Explicit(Decimal to Double)	Defines an explicit conversion of a Decimal to a double-precision floating-point number.
Explicit(Decimal to Int16)	Defines an explicit conversion of a Decimal to a 16-bit signed integer.
Explicit(Decimal to Int32)	Defines an explicit conversion of a Decimal to a 32-bit signed integer.
Explicit(Decimal to Int64)	Defines an explicit conversion of a Decimal to a 64-bit signed integer.
Explicit(Decimal to SByte)	Defines an explicit conversion of a Decimal to an 8-bit signed integer. This API is not CLS-compliant.
Explicit(Decimal to Single)	Defines an explicit conversion of a Decimal to a single-precision floating-point number.
Explicit(Decimal to UInt16)	Defines an explicit conversion of a Decimal to a 16-bit unsigned integer. This API is not CLS-compliant.
Explicit(Decimal to UInt32)	Defines an explicit conversion of a Decimal to a 32-bit unsigned integer. This API is not CLS-compliant.
Explicit(Decimal to UInt64)	Defines an explicit conversion of a Decimal to a 64-bit unsigned integer. This API is not CLS-compliant.
Explicit(Double to Decimal)	Defines an explicit conversion of a double-precision floating-point number to a Decimal.
Explicit(Single to Decimal)	Defines an explicit conversion of a single-precision floating-point number to a Decimal.
GreaterThan(Decimal, Decimal)	Returns a value indicating whether a specified Decimal is greater than another specified Decimal.
GreaterThanOrEqual(Decimal, Decimal)	Returns a value indicating whether a specified Decimal is greater than or equal to another specified Decimal.
Implicit(Byte to Decimal)	Defines an implicit conversion of an 8-bit unsigned integer to a Decimal.

Implicit(Char to Decimal)	Defines an implicit conversion of a Unicode character to a Decimal.
Implicit(Int16 to Decimal)	Defines an implicit conversion of a 16-bit signed integer to a Decimal.
Implicit(Int32 to Decimal)	Defines an implicit conversion of a 32-bit signed integer to a Decimal.
Implicit(Int64 to Decimal)	Defines an implicit conversion of a 64-bit signed integer to a Decimal.
Implicit(SByte to Decimal)	Defines an implicit conversion of an 8-bit signed integer to a Decimal. This API is not CLS-compliant.
Implicit(UInt16 to Decimal)	Defines an implicit conversion of a 16-bit unsigned integer to a Decimal. This API is not CLS-compliant.
Implicit(UInt32 to Decimal)	Defines an implicit conversion of a 32-bit unsigned integer to a Decimal. This API is not CLS-compliant.
Implicit(UInt64 to Decimal)	Defines an implicit conversion of a 64-bit unsigned integer to a Decimal. This API is not CLS-compliant.
Increment(Decimal)	Increments the Decimal operand by 1.
Inequality(Decimal, Decimal)	Returns a value that indicates whether two Decimal objects have different values.
LessThan(Decimal, Decimal)	Returns a value indicating whether a specified Decimal is less than another specified Decimal.
LessThanOrEqual(Decimal, Decimal)	Returns a value indicating whether a specified Decimal is less than or equal to another specified Decimal.
Modulus(Decimal, Decimal)	Returns the remainder resulting from dividing two specified Decimal values.
Multiply(Decimal, Decimal)	Multiplies two specified Decimal values.
Subtraction(Decimal, Decimal)	Subtracts two specified Decimal values.
UnaryNegation(Decimal)	Negates the value of the specified Decimal operand.

UnaryPlus(Decimal)	Returns the value of the Decimal operand (the sign of the operand is unchanged).

Explicit Interface Implementations

Expand table

IAdditiveIdentity<Decimal,Decimal>.AdditiveIdentity	Gets the additive identity of the current type.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).

IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IDeserializationCallback.OnDeserialization(Object)	Runs when the deserialization of an object has been completed.
IFloatingPoint<Decimal>.GetExponentByteCount()	Gets the number of bytes that will be written as part of TryWriteExponentLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Decimal>.GetExponentShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current exponent.
IFloatingPoint<Decimal>.GetSignificandBitLength()	Gets the length, in bits, of the current significand.
IFloatingPoint<Decimal>.GetSignificandByteCount()	Gets the number of bytes that will be written as part of TryWriteSignificandLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Decimal>.TryWriteExponentBigEndian(Span<Byte>, Int32)	Tries to write the current exponent, in big-endian format, to a given span.
IFloatingPoint<Decimal>.TryWriteExponentLittleEndian(Span<Byte>, Int32)	Tries to write the current exponent, in little-endian format, to a given span.
IFloatingPoint<Decimal>.TryWriteSignificandBigEndian(Span<Byte>, Int32)	Tries to write the current significand, in big-endian format, to a given span.
IFloatingPoint<Decimal>.TryWriteSignificandLittleEndian(Span<Byte>, Int32)	Tries to write the current significand, in little-endian format, to a given span.
IFloatingPointConstants<Decimal>.E	Gets the mathematical constant `e`.
IFloatingPointConstants<Decimal>.Pi	Gets the mathematical constant `pi`.
IFloatingPointConstants<Decimal>.Tau	Gets the mathematical constant `tau`.
IMinMaxValue<Decimal>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Decimal>.MinValue	Gets the minimum value of the current type.

IMultiplicativeIdentity<Decimal,Decimal>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
INumber<Decimal>.MaxNumber(Decimal, Decimal)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<Decimal>.MinNumber(Decimal, Decimal)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<Decimal>.IsComplexNumber(Decimal)	Determines if a value represents a complex number.
INumberBase<Decimal>.IsFinite(Decimal)	Determines if a value is finite.
INumberBase<Decimal>.IsImaginaryNumber(Decimal)	Determines if a value represents a pure imaginary number.
INumberBase<Decimal>.IsInfinity(Decimal)	Determines if a value is infinite.
INumberBase<Decimal>.IsNaN(Decimal)	Determines if a value is NaN.
INumberBase<Decimal>.IsNegativeInfinity(Decimal)	Determines if a value is negative infinity.
INumberBase<Decimal>.IsNormal(Decimal)	Determines if a value is normal.
INumberBase<Decimal>.IsPositiveInfinity(Decimal)	Determines if a value is positive infinity.
INumberBase<Decimal>.IsRealNumber(Decimal)	Determines if a value represents a real number.
INumberBase<Decimal>.IsSubnormal(Decimal)	Determines if a value is subnormal.
INumberBase<Decimal>.IsZero(Decimal)	Determines if a value is zero.
INumberBase<Decimal>.MaxMagnitudeNumber(Decimal, Decimal)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Decimal>.MinMagnitudeNumber(Decimal, Decimal)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<Decimal>.One	Gets the value `1` for the type.
INumberBase<Decimal>.Radix	Gets the radix, or base, for the type.
INumberBase<Decimal>.TryConvertFromChecked<TOther>(TOther, Decimal)	

INumberBase<Decimal>.TryConvertFromSaturating<TOther>(TOther, Decimal)	
INumberBase<Decimal>.TryConvertFromTruncating<TOther>(TOther, Decimal)	
INumberBase<Decimal>.TryConvertToChecked<TOther>(Decimal, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Decimal>.TryConvertToSaturating<TOther>(Decimal, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Decimal>.TryConvertToTruncating<TOther>(Decimal, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Decimal>.Zero	Gets the value `0` for the type.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo with the data needed to serialize the target object.
ISignedNumber<Decimal>.NegativeOne	Gets the value `-1` for the type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Decimal Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of Decimal.

Overloads

Expand table

Decimal(Double)	Initializes a new instance of Decimal to the value of the specified double-precision floating-point number.
Decimal(Int32)	Initializes a new instance of Decimal to the value of the specified 32-bit signed integer.
Decimal(Int32[])	Initializes a new instance of Decimal to a decimal value represented in binary and contained in a specified array.
Decimal(Int64)	Initializes a new instance of Decimal to the value of the specified 64-bit signed integer.
Decimal(ReadOnlySpan<Int32>)	Initializes a new instance of Decimal to a decimal value represented in binary and contained in the specified span.
Decimal(Single)	Initializes a new instance of Decimal to the value of the specified single-precision floating-point number.
Decimal(UInt32)	Initializes a new instance of Decimal to the value of the specified 32-bit unsigned integer.
Decimal(UInt64)	Initializes a new instance of Decimal to the value of the specified 64-bit unsigned integer.
Decimal(Int32, Int32, Int32, Boolean, Byte)	Initializes a new instance of Decimal from parameters specifying the instance's constituent parts.

Decimal(Double)

Initializes a new instance of Decimal to the value of the specified double-precision floating-point number.

```
C#

public Decimal (double value);
```

Parameters

value Double

The value to represent as a Decimal.

Exceptions

OverflowException

`value` is greater than Decimal.MaxValue or less than Decimal.MinValue.

-or-

`value` is NaN, PositiveInfinity, or NegativeInfinity.

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with a Double value.

```
C#

// Example of the decimal( double ) constructor.
using System;

class DecimalCtorDoDemo
{
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' )+1 );
    }

    // Create a decimal object and display its value.
    public static void CreateDecimal( double value, string valToStr )
    {
        // Format and display the constructor.
        Console.Write( "{0,-34}",
            String.Format( "decimal( {0} )", valToStr ) );
```

```
        try
        {
            // Construct the decimal value.
            decimal decimalNum = new decimal( value );

            // Display the value if it was created successfully.
            Console.WriteLine( "{0,31}", decimalNum );
        }
        catch( Exception ex )
        {
            // Display the exception type if an exception was thrown.
            Console.WriteLine( "{0,31}", GetExceptionType( ex ) );
        }
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the decimal( double ) " +
            "constructor \ngenerates the following output.\n" );
        Console.WriteLine( "{0,-34}{1,31}", "Constructor",
            "Value or Exception" );
        Console.WriteLine( "{0,-34}{1,31}", "-----------",
            "------------------" );

        // Construct decimal objects from double values.
        CreateDecimal( 1.23456789E+5, "1.23456789E+5" );
        CreateDecimal( 1.234567890123E+15, "1.234567890123E+15" );
        CreateDecimal( 1.2345678901234567E+25,
            "1.2345678901234567E+25" );
        CreateDecimal( 1.2345678901234567E+35,
            "1.2345678901234567E+35" );
        CreateDecimal( 1.23456789E-5, "1.23456789E-5" );
        CreateDecimal( 1.234567890123E-15, "1.234567890123E-15" );
        CreateDecimal( 1.2345678901234567E-25,
            "1.2345678901234567E-25" );
        CreateDecimal( 1.2345678901234567E-35,
            "1.2345678901234567E-35" );
        CreateDecimal( 1.0 / 7.0, "1.0 / 7.0" );
    }
}

/*
This example of the decimal( double ) constructor
generates the following output.

Constructor                                   Value or Exception
-----------                                   ------------------
decimal( 1.23456789E+5 )                              123456.789
decimal( 1.234567890123E+15 )                   1234567890123000
decimal( 1.2345678901234567E+25 )      1234567890123460000000000

decimal( 1.2345678901234567E-25 )  0.0000000000000000000000001235
```

```
decimal( 1.2345678901234567E-35 )                                0
decimal( 1.0 / 7.0 )                            0.142857142857143
*/
```

Remarks

This constructor rounds `value` to 15 significant digits using rounding to nearest. This is done even if the number has more than 15 digits and the less significant digits are zero.

Decimal(Int32)

Initializes a new instance of Decimal to the value of the specified 32-bit signed integer.

C#

```
public Decimal (int value);
```

Parameters

`value` Int32

The value to represent as a Decimal.

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with an Int32 value.

C#

```
// Example of the decimal( int ) constructor.
using System;

class DecimalCtorIDemo
{
    // Create a decimal object and display its value.
    public static void CreateDecimal( int value, string valToStr )
    {
        decimal decimalNum = new decimal( value );

        // Format the constructor for display.
        string ctor = String.Format( "decimal( {0} )", valToStr );

        // Display the constructor and its value.
        Console.WriteLine( "{0,-30}{1,16}", ctor, decimalNum );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the decimal( int ) " +
            "constructor \ngenerates the following output.\n" );
        Console.WriteLine( "{0,-30}{1,16}", "Constructor", "Value" );
        Console.WriteLine( "{0,-30}{1,16}", "-----------", "-----" );

        // Construct decimal objects from int values.
        CreateDecimal( int.MinValue, "int.MinValue" );
        CreateDecimal( int.MaxValue, "int.MaxValue" );
        CreateDecimal( 0, "0" );
        CreateDecimal( 999999999, "999999999" );
        CreateDecimal( 0x40000000, "0x40000000" );
        CreateDecimal( unchecked( (int)0xC0000000 ),
            "(int)0xC0000000" );
    }
}

/*

Decimal(Int32[])

Initializes a new instance of Decimal to a decimal value represented in binary and contained in a specified array.

C#

```
public Decimal (int[] bits);
```

Parameters

`bits` Int32[]

An array of 32-bit signed integers containing a representation of a decimal value.

Exceptions

ArgumentNullException

`bits` is `null`.

ArgumentException

The length of the `bits` is not 4.

-or-

The representation of the decimal value in `bits` is not valid.

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with an array of four Int32 values.

C#

```
// Example of the decimal( int[ ] ) constructor.
using System;

class DecimalCtorIArrDemo
{
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Create a decimal object and display its value.
    public static void CreateDecimal( int[ ] bits )
    {
        // Format the constructor for display.
        string ctor = String.Format(
            "decimal( {{ 0x{0:X}", bits[ 0 ] );
        string valOrExc;

        for( int index = 1; index < bits.Length; index++ )
            ctor += String.Format( ", 0x{0:X}", bits[ index ] );
        ctor += " } )";

        try
        {
            // Construct the decimal value.
            decimal decimalNum = new decimal( bits );

            // Format the decimal value for display.
            valOrExc = decimalNum.ToString( );
        }
        catch( Exception ex )
        {
            // Save the exception type if an exception was thrown.
            valOrExc = GetExceptionType( ex );
        }

        // Display the constructor and decimal value or exception.
        int ctorLen = 76 - valOrExc.Length;

        // Display the data on one line if it will fit.
```

```
        if( ctorLen > ctor.Length )
            Console.WriteLine( "{0}{1}", ctor.PadRight( ctorLen ),
                valOrExc );

        // Otherwise, display the data on two lines.
        else
        {
            Console.WriteLine( "{0}", ctor );
            Console.WriteLine( "{0,76}", valOrExc );
        }
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the decimal( int[ ] ) constructor " +
            "\ngenerates the following output.\n" );
        Console.WriteLine( "{0,-38}{1,38}", "Constructor",
            "Value or Exception" );
        Console.WriteLine( "{0,-38}{1,38}", "-----------",
            "------------------" );

        // Construct decimal objects from integer arrays.
        CreateDecimal( new int[ ] { 0, 0, 0, 0 } );

```

Remarks

The binary representation of a Decimal number consists of a 1-bit sign, a 96-bit integer number, and a scaling factor used to divide the integer number and specify what portion of it is a decimal fraction. The scaling factor is implicitly the number 10, raised to an exponent ranging from 0 to 28.

`bits` is a four-element long array of 32-bit signed integers.

`bits` [0], `bits` [1], and `bits` [2] contain the low, middle, and high 32 bits of the 96-bit integer number.

`bits` [3] contains the scale factor and sign, and consists of following parts:

Bits 0 to 15, the lower word, are unused and must be zero.

Bits 16 to 23 must contain an exponent between 0 and 28, which indicates the power of 10 to divide the integer number.

Bits 24 to 30 are unused and must be zero.

Bit 31 contains the sign; 0 meaning positive, and 1 meaning negative.

A numeric value might have several possible binary representations; all are equally valid and numerically equivalent. Note that the bit representation differentiates between negative and positive zero. These values are treated as being equal in all operations.

Decimal(Int64)

Initializes a new instance of Decimal to the value of the specified 64-bit signed integer.

C#

```
public Decimal (long value);
```

Parameters

`value` Int64

The value to represent as a Decimal.

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with an Int64 value.

C#

```
// Example of the decimal( long ) constructor.
using System;

class DecimalCtorLDemo
{
    // Create a decimal object and display its value.
    public static void CreateDecimal( long value, string valToStr )
    {
        decimal decimalNum = new decimal( value );

        // Format the constructor for display.
        string ctor = String.Format( "decimal( {0} )", valToStr );

        // Display the constructor and its value.
        Console.WriteLine( "{0,-35}{1,22}", ctor, decimalNum );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the decimal( long ) " +

Decimal(ReadOnlySpan<Int32>)

Initializes a new instance of Decimal to a decimal value represented in binary and contained in the specified span.

C#

```
public Decimal (ReadOnlySpan<int> bits);
```

Parameters

`bits` ReadOnlySpan<Int32>

A span of four Int32 values that contains a binary representation of a decimal value.

Exceptions

ArgumentException

The length of `bits` is not 4, or the representation of the decimal value in `bits` is not valid.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Decimal(Single)

Initializes a new instance of Decimal to the value of the specified single-precision floating-point number.

```
C#

public Decimal (float value);
```

Parameters

`value` Single

The value to represent as a Decimal.

Exceptions

OverflowException

`value` is greater than Decimal.MaxValue or less than Decimal.MinValue.

-or-

`value` is NaN, PositiveInfinity, or NegativeInfinity.

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with a Single value.

```
C#

// Example of the decimal( float ) constructor.
using System;

class DecimalCtorSDemo
{
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
```

```
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Create a decimal object and display its value.
    public static void CreateDecimal( float value, string valToStr )
    {
        // Format and display the constructor.
        Console.Write( "{0,-27}",
            String.Format( "decimal( {0} )", valToStr ) );

        try
        {
            // Construct the decimal value.
            decimal decimalNum = new decimal( value );

            // Display the value if it was created successfully.
            Console.WriteLine( "{0,31}", decimalNum );
        }
        catch( Exception ex )
        {
            // Display the exception type if an exception was thrown.
            Console.WriteLine( "{0,31}", GetExceptionType( ex ) );
        }
    }

Decimal(UInt32)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of Decimal to the value of the specified 32-bit unsigned integer.

```
C#
```

```
[System.CLSCompliant(false)]
public Decimal (uint value);
```

Parameters

value UInt32

The value to represent as a Decimal.

Attributes CLSCompliantAttribute

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with a UInt32 value.

C#

```
// Example of the decimal( uint ) constructor.
using System;

class DecimalCtorUIDemo
{
    // Create a decimal object and display its value.
    public static void CreateDecimal( uint value, string valToStr )
    {
        decimal decimalNum = new decimal( value );

        // Format the constructor for display.
        string ctor = String.Format( "decimal( {0} )", valToStr );

        // Display the constructor and its value.
        Console.WriteLine( "{0,-33}{1,16}", ctor, decimalNum );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the decimal( uint ) " +
            "constructor \ngenerates the following output.\n" );
        Console.WriteLine( "{0,-33}{1,16}", "Constructor", "Value" );
        Console.WriteLine( "{0,-33}{1,16}", "-----------", "-----" );

        // Construct decimal objects from uint values.
        CreateDecimal( uint.MinValue, "uint.MinValue" );
        CreateDecimal( uint.MaxValue, "uint.MaxValue" );
        CreateDecimal( (uint)int.MaxValue, "(uint)int.MaxValue" );
        CreateDecimal( 999999999U, "999999999U" );
        CreateDecimal( 0x40000000U, "0x40000000U" );
        CreateDecimal( 0xC0000000, "0xC0000000" );
```

```
    }
}

/*
This example of the decimal( uint ) constructor
generates the following output.

Constructor                                 Value
-----------                                 -----
decimal( uint.MinValue )                        0
decimal( uint.MaxValue )               4294967295
decimal( (uint)int.MaxValue )          2147483647

Decimal(UInt64)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of Decimal to the value of the specified 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
```

```
public Decimal (ulong value);
```

Parameters

value UInt64

The value to represent as a Decimal.

Attributes CLSCompliantAttribute

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with a UInt64 value.

C#

```
// Example of the decimal( ulong ) constructor.
using System;

class DecimalCtorLDemo
{
    // Create a decimal object and display its value.
    public static void CreateDecimal( ulong value, string valToStr )
    {
        decimal decimalNum = new decimal( value );

        // Format the constructor for display.
        string ctor = String.Format( "decimal( {0} )", valToStr );

        // Display the constructor and its value.
        Console.WriteLine( "{0,-35}{1,22}", ctor, decimalNum );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the decimal( ulong ) " +
            "constructor \ngenerates the following output.\n" );
        Console.WriteLine( "{0,-35}{1,22}", "Constructor", "Value" );
        Console.WriteLine( "{0,-35}{1,22}", "-----------", "-----" );

        // Construct decimal objects from ulong values.
        CreateDecimal( ulong.MinValue, "ulong.MinValue" );
        CreateDecimal( ulong.MaxValue, "ulong.MaxValue" );
        CreateDecimal( long.MaxValue, "long.MaxValue" );
        CreateDecimal( 999999999999999999, "999999999999999999" );
        CreateDecimal( 0x2000000000000000, "0x2000000000000000" );
        CreateDecimal( 0xE000000000000000, "0xE000000000000000" );
    }
}
```

```
/*

Decimal(Int32, Int32, Int32, Boolean, Byte)

Initializes a new instance of Decimal from parameters specifying the instance's constituent parts.

C#

```
public Decimal (int lo, int mid, int hi, bool isNegative, byte scale);
```

Parameters

lo Int32

The low 32 bits of a 96-bit integer.

mid Int32

The middle 32 bits of a 96-bit integer.

hi Int32

The high 32 bits of a 96-bit integer.

isNegative Boolean

`true` to indicate a negative number; `false` to indicate a positive number.

scale Byte

A power of 10 ranging from 0 to 28.

Exceptions

ArgumentOutOfRangeException

`scale` is greater than 28.

Examples

The following code example creates several `Decimal` numbers using the constructor overload that initializes a `Decimal` structure with three Int32 value words, a Boolean sign, and a Byte scale factor.

C#

```
// Example of the decimal( int, int, int, bool, byte ) constructor.
using System;

class DecimalCtorIIIBByDemo
{
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Create a decimal object and display its value.
    public static void CreateDecimal( int low, int mid, int high,
        bool isNeg, byte scale )
    {
        // Format the constructor for display.
        string ctor = String.Format(
            "decimal( {0}, {1}, {2}, {3}, {4} )",
            low, mid, high, isNeg, scale );
```

```
        string valOrExc;

        try
        {
            // Construct the decimal value.
            decimal decimalNum = new decimal(
                low, mid, high, isNeg, scale );

            // Format and save the decimal value.
            valOrExc = decimalNum.ToString( );
        }
        catch( Exception ex )
        {
            // Save the exception type if an exception was thrown.
            valOrExc = GetExceptionType( ex );
        }

        // Display the constructor and decimal value or exception.
        int ctorLen = 76 - valOrExc.Length;

        // Display the data on one line if it will fit.
        if ( ctorLen > ctor.Length )
            Console.WriteLine( "{0}{1}", ctor.PadRight( ctorLen ),
                valOrExc );

        // Otherwise, display the data on two lines.
        else
        {
            Console.WriteLine( "{0}", ctor );
            Console.WriteLine( "{0,76}", valOrExc );
        }
    }

    public static void Main( )
    {

        Console.WriteLine( "This example of the decimal( int, int, " +
            "int, bool, byte ) \nconstructor " +
            "generates the following output.\n" );
        Console.WriteLine( "{0,-38}{1,38}", "Constructor",
            "Value or Exception" );
        Console.WriteLine( "{0,-38}{1,38}", "-----------",
            "-----------------" );

        // Construct decimal objects from the component fields.
        CreateDecimal( 0, 0, 0, false, 0 );
        CreateDecimal( 0, 0, 0, false, 27 );
        CreateDecimal( 0, 0, 0, true, 0 );
        CreateDecimal( 1000000000, 0, 0, false, 0 );
        CreateDecimal( 0, 1000000000, 0, false, 0 );
        CreateDecimal( 0, 0, 1000000000, false, 0 );
        CreateDecimal( 1000000000, 1000000000, 1000000000, false, 0 );
        CreateDecimal( -1, -1, -1, false, 0 );
        CreateDecimal( -1, -1, -1, true, 0 );
        CreateDecimal( -1, -1, -1, false, 15 );
```

```
        CreateDecimal( -1, -1, -1, false, 28 );
        CreateDecimal( -1, -1, -1, false, 29 );
        CreateDecimal( int.MaxValue, 0, 0, false, 18 );
        CreateDecimal( int.MaxValue, 0, 0, false, 28 );
        CreateDecimal( int.MaxValue, 0, 0, true, 28 );
    }
}

/*

*/
```

The following example uses the GetBits method to retrieve the component parts of an array. It then uses this array in the call to the Decimal(Int32, Int32, Int32, Boolean, Byte) constructor to instantiate a new Decimal value.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal[] values = { 1234.96m, -1234.96m };
      foreach (var value in values) {
         int[] parts = Decimal.GetBits(value);
         bool sign = (parts[3] & 0x80000000) != 0;

         byte scale = (byte) ((parts[3] >> 16) & 0x7F);
         Decimal newValue = new Decimal(parts[0], parts[1], parts[2],
sign, scale);
         Console.WriteLine("{0} --> {1}", value, newValue);
      }
   }
}
// The example displays the following output:
//       1234.96 --> 1234.96
//       -1234.96 --> -1234.96
```

Remarks

The binary representation of a Decimal number consists of a 1-bit sign, a 96-bit integer number, and a scaling factor used to divide the integer number and specify what portion of it is a decimal fraction. The scaling factor is implicitly the number 10 raised to an exponent ranging from 0 to 28.

Decimal.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of Decimal. This field is constant and read-only.

C#

```
public static readonly decimal MaxValue;
```

Field Value

Decimal

Examples

The following code sample illustrates the use of `MaxValue` :

C#

```
class PiggyBank {
    public decimal Capacity {
        get {
            return Decimal.MaxValue;
        }
    }

    protected decimal MyFortune;

    public void AddPenny() {
        MyFortune += .01m;
    }
}
```

Remarks

The value of this constant is positive 79,228,162,514,264,337,593,543,950,335.

Decimal.MinusOne Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number negative one (-1).

C#

```
public static readonly decimal MinusOne;
```

Field Value

Decimal

Examples

The following code example illustrates the use of the `MinusOne` field.

C#

```
// Example of the Decimal fields.
using System;

class DecimalFieldsDemo
{
    public static void Main( )
    {
        const string numberFmt = "{0,-25}{1,45:N0}";
        const string exprFmt = "{0,-55}{1,15}";

        Console.WriteLine(
            "This example of the fields of the Decimal structure " +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field or Expression", "Value" );
        Console.WriteLine( numberFmt, "-------------------", "-----" );

        // Display the values of the Decimal fields.
        Console.WriteLine( numberFmt, "Decimal.MaxValue",
            Decimal.MaxValue );
        Console.WriteLine( numberFmt, "Decimal.MinValue",
            Decimal.MinValue );
```

```
        Console.WriteLine( numberFmt, "Decimal.MinusOne",
            Decimal.MinusOne );
        Console.WriteLine( numberFmt, "Decimal.One", Decimal.One );
        Console.WriteLine( numberFmt, "Decimal.Zero", Decimal.Zero );
        Console.WriteLine( );

        // Display the values of expressions of the Decimal fields.
        Console.WriteLine( exprFmt,
            "( Decimal.MinusOne + Decimal.One ) == Decimal.Zero",
            (Decimal.MinusOne + Decimal.One ) == Decimal.Zero );
        Console.WriteLine( exprFmt,
            "Decimal.MaxValue + Decimal.MinValue",
            Decimal.MaxValue + Decimal.MinValue );
        Console.WriteLine( exprFmt,
            "Decimal.MinValue / Decimal.MaxValue",
            Decimal.MinValue / Decimal.MaxValue );
        Console.WriteLine( "{0,-40}{1,30}",
            "100000000000000M / Decimal.MaxValue",
            100000000000000M / Decimal.MaxValue );
    }
}

Decimal.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of Decimal. This field is constant and read-only.

C#

```
public static readonly decimal MinValue;
```

Field Value

Decimal

Examples

The following code example illustrates the use of the `MinValue` field.

C#

```
// Example of the Decimal fields.
using System;

class DecimalFieldsDemo
{
    public static void Main( )
    {
        const string numberFmt = "{0,-25}{1,45:N0}";
        const string exprFmt = "{0,-55}{1,15}";

        Console.WriteLine(
            "This example of the fields of the Decimal structure " +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field or Expression", "Value" );
        Console.WriteLine( numberFmt, "-------------------", "-----" );

        // Display the values of the Decimal fields.
        Console.WriteLine( numberFmt, "Decimal.MaxValue",
            Decimal.MaxValue );
        Console.WriteLine( numberFmt, "Decimal.MinValue",
            Decimal.MinValue );
```

```
        Console.WriteLine( numberFmt, "Decimal.MinusOne",
            Decimal.MinusOne );
        Console.WriteLine( numberFmt, "Decimal.One", Decimal.One );
        Console.WriteLine( numberFmt, "Decimal.Zero", Decimal.Zero );
        Console.WriteLine( );

        // Display the values of expressions of the Decimal fields.
        Console.WriteLine( exprFmt,
            "( Decimal.MinusOne + Decimal.One ) == Decimal.Zero",
            (Decimal.MinusOne + Decimal.One ) == Decimal.Zero );
        Console.WriteLine( exprFmt,
            "Decimal.MaxValue + Decimal.MinValue",
            Decimal.MaxValue + Decimal.MinValue );
        Console.WriteLine( exprFmt,
            "Decimal.MinValue / Decimal.MaxValue",
            Decimal.MinValue / Decimal.MaxValue );
        Console.WriteLine( "{0,-40}{1,30}",
            "100000000000000M / Decimal.MaxValue",
            100000000000000M / Decimal.MaxValue );
    }
}

/*
This example of the fields of the Decimal structure
generates the following output.

Field or Expression                                          Value
-------------------                                          -----
Decimal.MaxValue                 79,228,162,514,264,337,593,543,950,335
Decimal.MinValue                -79,228,162,514,264,337,593,543,950,335
Decimal.MinusOne                                                    -1
Decimal.One                                                          1

Decimal.One Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number one (1).

C#

```
public static readonly decimal One;
```

Field Value

Decimal

Examples

The following code example illustrates the use of the `One` field.

C#

```
// Example of the Decimal fields.
using System;

class DecimalFieldsDemo
{
    public static void Main( )
    {
        const string numberFmt = "{0,-25}{1,45:N0}";
        const string exprFmt = "{0,-55}{1,15}";

        Console.WriteLine(
            "This example of the fields of the Decimal structure " +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field or Expression", "Value" );
        Console.WriteLine( numberFmt, "-------------------", "-----" );

        // Display the values of the Decimal fields.
        Console.WriteLine( numberFmt, "Decimal.MaxValue",
            Decimal.MaxValue );
        Console.WriteLine( numberFmt, "Decimal.MinValue",
            Decimal.MinValue );
```

```
        Console.WriteLine( numberFmt, "Decimal.MinusOne",
            Decimal.MinusOne );
        Console.WriteLine( numberFmt, "Decimal.One", Decimal.One );
        Console.WriteLine( numberFmt, "Decimal.Zero", Decimal.Zero );
        Console.WriteLine( );

        // Display the values of expressions of the Decimal fields.
        Console.WriteLine( exprFmt,
            "( Decimal.MinusOne + Decimal.One ) == Decimal.Zero",
            (Decimal.MinusOne + Decimal.One ) == Decimal.Zero );
        Console.WriteLine( exprFmt,
            "Decimal.MaxValue + Decimal.MinValue",
            Decimal.MaxValue + Decimal.MinValue );
        Console.WriteLine( exprFmt,
            "Decimal.MinValue / Decimal.MaxValue",
            Decimal.MinValue / Decimal.MaxValue );
        Console.WriteLine( "{0,-40}{1,30}",
            "100000000000000M / Decimal.MaxValue",

Decimal.Scale Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the scaling factor of the decimal, which is a number from 0 to 28 that represents the number of decimal digits.

C#

```
public byte Scale { get; }
```

Property Value

Byte

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.Abs(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static decimal Abs (decimal value);
```

Parameters

`value` Decimal

The value for which to get its absolute.

Returns

Decimal

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.Add(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two specified Decimal values.

C#

```
public static decimal Add (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to add.

d2 Decimal

The second value to add.

Returns

Decimal

The sum of `d1` and `d2`.

Exceptions

OverflowException

The sum of `d1` and `d2` is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The following code sample illustrates the use of `Add` :

C#

```
class PiggyBank {
    public void AddPenny() {
        MyFortune = Decimal.Add(MyFortune, .01m);
    }

    public override string ToString() {
        return MyFortune.ToString("C")+" in piggy bank";
    }

    protected decimal MyFortune;
}
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.Ceiling(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smallest integral value that is greater than or equal to the specified decimal number.

C#

```
public static decimal Ceiling (decimal d);
```

Parameters

d Decimal

A decimal number.

Returns

Decimal

The smallest integral value that is greater than or equal to the `d` parameter. Note that this method returns a Decimal instead of an integral type.

Implements

Ceiling(TSelf)

Examples

The following example illustrates the Ceiling method and contrasts it with the Floor method.

C#

```
using System;

public class Example
```

```
{
   public static void Main()
   {
      decimal[] values = {12.6m, 12.1m, 9.5m, 8.16m, .1m, -.1m,  -1.1m,
                          -1.9m, -3.9m};
      Console.WriteLine("{0,-8} {1,10} {2,10}\n",
                        "Value", "Ceiling", "Floor");
      foreach (decimal value in values)
      Console.WriteLine("{0,-8} {1,10} {2,10}", value,
                        Decimal.Ceiling(value), Decimal.Floor(value));
   }
}
// The example displays the following output:
//       Value       Ceiling      Floor
//
//       12.6             13         12
//       12.1             13         12
//       9.5              10          9
//       8.16              9          8
//       0.1               1          0
//       -0.1              0         -1
//       -1.1             -1         -2
//       -1.9             -1         -2
//       -3.9             -3         -4
```

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward positive infinity. In other words, if `d` is positive, the presence of any fractional component causes `d` to be rounded to the next highest integer. If `d` is negative, the rounding operation causes any fractional component of `d` to be discarded. The operation of this method differs from the Floor method, which supports rounding toward negative infinity.

Decimal.Clamp(Decimal, Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static decimal Clamp (decimal value, decimal min, decimal max);
```

Parameters

`value` Decimal

The value to clamp.

`min` Decimal

The inclusive minimum to which `value` should clamp.

`max` Decimal

The inclusive maximum to which `value` should clamp.

Returns

Decimal

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.Compare(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two specified Decimal values.

C#

```
public static int Compare (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Int32

A signed number indicating the relative values of `d1` and `d2`.

Expand table

Return value	Meaning
Less than zero	`d1` is less than `d2`.
Zero	`d1` and `d2` are equal.
Greater than zero	`d1` is greater than `d2`.

Examples

The following example compares several Decimal values. Note that the first comparison indicates that the two values are equal despite the subtraction operation performed on the `value2` variable. This is because the Decimal type has 29 digits of precision, whereas a difference between these two values can be detected only with 30 digits of precision.

C#

```
using System;

public enum Relationship
{  LessThan = -1, Equals = 0, GreaterThan = 1 }

public class Example
{
   public static void Main()
   {
      decimal value1 = Decimal.MaxValue;
      decimal value2 = value1 - .01m;
      Console.WriteLine("{0} {2} {1}", value1, value2,
                        (Relationship) Decimal.Compare(value1, value2));

      value2 = value1 / 12m - .1m;
      value1 = value1 / 12m;
      Console.WriteLine("{0} {2} {1}", value1, value2,
                        (Relationship) Decimal.Compare(value1, value2));

      value1 = value1 - .2m;
      value2 = value2 + .1m;
      Console.WriteLine("{0} {2} {1}", value1, value2,
                        (Relationship) Decimal.Compare(value1, value2));
   }
}
// The example displays the following output:

Decimal.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or Decimal and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Decimal)	Compares this instance to a specified Decimal object and returns a comparison of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns a comparison of their relative values.

CompareTo(Decimal)

Compares this instance to a specified Decimal object and returns a comparison of their relative values.

C#

```
public int CompareTo (decimal value);
```

Parameters

`value` Decimal

The object to compare with this instance.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return value	Meaning
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");
```

```
    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;
    Int16    c1 = -2,    c2 = 2;

        Show("UInt16:   ", x1, x2, x1.CompareTo(x2),
x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                            resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
```

```
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Decimal.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the parameter as an Int32 object, then generates a Int32.CompareTo method to compare the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

CompareTo(Object)

Compares this instance to a specified object and returns a comparison of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

The object to compare with this instance, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return value	Meaning
Less than zero	This instance is less than `value`.

Return value	Meaning
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a Decimal.

Examples

The following code example compares several `Decimal` and other objects to a reference `Decimal` value using the `CompareTo` method.

C#

```
// Example of the decimal.CompareTo and decimal.Equals instance
// methods.
using System;

class DecCompToEqualsObjDemo
{
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Compare the decimal to the object parameters,
    // and display the object parameters with the results.
    public static void CompDecimalToObject( decimal Left,
        object Right, string RightText )
    {

        Console.WriteLine( "{0,-46}{1}", "object: "+RightText,
            Right );
        Console.WriteLine( "{0,-46}{1}", "Left.Equals( object )",
            Left.Equals( Right ) );
        Console.Write( "{0,-46}", "Left.CompareTo( object )" );
```

```
        try
        {
            // Catch the exception if CompareTo( ) throws one.
            Console.WriteLine( "{0}\n", Left.CompareTo( Right ) );
        }
        catch( Exception ex )
        {
            Console.WriteLine( "{0}\n", GetExceptionType( ex ) );
        }
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the decimal.Equals( object ) and \n" +
            "decimal.CompareTo( object ) methods generates the \n" +
            "following output. It creates several different " +
            "decimal \nvalues and compares them with the following " +
            "reference value.\n" );

        // Create a reference decimal value.
        decimal Left = new decimal( 987.654 );

        Console.WriteLine( "{0,-46}{1}\n",
            "Left: decimal( 987.654 )", Left );

        // Create objects to compare with the reference.
        CompDecimalToObject( Left, new decimal( 9.8765400E+2 ),
            "decimal( 9.8765400E+2 )" );
        CompDecimalToObject( Left, 987.6541M, "987.6541D" );
        CompDecimalToObject( Left, 987.6539M, "987.6539D" );
        CompDecimalToObject( Left,
            new decimal( 987654000, 0, 0, false, 6 ),
            "decimal( 987654000, 0, 0, false, 6 )" );
        CompDecimalToObject( Left, 9.8765400E+2,
            "Double 9.8765400E+2" );
        CompDecimalToObject( Left, "987.654", "String \"987.654\"" );
    }
}

/*
This example of the decimal.Equals( object ) and
decimal.CompareTo( object ) methods generates the
following output. It creates several different decimal
values and compares them with the following reference value.

Left: decimal( 987.654 )                      987.654

object: decimal( 9.8765400E+2 )               987.654
Left.Equals( object )                         True
Left.CompareTo( object )                      0

object: 987.6541D                             987.6541
Left.Equals( object )                         False
Left.CompareTo( object )                      -1
```

```
object: 987.6539D                              987.6539
Left.Equals( object )                          False
Left.CompareTo( object )                       1

object: decimal( 987654000, 0, 0, false, 6 )   987.654000
Left.Equals( object )                          True
Left.CompareTo( object )                       0

object: Double 9.8765400E+2                    987.654
Left.Equals( object )                          False
Left.CompareTo( object )                       ArgumentException

object: String "987.654"                       987.654
Left.Equals( object )                          False
Left.CompareTo( object )                       ArgumentException
*/
```

Remarks

Any instance of Decimal, regardless of its value, is considered greater than `null`.

Parameter `value` must be `null` or an instance of Decimal; otherwise, an exception is thrown.

Decimal.CopySign(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
public static decimal CopySign (decimal value, decimal sign);
```

Parameters

`value` Decimal

The value whose magnitude is used in the result.

`sign` Decimal

The value whose sign is used in the result.

Returns

Decimal

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static decimal CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Decimal

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.CreateSaturating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static decimal CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Decimal

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static decimal CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Decimal

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.Divide(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two specified Decimal values.

C#

```
public static decimal Divide (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The dividend.

d2 Decimal

The divisor.

Returns

Decimal

The result of dividing `d1` by `d2`.

Exceptions

DivideByZeroException

`d2` is zero.

OverflowException

The return value (that is, the quotient) is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example calls the Divide method to divide a range of values by 22.1.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Divide a series of numbers by 22.1
      Decimal dividend = 1230.0m;
      Decimal divisor = 22.1m;
      for (int ctr = 0; ctr <= 10; ctr++) {
         Console.WriteLine("{0:N1} / {1:N1} = {2:N4}", dividend, divisor,
                           Decimal.Divide(dividend, divisor));
         dividend += .1m;
      }
   }
}
// The example displays the following output:
//       1,230.0 / 22.1 = 55.6561
//       1,230.1 / 22.1 = 55.6606
//       1,230.2 / 22.1 = 55.6652
//       1,230.3 / 22.1 = 55.6697
//       1,230.4 / 22.1 = 55.6742
//       1,230.5 / 22.1 = 55.6787
//       1,230.6 / 22.1 = 55.6833
//       1,230.7 / 22.1 = 55.6878
//       1,230.8 / 22.1 = 55.6923
//       1,230.9 / 22.1 = 55.6968
//       1,231.0 / 22.1 = 55.7014
```

Decimal.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two instances of Decimal represent the same value.

Overloads

Expand table

Equals(Decimal, Decimal)	Returns a value indicating whether two specified instances of Decimal represent the same value.
Equals(Object)	Returns a value indicating whether this instance and a specified Object represent the same type and value.
Equals(Decimal)	Returns a value indicating whether this instance and a specified Decimal object represent the same value.

Equals(Decimal, Decimal)

Returns a value indicating whether two specified instances of Decimal represent the same value.

C#

```
public static bool Equals (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` and `d2` are equal; otherwise, `false`.

Examples

The following code example compares several `Decimal` values to a reference `Decimal` value using the static `Equals` method.

C#

```
// Example of the decimal.Compare and static decimal.Equals methods.
using System;

class DecCompareEqualsDemo
{
    const string dataFmt = "{0,-45}{1}";

    // Compare decimal parameters, and display them with the results.
    public static void CompareDecimals( decimal Left, decimal Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: "+RightText, Right );
        Console.WriteLine( dataFmt, "decimal.Equals( Left, Right )",
            Decimal.Equals( Left, Right ) );
        Console.WriteLine( dataFmt, "decimal.Compare( Left, Right )",
            Decimal.Compare( Left, Right ) );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the " +
            "decimal.Equals( decimal, decimal ) and \n" +
            "decimal.Compare( decimal, decimal ) methods " +
            "generates the \nfollowing output. It creates several " +
            "different decimal \nvalues and compares them with " +
            "the following reference value.\n" );

        // Create a reference decimal value.
        decimal Left = new decimal( 123.456 );

        Console.WriteLine( dataFmt, "Left: decimal( 123.456 )",
            Left );

        // Create decimal values to compare with the reference.
        CompareDecimals( Left, new decimal( 1.2345600E+2 ),
            "decimal( 1.2345600E+2 )" );
        CompareDecimals( Left, 123.4561M, "123.4561M" );
        CompareDecimals( Left, 123.4559M, "123.4559M" );
```

```
        CompareDecimals( Left, 123.456000M, "123.456000M" );
        CompareDecimals( Left,
            new decimal( 123456000, 0, 0, false, 6 ),
            "decimal( 123456000, 0, 0, false, 6 )" );
    }
}

/*
This example of the decimal.Equals( decimal, decimal ) and
decimal.Compare( decimal, decimal ) methods generates the
following output. It creates several different decimal
values and compares them with the following reference value.

Left: decimal( 123.456 )                    123.456

Right: decimal( 1.2345600E+2 )              123.456
decimal.Equals( Left, Right )               True
decimal.Compare( Left, Right )              0

Right: 123.4561M                            123.4561
decimal.Equals( Left, Right )               False
decimal.Compare( Left, Right )              -1

Right: 123.4559M                            123.4559
decimal.Equals( Left, Right )               False
decimal.Compare( Left, Right )              1

Right: 123.456000M                          123.456000
decimal.Equals( Left, Right )               True
decimal.Compare( Left, Right )              0

Right: decimal( 123456000, 0, 0, false, 6 )  123.456000
decimal.Equals( Left, Right )               True
decimal.Compare( Left, Right )              0
*/

Equals(Object)

Returns a value indicating whether this instance and a specified Object represent the same type and value.

C#

```
public override bool Equals (object? value);
```

Parameters

`value` Object

The object to compare with this instance.

Returns

Boolean

`true` if `value` is a Decimal and equal to this instance; otherwise, `false`.

Examples

The following code example compares several `Decimal` and other objects to a reference `Decimal` value using the `Equals` method.

C#

```
// Example of the decimal.CompareTo and decimal.Equals instance
// methods.
using System;

class DecCompToEqualsObjDemo
{
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
```

```
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Compare the decimal to the object parameters,
    // and display the object parameters with the results.
    public static void CompDecimalToObject( decimal Left,
        object Right, string RightText )
    {

        Console.WriteLine( "{0,-46}{1}", "object: "+RightText,
            Right );
        Console.WriteLine( "{0,-46}{1}", "Left.Equals( object )",
            Left.Equals( Right ) );
        Console.Write( "{0,-46}", "Left.CompareTo( object )" );

        try
        {
            // Catch the exception if CompareTo( ) throws one.
            Console.WriteLine( "{0}\n", Left.CompareTo( Right ) );
        }
        catch( Exception ex )
        {
            Console.WriteLine( "{0}\n", GetExceptionType( ex ) );
        }
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the decimal.Equals( object ) and \n" +
            "decimal.CompareTo( object ) methods generates the \n" +
            "following output. It creates several different " +

Left.Equals( object )                         False
Left.CompareTo( object )                      ArgumentException

object: String "987.654"                      987.654
Left.Equals( object )                         False
Left.CompareTo( object )                      ArgumentException
*/
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Object) method overloads. If an implicit conversion between the `obj` argument and a Decimal is defined and the argument is not typed as an Object, compilers may perform an implicit conversion and call the Equals(Decimal) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a Decimal value. The following example illustrates the difference in behavior between the two method overloads. In the case of all primitive integral types, including both signed and unsigned types, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the

Equals(Decimal) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static decimal value = 112m;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,17}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,19}", value.Equals(int1));
      TestObjectForEquality(int1);

      long long1 = 112;
      Console.WriteLine("value = long1: {0,18}", value.Equals(long1));
      TestObjectForEquality(long1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);

      ushort ushort1 = 112;
      Console.WriteLine("value = ushort1: {0,17}",
value.Equals(ushort1));
      TestObjectForEquality(ushort1);

      uint uint1 = 112;
      Console.WriteLine("value = uint1: {0,19}", value.Equals(uint1));
      TestObjectForEquality(uint1);

      ulong ulong1 = 112;
      Console.WriteLine("value = ulong1: {0,18}", value.Equals(ulong1));
      TestObjectForEquality(ulong1);

      float sng1 = 112;
      Console.WriteLine("value = sng1: {0,21}", value.Equals(sng1));
      TestObjectForEquality(sng1);

      double dbl1 = 112;
      Console.WriteLine("value = dbl1: {0,21}", value.Equals(dbl1));
      TestObjectForEquality(dbl1);
   }
```

```
    private static void TestObjectForEquality(Object obj)
    {
       Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                         value, value.GetType().Name,
                         obj, obj.GetType().Name,
                         value.Equals(obj));
    }
 }
 // The example displays the following output:
 //       value = byte1:              True
 //       112 (Decimal) = 112 (Byte): False
 //
 //       value = short1:              True
 //       112 (Decimal) = 112 (Int16): False
 //
 //       value = int1:                True
 //       112 (Decimal) = 112 (Int32): False
 //
 //       value = long1:               True
 //       112 (Decimal) = 112 (Int64): False
 //
 //       value = sbyte1:              True
 //       112 (Decimal) = 112 (SByte): False
 //
 //       value = ushort1:              True
 //       112 (Decimal) = 112 (UInt16): False
 //
 //       value = uint1:                True
 //       112 (Decimal) = 112 (UInt32): False
 //
 //       value = ulong1:               True
 //       112 (Decimal) = 112 (UInt64): False
 //
 //       value = sng1:                 False
 //       112 (Decimal) = 112 (Single): False
 //
 //       value = dbl1:                 False
 //       112 (Decimal) = 112 (Double): False
```

Equals(Decimal)

Returns a value indicating whether this instance and a specified Decimal object represent the same value.

```
C#

public bool Equals (decimal value);
```

Parameters

`value` Decimal

An object to compare to this instance.

Returns

Boolean

`true` if `value` is equal to this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `value` parameter to an object.

If `value` has fewer bits (is narrower) than the instance type, some programming languages perform an implicit widening conversion that transforms the value of the parameter into a value with more bits.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method to compare the Int32 instance and parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Object) method overloads. If an implicit conversion between the `obj` argument and a Decimal is defined and the argument is not typed as an Object, compilers may perform an implicit conversion and call the Equals(Decimal) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a Decimal value. The following example illustrates the difference in behavior between the two method overloads. In the case of all primitive integral types, including both signed and unsigned types, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Decimal) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static decimal value = 112m;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,17}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,19}", value.Equals(int1));
```

```
        TestObjectForEquality(int1);

        long long1 = 112;
        Console.WriteLine("value = long1: {0,18}", value.Equals(long1));
        TestObjectForEquality(long1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,17}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,19}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,18}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        float sng1 = 112;
        Console.WriteLine("value = sng1: {0,21}", value.Equals(sng1));
        TestObjectForEquality(sng1);

        double dbl1 = 112;

Decimal.Floor(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rounds a specified Decimal number to the closest integer toward negative infinity.

C#

```
public static decimal Floor (decimal d);
```

Parameters

d Decimal

The value to round.

Returns

Decimal

If `d` has a fractional part, the next whole Decimal number toward negative infinity that is less than `d`.

-or-

If `d` doesn't have a fractional part, `d` is returned unchanged. Note that the method returns an integral value of type Decimal.

Implements

Floor(TSelf)

Examples

The following example illustrates the Floor method and contrasts it with the Ceiling method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      decimal[] values = {12.6m, 12.1m, 9.5m, 8.16m, .1m, -.1m,  -1.1m,
                          -1.9m, -3.9m};
      Console.WriteLine("{0,-8} {1,10} {2,10}\n",
                        "Value", "Ceiling", "Floor");
      foreach (decimal value in values)
      Console.WriteLine("{0,-8} {1,10} {2,10}", value,
                        Decimal.Ceiling(value), Decimal.Floor(value));
   }
}
// The example displays the following output:
//       Value       Ceiling      Floor
//
//       12.6             13         12
//       12.1             13         12
//       9.5              10          9
//       8.16              9          8
//       0.1               1          0
//       -0.1              0         -1
//       -1.1             -1         -2
//       -1.9             -1         -2
//       -3.9             -3         -4
```

Remarks

The behavior of this method follows IEEE Standard 754, Section 4. This kind of rounding is sometimes called rounding toward negative infinity. In other words, if `d` is positive, any fractional component is truncated. If `d` is negative, the presence of any fractional component causes it to be rounded to the smaller integer. The operation of this method differs from the Ceiling method, which supports rounding toward positive infinity.

Decimal.FromOACurrency(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified 64-bit signed integer, which contains an OLE Automation Currency value, to the equivalent Decimal value.

C#

```
public static decimal FromOACurrency (long cy);
```

Parameters

cy Int64

An OLE Automation Currency value.

Returns

Decimal

A Decimal that contains the equivalent of `cy`.

Examples

The following code example uses the `FromOACurrency` method to convert Int64 fields that contain OLE Automation Currency values to the equivalent `Decimal` numbers.

C#

```
// Example of the decimal.FromOACurrency method.
using System;

class DecimalFromOACurrencyDemo
{
    const string dataFmt = "{0,21}{1,25}";
```

```
    // Display the decimal.FromOACurrency parameter and decimal result.
    public static void ShowDecimalFromOACurrency( long Argument )
    {
        decimal decCurrency = decimal.FromOACurrency( Argument );

        Console.WriteLine( dataFmt, Argument, decCurrency );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the " +
            "decimal.FromOACurrency( ) method generates \nthe " +
            "following output. It displays the OLE Automation " +
            "Currency \nvalue as a long and the result as a " +
            "decimal.\n" );
        Console.WriteLine( dataFmt, "OA Currency", "Decimal Value" );
        Console.WriteLine( dataFmt, "-----------", "-------------" );

        // Convert OLE Automation Currency values to decimal objects.
        ShowDecimalFromOACurrency( 0L );
        ShowDecimalFromOACurrency( 1L );
        ShowDecimalFromOACurrency( 100000L );
        ShowDecimalFromOACurrency( 100000000000L );
        ShowDecimalFromOACurrency( 1000000000000000000L );
        ShowDecimalFromOACurrency( 1000000000000000001L );
        ShowDecimalFromOACurrency( long.MaxValue );
        ShowDecimalFromOACurrency( long.MinValue );
        ShowDecimalFromOACurrency( 123456789L );
        ShowDecimalFromOACurrency( 1234567890000L );
        ShowDecimalFromOACurrency( 1234567890987654321 );
        ShowDecimalFromOACurrency( 4294967295L );
    }
}

/*
This example of the decimal.FromOACurrency( ) method generates
the following output. It displays the OLE Automation Currency
value as a long and the result as a decimal.

          OA Currency            Decimal Value
          -----------            -------------
                    0                        0

Decimal.GetBits Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetBits(Decimal)	Converts the value of a specified instance of Decimal to its equivalent binary representation.
GetBits(Decimal, Span<Int32>)	Converts the value of a specified instance of Decimal to its equivalent binary representation.

GetBits(Decimal)

Converts the value of a specified instance of Decimal to its equivalent binary representation.

C#

```
public static int[] GetBits (decimal d);
```

Parameters

d Decimal

The value to convert.

Returns

Int32[]

A 32-bit signed integer array with four elements that contain the binary representation of `d`.

Examples

The following example uses the `GetBits` method to convert several `Decimal` values to their equivalent binary representations. It then displays the decimal values and the hexadecimal value of the elements in the array returned by the GetBits method.

C#

```
using System;

class Example
{
   public static void Main()
   {
      // Define an array of Decimal values.
      Decimal[] values = { 1M, 100000000000000M,
1000000000000000000000000000M,
                           100000000000000.00000000000000M,
1.0000000000000000000000000000M,
                           123456789M, 0.123456789M,
0.000000000123456789M,
                           0.000000000000000000123456789M, 4294967295M,
                           18446744073709551615M, Decimal.MaxValue,
                           Decimal.MinValue,
-7.9228162514264337593543950335M };

      Console.WriteLine("{0,31}  {1,10:X8}{2,10:X8}{3,10:X8}{4,10:X8}",
                        "Argument", "Bits[3]", "Bits[2]", "Bits[1]",
                        "Bits[0]" );
      Console.WriteLine( "{0,31}  {1,10:X8}{2,10:X8}{3,10:X8}{4,10:X8}",
                         "--------", "-------", "-------", "-------",
                         "-------" );

      // Iterate each element and display its binary representation
      foreach (var value in values) {
        int[] bits = decimal.GetBits(value);
        Console.WriteLine("{0,31}  {1,10:X8}{2,10:X8}{3,10:X8}{4,10:X8}",
                          value, bits[3], bits[2], bits[1], bits[0]);
      }
   }
}
// The example displays the following output:
//                           Argument     Bits[3]   Bits[2]   Bits[1]
Bits[0]
//                           --------     -------   -------   -------   -
------
//                                  1    00000000  00000000  00000000
00000001
//                    100000000000000    00000000  00000000  00005AF3
107A4000
//      1000000000000000000000000000    00000000  204FCE5E  3E250261

10000000
//                          123456789    00000000  00000000  00000000
075BCD15
//                        0.123456789    00090000  00000000  00000000
075BCD15
//               0.000000000123456789    00120000  00000000  00000000
075BCD15
//      0.000000000000000000123456789    001B0000  00000000  00000000
075BCD15
//                         4294967295    00000000  00000000  00000000
FFFFFFFF
//               18446744073709551615    00000000  00000000  FFFFFFFF
FFFFFFFF
//      79228162514264337593543950335    00000000  FFFFFFFF  FFFFFFFF
FFFFFFFF
//     -79228162514264337593543950335    80000000  FFFFFFFF  FFFFFFFF
FFFFFFFF
//    -7.9228162514264337593543950335    801C0000  FFFFFFFF  FFFFFFFF
FFFFFFFF
```

The following example uses the GetBits method to retrieve the component parts of an array. It then uses this array in the call to the Decimal(Int32, Int32, Int32, Boolean, Byte) constructor to instantiate a new Decimal value.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal[] values = { 1234.96m, -1234.96m };
      foreach (var value in values) {
         int[] parts = Decimal.GetBits(value);
         bool sign = (parts[3] & 0x80000000) != 0;

         byte scale = (byte) ((parts[3] >> 16) & 0x7F);
         Decimal newValue = new Decimal(parts[0], parts[1], parts[2],
sign, scale);
         Console.WriteLine("{0} --> {1}", value, newValue);
      }
   }
}
// The example displays the following output:
//       1234.96 --> 1234.96
//       -1234.96 --> -1234.96
```

Remarks

The binary representation of a Decimal number consists of a 1-bit sign, a 96-bit integer number, and a scaling factor used to divide the integer number and specify what portion of it is a decimal fraction. The scaling factor is implicitly the number 10, raised to an exponent ranging from 0 to 28.

The return value is a four-element array of 32-bit signed integers.

The first, second, and third elements of the returned array contain the low, middle, and high 32 bits of the 96-bit integer number.

The fourth element of the returned array contains the scale factor and sign. It consists of the following parts:

Bits 0 to 15, the lower word, are unused and must be zero.

Bits 16 to 23 must contain an exponent between 0 and 28, which indicates the power of 10 to divide the integer number.

Bits 24 to 30 are unused and must be zero.

Bit 31 contains the sign: 0 mean positive, and 1 means negative.

Note that the bit representation differentiates between negative and positive zero. These values are treated as being equal in all operations.

GetBits(Decimal, Span<Int32>)

Converts the value of a specified instance of Decimal to its equivalent binary representation.

```
C#

public static int GetBits (decimal d, Span<int> destination);
```

Parameters

d Decimal

The value to convert.

destination Span<Int32>

The span into which to store the four-integer binary representation.

Returns

Int32

`4`, which is the number of integers in the binary representation.

Exceptions

ArgumentException

The destination span was not long enough to store the binary representation.

Decimal.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions

Decimal.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Decimal.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant Decimal.

Implements

GetTypeCode()

Examples

The following code example uses the `GetTypeCode` method to return the type code for `Decimal` value type.

C#

```
// Example of the decimal.GetTypeCode method.
using System;

class DecimalGetTypeCodeDemo
{
    public static void Main( )
    {
        Console.WriteLine( "This example of the " +
            "decimal.GetTypeCode( ) \nmethod " +
            "generates the following output.\n" );

        // Create a decimal object and get its type code.
```

```
        decimal aDecimal = new decimal( 1.0 );
        TypeCode typCode = aDecimal.GetTypeCode( );

        Console.WriteLine( "Type Code:      \"{0}\"", typCode );
        Console.WriteLine( "Numeric value:  {0}", (int)typCode );
    }
}

/*
This example of the decimal.GetTypeCode( )
method generates the following output.

Type Code:      "Decimal"
Numeric value:  15
*/
```

Decimal.IsCanonical(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
public static bool IsCanonical (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.IsEvenInteger(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.IsInteger(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
public static bool IsInteger (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` and `3.0` will return `true` while `2.2` and `3.3` will return `false`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.IsNegative(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Decimal.IsOddInteger(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Decimal.IsPositive(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.Max(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static decimal Max (decimal x, decimal y);
```

Parameters

x Decimal

The value to compare with `y`.

y Decimal

The value to compare with `x`.

Returns

Decimal

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf>, this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Decimal.MaxMagnitude(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static decimal MaxMagnitude (decimal x, decimal y);
```

Parameters

x Decimal

The value to compare with `y`.

y Decimal

The value to compare with `x`.

Returns

Decimal

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf>, this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Decimal.Min(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

C#

```
public static decimal Min (decimal x, decimal y);
```

Parameters

x Decimal

The value to compare with `y`.

y Decimal

The value to compare with `x`.

Returns

Decimal

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf>, this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.Multiply(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two specified Decimal values.

C#

```
public static decimal Multiply (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The multiplicand.

d2 Decimal

The multiplier.

Returns

Decimal

The result of multiplying `d1` and `d2`.

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following code example creates several pairs of `Decimal` values and calculates their products with the `Multiply` method.

C#

```
// Example of the decimal.Multiply, decimal.Divide, and
// decimal.Remainder methods.
using System;
using Microsoft.VisualBasic;

class DecimalMulDivRemDemo
{
    const string dataFmt = "{0,-35}{1,31}";

    // Display decimal parameters and their product, quotient, and
    // remainder.
    public static void ShowDecimalProQuoRem( decimal Left, decimal Right )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "decimal Left", Left );
        Console.WriteLine( dataFmt, "decimal Right", Right );
        Console.WriteLine( dataFmt, "decimal.Multiply( Left, Right )",
            decimal.Multiply( Left, Right ) );
        Console.WriteLine( dataFmt, "decimal.Divide( Left, Right )",
            decimal.Divide( Left, Right ) );
        Console.WriteLine( dataFmt, "decimal.Remainder( Left, Right )",
            decimal.Remainder( Left, Right ) );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the \n" +
            "  decimal.Multiply( decimal, decimal ), \n" +
            "  decimal.Divide( decimal, decimal ), and \n" +
            "  decimal.Remainder( decimal, decimal ) \n" +
            "methods generates the following output. It displays " +
            "the product, \nquotient, and remainder of several " +
            "pairs of decimal objects." );

        // Create pairs of decimal objects.
        ShowDecimalProQuoRem( 1000M, 7M );
        ShowDecimalProQuoRem( -1000M, 7M );
        ShowDecimalProQuoRem(
            new decimal( 1230000000, 0, 0, false, 7 ), 0.0012300M );
        ShowDecimalProQuoRem( 12345678900000000M,
            0.0000000012345678M );
        ShowDecimalProQuoRem( 123456789.0123456789M,
            123456789.1123456789M );
    }
}

/*
This example of the
  decimal.Multiply( decimal, decimal ),
  decimal.Divide( decimal, decimal ), and
  decimal.Remainder( decimal, decimal )
methods generates the following output. It displays the product,
```

```
quotient, and remainder of several pairs of decimal objects.

decimal Left                                                  1000

Decimal.Negate(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the result of multiplying the specified Decimal value by negative one.

```
C#

public static decimal Negate (decimal d);
```

Parameters

d Decimal

The value to negate.

Returns

Decimal

A decimal number with the value of `d`, but the opposite sign.

-or-

Zero, if `d` is zero.

Examples

The following code example uses the `Negate` method to change the sign of several `Decimal` values.

```
C#

// Example of the decimal.Negate, decimal.Floor, and decimal.Truncate
// methods.
using System;

class DecimalFloorNegTruncDemo
{
```

```
    const string dataFmt = "{0,-30}{1,26}";

    // Display decimal parameters and the method results.
    public static void ShowDecimalFloorNegTrunc( decimal Argument )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "decimal Argument", Argument );
        Console.WriteLine( dataFmt, "decimal.Negate( Argument )",
            decimal.Negate( Argument ) );
        Console.WriteLine( dataFmt, "decimal.Floor( Argument )",
            decimal.Floor( Argument ) );
        Console.WriteLine( dataFmt, "decimal.Truncate( Argument )",
            decimal.Truncate( Argument ) );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the \n" +
            "  decimal.Negate( decimal ), \n" +
            "  decimal.Floor( decimal ), and \n" +
            "  decimal.Truncate( decimal ) \n" +
            "methods generates the following output." );

        // Create pairs of decimal objects.
        ShowDecimalFloorNegTrunc( 0M );
        ShowDecimalFloorNegTrunc( 123.456M );
        ShowDecimalFloorNegTrunc( -123.456M );
        ShowDecimalFloorNegTrunc(
            new decimal( 1230000000, 0, 0, true, 7 ) );
        ShowDecimalFloorNegTrunc( -9999999999.9999999999M );
    }
}

/*
This example of the
  decimal.Negate( decimal ),
  decimal.Floor( decimal ), and
  decimal.Truncate( decimal )
methods generates the following output.

decimal Argument                                    0
decimal.Negate( Argument )                          0
decimal.Floor( Argument )                           0
decimal.Truncate( Argument )                        0

decimal Argument                              123.456
decimal.Negate( Argument )                   -123.456
decimal.Floor( Argument )                         123
decimal.Truncate( Argument )                      123

decimal Argument                             -123.456
decimal.Negate( Argument )                    123.456
decimal.Floor( Argument )                        -124
decimal.Truncate( Argument )                     -123
```

```
decimal Argument                          -123.0000000
decimal.Negate( Argument )                 123.0000000
decimal.Floor( Argument )                         -123
decimal.Truncate( Argument )                      -123

Decimal.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its Decimal equivalent.

Overloads

Expand table

Parse(String)	Converts the string representation of a number to its Decimal equivalent.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its Decimal equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number to its Decimal equivalent using the specified culture-specific format information.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number to its Decimal equivalent using the specified style and culture-specific format.

Parse(String)

Converts the string representation of a number to its Decimal equivalent.

```
C#

public static decimal Parse (string s);
```

Parameters

s String

The string representation of the number to convert.

Returns

Decimal

The equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following code example uses the Parse(String) method to parse string representations of Decimal values.

```
C#

string value;
decimal number;
// Parse an integer with thousands separators.
value = "16,523,421";
number = Decimal.Parse(value);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '16,523,421' converted to 16523421.
```

```
// Parse a floating point value with thousands separators
value = "25,162.1378";
number = Decimal.Parse(value);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '25,162.1378' converted to 25162.1378.

// Parse a floating point number with US currency symbol.
value = "$16,321,421.75";
try
{
   number = Decimal.Parse(value);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '$16,321,421.75'.

// Parse a number in exponential notation
value = "1.62345e-02";
try
{
   number = Decimal.Parse(value);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '1.62345e-02'.
```

Remarks

Parameter `s` contains a number of the form:

[ws][sign][digits,]digits[.fractional-digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.

Element	Description
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.
,	A culture-specific thousands separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A sequence of digits ranging from 0 to 9.

Parameter `s` is interpreted using the NumberStyles.Number style. This means that white space and thousands separators are allowed but currency symbols are not. To explicitly define the elements (such as currency symbols, thousands separators, and white space) that can be present in `s`, use either the Decimal.Parse(String, NumberStyles) or the Decimal.Parse(String, NumberStyles, IFormatProvider) method.

Parameter `s` is parsed using the formatting information in a NumberFormatInfo initialized for the current system culture. For more information, see CurrentInfo. To parse a string using the formatting information of some other culture, use the Decimal.Parse(String, IFormatProvider) or Decimal.Parse(String, NumberStyles, IFormatProvider) method.

If necessary, the value of `s` is rounded using rounding to nearest.

A Decimal has 29 digits of precision. If `s` represents a number that has more than 29 digits, but has a fractional part and is within the range of MaxValue and MinValue, the number is rounded, not truncated, to 29 digits using rounding to nearest.

If during a parse operation a separator is encountered in the `s` parameter, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static decimal Parse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Decimal

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static decimal Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Decimal

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its Decimal equivalent.

```
C#

public static decimal Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

The string representation of the number to convert.

`style` NumberStyles

A bitwise combination of NumberStyles values that indicates the style elements that can be present in `s`. A typical value to specify is Number.

Returns

Decimal

The Decimal number equivalent to the number contained in `s` as specified by `style`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Decimal.MinValue or greater than Decimal.MaxValue

Examples

The following code example uses the Parse(String, NumberStyles) method to parse the string representations of Decimal values using the en-US culture.

C#

```
string value;
decimal number;
NumberStyles style;

// Parse string with a floating point value using NumberStyles.None.
value = "8694.12";
style = NumberStyles.None;
try
{
   number = Decimal.Parse(value, style);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '8694.12'.

// Parse string with a floating point value and allow decimal point.
style = NumberStyles.AllowDecimalPoint;
number = Decimal.Parse(value, style);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '8694.12' converted to 8694.12.

// Parse string with negative value in parentheses
value = "(1,789.34)";
style = NumberStyles.AllowDecimalPoint | NumberStyles.AllowThousands |
        NumberStyles.AllowParentheses;
number = Decimal.Parse(value, style);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '(1,789.34)' converted to -1789.34.

// Parse string using Number style
value = " -17,623.49 ";
style = NumberStyles.Number;
number = Decimal.Parse(value, style);
Console.WriteLine("'{0}' converted to {1}.", value, number);
```

```
// Displays:
//    ' -17,623.49 ' converted to -17623.49.
```

Remarks

The `style` parameter defines the style elements (such as thousands separators, white space, and currency symbols) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- NumberStyles.AllowHexSpecifier
- HexNumber

Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional-digits][e[sign]digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits ranging from 0 to 9.
,	A culture-specific thousands separator symbol. The current culture's thousands separator can appear in `s` if `style` includes the NumberStyles.AllowThousands

Element	Description
	flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional-digits	A sequence of digits ranging from 0 to 9. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the None style) always parses successfully if it is in the range of the Decimal type. The remaining NumberStyles members control elements that may be but are not required to be present in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in s in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The . and *fractional-digits* elements.
AllowExponent	The `s` parameter can also use exponential notation. This flag supports values in the form *digits*E*digits*; additional flags are needed to successfully parse strings with elements such as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.

NumberStyles value	Elements permitted in s in addition to digits
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The , element.
AllowCurrencySymbol	The *$* element.
Currency	All. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the `.` symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, `,` and `.` elements.
Any	All styles, except `s` cannot represent a hexadecimal number.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object initialized for the current system culture. For more information, see CurrentInfo.

A Decimal has 29 digits of precision. If `s` represents a number that has more than 29 digits, but has a fractional part and is within the range of MaxValue and MinValue, the number is rounded, not truncated, to 29 digits using rounding to nearest.

If a separator is encountered in the `s` parameter during a parse operation, `styles` includes the NumberStyles.AllowThousands and NumberStyles.AllowDecimalPoint values, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

UWP	10.0

Parse(String, IFormatProvider)

Converts the string representation of a number to its Decimal equivalent using the specified culture-specific format information.

```
C#

public static decimal Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

The string representation of the number to convert.

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific parsing information about `s`.

Returns

Decimal

The Decimal number equivalent to the number contained in `s` as specified by `provider`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not of the correct format.

OverflowException

`s` represents a number less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to a Decimal value.

C#

```
protected void OkToDecimal_Click(object sender, EventArgs e)
{
    string locale;
    decimal number;
    CultureInfo culture;

    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;

    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = Decimal.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
```

```
        return;
    }
    catch (Exception)
    {
        return;
    }
    // Output number to label on web form
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

This overload of the Parse(String, IFormatProvider) method is commonly used to convert text that can be formatted in a variety of ways to a Decimal value. For example, it can be used to convert the text entered by a user into an HTML text box to a numeric value.

The `s` parameter contains a number of the form:

[ws][sign][digits,]digits[.fractional-digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.
,	A culture-specific thousands separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Number style. This means that white space and thousands separators are allowed but currency symbols are not. To explicitly define the elements (such as currency symbols, thousands separators, and white space) that can be present in `s`, use the Decimal.Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null`, the thread current culture is used.

A Decimal object has 29 digits of precision. If `s` represents a number that has more than 29 digits, but has a fractional part and is within the range of MaxValue and MinValue, the number is rounded, not truncated, to 29 digits using rounding to nearest.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```C#
public static decimal Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Number, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Decimal

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format.

```C#
public static decimal Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Number, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

The span containing the characters representing the number to convert.

`style` NumberStyles

A bitwise combination of NumberStyles values that indicates the style elements that can be present in `s`. A typical value to specify is Number.

`provider` IFormatProvider

An IFormatProvider object that supplies culture-specific information about the format of `s`.

Returns

Decimal

The Decimal number equivalent to the number contained in `s` as specified by `style` and `provider`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number to its Decimal equivalent using the specified style and culture-specific format.

```
C#

public static decimal Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

The string representation of the number to convert.

`style` NumberStyles

A bitwise combination of NumberStyles values that indicates the style elements that can be present in `s`. A typical value to specify is Number.

`provider` IFormatProvider

An IFormatProvider object that supplies culture-specific information about the format of `s`.

Returns

Decimal

The Decimal number equivalent to the number contained in `s` as specified by `style` and `provider`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Decimal.MinValue or greater than Decimal.MaxValue.

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

Examples

The following example uses a variety of `style` and `provider` parameters to parse the string representations of Decimal values.

C#

```
string value;
decimal number;
NumberStyles style;
CultureInfo provider;

// Parse string using " " as the thousands separator
// and "," as the decimal separator for fr-FR culture.
value = "892 694,12";
style = NumberStyles.AllowDecimalPoint | NumberStyles.AllowThousands;
provider = new CultureInfo("fr-FR");

number = Decimal.Parse(value, style, provider);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '892 694,12' converted to 892694.12.

try
{
   number = Decimal.Parse(value, style, CultureInfo.InvariantCulture);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '892 694,12'.

// Parse string using "$" as the currency symbol for en-GB and
```

```
// en-US cultures.
value = "$6,032.51";
style = NumberStyles.Number | NumberStyles.AllowCurrencySymbol;
provider = new CultureInfo("en-GB");

try
{
   number = Decimal.Parse(value, style, provider);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '$6,032.51'.

provider = new CultureInfo("en-US");
number = Decimal.Parse(value, style, provider);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '$6,032.51' converted to 6032.51.
```

Remarks

The `style` parameter defines the allowable format of the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- NumberStyles.AllowHexSpecifier
- HexNumber

Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional-digits][e[sign]digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyNegativePattern and CurrencyPositivePattern properties of the NumberFormatInfo object returned by the GetFormat method of the `provider`

Element	Description
	parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits ranging from 0 to 9.
,	A culture-specific thousands separator symbol. The thousands separator of the culture defined by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture defined by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional-digits	A sequence of digits ranging from 0 to 9. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the None style) always parses successfully if it is in the range of the Decimal type. The remaining NumberStyles members control elements that may be but are not required to be present in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in s in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The . and *fractional-digits* elements.
AllowExponent	The `s` parameter can also use exponential notation. This flag supports values in the form *digits*E*digits*; additional flags are needed to successfully parse strings with elements such as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The , element.
AllowCurrencySymbol	The *$* element.
Currency	All. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the . symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, ,, and . elements.
Any	All styles, except `s` cannot represent a hexadecimal number.

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null`, the thread current culture is used.

A Decimal object has 29 digits of precision. If `s` represents a number that has more than 29 digits, but has a fractional part and is within the range of MaxValue and MinValue, the number is rounded, not truncated, to 29 digits using rounding to nearest.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse

operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Decimal.Remainder(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the remainder after dividing two Decimal values.

C#

```
public static decimal Remainder (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The dividend.

d2 Decimal

The divisor.

Returns

Decimal

The remainder after dividing `d1` by `d2`.

Exceptions

DivideByZeroException

`d2` is zero.

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example uses the Remainder method to calculate the remainder in a series of division operations.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        // Create parallel arrays of Decimals to use as the dividend and
divisor.
        Decimal[] dividends = { 79m, 1000m, -1000m, 123m, 1234567800000m,
                                1234.0123m };
        Decimal[] divisors = { 11m, 7m, 7m, .00123m, 0.12345678m, 1234.5678m
};

        for (int ctr = 0; ctr < dividends.Length; ctr++)
        {
           Decimal dividend = dividends[ctr];
           Decimal divisor = divisors[ctr];
           Console.WriteLine("{0:N3} / {1:N3} = {2:N3} Remainder {3:N3}",
dividend,
                             divisor, Decimal.Divide(dividend, divisor),
                             Decimal.Remainder(dividend, divisor));
        }
    }
}
// The example displays the following output:
//       79.000 / 11.000 = 7.182 Remainder 2.000
//       1,000.000 / 7.000 = 142.857 Remainder 6.000
//       -1,000.000 / 7.000 = -142.857 Remainder -6.000
//       123.000 / 0.001 = 100,000.000 Remainder 0.000
//       1,234,567,800,000.000 / 0.123 = 10,000,000,000,000.000 Remainder
0.000
//       1,234.012 / 1,234.568 = 1.000 Remainder 1,234.012
```

Decimal.Round Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rounds a value to the nearest integer or specified number of decimal places.

Overloads

Expand table

Round(Decimal, Int32, MidpointRounding)	Rounds a decimal value to the specified precision using the specified rounding strategy.
Round(Decimal, MidpointRounding)	Rounds a decimal value to an integer using the specified rounding strategy.
Round(Decimal, Int32)	Rounds a Decimal value to a specified number of decimal places.
Round(Decimal)	Rounds a decimal value to the nearest integer.

Round(Decimal, Int32, MidpointRounding)

Rounds a decimal value to the specified precision using the specified rounding strategy.

C#

```
public static decimal Round (decimal d, int decimals, MidpointRounding
mode);
```

Parameters

d Decimal

A decimal number to round.

`decimals` Int32

The number of significant decimal places (precision) in the return value.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Decimal

The number that `d` is rounded to using the `mode` rounding strategy and with a precision of `decimals`. If the precision of `d` is less than `decimals`, `d` is returned unchanged.

Implements

Round(TSelf, Int32, MidpointRounding)

Exceptions

ArgumentOutOfRangeException

`decimals` is less than 0 or greater than 28.

ArgumentException

`mode` is not a MidpointRounding value.

OverflowException

The result is outside the range of a Decimal object.

Examples

The following example demonstrates how to use the Round(Decimal, Int32, MidpointRounding) method with the MidpointRounding enumeration.

C#

```
decimal result;

// Round a positive value using different strategies.
// The precision of the result is 1 decimal place.

result = Math.Round(3.45m, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result} = Math.Round({3.45m}, 1,
```

```
MidpointRounding.ToEven)");
result = Math.Round(3.45m, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result} = Math.Round({3.45m}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(3.47m, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result} = Math.Round({3.47m}, 1,
MidpointRounding.ToZero)\n");

// Round a negative value using different strategies.
// The precision of the result is 1 decimal place.

result = Math.Round(-3.45m, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result} = Math.Round({-3.45m}, 1,
MidpointRounding.ToEven)");
result = Math.Round(-3.45m, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result} = Math.Round({-3.45m}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(-3.47m, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result} = Math.Round({-3.47m}, 1,
MidpointRounding.ToZero)\n");

/*
This code example produces the following results:

3.4 = Math.Round(3.45, 1, MidpointRounding.ToEven)
3.5 = Math.Round(3.45, 1, MidpointRounding.AwayFromZero)
3.4 = Math.Round(3.47, 1, MidpointRounding.ToZero)

-3.4 = Math.Round(-3.45, 1, MidpointRounding.ToEven)
-3.5 = Math.Round(-3.45, 1, MidpointRounding.AwayFromZero)
-3.4 = Math.Round(-3.47, 1, MidpointRounding.ToZero)
*/
```

Remarks

The `decimals` parameter specifies the number of significant decimal places in the return value and ranges from 0 to 28. If `decimals` is zero, an integer is returned.

If you specify ToEven or AwayFromZero for the `mode` parameter, those rounding strategies are only applied for midpoint values, that is, values whose least significant digit is 5.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Round(Decimal, MidpointRounding)

Rounds a decimal value to an integer using the specified rounding strategy.

```
C#

public static decimal Round (decimal d, MidpointRounding mode);
```

Parameters

`d` Decimal

A decimal number to round.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Decimal

The integer that `d` is rounded to using the `mode` rounding strategy.

Implements

Round(TSelf, MidpointRounding)

Exceptions

ArgumentException

`mode` is not a MidpointRounding value.

OverflowException

The result is outside the range of a Decimal object.

Examples

The following example displays values returned by the Round(Decimal, MidpointRounding) method with different `mode` arguments.

C#

```
Console.WriteLine($"{"Value",-10} {"Default",-10} {"ToEven",-10}
{"AwayFromZero",-15} {"ToZero",-15}");
for (decimal value = 12.0m; value <= 13.0m; value += 0.1m)
    Console.WriteLine($"{value,-10} {Math.Round(value),-10} " +
        $"{Math.Round(value, MidpointRounding.ToEven),-10} " +
        $"{Math.Round(value, MidpointRounding.AwayFromZero),-15} " +
        $"{Math.Round(value, MidpointRounding.ToZero),-15}");

// The example displays the following output:
//       Value      Default    ToEven     AwayFromZero    ToZero
//       12.0       12         12         12              12
//       12.1       12         12         12              12
//       12.2       12         12         12              12
//       12.3       12         12         12              12
//       12.4       12         12         12              12
//       12.5       12         12         13              12
//       12.6       13         13         13              12
//       12.7       13         13         13              12
//       12.8       13         13         13              12
//       12.9       13         13         13              12
//       13.0       13         13         13              13
```

Remarks

If you specify ToEven or AwayFromZero for the `mode` parameter, those rounding strategies are only applied for midpoint values, that is, values whose least significant digit is 5.

.NET Standard	2.0, 2.1

Round(Decimal, Int32)

Rounds a Decimal value to a specified number of decimal places.

```
C#
public static decimal Round (decimal d, int decimals);
```

Parameters

`d` Decimal

A decimal number to round.

`decimals` Int32

A value from 0 to 28 that specifies the number of decimal places to round to.

Returns

Decimal

The decimal number equivalent to `d` rounded to `decimals` decimal places.

Implements

Round(TSelf, Int32)

Exceptions

ArgumentOutOfRangeException

`decimals` is not a value from 0 to 28.

Examples

The following example rounds several `Decimal` values to a specified number of decimal places using the `Round` method.

C#

```
using System;

class Example12
{
   public static void Main()
   {
      // Define a set of Decimal values.
      decimal[] values = { 1.45m, 1.55m, 123.456789m, 123.456789m,
                           123.456789m, -123.456m,
                           new Decimal(1230000000, 0, 0, true, 7 ),
                           new Decimal(1230000000, 0, 0, true, 7 ),
                           -9999999999.9999999999m,
                           -9999999999.9999999999m };
      // Define a set of integers to for decimals argument.
      int[] decimals = { 1, 1, 4, 6, 8, 0, 3, 11, 9, 10};

      Console.WriteLine("{0,26}{1,8}{2,26}",
                        "Argument", "Digits", "Result" );
      Console.WriteLine("{0,26}{1,8}{2,26}",
                        "--------", "------", "------" );
      for (int ctr = 0; ctr < values.Length; ctr++)
        Console.WriteLine("{0,26}{1,8}{2,26}",
                          values[ctr], decimals[ctr],
                          Decimal.Round(values[ctr], decimals[ctr]));
    }
}
// The example displays the following output:
//                    Argument  Digits                    Result
//                    --------  ------                    ------
//                        1.45       1                       1.4
//                        1.55       1                       1.6
//                  123.456789       4                  123.4568
//                  123.456789       6                 123.456789
//                  123.456789       8                 123.456789
//                    -123.456       0                      -123
//                -123.0000000       3                  -123.000
//                -123.0000000      11               -123.0000000
//      -9999999999.9999999999       9    -10000000000.000000000
//      -9999999999.9999999999      10    -9999999999.9999999999
```

Remarks

This method is equivalent to calling the Round(Decimal, Int32, MidpointRounding) method with a `mode` argument of MidpointRounding.ToEven. When `d` is exactly halfway between two rounded values, the result is the rounded value that has an

even digit in the far right decimal position. For example, when rounded to two decimals, the value 2.345 becomes 2.34 and the value 2.355 becomes 2.36. This process is known as *rounding toward even*, or *banker's rounding*. It minimizes rounding errors that result from consistently rounding a midpoint value in a single direction.

- Round(Decimal, Int32)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Round(Decimal)

Rounds a decimal value to the nearest integer.

C#

```
public static decimal Round (decimal d);
```

Parameters

d Decimal

A decimal number to round.

Returns

Decimal

The integer that is nearest to the `d` parameter. If `d` is halfway between two integers, one of which is even and the other odd, the even number is returned.

Implements

Round(TSelf)

Exceptions

OverflowException

The result is outside the range of a Decimal value.

Examples

The following example rounds a range of Decimal values between 100 and 102 to the nearest integer. Because the method uses banker's rounding, 100.5 rounds to 100 and 101.5 rounds to 102.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      for (decimal value = 100m; value <= 102m; value += .1m)
         Console.WriteLine("{0} --> {1}", value, Decimal.Round(value));
   }
}
// The example displays the following output:
//     100 --> 100
//     100.1 --> 100
//     100.2 --> 100
//     100.3 --> 100
//     100.4 --> 100
//     100.5 --> 100
//     100.6 --> 101
//     100.7 --> 101
//     100.8 --> 101
//     100.9 --> 101
//     101.0 --> 101
//     101.1 --> 101
//     101.2 --> 101
//     101.3 --> 101
//     101.4 --> 101
//     101.5 --> 102
//     101.6 --> 102
//     101.7 --> 102
```

```
//     101.8 --> 102
//     101.9 --> 102
//     102.0 --> 102
```

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called *round half to even* or *banker's rounding*. It minimizes rounding errors that result from consistently rounding a midpoint value in a single direction. It is equivalent to calling the Round(Decimal, MidpointRounding) method with a `mode` argument of MidpointRounding.ToEven.

Decimal.Sign(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (decimal d);
```

Parameters

d Decimal

The value whose sign is to be computed.

Returns

Int32

A positive value if `d` is positive, Zero if `d` is zero, and a negative value if `d` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.Subtract(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts one specified Decimal value from another.

C#

```
public static decimal Subtract (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The minuend.

d2 Decimal

The subtrahend.

Returns

Decimal

The result of subtracting `d2` from `d1`.

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Examples

The following example illustrates the use of `Subtract`.

C#

```
class PiggyBank {
    public decimal Cents {
        get {
            return Decimal.Subtract(MyFortune, Decimal.Floor(MyFortune));
        }
    }

    protected decimal MyFortune;

    public void AddPenny() {
        MyFortune += .01m;
    }
}
```

Decimal.ToByte(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified Decimal to the equivalent 8-bit unsigned integer.

C#

```
public static byte ToByte (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Byte

An 8-bit unsigned integer equivalent to `value`.

Exceptions

OverflowException

`value` is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example uses the ToByte method to convert decimal numbers to Byte values.

C#

```
using System;

class Example
{
```

```
    public static void Main( )
    {
       decimal[] values = { 123m, new Decimal(78000, 0, 0, false, 3),
                            78.999m, 255.999m, 256m,
                            127.999m, 128m, -0.999m,
                            -1m,  -128.999m, -129m };

       foreach (var value in values) {
          try {
             byte number = Decimal.ToByte(value);
             Console.WriteLine("{0} --> {1}", value, number);
          }
          catch (OverflowException e)
          {
              Console.WriteLine("{0}: {1}", e.GetType().Name, value);
          }
       }
    }
 }
 // The example displays the following output:
 //     78 --> 78
 //     78.000 --> 78
 //     78.999 --> 78
 //     255.999 --> 255
 //     OverflowException: 256
 //     127.999 --> 127
 //     128 --> 128
 //     -0.999 --> 0
 //     OverflowException: -1
 //     OverflowException: -128.999
 //     OverflowException: -129
```

Remarks

Parameter `value` is rounded to the nearest integer value toward zero, and that result is returned.

You can also convert a Decimal value to an 8-bit unsigned integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Decimal.ToDouble(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified Decimal to the equivalent double-precision floating-point number.

```
C#

public static double ToDouble (decimal d);
```

Parameters

d Decimal

The decimal number to convert.

Returns

Double

A double-precision floating-point number equivalent to `d`.

Examples

The following code example converts `Decimal` numbers to Double values using `ToDouble` method.

```
C#

// Example of the decimal.ToSingle and decimal.ToDouble methods.
using System;

class DecimalToSgl_DblDemo
{
    static string formatter = "{0,30}{1,17}{2,23}";

    // Convert the decimal argument; no exceptions are thrown.
    public static void DecimalToSgl_Dbl( decimal argument )
```

```
    {
        object SingleValue;
        object DoubleValue;

        // Convert the argument to a float value.
        SingleValue = decimal.ToSingle( argument );

        // Convert the argument to a double value.
        DoubleValue = decimal.ToDouble( argument );

        Console.WriteLine( formatter, argument,
            SingleValue, DoubleValue );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the \n" +
            "  decimal.ToSingle( decimal ) and \n" +
            "  decimal.ToDouble( decimal ) \nmethods " +
            "generates the following output. It \ndisplays " +
            "several converted decimal values.\n" );
        Console.WriteLine( formatter, "decimal argument",
            "float", "double" );
        Console.WriteLine( formatter, "----------------",
            "-----", "------" );

        // Convert decimal values and display the results.
        DecimalToSgl_Dbl( 0.0000000000000000000000000001M );
        DecimalToSgl_Dbl( 0.0000000000123456789123456789M );
        DecimalToSgl_Dbl( 123M );
        DecimalToSgl_Dbl( new decimal( 123000000, 0, 0, false, 6 ) );
        DecimalToSgl_Dbl( 123456789.123456789M );
        DecimalToSgl_Dbl( 1234567891234567891234567 89M );
        DecimalToSgl_Dbl( decimal.MinValue );
        DecimalToSgl_Dbl( decimal.MaxValue );
    }
}

/*
This example of the
  decimal.ToSingle( decimal ) and
  decimal.ToDouble( decimal )
methods generates the following output. It
displays several converted decimal values.

               decimal argument            float                  double
               ----------------            -----                  ------
0.0000000000000000000000000001             1E-28                   1E-28
0.0000000000123456789123456789     1.234568E-11   1.23456789123457E-11
                            123              123                     123
                     123.000000              123                     123
           123456789.123456789     1.234568E+08       123456789.123457

```

```
 79228162514264337593543950335     7.922816E+28   7.92281625142643E+28
*/
```

Remarks

This operation can produce round-off errors because a double-precision floating-point number has fewer significant digits than a Decimal.

You can also convert a Decimal to a Double value by using the Explicit assignment operator. Because the conversion can entail a loss of precision, you must use a casting operator in C# or a conversion function in Visual Basic.

Applies to

Decimal.ToInt16(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified Decimal to the equivalent 16-bit signed integer.

C#

```
public static short ToInt16 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Int16

A 16-bit signed integer equivalent to `value`.

Exceptions

OverflowException

`value` is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example uses the ToInt16 method to convert decimal numbers to Int16 values.

C#

```
using System;

class Example
{
```

```
    public static void Main( )
    {
       decimal[] values = { 123m, new Decimal(123000, 0, 0, false, 3),
                            123.999m, 65535.999m, 65536m,
                            32767.999m, 32768m, -0.999m,
                            -1m,  -32768.999m, -32769m };

       foreach (var value in values) {
          try {
             short number = Decimal.ToInt16(value);
             Console.WriteLine("{0} --> {1}", value, number);
          }
          catch (OverflowException e)
          {
              Console.WriteLine("{0}: {1}", e.GetType().Name, value);
          }
       }
    }
 }
 // The example displays the following output:
 //     123 --> 123
 //     123.000 --> 123
 //     123.999 --> 123
 //     OverflowException: 65535.999
 //     OverflowException: 65536
 //     32767.999 --> 32767
 //     OverflowException: 32768
 //     -0.999 --> 0
 //     -1 --> -1
 //     -32768.999 --> -32768
 //     OverflowException: -32769
```

Remarks

You can also convert a Decimal value to a 16-bit integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.ToInt32(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified Decimal to the equivalent 32-bit signed integer.

C#

```
public static int ToInt32 (decimal d);
```

Parameters

d Decimal

The decimal number to convert.

Returns

Int32

A 32-bit signed integer equivalent to the value of `d`.

Exceptions

OverflowException

`d` is less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example uses the ToInt32 method to convert decimal numbers to Int32 values.

C#

```
using System;

class Example
{
```

```
    public static void Main( )
    {
       decimal[] values = { 123m, new decimal(123000, 0, 0, false, 3),
                            123.999m, 4294967295.999m, 4294967296m,
                            4294967296m, 2147483647.999m, 2147483648m,
                            -0.999m, -1m, -2147483648.999m, -2147483649m };

       foreach (var value in values) {
          try {
             int number = Decimal.ToInt32(value);
             Console.WriteLine("{0} --> {1}", value, number);
          }
          catch (OverflowException e)
          {
              Console.WriteLine("{0}: {1}", e.GetType().Name, value);
          }
       }
    }
 }
 // The example displays the following output:
 //      123 --> 123
 //      123.000 --> 123
 //      123.999 --> 123
 //      OverflowException: 4294967295.999
 //      OverflowException: 4294967296
 //      OverflowException: 4294967296
 //      2147483647.999 --> 2147483647
 //      OverflowException: 2147483648
 //      -0.999 --> 0
 //      -1 --> -1
 //      -2147483648.999 --> -2147483648
 //      OverflowException: -2147483649
```

Remarks

The return value is the integral part of the decimal value; fractional digits are truncated.

You can also convert a Decimal value to a 32-bit integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.ToInt64(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified Decimal to the equivalent 64-bit signed integer.

C#

```
public static long ToInt64 (decimal d);
```

Parameters

d Decimal

The decimal number to convert.

Returns

Int64

A 64-bit signed integer equivalent to the value of `d`.

Exceptions

OverflowException

`d` is less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example uses the ToInt64 method to convert decimal numbers to Int64 values.

C#

```
using System;

class Example
{
```

```
    public static void Main( )
    {
       decimal[] values = { 123m, new Decimal(123000, 0, 0, false, 3),
                            123.999m, 18446744073709551615.999m,
                            18446744073709551616m, 9223372036854775807.999m,
                            9223372036854775808m, -0.999m, -1m,
                            -9223372036854775808.999m,
                            -9223372036854775809m };

       foreach (var value in values) {
          try {
             long number = Decimal.ToInt64(value);
             Console.WriteLine("{0} --> {1}", value, number);
          }
          catch (OverflowException e)
          {
              Console.WriteLine("{0}: {1}", e.GetType().Name, value);
          }
       }
    }
 }
 // The example displays the following output:
 //   123 --> 123
 //   123.000 --> 123
 //   123.999 --> 123
 //   OverflowException: 18446744073709551615.999
 //   OverflowException: 18446744073709551616
 //   9223372036854775807.999 --> 9223372036854775807
 //   OverflowException: 9223372036854775808
 //   -0.999 --> 0
 //   -1 --> -1
 //   -9223372036854775808.999 --> -9223372036854775808
 //   OverflowException: -9223372036854775809
```

Remarks

The return value is the integral part of the decimal value; fractional digits are truncated.

You can also convert a Decimal value to a 64-bit integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Decimal.ToOACurrency(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified Decimal value to the equivalent OLE Automation Currency value, which is contained in a 64-bit signed integer.

```
C#

public static long ToOACurrency (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

Int64

A 64-bit signed integer that contains the OLE Automation equivalent of `value`.

Examples

The following code example uses the `ToOACurrency` method to convert `Decimal` numbers to the equivalent OLE Automation Currency values that are contained in Int64 fields.

```
C#

// Example of the decimal.ToOACurrency method.
using System;

class DecimalToOACurrencyDemo
{
    const string dataFmt = "{0,31}{1,27}";
```

```
    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Display the decimal.ToOACurrency parameter and the result
    // or exception.
    public static void ShowDecimalToOACurrency( decimal Argument )
    {
        // Catch the exception if ToOACurrency( ) throws one.
        try
        {
            long oaCurrency = decimal.ToOACurrency( Argument );
            Console.WriteLine( dataFmt, Argument, oaCurrency );
        }
        catch( Exception ex )
        {
            Console.WriteLine( dataFmt, Argument,
                GetExceptionType( ex ) );
        }
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the " +
            "decimal.ToOACurrency( ) method generates \nthe " +
            "following output. It displays the argument as a " +
            "decimal \nand the OLE Automation Currency value " +
            "as a long.\n" );
        Console.WriteLine( dataFmt, "Argument",
            "OA Currency or Exception" );
        Console.WriteLine( dataFmt, "--------",
            "------------------------" );

        // Convert decimal values to OLE Automation Currency values.
        ShowDecimalToOACurrency( 0M );
        ShowDecimalToOACurrency( 1M );
        ShowDecimalToOACurrency( 1.0000000000000000000000000000M );
        ShowDecimalToOACurrency( 100000000000000M );
        ShowDecimalToOACurrency( 100000000000000.00000000000000M );
        ShowDecimalToOACurrency( 1000000000000000000000000000M );
        ShowDecimalToOACurrency( 0.000000000123456789M );
        ShowDecimalToOACurrency( 0.123456789M );
        ShowDecimalToOACurrency( 123456789M );
        ShowDecimalToOACurrency( 123456789000000000M );
        ShowDecimalToOACurrency( 4294967295M );
        ShowDecimalToOACurrency( 18446744073709551615M );

Decimal.ToSByte(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.ToInt16(Decimal)**

Converts the value of the specified Decimal to the equivalent 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static sbyte ToSByte (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

SByte

An 8-bit signed integer equivalent to `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example uses the ToSByte method to convert decimal numbers to SByte values.

C#

```
using System;

class Example
{
   public static void Main( )
   {
      decimal[] values = { 123m, new Decimal(78000, 0, 0, false, 3),
                           78.999m, 255.999m, 256m,
                           127.999m, 128m, -0.999m,
                           -1m,  -128.999m, -129m };

      foreach (var value in values) {
         try {
            sbyte number = Decimal.ToSByte(value);
            Console.WriteLine("{0} --> {1}", value, number);
         }
         catch (OverflowException e)
         {
             Console.WriteLine("{0}: {1}", e.GetType().Name, value);
         }
      }
   }
}
// The example displays the following output:
//     78 --> 78
//     78.000 --> 78
//     78.999 --> 78
//     OverflowException: 255.999
//     OverflowException: 256
//     127.999 --> 127
//     OverflowException: 128
//     -0.999 --> 0
//     -1 --> -1
//     -128.999 --> -128
//     OverflowException: -129
```

Remarks

You can also convert a Decimal value to an 8-bit signed integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.ToSingle(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the specified Decimal to the equivalent single-precision floating-point number.

C#

```
public static float ToSingle (decimal d);
```

Parameters

d Decimal

The decimal number to convert.

Returns

Single

A single-precision floating-point number equivalent to the value of `d`.

Examples

The following code example converts `Decimal` numbers to Single values using the `ToSingle` method.

C#

```
// Example of the decimal.ToSingle and decimal.ToDouble methods.
using System;

class DecimalToSgl_DblDemo
{
    static string formatter = "{0,30}{1,17}{2,23}";

    // Convert the decimal argument; no exceptions are thrown.
    public static void DecimalToSgl_Dbl( decimal argument )
```

```
    {
        object SingleValue;
        object DoubleValue;

        // Convert the argument to a float value.
        SingleValue = decimal.ToSingle( argument );

        // Convert the argument to a double value.
        DoubleValue = decimal.ToDouble( argument );

        Console.WriteLine( formatter, argument,
            SingleValue, DoubleValue );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the \n" +
            "  decimal.ToSingle( decimal ) and \n" +
            "  decimal.ToDouble( decimal ) \nmethods " +
            "generates the following output. It \ndisplays " +
            "several converted decimal values.\n" );
        Console.WriteLine( formatter, "decimal argument",
            "float", "double" );
        Console.WriteLine( formatter, "----------------",
            "-----", "------" );

        // Convert decimal values and display the results.
        DecimalToSgl_Dbl( 0.0000000000000000000000000001M );
        DecimalToSgl_Dbl( 0.0000000000123456789123456789M );
        DecimalToSgl_Dbl( 123M );
        DecimalToSgl_Dbl( new decimal( 123000000, 0, 0, false, 6 ) );
        DecimalToSgl_Dbl( 123456789.123456789M );
        DecimalToSgl_Dbl( 1234567891234567891234567 89M );
        DecimalToSgl_Dbl( decimal.MinValue );
        DecimalToSgl_Dbl( decimal.MaxValue );
    }
}

/*
This example of the
  decimal.ToSingle( decimal ) and
  decimal.ToDouble( decimal )
methods generates the following output. It
displays several converted decimal values.

               decimal argument            float                  double
               ----------------            -----                  ------
0.0000000000000000000000000001             1E-28                   1E-28
0.0000000000123456789123456789     1.234568E-11   1.23456789123457E-11
                            123              123                     123
                     123.000000              123                     123
           123456789.123456789     1.234568E+08       123456789.123457
   1234567891234567891234567 89     1.234568E+26   1.23456789123457E+26
-79228162514264337593543950335    -7.922816E+28  -7.92281625142643E+28
```

```
 79228162514264337593543950335     7.922816E+28   7.92281625142643E+28
*/
```

Remarks

This operation can produce round-off errors because a single-precision floating-point number has fewer significant digits than a Decimal.

You can also convert a Decimal to a Single value by using the Explicit assignment operator. Because the conversion can entail a loss of precision, you must use a casting operator in C# or a conversion function in Visual Basic.

Applies to

Product	Versions

Decimal.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent String representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

A string that represents the value of this instance.

Examples

The following example displays a Decimal value using the default ToString() method. It also displays the string representations of the Decimal value that result from using a number of standard format specifiers.

C#

```
decimal value = -16325.62m;
// Display value using default ToString method.
Console.WriteLine(value.ToString());            // Displays -16325.62
// Display value using some standard format specifiers.
Console.WriteLine(value.ToString("G"));         // Displays -16325.62
Console.WriteLine(value.ToString("C"));         // Displays ($16,325.62)
Console.WriteLine(value.ToString("F"));         // Displays -16325.62
```

The following example displays the amount of money in an account.

C#

```
class PiggyBank {
    public void AddPenny() {
        MyFortune = Decimal.Add(MyFortune, .01m);
    }

    public override string ToString() {
        return MyFortune.ToString("C")+" in piggy bank";
    }

    protected decimal MyFortune;
}
```

Remarks

The ToString() method formats a Decimal value in the default ("G", or general) format of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

See also

- Parse(String)
- Formatting Types in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example displays the string representation of a Decimal value using CultureInfo objects that represent several different cultures.

C#

```
decimal value = -16325.62m;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));
// This example displays the following output to the console:
//       -16325.62
//       -16325.62
//       -16325,62
```

Remarks

The ToString(IFormatProvider) method formats a Decimal value in the default ("G", or general) format of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose IFormatProvider.GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a NumberFormatInfo object or a CultureInfo object. The `provider` parameter supplies culture-specific information used in formatting. If `provider` is `null`, the thread current culture is used.

To convert a Decimal value to its string representation using a specified culture and a specific format string, call the Decimal.ToString(String, IFormatProvider) method.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

format String

A standard or custom numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid.

Examples

The following example displays a Decimal value using each of the supported standard numeric format specifiers, together with two custom numeric format strings. In converting the numeric values to strings, the example uses the formatting conventions of the en-US culture.

```
C#

decimal value = 16325.62m;
string specifier;

// Use standard numeric format specifiers.
specifier = "G";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    G: 16325.62
specifier = "C";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    C: $16,325.62
specifier = "E04";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    E04: 1.6326E+004
specifier = "F";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    F: 16325.62
specifier = "N";
```

```
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    N: 16,325.62
specifier = "P";
Console.WriteLine("{0}: {1}", specifier,
(value/10000).ToString(specifier));
// Displays:    P: 163.26 %

// Use custom numeric format specifiers.
specifier = "0,0.000";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    0,0.000: 16,325.620
specifier = "#,#.00#;(#,#.00#)";
Console.WriteLine("{0}: {1}", specifier, (value*-1).ToString(specifier));
// Displays:    #,#.00#;(#,#.00#): (16,325.62)
```

Remarks

The ToString(String) method formats a Decimal value in a specified format by using the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The ToString method uses the standard or custom numeric format string specified by the `format` parameter to convert the value of the current instance into its string representation. The `format` parameter can be any valid standard numeric format specifier except for D, R, and X, as well as any combination of custom numeric format specifiers. If `format` is `null` or an empty string, the return value of this instance is formatted with the general numeric format specifier (G).

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The return value is formatted by using the NumberFormatInfo object for the current culture. To apply the formatting conventions of a specified culture, call the ToString(String, IFormatProvider) method.

UWP	10.0

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` is invalid.

Examples

The following example displays a Decimal value using each of the supported standard numeric format specifiers for several different cultures.

C#

```
decimal value = 16325.62m;
string specifier;
CultureInfo culture;

// Use standard numeric format specifiers.
specifier = "G";
culture = CultureInfo.CreateSpecificCulture("eu-ES");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325,62
Console.WriteLine(value.ToString(specifier,
CultureInfo.InvariantCulture));
// Displays:    16325.62

specifier = "C";
culture = CultureInfo.CreateSpecificCulture("en-US");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    $16,325.62
culture = CultureInfo.CreateSpecificCulture("en-GB");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    £16,325.62
```

```
specifier = "E04";
culture = CultureInfo.CreateSpecificCulture("sv-SE");
Console.WriteLine(value.ToString(specifier, culture));
// Displays: 1,6326E+004
 culture = CultureInfo.CreateSpecificCulture("en-NZ");
 Console.WriteLine(value.ToString(specifier, culture));
// Displays:    1.6326E+004

specifier = "F";
culture = CultureInfo.CreateSpecificCulture("fr-FR");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325,62
culture = CultureInfo.CreateSpecificCulture("en-CA");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325.62

specifier = "N";
culture = CultureInfo.CreateSpecificCulture("es-ES");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16.325,62
culture = CultureInfo.CreateSpecificCulture("fr-CA");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16 325,62

specifier = "P";
culture = CultureInfo.InvariantCulture;
Console.WriteLine((value/10000).ToString(specifier, culture));
// Displays:    163.26 %
culture = CultureInfo.CreateSpecificCulture("ar-EG");
Console.WriteLine((value/10000).ToString(specifier, culture));
// Displays:    163.256 %
```

Remarks

The ToString(String, IFormatProvider) method formats a Decimal value in a specified format of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be any valid standard numeric format specifier except for D, R, and X, as well as any combination of custom numeric format specifiers. If

`format` is `null` or an empty string, the return value for this instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose IFormatProvider.GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in formatting. If `provider` is `null`, the thread current culture is used.

Decimal.ToUInt16(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.ToInt32(Decimal)**

Converts the value of the specified Decimal to the equivalent 16-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ushort ToUInt16 (decimal value);
```

Parameters

`value` Decimal

The decimal number to convert.

Returns

UInt16

A 16-bit unsigned integer equivalent to the value of `value`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is greater than UInt16.MaxValue or less than UInt16.MinValue.

Examples

The following example uses the ToUInt16 method to convert decimal numbers to UInt16 values.

C#

```
using System;

class Example
{
   public static void Main( )
   {
      decimal[] values = { 123m, new Decimal(123000, 0, 0, false, 3),
                           123.999m, 65535.999m, 65536m,
                           32767.999m, 32768m, -0.999m,
                           -1m,  -32768.999m, -32769m };

      foreach (var value in values) {
         try {
            ushort number = Decimal.ToUInt16(value);
            Console.WriteLine("{0} --> {1}", value, number);
         }
         catch (OverflowException e)
         {
             Console.WriteLine("{0}: {1}", e.GetType().Name, value);
         }
      }
   }
}
// The example displays the following output:
//     123 --> 123
//     123.000 --> 123
//     123.999 --> 123
//     65535.999 --> 65535
//     OverflowException: 65536
//     32767.999 --> 32767
//     32768 --> 32768
//     -0.999 --> 0
//     OverflowException: -1
//     OverflowException: -32768.999
//     OverflowException: -32769
```

Remarks

The return value is the integral part of the decimal value; fractional digits are truncated.

You can also convert a Decimal value to a 16-bit unsigned integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must

use a casting operator in C# or a conversion function in Visual Basic.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.ToUInt32(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.ToInt64(Decimal)**

Converts the value of the specified Decimal to the equivalent 32-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static uint ToUInt32 (decimal d);
```

Parameters

d Decimal

The decimal number to convert.

Returns

UInt32

A 32-bit unsigned integer equivalent to the value of `d`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`d` is negative or greater than UInt32.MaxValue.

Examples

The following example uses the ToUInt32 method to convert decimal numbers to UInt32 values.

C#

```
using System;

class Example
{
   public static void Main( )
   {
      decimal[] values = { 123m, new decimal(123000, 0, 0, false, 3),
                           123.999m, 4294967295.999m, 4294967296m,
                           4294967296m, 2147483647.999m, 2147483648m,
                           -0.999m, -1m, -2147483648.999m, -2147483649m };

      foreach (var value in values) {
         try {
            uint number = Decimal.ToUInt32(value);
            Console.WriteLine("{0} --> {1}", value, number);
         }
         catch (OverflowException e)
         {
             Console.WriteLine("{0}: {1}", e.GetType().Name, value);
         }
      }
   }
}
// The example displays the following output:
//     123 --> 123
//     123.000 --> 123
//     123.999 --> 123
//     4294967295.999 --> 4294967295
//     OverflowException: 4294967296
//     OverflowException: 4294967296
//     2147483647.999 --> 2147483647
//     2147483648 --> 2147483648
//     -0.999 --> 0
//     OverflowException: -1
//     OverflowException: -2147483648.999
//     OverflowException: -2147483649
```

Remarks

The return value is the integral part of the decimal value; fractional digits are truncated.

You can also convert a Decimal value to an 32-bit unsigned integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Decimal.ToUInt64(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified Decimal to the equivalent 64-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static ulong ToUInt64 (decimal d);
```

Parameters

d Decimal

The decimal number to convert.

Returns

UInt64

A 64-bit unsigned integer equivalent to the value of `d`.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`d` is negative or greater than UInt64.MaxValue.

Examples

The following example uses the ToUInt64 method to convert decimal numbers to UInt64 values.

C#

```
using System;

class Example
{
   public static void Main( )
   {
      decimal[] values = { 123m, new Decimal(123000, 0, 0, false, 3),
                           123.999m, 18446744073709551615.999m,
                           18446744073709551616m, 9223372036854775807.999m,
                           9223372036854775808m, -0.999m, -1m,
                           -9223372036854775808.999m,
                           -9223372036854775809m };

      foreach (var value in values) {
         try {
            ulong number = Decimal.ToUInt64(value);
            Console.WriteLine("{0} --> {1}", value, number);
         }
         catch (OverflowException e)
         {
             Console.WriteLine("{0}: {1}", e.GetType().Name, value);
         }
      }
   }
}
// The example displays the following output:
//     123 --> 123
//     123.000 --> 123
//     123.999 --> 123
//     18446744073709551615.999 --> 18446744073709551615
//     OverflowException: 18446744073709551616
//     9223372036854775807.999 --> 9223372036854775807
//     9223372036854775808 --> 9223372036854775808
//     -0.999 --> 0
//     OverflowException: -1
//     OverflowException: -9223372036854775808.999
//     OverflowException: -9223372036854775809
```

Remarks

The return value is the integral part of the decimal value; fractional digits are truncated.

You can also convert a Decimal value to an 64-bit unsigned integer by using the Explicit assignment operator. Because the operator performs a narrowing conversion, you must use a casting operator in C# or a conversion function in Visual Basic.

Decimal.Truncate(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the integral digits of the specified Decimal; any fractional digits are discarded.

C#

```
public static decimal Truncate (decimal d);
```

Parameters

d Decimal

The decimal number to truncate.

Returns

Decimal

The result of `d` rounded toward zero, to the nearest whole number.

Implements

Truncate(TSelf)

Examples

The following code example uses the `Truncate` method to discard the fractional digits of several `Decimal` values.

C#

```
// Example of the decimal.Negate, decimal.Floor, and decimal.Truncate
// methods.
using System;

class DecimalFloorNegTruncDemo
```

```
{
    const string dataFmt = "{0,-30}{1,26}";

    // Display decimal parameters and the method results.
    public static void ShowDecimalFloorNegTrunc( decimal Argument )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "decimal Argument", Argument );
        Console.WriteLine( dataFmt, "decimal.Negate( Argument )",
            decimal.Negate( Argument ) );
        Console.WriteLine( dataFmt, "decimal.Floor( Argument )",
            decimal.Floor( Argument ) );
        Console.WriteLine( dataFmt, "decimal.Truncate( Argument )",
            decimal.Truncate( Argument ) );
    }

    public static void Main( )
    {
        Console.WriteLine( "This example of the \n" +
            "  decimal.Negate( decimal ), \n" +
            "  decimal.Floor( decimal ), and \n" +
            "  decimal.Truncate( decimal ) \n" +
            "methods generates the following output." );

        // Create pairs of decimal objects.
        ShowDecimalFloorNegTrunc( 0M );
        ShowDecimalFloorNegTrunc( 123.456M );
        ShowDecimalFloorNegTrunc( -123.456M );
        ShowDecimalFloorNegTrunc(
            new decimal( 1230000000, 0, 0, true, 7 ) );
        ShowDecimalFloorNegTrunc( -9999999999.9999999999M );
    }
}

/*
This example of the
  decimal.Negate( decimal ),
  decimal.Floor( decimal ), and
  decimal.Truncate( decimal )
methods generates the following output.

decimal Argument                                    0
decimal.Negate( Argument )                          0
decimal.Floor( Argument )                           0
decimal.Truncate( Argument )                        0

decimal Argument                              123.456
decimal.Negate( Argument )                   -123.456
decimal.Floor( Argument )                         123
decimal.Truncate( Argument )                      123

decimal Argument                             -123.456
decimal.Negate( Argument )                    123.456
decimal.Floor( Argument )                        -124
decimal.Truncate( Argument )                     -123
```

```
decimal Argument                            -123.0000000
decimal.Negate( Argument )                   123.0000000
decimal.Floor( Argument )                           -123
decimal.Truncate( Argument )                        -123

decimal Argument                  -9999999999.9999999999
decimal.Negate( Argument )         9999999999.9999999999
decimal.Floor( Argument )                  -10000000000
decimal.Truncate( Argument )                -9999999999
*/
```

Remarks

This method rounds `d` toward zero, to the nearest whole number, which corresponds to discarding any digits after the decimal point.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current decimal instance into the provided span of characters.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current decimal instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

See also

- Standard numeric format strings
- Custom numeric format strings

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

```
C#
```

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Decimal.TryGetBits(Decimal, Span<Int32>, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the value of a specified instance of Decimal to its equivalent binary representation.

C#

```
public static bool TryGetBits (decimal d, Span<int> destination, out int valuesWritten);
```

Parameters

d Decimal

The value to convert.

destination Span<Int32>

The span into which to store the binary representation.

valuesWritten Int32

When this method returns, contains the number of integers written to the destination.

Returns

Boolean

`true` if the decimal's binary representation was written to the destination; `false` if the destination wasn't long enough.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Decimal.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its Decimal equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, Decimal)	Tries to convert a UTF-8 character span containing the string representation of a number to its signed decimal equivalent.
TryParse(ReadOnlySpan<Char>, Decimal)	Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Decimal)	Converts the string representation of a number to its Decimal equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Decimal)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Decimal)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Decimal)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Decimal)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Decimal)	Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.

TryParse(String, NumberStyles, IFormatProvider, Decimal)	Converts the string representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, Decimal)

Tries to convert a UTF-8 character span containing the string representation of a number to its signed decimal equivalent.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text, out decimal
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` Decimal

When this method returns, contains the signed decimal value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, Decimal)

Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out decimal result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

result Decimal

When this method returns, contains the Decimal number that is equivalent to the numeric value contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not a number in a format compliant with `style`, or represents a number less than Decimal.MinValue or greater than Decimal.MaxValue. This parameter is passed uininitialized; any value originally supplied in `result` is overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Decimal)

Converts the string representation of a number to its Decimal equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (string? s, out decimal result);
```

Parameters

`s` String

The string representation of the number to convert.

`result` Decimal

When this method returns, contains the Decimal number that is equivalent to the numeric value contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not a number in a valid format, or represents a number less than Decimal.MinValue or greater than Decimal.MaxValue. This parameter is passed uininitialized; any value originally supplied in `result` is overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example uses the Decimal.TryParse(String, Decimal) method to convert the string representations of numeric values to Decimal values. It assumes that en-US is the current culture.

```
C#

string value;
decimal number;

// Parse a floating-point value with a thousands separator.
value = "1,643.57";
if (Decimal.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);
```

```
// Parse a floating-point value with a currency symbol and a
// thousands separator.
value = "$1,643.57";
if (Decimal.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);

// Parse value in exponential notation.
value = "-1.643e6";
if (Decimal.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);

// Parse a negative integer value.
value = "-1689346178821";
if (Decimal.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);
// The example displays the following output to the console:
//       1643.57
//       Unable to parse '$1,643.57'.
//       Unable to parse '-1.643e6'.
//       -1689346178821
```

Remarks

This overload differs from the Decimal.Parse(String) method by returning a Boolean value that indicates whether the parse operation succeeded instead of returning the parsed numeric value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

Parameter `s` contains a number of the form:

[ws][sign][digits,]digits[.fractional-digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.

Element	Description
digits	A sequence of digits ranging from 0 to 9.
,	A culture-specific thousands separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A sequence of digits ranging from 0 to 9.

Parameter `s` is interpreted using the NumberStyles.Number style. This means that white space and thousands separators are allowed but currency symbols are not. To explicitly define the elements (such as currency symbols, thousands separators, and white space) that can be present in `s`, use the Decimal.TryParse(String, NumberStyles, IFormatProvider, Decimal) method overload.

Parameter `s` is parsed using the formatting information in a NumberFormatInfo object initialized for the current system culture. For more information, see CurrentInfo. To parse a string using the formatting information of some other specified culture, use the Decimal.TryParse(String, NumberStyles, IFormatProvider, Decimal) method overload.

If necessary, the value of `s` is rounded using rounding to nearest.

A Decimal object has 29 digits of precision. If `s` represents a number that has more than 29 digits, but has a fractional part and is within the range of MaxValue and MinValue, the number is rounded, not truncated, to 29 digits using rounding to nearest.

If during a parse operation a separator is encountered in the `s` parameter, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

UWP	10.0

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Decimal)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out decimal result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Decimal

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, Decimal)

Tries to parse a span of characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out decimal result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Decimal

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Decimal)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
decimal result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Decimal

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Decimal)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
decimal result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Decimal

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Decimal)

Converts the span representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
decimal result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Number.

`provider` IFormatProvider

An object that supplies culture-specific parsing information about `s`.

`result` Decimal

When this method returns, contains the Decimal number that is equivalent to the numeric value contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not a number in a format compliant with `style`, or represents a number less than Decimal.MinValue or greater than Decimal.MaxValue. This parameter is passed uininitialized; any value originally supplied in `result` is overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Decimal)

Converts the string representation of a number to its Decimal equivalent using the specified style and culture-specific format. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out decimal result);
```

Parameters

`s` String

The string representation of the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Number.

`provider` IFormatProvider

An object that supplies culture-specific parsing information about `s`.

`result` Decimal

When this method returns, contains the Decimal number that is equivalent to the numeric value contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not a number in a format compliant with `style`, or represents a number less than Decimal.MinValue or greater than Decimal.MaxValue. This parameter is passed uininitialized; any value originally supplied in `result` is overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

Examples

The following example demonstrates the use of the TryParse(String, NumberStyles, IFormatProvider, Decimal) method to parse the string representation of a number that has a particular style and is formatted using the conventions of a particular culture.

C#

```
string value;
NumberStyles style;
CultureInfo culture;
decimal number;

// Parse currency value using en-GB culture.
value = "£1,097.63";
style = NumberStyles.Number | NumberStyles.AllowCurrencySymbol;
culture = CultureInfo.CreateSpecificCulture("en-GB");
if (Decimal.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Converted '£1,097.63' to 1097.63.

value = "1345,978";
style = NumberStyles.AllowDecimalPoint;
culture = CultureInfo.CreateSpecificCulture("fr-FR");
if (Decimal.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Converted '1345,978' to 1345.978.
```

```
value = "1.345,978";
style = NumberStyles.AllowDecimalPoint | NumberStyles.AllowThousands;
culture = CultureInfo.CreateSpecificCulture("es-ES");
if (Decimal.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Converted '1.345,978' to 1345.978.

value = "1 345,978";
if (Decimal.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Unable to convert '1 345,978'.
```

Remarks

This overload differs from the Decimal.Parse(String, NumberStyles, IFormatProvider) method by returning a Boolean value that indicates whether the parse operation succeeded instead of returning the parsed numeric value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `style` parameter defines the allowable format of the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- NumberStyles.AllowHexSpecifier
- NumberStyles.HexNumber

Depending on the value of style, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional-digits][e[sign]digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag. It can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern or NumberFormatInfo.CurrencyPositivePattern properties of the NumberFormatInfo object returned by the IFormatProvider.GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.
.	A culture-specific decimal point symbol.
fractional-digits	A sequence of digits ranging from 0 to 9.

The `style` parameter specifies the permitted format of the `s` parameter, and can be one or more NumberStyles enumerated constants combined using a bitwise OR operation. If `style` is null, `s` is interpreted using the NumberStyles.Number style.

The `provider` parameter is an IFormatProvider implementation such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null`, the thread current culture is used.

A Decimal object has 29 digits of precision. If `s` represents a number that has more than 29 digits, but has a fractional part and is within the range of MaxValue and MinValue, the number is rounded, not truncated, to 29 digits using rounding to nearest.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Decimal.Addition(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two specified Decimal values.

```
C#
public static decimal operator + (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to add.

d2 Decimal

The second value to add.

Returns

Decimal

The result of adding `d1` and `d2`.

Implements

Addition(TSelf, TOther)

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Addition method defines the operation of the addition operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 120.07m;
      Decimal number2 = 163.19m;
      Decimal number3 = number1 + number2;
      Console.WriteLine("{0} + {1} = {2}",
                        number1, number2, number3);
   }
}
// The example displays the following output:
//        120.07 + 163.19 = 283.26
```

If the language you're using doesn't support custom operators, call the Add method instead.

The equivalent method for this operator is Decimal.Add(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Decrement(Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements the Decimal operand by one.

C#

```
public static decimal operator -- (decimal d);
```

Parameters

d Decimal

The value to decrement.

Returns

Decimal

The value of `d` decremented by 1.

Implements

Decrement(TSelf)

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Decrement method defines the operation of the decrement operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number = 1079.8m;
      Console.WriteLine("Original value:    {0:N}", number);
      Console.WriteLine("Decremented value: {0:N}", --number);
   }
}
// The example displays the following output:
//       Original value:    1,079.80
//       Decremented value: 1,078.80
```

Some languages (such as Visual Basic) that lack an increment operator can call the Decrement method directly, as the following example shows.

VB

```
Module Example
   Public Sub Main()
      Dim number As Decimal = 1079.8d
      Console.WriteLine("Original value:    {0:N}", number)
      Console.WriteLine("Decremented value: {0:N}",
Decimal.op_Decrement(number))
   End Sub
End Module
' The example displays the following output:
'       Original value:    1,079.80
'       Decremented value: 1,078.80
```

If your language does not support custom operators, call the Subtract method instead, as the following example shows.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number = 1079.8m;
      Console.WriteLine("Original value:    {0:N}", number);
      Console.WriteLine("Decremented value: {0:N}", Decimal.Subtract(number,
1));
   }
}
// The example displays the following output:
```

```
//       Original value:    1,079.80
//       Decremented value: 1,078.80
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Division(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two specified Decimal values.

```
C#
public static decimal operator / (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The dividend.

d2 Decimal

The divisor.

Returns

Decimal

The result of dividing `d1` by `d2`.

Implements

Division(TSelf, TOther)

Exceptions

DivideByZeroException

`d2` is zero.

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Division method defines the operation of the division operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16.8m;
      Decimal number2 = 4.1m;
      Decimal number3 = number1 / number2;
      Console.WriteLine("{0:N2} / {1:N2} = {2:N2}",
                        number1, number2, number3);
   }
}
// The example displays the following output:
//        16.80 / 4.10 = 4.10
```

If the language you're using doesn't support custom operators, call the Divide method instead.

The equivalent method for this operator is Decimal.Divide(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Equality(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two Decimal values are equal.

```
C#
public static bool operator == (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` and `d2` are equal; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Remarks

The Equality method defines the operation of the equality operator for Decimal values. It enables code such as the following:

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16354.0695m;
      Decimal number2 = 16354.0699m;
      Console.WriteLine("{0} = {1}: {2}", number1,
                        number2, number1 == number2);

      number1 = Decimal.Round(number1, 2);
      number2 = Decimal.Round(number2, 2);
      Console.WriteLine("{0} = {1}: {2}", number1,
                        number2, number1 == number2);
   }
}
// The example displays the following output:
//       16354.0695 = 16354.0699: False
//       16354.07 = 16354.07: True
```

If the language you're using doesn't support custom operators, call the Equals method instead.

The equivalent method for this operator is Decimal.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.Explicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines an explicit conversion between a Decimal object and another type.

Overloads

Expand table

Explicit(Single to Decimal)	Defines an explicit conversion of a single-precision floating-point number to a Decimal.
Explicit(Double to Decimal)	Defines an explicit conversion of a double-precision floating-point number to a Decimal.
Explicit(Decimal to UInt64)	Defines an explicit conversion of a Decimal to a 64-bit unsigned integer. This API is not CLS-compliant.
Explicit(Decimal to UInt32)	Defines an explicit conversion of a Decimal to a 32-bit unsigned integer. This API is not CLS-compliant.
Explicit(Decimal to UInt16)	Defines an explicit conversion of a Decimal to a 16-bit unsigned integer. This API is not CLS-compliant.
Explicit(Decimal to SByte)	Defines an explicit conversion of a Decimal to an 8-bit signed integer. This API is not CLS-compliant.
Explicit(Decimal to Single)	Defines an explicit conversion of a Decimal to a single-precision floating-point number.
Explicit(Decimal to Int32)	Defines an explicit conversion of a Decimal to a 32-bit signed integer.

Explicit(Decimal to Int16)	Defines an explicit conversion of a Decimal to a 16-bit signed integer.
Explicit(Decimal to Double)	Defines an explicit conversion of a Decimal to a double-precision floating-point number.
Explicit(Decimal to Char)	Defines an explicit conversion of a Decimal to a Unicode character.
Explicit(Decimal to Byte)	Defines an explicit conversion of a Decimal to an 8-bit unsigned integer.
Explicit(Decimal to Int64)	Defines an explicit conversion of a Decimal to a 64-bit signed integer.

Explicit(Single to Decimal)

Defines an explicit conversion of a single-precision floating-point number to a Decimal.

C#

```
public static explicit operator decimal (float value);
```

Parameters

`value` Single

The single-precision floating-point number to convert.

Returns

Decimal

The converted single-precision floating point number.

Exceptions

OverflowException

`value` is greater than Decimal.MaxValue or less than Decimal.MinValue.

-or-

`value` is NaN, PositiveInfinity, or NegativeInfinity.

Examples

The following example converts Single values to Decimal numbers by using the Single to Decimal conversion operator. This conversion requires the op_Explicit operator in Visual Basic.

C#

```
// Example of the explicit conversion from float to decimal.
using System;

class DecimalFromSingleDemo
{
    const string formatter = "{0,16:E7}{1,33}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the float argument; catch exceptions that are thrown.
    public static void DecimalFromSingle( float argument )
    {
        object decValue;

        // Convert the float argument to a decimal value.
        try
        {
            decValue = (decimal)argument;
        }
        catch( Exception ex )
        {
            decValue = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument, decValue );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the explicit conversion from float " +
            "to decimal \ngenerates the following output.\n" );
        Console.WriteLine( formatter, "float argument",
            "decimal value" );
        Console.WriteLine( formatter, "--------------",
            "-------------" );

        // Convert float values and display the results.
        DecimalFromSingle( 1.2345E-30F );
```

```
        DecimalFromSingle( 1.2345E-26F );
        DecimalFromSingle( 1.23456E-22F );
        DecimalFromSingle( 1.23456E-12F );
        DecimalFromSingle( 1.234567F );
        DecimalFromSingle( 1.234567E+12F );
        DecimalFromSingle( 1.2345678E+28F );
        DecimalFromSingle( 1.2345678E+30F );
    }
}

/*
This example of the explicit conversion from float to decimal
generates the following output.

  float argument                    decimal value
  --------------                    -------------
  1.2345000E-030                                0

Explicit(Double to Decimal)

Defines an explicit conversion of a double-precision floating-point number to a Decimal.

```
C#

public static explicit operator decimal (double value);
```

Parameters

`value` Double

The double-precision floating-point number to convert.

Returns

Decimal

The converted double-precision floating point number.

Exceptions

OverflowException

`value` is greater than Decimal.MaxValue or less than Decimal.MinValue.

-or-

`value` is NaN, PositiveInfinity, or NegativeInfinity.

Examples

The following example converts Double values to Decimal numbers by using the Double to Decimal conversion operator. This conversion requires the op_Explicit operator in Visual Basic.

```
C#

// Example of the explicit conversion from double to decimal.
using System;

class DecimalFromDoubleDemo
{
    const string formatter = "{0,25:E16}{1,33}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
```

```
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the double argument; catch exceptions that are thrown.
    public static void DecimalFromDouble( double argument )
    {
        object decValue;

        // Convert the double argument to a decimal value.
        try
        {
            decValue = (decimal)argument;
        }
        catch( Exception ex )
        {
            decValue = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument, decValue );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the explicit conversion from double " +
            "to decimal \ngenerates the following output.\n" );
        Console.WriteLine( formatter, "double argument",
            "decimal value" );
        Console.WriteLine( formatter, "---------------",
            "-------------" );

        // Convert double values and display the results.
        DecimalFromDouble( 1.234567890123E-30 );
        DecimalFromDouble( 1.2345678901234E-25 );
        DecimalFromDouble( 1.23456789012345E-20 );
        DecimalFromDouble( 1.234567890123456E-10 );

Explicit(Decimal to UInt64)

> Important
>
> This API is not CLS-compliant.

Defines an explicit conversion of a Decimal to a 64-bit unsigned integer.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static explicit operator ulong (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

UInt64

A 64-bit unsigned integer that represents the converted Decimal.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is negative or greater than UInt64.MaxValue.

Examples

The following example converts Decimal numbers to UInt64 values by using the explicit Decimal to UInt64 conversion operator.

C#

```
// Example of the explicit conversions from decimal to long and
// decimal to ulong.
using System;

class DecimalToU_Int64Demo
{
    const string formatter = "{0,25}{1,22}{2,22}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the decimal argument; catch exceptions that are thrown.
    public static void DecimalToU_Int64( decimal argument )
    {
        object Int64Value;
        object UInt64Value;

        // Convert the argument to a long value.
        try
        {
```

```
            Int64Value = (long)argument;
        }
        catch( Exception ex )
        {
            Int64Value = GetExceptionType( ex );
        }

        // Convert the argument to a ulong value.
        try
        {
            UInt64Value = (ulong)argument;
        }
        catch( Exception ex )
        {
            UInt64Value = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument,
            Int64Value, UInt64Value );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the explicit conversions from decimal " +
            "to long \nand decimal to ulong generates the following " +
            "output. It displays \nseveral converted decimal " +
            "values.\n" );
        Console.WriteLine( formatter, "decimal argument",

      -9223372036854775809     OverflowException     OverflowException
 */
```

Remarks

This operator supports the explicit conversion of a Decimal to a UInt64. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a UInt64 value by using C# and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToUInt64(Decimal) or the Convert.ToUInt64(Decimal) method.

Explicit(Decimal to UInt32)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.ToInt64(Decimal)**

Defines an explicit conversion of a Decimal to a 32-bit unsigned integer.

This API is not CLS-compliant.

```
C#

[System.CLSCompliant(false)]
public static explicit operator uint (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

UInt32

A 32-bit unsigned integer that represents the converted Decimal.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example converts Decimal numbers to UInt32 values by using the explicit Decimal to UInt32 conversion operator.

```
C#

// Example of the explicit conversions from decimal to int and
// decimal to uint.
using System;
```

```
class DecimalToU_Int32Demo
{
    const string formatter = "{0,17}{1,19}{2,19}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the decimal argument; catch exceptions that are thrown.
    public static void DecimalToU_Int32( decimal argument )
    {
        object Int32Value;
        object UInt32Value;

        // Convert the argument to an int value.
        try
        {
            Int32Value = (int)argument;
        }
        catch( Exception ex )
        {
            Int32Value = GetExceptionType( ex );
        }

        // Convert the argument to a uint value.
        try
        {
            UInt32Value = (uint)argument;
        }
        catch( Exception ex )
        {
            UInt32Value = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument,
            Int32Value, UInt32Value );
    }

    public static void Main( )
    {
        Console.WriteLine(

*/
```

Remarks

This operator supports the explicit conversion of a Decimal to a UInt32. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a UInt32 value by using C# and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToUInt32(Decimal) or the Convert.ToUInt32(Decimal) method.

Explicit(Decimal to UInt16)

> Important
>
> This API is not CLS-compliant.

Defines an explicit conversion of a Decimal to a 16-bit unsigned integer.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static explicit operator ushort (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

UInt16

A 16-bit unsigned integer that represents the converted Decimal.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example converts Decimal numbers to UInt16 values by using the explicit Decimal to UInt16 conversion operator.

C#

```
// Example of the explicit conversions from decimal to short and
// decimal to ushort.
using System;

class DecimalToU_Int16Demo
{
    const string formatter = "{0,16}{1,19}{2,19}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the decimal argument; catch exceptions that are thrown.
    public static void DecimalToU_Int16( decimal argument )
    {
        object Int16Value;
        object UInt16Value;

        // Convert the argument to a short value.
        try
        {
            Int16Value = (short)argument;
        }
        catch( Exception ex )
        {
            Int16Value = GetExceptionType( ex );
        }

        // Convert the argument to a ushort value.
        try
        {
            UInt16Value = (ushort)argument;
        }
        catch( Exception ex )
        {
            UInt16Value = GetExceptionType( ex );
```

```
        }

        Console.WriteLine( formatter, argument,
            Int16Value, UInt16Value );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the explicit conversions from decimal " +
            "to short \nand decimal to ushort generates the " +
            "following output. It displays \nseveral converted " +
            "decimal values.\n" );
        Console.WriteLine( formatter, "decimal argument",
            "short/exception", "ushort/exception" );
        Console.WriteLine( formatter, "----------------",
            "---------------", "----------------" );

        // Convert decimal values and display the results.
        DecimalToU_Int16( 123M );
        DecimalToU_Int16( new decimal( 123000, 0, 0, false, 3 ) );
        DecimalToU_Int16( 123.999M );
        DecimalToU_Int16( 65535.999M );
        DecimalToU_Int16( 65536M );
        DecimalToU_Int16( 32767.999M );
        DecimalToU_Int16( 32768M );
        DecimalToU_Int16( - 0.999M );
        DecimalToU_Int16( - 1M );
        DecimalToU_Int16( - 32768.999M );
        DecimalToU_Int16( - 32769M );
    }
}

/*
This example of the explicit conversions from decimal to short
and decimal to ushort generates the following output. It displays
several converted decimal values.

decimal argument    short/exception   ushort/exception
----------------    ---------------   ----------------
             123                123                123
         123.000                123                123
         123.999                123                123
       65535.999  OverflowException              65535
           65536  OverflowException  OverflowException
       32767.999              32767              32767
           32768  OverflowException              32768
          -0.999                  0                  0
              -1                 -1  OverflowException
      -32768.999             -32768  OverflowException
          -32769  OverflowException  OverflowException
*/
```

Remarks

This operator supports the explicit conversion of a Decimal to a UInt16. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a UInt16 value by using C# and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToUInt16(Decimal) or the Convert.ToUInt16(Decimal) method.

Explicit(Decimal to SByte)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.ToInt16(Decimal)**

Defines an explicit conversion of a Decimal to an 8-bit signed integer.

This API is not CLS-compliant.

```
C#
```

```
[System.CLSCompliant(false)]
public static explicit operator sbyte (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

SByte

An 8-bit signed integer that represents the converted Decimal.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` is less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example converts Decimal numbers to SByte values by using the explicit Decimal to SByte conversion operator.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of decimal values.
       decimal[] values = { 78m, new Decimal(78000, 0, 0, false, 3),
                            78.999m, 255.999m, 256m, 127.999m,
                            128m, -0.999m, -1m, -128.999m, -129m };
       foreach (var value in values) {
          try {
              SByte byteValue = (SByte) value;
              Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                                value.GetType().Name, byteValue,
                                byteValue.GetType().Name);
           }
```

```
            catch (OverflowException) {
               Console.WriteLine("OverflowException: Cannot convert {0}",
                                 value);
            }
        }
    }
}
// The example displays the following output:
//       78 (Decimal) --> 78 (SByte)
//       78.000 (Decimal) --> 78 (SByte)
//       78.999 (Decimal) --> 78 (SByte)
//       OverflowException: Cannot convert 255.999
//       OverflowException: Cannot convert 256
//       127.999 (Decimal) --> 127 (SByte)
//       OverflowException: Cannot convert 128
//       -0.999 (Decimal) --> 0 (SByte)
//       -1 (Decimal) --> -1 (SByte)
//       -128.999 (Decimal) --> -128 (SByte)
//       OverflowException: Cannot convert -129
```

Remarks

This operator supports the explicit conversion of a Decimal to a SByte. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a Byte and an SByte value by using C# and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToSByte(Decimal) method or the Convert.ToSByte(Decimal) method.

Explicit(Decimal to Single)

Defines an explicit conversion of a Decimal to a single-precision floating-point number.

C#

```
public static explicit operator float (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Single

A single-precision floating-point number that represents the converted Decimal.

Examples

The following example converts Decimal numbers to Single values by using the explicit Decimal to Single conversion operator.

C#

```
using System;

class Example
{
    public static void Main( )
    {
        // Define an array of decimal values.
        decimal[] values = { 0.0000000000000000000000000001M,
                             0.0000000000123456789123456789M,
                             123M, new decimal(123000000, 0, 0, false,
6),
                             123456789.123456789M,
```

```
                                 1234567891234567891234567 89M,
                                 decimal.MinValue, decimal.MaxValue };
            // Convert each value to a double.
            foreach (var value in values) {
                float dblValue = (float) value;
                Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                                  value.GetType().Name, dblValue,
                                  dblValue.GetType().Name);
            }
        }
    }
// The example displays the following output:
//    0.0000000000000000000000000001 (Decimal) --> 1E-28 (Single)
//    0.0000000000123456789123456789 (Decimal) --> 1.234568E-11 (Single)
//    123 (Decimal) --> 123 (Single)
//    123.000000 (Decimal) --> 123 (Single)
//    123456789.123456789 (Decimal) --> 1.234568E+08 (Single)
//    1234567891234567891234567 89 (Decimal) --> 1.234568E+26 (Single)
//    -7922816251426433759354395033 5 (Decimal) --> -7.922816E+28 (Single)
//    7922816251426433759354395033 5 (Decimal) --> 7.922816E+28 (Single)
```

Remarks

This operation can result in a loss of precision, because a single-precision floating-point number has fewer significant digits than a Decimal.

This operator supports the explicit conversion of a Decimal to a Single. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a Single value by using C# and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToSingle(Decimal) or the Convert.ToSingle(Decimal) method.

Explicit(Decimal to Int32)

Defines an explicit conversion of a Decimal to a 32-bit signed integer.

```
C#

public static explicit operator int (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Int32

A 32-bit signed integer that represents the converted Decimal.

Exceptions

OverflowException

`value` is less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example converts Decimal numbers to Int32 values by using the explicit Decimal to Int32 conversion operator.

```
C#

// Example of the explicit conversions from decimal to int and
// decimal to uint.
using System;
```

```
class DecimalToU_Int32Demo
{
    const string formatter = "{0,17}{1,19}{2,19}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the decimal argument; catch exceptions that are thrown.
    public static void DecimalToU_Int32( decimal argument )
    {
        object Int32Value;
        object UInt32Value;

        // Convert the argument to an int value.
        try
        {
            Int32Value = (int)argument;
        }
        catch( Exception ex )
        {
            Int32Value = GetExceptionType( ex );
        }

        // Convert the argument to a uint value.
        try
        {
            UInt32Value = (uint)argument;
        }
        catch( Exception ex )
        {
            UInt32Value = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument,
            Int32Value, UInt32Value );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the explicit conversions from decimal " +
            "to int \nand decimal to uint generates the following " +
            "output. It displays \nseveral converted decimal " +
            "values.\n" );
        Console.WriteLine( formatter, "decimal argument",
            "int/exception", "uint/exception" );
        Console.WriteLine( formatter, "----------------",
            "-------------", "--------------" );
```

```
        // Convert decimal values and display the results.
        DecimalToU_Int32( 123M );
        DecimalToU_Int32( new decimal( 123000, 0, 0, false, 3 ) );
        DecimalToU_Int32( 123.999M );
        DecimalToU_Int32( 4294967295.999M );
        DecimalToU_Int32( 4294967296M );
        DecimalToU_Int32( 2147483647.999M );
        DecimalToU_Int32( 2147483648M );
        DecimalToU_Int32( - 0.999M );
        DecimalToU_Int32( - 1M );
        DecimalToU_Int32( - 2147483648.999M );
        DecimalToU_Int32( - 2147483649M );
    }
}

/*
This example of the explicit conversions from decimal to int
and decimal to uint generates the following output. It displays
several converted decimal values.

 decimal argument      int/exception     uint/exception
 ----------------      -------------     --------------
              123                123                123
          123.000                123                123
          123.999                123                123

               -1                 -1  OverflowException
  -2147483648.999        -2147483648  OverflowException
      -2147483649  OverflowException  OverflowException
*/
```

Remarks

This operator supports the explicit conversion of a Decimal to an Int32. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to an Int32 value by using C#, C++, and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToInt32(Decimal) or the Convert.ToInt32(Decimal) method.

Explicit(Decimal to Int16)

Defines an explicit conversion of a Decimal to a 16-bit signed integer.

C#

```
public static explicit operator short (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Int16

A 16-bit signed integer that represents the converted Decimal.

Exceptions

OverflowException

`value` is less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example converts Decimal numbers to Int16 values by using the explicit Decimal to Int16 conversion operator.

C#

```
// Example of the explicit conversions from decimal to short and
// decimal to ushort.
using System;

class DecimalToU_Int16Demo
{
    const string formatter = "{0,16}{1,19}{2,19}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the decimal argument; catch exceptions that are thrown.
    public static void DecimalToU_Int16( decimal argument )
    {
        object Int16Value;
        object UInt16Value;

        // Convert the argument to a short value.
        try
        {
            Int16Value = (short)argument;
        }
        catch( Exception ex )
        {
            Int16Value = GetExceptionType( ex );
        }

        // Convert the argument to a ushort value.
        try
        {
            UInt16Value = (ushort)argument;
        }
        catch( Exception ex )
        {
            UInt16Value = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument,
            Int16Value, UInt16Value );
    }

    public static void Main( )
    {
        Console.WriteLine(
```

```
            "This example of the explicit conversions from decimal " +
            "to short \nand decimal to ushort generates the " +
            "following output. It displays \nseveral converted " +
            "decimal values.\n" );
        Console.WriteLine( formatter, "decimal argument",
            "short/exception", "ushort/exception" );
        Console.WriteLine( formatter, "----------------",
            "---------------", "----------------" );

        // Convert decimal values and display the results.
        DecimalToU_Int16( 123M );
        DecimalToU_Int16( new decimal( 123000, 0, 0, false, 3 ) );
        DecimalToU_Int16( 123.999M );
        DecimalToU_Int16( 65535.999M );
        DecimalToU_Int16( 65536M );
        DecimalToU_Int16( 32767.999M );
        DecimalToU_Int16( 32768M );
        DecimalToU_Int16( - 0.999M );
        DecimalToU_Int16( - 1M );
        DecimalToU_Int16( - 32768.999M );
        DecimalToU_Int16( - 32769M );
    }
}

/*
This example of the explicit conversions from decimal to short
and decimal to ushort generates the following output. It displays
several converted decimal values.

decimal argument    short/exception   ushort/exception
----------------    ---------------   ----------------
             123                123                123
         123.000                123                123
         123.999                123                123
       65535.999  OverflowException              65535
           65536  OverflowException  OverflowException
       32767.999              32767              32767
           32768  OverflowException              32768
          -0.999                  0                  0
              -1                 -1  OverflowException
      -32768.999             -32768  OverflowException
          -32769  OverflowException  OverflowException
*/
```

Remarks

This operator supports the explicit conversion of a Decimal to an Int16. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to an Int16 value by using C#, Visual Basic, and C++. To perform a conversion

that is independent of language, you can call the Decimal.ToInt16(Decimal) or the Convert.ToInt16(Decimal) method.

Explicit(Decimal to Double)

Defines an explicit conversion of a Decimal to a double-precision floating-point number.

C#

```
public static explicit operator double (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Double

A double-precision floating-point number that represents the converted Decimal.

Examples

The following example converts Decimal numbers to Double values by using the explicit Decimal to Double conversion operator.

C#

```
using System;

class Example
{
    public static void Main( )
    {
        // Define an array of decimal values.
        decimal[] values = { 0.0000000000000000000000000001M,
                             0.0000000000123456789123456789M,
                             123M, new decimal(123000000, 0, 0, false,
6),
                             123456789.123456789M,
                             1234567891234567891234567 89M,
                             decimal.MinValue, decimal.MaxValue };
        // Convert each value to a double.
        foreach (var value in values) {
            double dblValue = (double) value;
            Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                              value.GetType().Name, dblValue,
                              dblValue.GetType().Name);
       }
    }
}
// The example displays the following output:
//    0.0000000000000000000000000001 (Decimal) --> 1E-28 (Double)
//    0.0000000000123456789123456789 (Decimal) --> 1.23456789123457E-11
(Double)
//    123 (Decimal) --> 123 (Double)
//    123.000000 (Decimal) --> 123 (Double)
//    123456789.123456789 (Decimal) --> 123456789.123457 (Double)
//    1234567891234567891234567 89 (Decimal) --> 1.23456789123457E+26
(Double)
//    -7922816251426433759354395033 5 (Decimal) --> -7.92281625142643E+28
(Double)
//    7922816251426433759354395033 5 (Decimal) --> 7.92281625142643E+28
(Double)
```

Remarks

This operation can result in a loss of precision, because a double-precision floating-point number has fewer significant digits than a Decimal.

This operator supports the explicit conversion of a Decimal to a Double. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a Double value by using C#, C++, and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToDouble(Decimal) or the Convert.ToDouble(Decimal) method.

Explicit(Decimal to Char)

Defines an explicit conversion of a Decimal to a Unicode character.

C#

```
public static explicit operator char (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Char

A Unicode character that represents the converted Decimal.

Exceptions

OverflowException

`value` is less than Char.MinValue or greater than Char.MaxValue.

Examples

The following example converts Decimal numbers to Char values (Unicode characters) by using the explicit Decimal to Char conversion operator.

C#

```
using System;

class Example
{
   public static void Main( )
   {
      // Define an array of decimal values.
      decimal[] values = { 3.33m, 55.5m, 77.7m, 123m, 123.999m, 170m,
                           188.88m, 222m, 244m, 8217m, 8250m, 65536m,
                           -1m };
      // Convert each value to a Char.
      foreach (decimal value in values) {
         try {
            char charValue = (char) value;
            Console.WriteLine("{0} --> {1} ({2:X4})", value,
                              charValue, (ushort) charValue);
         }
         catch (OverflowException) {
            Console.WriteLine("OverflowException: Cannot convert {0}",
                              value);
         }
      }
   }
}
// The example displays the following output:
//       3.33 --> ? (0003)
//       55.5 --> 7 (0037)
//       77.7 --> M (004D)
//       123 --> { (007B)
//       123.999 --> { (007B)
//       170 --> ª (00AA)
//       188.88 --> ¼ (00BC)
//       222 --> _ (00DE)
//       244 --> ô (00F4)
```

```
//       8217 --> ' (2019)
//       8250 --> > (203A)
//       OverflowException: Cannot convert 65536
//       OverflowException: Cannot convert -1
```

Remarks

This operator supports the explicit conversion of a Decimal to a Char. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results, or might not support the conversion at all. For example, the Visual Basic and C++ compilers do not support an explicit Decimal to a Char conversion.

Explicit(Decimal to Byte)

Defines an explicit conversion of a Decimal to an 8-bit unsigned integer.

C#

```
public static explicit operator byte (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Byte

An 8-bit unsigned integer that represents the converted Decimal.

Exceptions

OverflowException

`value` is less than Byte.MinValue or greater than Byte.MaxValue.

Examples

The following example converts Decimal numbers to Byte values by using the explicit Decimal to Byte conversion operator.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of decimal values.
       decimal[] values = { 78m, new Decimal(78000, 0, 0, false, 3),
                            78.999m, 255.999m, 256m, 127.999m,
                            128m, -0.999m, -1m, -128.999m, -129m };
       foreach (var value in values) {
          try {
              Byte byteValue = (Byte) value;
              Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                                value.GetType().Name, byteValue,
                                byteValue.GetType().Name);
           }
           catch (OverflowException) {
              Console.WriteLine("OverflowException: Cannot convert {0}",
                                value);
           }
       }
    }
}
// The example displays the following output:
//       78 (Decimal) --> 78 (Byte)
//       78.000 (Decimal) --> 78 (Byte)
//       78.999 (Decimal) --> 78 (Byte)
```

```
//       255.999 (Decimal) --> 255 (Byte)
//       OverflowException: Cannot convert 256
//       127.999 (Decimal) --> 127 (Byte)
//       128 (Decimal) --> 128 (Byte)
//       -0.999 (Decimal) --> 0 (Byte)
//       OverflowException: Cannot convert -1
//       OverflowException: Cannot convert -128.999
//       OverflowException: Cannot convert -129
```

Remarks

This operator supports the explicit conversion of a Decimal to a Byte. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to a Byte value by using C#, C++, and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToByte(Decimal) or the Convert.ToByte(Decimal) method.

Explicit(Decimal to Int64)

Defines an explicit conversion of a Decimal to a 64-bit signed integer.

```C#
public static explicit operator long (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Int64

A 64-bit signed integer that represents the converted Decimal.

Exceptions

OverflowException

`value` is less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example converts Decimal numbers to Int64 values by using the explicit Decimal to Int64 conversion operator.

```C#
// Example of the explicit conversions from decimal to long and
// decimal to ulong.
using System;

class DecimalToU_Int64Demo
{
    const string formatter = "{0,25}{1,22}{2,22}";

    // Get the exception type name; remove the namespace prefix.
    public static string GetExceptionType( Exception ex )
    {
        string exceptionType = ex.GetType( ).ToString( );
        return exceptionType.Substring(
            exceptionType.LastIndexOf( '.' ) + 1 );
    }

    // Convert the decimal argument; catch exceptions that are thrown.
    public static void DecimalToU_Int64( decimal argument )
    {
        object Int64Value;
```

```
        object UInt64Value;

        // Convert the argument to a long value.
        try
        {
            Int64Value = (long)argument;
        }
        catch( Exception ex )
        {
            Int64Value = GetExceptionType( ex );
        }

        // Convert the argument to a ulong value.
        try
        {
            UInt64Value = (ulong)argument;
        }
        catch( Exception ex )
        {
            UInt64Value = GetExceptionType( ex );
        }

        Console.WriteLine( formatter, argument,
            Int64Value, UInt64Value );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the explicit conversions from decimal " +
            "to long \nand decimal to ulong generates the following " +
            "output. It displays \nseveral converted decimal " +
            "values.\n" );
        Console.WriteLine( formatter, "decimal argument",
            "long/exception", "ulong/exception" );
        Console.WriteLine( formatter, "----------------",
            "--------------", "---------------" );

        // Convert decimal values and display the results.
        DecimalToU_Int64( 123M );

*/
```

Remarks

This operator supports the explicit conversion of a Decimal to an Int64. The syntax for such explicit conversions is language-dependent, and individual language compilers can provide different implementations and return different results. The example illustrates the different return values when you explicitly convert a Decimal value to an Int64 value by using C# and Visual Basic. To perform a conversion that is independent of language, you can call the Decimal.ToInt64(Decimal) or the Convert.ToInt64(Decimal) method.

Decimal.GreaterThan(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether a specified Decimal is greater than another specified Decimal.

C#

```
public static bool operator > (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` is greater than `d2`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Remarks

The GreaterThan method defines the operation of the greater than operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16354.0699m;
      Decimal number2 = 16354.0695m;
      Console.WriteLine("{0} > {1}: {2}", number1,
                        number2, number1 > number2);

      number1 = Decimal.Round(number1, 2);
      number2 = Decimal.Round(number2, 2);
      Console.WriteLine("{0} > {1}: {2}", number1,
                        number2, number1 > number2);
   }
}
// The example displays the following output:
//       16354.0699 > 16354.0695: True
//       16354.07 > 16354.07: False
```

Languages that do not support custom operators can call the Compare method instead. They may also be able to call the GreaterThan method directly, as the following example shows.

VB

```
Module Example
   Public Sub Main()
      Dim number1 As Decimal = 16354.0699d
      Dim number2 As Decimal = 16354.0695d
      Console.WriteLine("{0} > {1}: {2}", number1, number2,
                        Decimal.op_GreaterThan(number1, number2))

      number1 = Decimal.Round(number1, 2)
      number2 = Decimal.Round(number2, 2)
      Console.WriteLine("{0} > {1}: {2}", number1, number2,
                        Decimal.op_GreaterThan(number1, number2))
   End Sub
End Module
' The example displays the following output:
'       16354.0699 > 16354.0695: True
'       16354.07 > 16354.07: False
```

The equivalent method for this operator is Decimal.Compare(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Decimal.GreaterThanOrEqual(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether a specified Decimal is greater than or equal to another specified Decimal.

C#

```
public static bool operator >= (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` is greater than or equal to `d2`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Remarks

The GreaterThanOrEqual method defines the operation of the greater than or equal operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16354.0699m;
      Decimal number2 = 16354.0695m;
      Console.WriteLine("{0} >= {1}: {2}", number1,
                        number2, number1 >= number2);

      number1 = Decimal.Round(number1, 2);
      number2 = Decimal.Round(number2, 2);
      Console.WriteLine("{0} >= {1}: {2}", number1,
                        number2, number1 >= number2);
   }
}
// The example displays the following output:
//       16354.0699 >= 16354.0695: True
//       16354.07 >= 16354.07: True
```

Languages that do not support custom operators can call the Compare method instead. They may also be able to call the GreaterThanOrEqual method directly, as the following example shows.

VB

```
Module Example
   Public Sub Main()
      Dim number1 As Decimal = 16354.0699d
      Dim number2 As Decimal = 16354.0695d
      Console.WriteLine("{0} >= {1}: {2}", number1, number2,
                        Decimal.op_GreaterThanOrEqual(number1, number2))

      number1 = Decimal.Round(number1, 2)
      number2 = Decimal.Round(number2, 2)
      Console.WriteLine("{0} >= {1}: {2}", number1, number2,
                        Decimal.op_GreaterThanOrEqual(number1, number2))
   End Sub
End Module
' The example displays the following output:
'       16354.0699 >= 16354.0695: True
'       16354.07 >= 16354.07: True
```

The equivalent method for this operator is Decimal.Compare(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines an implicit conversion of the value of a type to a Decimal value.

Overloads

Expand table

Implicit(UInt16 to Decimal)	Defines an implicit conversion of a 16-bit unsigned integer to a Decimal. This API is not CLS-compliant.
Implicit(UInt64 to Decimal)	Defines an implicit conversion of a 64-bit unsigned integer to a Decimal. This API is not CLS-compliant.
Implicit(UInt32 to Decimal)	Defines an implicit conversion of a 32-bit unsigned integer to a Decimal. This API is not CLS-compliant.
Implicit(Int64 to Decimal)	Defines an implicit conversion of a 64-bit signed integer to a Decimal.
Implicit(SByte to Decimal)	Defines an implicit conversion of an 8-bit signed integer to a Decimal. This API is not CLS-compliant.
Implicit(Int16 to Decimal)	Defines an implicit conversion of a 16-bit signed integer to a Decimal.
Implicit(Char to Decimal)	Defines an implicit conversion of a Unicode character to a Decimal.
Implicit(Byte to Decimal)	Defines an implicit conversion of an 8-bit unsigned integer to a Decimal.

Implicit(Int32 to Decimal)	Defines an implicit conversion of a 32-bit signed integer to a Decimal.

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(UInt16 to Decimal)

> Important
>
> This API is not CLS-compliant.

Defines an implicit conversion of a 16-bit unsigned integer to a Decimal.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static implicit operator decimal (ushort value);
```

Parameters

`value` UInt16

The 16-bit unsigned integer to convert.

Returns

Decimal

The converted 16-bit unsigned integer.

Attributes CLSCompliantAttribute

Examples

The following example converts UInt16 values to Decimal numbers.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of 16-bit unsigned integer values.
        ushort[] values = { ushort.MinValue, ushort.MaxValue,
                            0xFFF, 12345, 40000 };
        // Convert each value to a Decimal.
        foreach (var value in values) {
           Decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//       0 (UInt16) --> 0 (Decimal)
//       65535 (UInt16) --> 65535 (Decimal)
//       4095 (UInt16) --> 4095 (Decimal)
//       12345 (UInt16) --> 12345 (Decimal)
//       40000 (UInt16) --> 40000 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(UInt64 to Decimal)

> Important
>
> This API is not CLS-compliant.

Defines an implicit conversion of a 64-bit unsigned integer to a Decimal.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static implicit operator decimal (ulong value);
```

Parameters

`value` UInt64

The 64-bit unsigned integer to convert.

Returns

Decimal

The converted 64-bit unsigned integer.

Attributes CLSCompliantAttribute

Examples

The following example converts UInt64 values to Decimal numbers by using the UInt64 to Decimal conversion operator.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        // Define an array of 64-bit unsigned integer values.
        ulong[] values = { ulong.MinValue, ulong.MaxValue,
                           0xFFFFFFFFFFFF, 123456789123456789,
                           1000000000000000 };
        // Convert each value to a Decimal.
        foreach (var value in values) {
           Decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//    0 (UInt64) --> 0 (Decimal)
//    18446744073709551615 (UInt64) --> 18446744073709551615 (Decimal)
//    281474976710655 (UInt64) --> 281474976710655 (Decimal)
//    123456789123456789 (UInt64) --> 123456789123456789 (Decimal)
//    1000000000000000 (UInt64) --> 1000000000000000 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(UInt32 to Decimal)

> Important
>
> This API is not CLS-compliant.

Defines an implicit conversion of a 32-bit unsigned integer to a Decimal.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static implicit operator decimal (uint value);
```

Parameters

`value` UInt32

The 32-bit unsigned integer to convert.

Returns

Decimal

The converted 32-bit unsigned integer.

Attributes CLSCompliantAttribute

Examples

The following example converts UInt32 values to Decimal numbers.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of 32-bit unsigned integer values.
        uint[] values = { uint.MinValue, uint.MaxValue, 0xFFFFFF,
                          123456789, 4000000000 };
        // Convert each value to a Decimal.
        foreach (var value in values) {
           Decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//       0 (UInt32) --> 0 (Decimal)
//       4294967295 (UInt32) --> 4294967295 (Decimal)
//       16777215 (UInt32) --> 16777215 (Decimal)
//       123456789 (UInt32) --> 123456789 (Decimal)
//       4000000000 (UInt32) --> 4000000000 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(Int64 to Decimal)

Defines an implicit conversion of a 64-bit signed integer to a Decimal.

C#

```
public static implicit operator decimal (long value);
```

Parameters

`value` Int64

The 64-bit signed integer to convert.

Returns

Decimal

The converted 64-bit signed integer.

Examples

The following example converts Int64 values to Decimal numbers.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of 64-bit integer values.
        long[] values = { long.MinValue, long.MaxValue,
```

```
                            0xFFFFFFFFFFFF, 123456789123456789,
                            -1000000000000000 };
         // Convert each value to a Decimal.
         foreach (var value in values) {
            Decimal decValue = value;
            Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                              value.GetType().Name, decValue,
                              decValue.GetType().Name);
         }
      }
   }
   // The example displays the following output:
   //    -9223372036854775808 (Int64) --> -9223372036854775808 (Decimal)
   //    9223372036854775807 (Int64) --> 9223372036854775807 (Decimal)
   //    281474976710655 (Int64) --> 281474976710655 (Decimal)
   //    123456789123456789 (Int64) --> 123456789123456789 (Decimal)
   //    -1000000000000000 (Int64) --> -1000000000000000 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(SByte to Decimal)

> Important
>
> This API is not CLS-compliant.

Defines an implicit conversion of an 8-bit signed integer to a Decimal.

This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static implicit operator decimal (sbyte value);
```

Parameters

`value` SByte

The 8-bit signed integer to convert.

Returns

Decimal

The converted 8-bit signed integer.

Attributes CLSCompliantAttribute

Examples

The following example converts SByte values to Decimal numbers.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of 8-bit signed integer values.
        sbyte[] values = { sbyte.MinValue, sbyte.MaxValue,
                           0x3F, 123, -100 };
        // Convert each value to a Decimal.
```

```
        foreach (var value in values) {
           Decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//    -128 (SByte) --> -128 (Decimal)
//    127 (SByte) --> 127 (Decimal)
//    63 (SByte) --> 63 (Decimal)
//    123 (SByte) --> 123 (Decimal)
//    -100 (SByte) --> -100 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Defines an implicit conversion of a 16-bit signed integer to a Decimal.

C#

```
public static implicit operator decimal (short value);
```

Parameters

`value` Int16

The 16-bit signed integer to convert.

Returns

Decimal

The converted 16-bit signed integer.

Examples

The following example converts Int16 values to Decimal numbers. This conversion requires the op_Implicit operator in Visual Basic, but not in C# and C++.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of 16-bit integer values.
        short[] values = { short.MinValue, short.MaxValue,
                           0xFFF, 12345, -10000 };
        // Convert each value to a Decimal.
        foreach (var value in values) {
           Decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//       -32768 (Int16) --> -32768 (Decimal)
//       32767 (Int16) --> 32767 (Decimal)
//       4095 (Int16) --> 4095 (Decimal)
//       12345 (Int16) --> 12345 (Decimal)
//       -10000 (Int16) --> -10000 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

UWP	10.0

Implicit(Char to Decimal)

Defines an implicit conversion of a Unicode character to a Decimal.

C#

```
public static implicit operator decimal (char value);
```

Parameters

`value` Char

The Unicode character to convert.

Returns

Decimal

The converted Unicode character.

Examples

The following example converts Char values (Unicode characters) to Decimal numbers. This conversion requires the op_Implicit operator in Visual Basic, but not in C# and C++.

C#

```
using System;

class Example
{
    public static void Main()
    {
        // Define an array of Char values.
        Char[] values = { '\0', ' ', '*', 'A', 'a', '{', 'Æ' };

        // Convert each Char value to a Decimal.
        foreach (var value in values) {
           decimal decValue = value;
           Console.WriteLine("'{0}' ({1}) --> {2} ({3})", value,
                              value.GetType().Name, decValue,
                              decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//       ' ' (Char) --> 0 (Decimal)
//       ' ' (Char) --> 32 (Decimal)
//       '*' (Char) --> 42 (Decimal)
//       'A' (Char) --> 65 (Decimal)
//       'a' (Char) --> 97 (Decimal)
//       '{' (Char) --> 123 (Decimal)
//       'Æ' (Char) --> 198 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(Byte to Decimal)

Defines an implicit conversion of an 8-bit unsigned integer to a Decimal.

C#

```
public static implicit operator decimal (byte value);
```

Parameters

`value` Byte

The 8-bit unsigned integer to convert.

Returns

Decimal

The converted 8-bit unsigned integer.

Examples

The following example converts Byte values to Decimal numbers.

C#

```
using System;

class Example
```

```
{
    public static void Main()
    {
        // Define an array of byte values.
        byte[] values = { byte.MinValue, byte.MaxValue,
                          0x3F, 123, 200 };
        // Convert each value to a Decimal.
        foreach (var value in values) {
           decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
    }
}
// The example displays the following output:
//       0 (Byte) --> 0 (Decimal)
//       255 (Byte) --> 255 (Decimal)
//       63 (Byte) --> 63 (Decimal)
//       123 (Byte) --> 123 (Decimal)
//       200 (Byte) --> 200 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Implicit(Int32 to Decimal)

Defines an implicit conversion of a 32-bit signed integer to a Decimal.

```
C#

public static implicit operator decimal (int value);
```

Parameters

`value` Int32

The 32-bit signed integer to convert.

Returns

Decimal

The converted 32-bit signed integer.

Examples

The following example converts Int32 values to Decimal numbers.

```
C#

using System;

class Example
{
    public static void Main()
    {
        // Define an array of 32-bit integer values.
        int[] values = { int.MinValue, int.MaxValue, 0xFFFFFF,
                         123456789, -1000000000 };
        // Convert each value to a Decimal.
        foreach (var value in values) {
           Decimal decValue = value;
           Console.WriteLine("{0} ({1}) --> {2} ({3})", value,
                             value.GetType().Name, decValue,
                             decValue.GetType().Name);
        }
```

```
    }
}
// The example displays the following output:
//    -2147483648 (Int32) --> -2147483648 (Decimal)
//    2147483647 (Int32) --> 2147483647 (Decimal)
//    16777215 (Int32) --> 16777215 (Decimal)
//    123456789 (Int32) --> 123456789 (Decimal)
//    -1000000000 (Int32) --> -1000000000 (Decimal)
```

Remarks

The overloads of the Implicit method define the types from which the compiler can automatically convert a Decimal value without an explicit casting operator (in C#) or a call to a conversion function (in Visual Basic). They are widening conversions that do not involve data loss and do not throw an OverflowException exception.

Decimal.Increment(Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments the Decimal operand by 1.

C#

```
public static decimal operator ++ (decimal d);
```

Parameters

d Decimal

The value to increment.

Returns

Decimal

The value of `d` incremented by 1.

Implements

Increment(TSelf)

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Increment method defines the operation of the increment operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number = 1079.8m;
      Console.WriteLine("Original value:    {0:N}", number);
      Console.WriteLine("Incremented value: {0:N}", ++number);
   }
}
// The example displays the following output:
//       Original value:    1,079.80
//       Incremented value: 1,080.80
```

Some languages (such as Visual Basic) that lack an increment operator can call the Increment method directly, as the following example shows.

VB

```
Module Example
   Public Sub Main()
      Dim number As Decimal = 1079.8d
      Console.WriteLine("Original value:    {0:N}", number)
      Console.WriteLine("Incremented value: {0:N}",
Decimal.op_Increment(number))
   End Sub
End Module
' The example displays the following output:
'       Original value:    1,079.80
'       Incremented value: 1,080.80
```

If your language does not support custom operators, call the Add method instead, as the following example shows.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number = 1079.8m;
      Console.WriteLine("Original value:    {0:N}", number);
      Console.WriteLine("Incremented value: {0:N}", Decimal.Add(number, 1));
   }
}
// The example displays the following output:
```

```
//       Original value:    1,079.80
//       Incremented value: 1,080.80
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Inequality(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two Decimal objects have different values.

```
C#
public static bool operator != (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` and `d2` are not equal; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Remarks

The Inequality method defines the operation of the inequality operator for Decimal values. It enables code such as the following:

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16354.0695m;
      Decimal number2 = 16354.0699m;
      Console.WriteLine("{0} <> {1}: {2}", number1,
                        number2, number1 != number2);

      number1 = Decimal.Round(number1, 2);
      number2 = Decimal.Round(number2, 2);
      Console.WriteLine("{0} <> {1}: {2}", number1,
                        number2, number1 != number2);
   }
}
// The example displays the following output:
//       16354.0695 <> 16354.0699: True
//       16354.07 <> 16354.07: False
```

If the language you're using doesn't support custom operators, you can test for inequality by using one of the following techniques:

- Calling the Compare method, which indicates the relationship between two Decimal values.
- Calling the Equals method and reversing its value.

The equivalent method for this operator is Decimal.Compare(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.LessThan(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether a specified Decimal is less than another specified Decimal.

C#

```
public static bool operator < (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` is less than `d2`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Remarks

The LessThan method defines the operation of the less than operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16354.0699m;
      Decimal number2 = 16354.0695m;
      Console.WriteLine("{0} < {1}: {2}", number1,
                        number2, number1 < number2);

      number1 = Decimal.Round(number1, 2);
      number2 = Decimal.Round(number2, 2);
      Console.WriteLine("{0} < {1}: {2}", number1,
                        number2, number1 < number2);
   }
}
// The example displays the following output:
//       16354.0699 < 16354.0695: False
//       16354.07 < 16354.07: False
```

Languages that do not support custom operators can call the Compare method instead. They may also be able to call the LessThan method directly, as the following example shows.

VB

```
Module Example
   Public Sub Main()
      Dim number1 As Decimal = 16354.0699d
      Dim number2 As Decimal = 16354.0695d
      Console.WriteLine("{0} < {1}: {2}", number1, number2,
                        Decimal.op_LessThan(number1, number2))

      number1 = Decimal.Round(number1, 2)
      number2 = Decimal.Round(number2, 2)
      Console.WriteLine("{0} < {1}: {2}", number1, number2,
                        Decimal.op_LessThan(number1, number2))
   End Sub
End Module
' The example displays the following output:
'       16354.0699 < 16354.0695: False
'       16354.07 < 16354.07: False
```

The equivalent method for this operator is Decimal.Compare(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.LessThanOrEqual(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether a specified Decimal is less than or equal to another specified Decimal.

```
C#
public static bool operator <= (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to compare.

d2 Decimal

The second value to compare.

Returns

Boolean

`true` if `d1` is less than or equal to `d2`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Remarks

The LessThanOrEqual method defines the operation of the less than or equal operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16354.0699m;
      Decimal number2 = 16354.0695m;
      Console.WriteLine("{0} <= {1}: {2}", number1,
                        number2, number1 <= number2);

      number1 = Decimal.Round(number1, 2);
      number2 = Decimal.Round(number2, 2);
      Console.WriteLine("{0} <= {1}: {2}", number1,
                        number2, number1 <= number2);
   }
}
// The example displays the following output:
//       16354.0699 <= 16354.0695: False
//       16354.07 <= 16354.07: True
```

Languages that do not support custom operators can call the Compare method instead. They may also be able to call the LessThanOrEqual method directly, as the following example shows.

VB

```
Module Example
   Public Sub Main()
      Dim number1 As Decimal = 16354.0699d
      Dim number2 As Decimal = 16354.0695d
      Console.WriteLine("{0} <= {1}: {2}", number1, number2,
                        Decimal.op_LessThanOrEqual(number1, number2))

      number1 = Decimal.Round(number1, 2)
      number2 = Decimal.Round(number2, 2)
      Console.WriteLine("{0} <= {1}: {2}", number1, number2,
                        Decimal.op_LessThanOrEqual(number1, number2))
   End Sub
End Module
' The example displays the following output:
'       16354.0699 >= 16354.0695: False
'       16354.07 >= 16354.07: True
```

The equivalent method for this operator is Decimal.Compare(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Modulus(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the remainder resulting from dividing two specified Decimal values.

```
C#
public static decimal operator % (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The dividend.

d2 Decimal

The divisor.

Returns

Decimal

The remainder resulting from dividing `d1` by `d2`.

Implements

Modulus(TSelf, TOther)

Exceptions

DivideByZeroException

`d2` is `zero`.

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Modulus operator defines the remainder operation that returns the remainder resulting from dividing two specified Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16.8m;
      Decimal number2 = 4.1m;
      Decimal number3 = number1 % number2;
      Console.WriteLine("{0:N2} % {1:N2} = {2:N2}",
                        number1, number2, number3);
   }
}
// The example displays the following output:
//        16.80 % 4.10 = 0.40
```

The sign of the value returned by the remainder operation depends on the sign of dividend. If dividend is positive, the remainder operation returns a positive result; if it is negative, the remainder operation returns a negative result.

The equivalent method for this operator is Decimal.Remainder(Decimal, Decimal). If the language you're using doesn't support custom operators, call the Remainder method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Multiply(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two specified Decimal values.

C#

```
public static decimal operator * (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The first value to multiply.

d2 Decimal

The second value to multiply.

Returns

Decimal

The result of multiplying `d1` by `d2`.

Implements

Multiply(TSelf, TOther)

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Multiply method defines the operation of the multiplication operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 16.8m;
      Decimal number2 = 4.1m;
      Decimal number3 = number1 * number2;
      Console.WriteLine("{0:N2} x {1:N2} = {2:N2}",
                        number1, number2, number3);
   }
}
// The example displays the following output:
//        16.80 x 4.10 = 68.88
```

If the language you're using doesn't support custom operators, call the Multiply method instead.

The equivalent method for this operator is Decimal.Multiply(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.Subtraction(Decimal, Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two specified Decimal values.

```
C#
public static decimal operator - (decimal d1, decimal d2);
```

Parameters

d1 Decimal

The minuend.

d2 Decimal

The subtrahend.

Returns

Decimal

The result of subtracting `d2` from `d1`.

Implements

Subtraction(TSelf, TOther)

Exceptions

OverflowException

The return value is less than Decimal.MinValue or greater than Decimal.MaxValue.

Remarks

The Subtraction method defines the operation of the subtraction operator for Decimal values. It enables code such as the following:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Decimal number1 = 120.07m;
      Decimal number2 = 163.19m;
      Decimal number3 = number1 - number2;
      Console.WriteLine("{0} - {1} = {2}",
                        number1, number2, number3);
   }
}
// The example displays the following output:
//        120.07 - 163.19 = -43.12
```

If the language you're using doesn't support custom operators, call the Subtract method instead.

The equivalent method for this operator is Decimal.Subtract(Decimal, Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.UnaryNegation(Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Negates the value of the specified Decimal operand.

```
C#
public static decimal operator - (decimal d);
```

Parameters

d Decimal

The value to negate.

Returns

Decimal

The result of `d` multiplied by negative one (-1).

Implements

UnaryNegation(TSelf)

Remarks

The UnaryPlus method defines the operation of the unary negation operator (or the additive inverse operator) for Decimal values. The operation produces a value that results in 0 (zero) when it is added to the original number. Languages that do not support custom operators can call the Negate method instead.

The equivalent method for this operator is Decimal.Negate(Decimal)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.UnaryPlus(Decimal) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the value of the Decimal operand (the sign of the operand is unchanged).

C#

```
public static decimal operator + (decimal d);
```

Parameters

d Decimal

The operand to return.

Returns

Decimal

The value of the operand, `d`.

Implements

UnaryPlus(TSelf)

Remarks

The UnaryPlus method defines the operation of the unary positive operator for Decimal values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Decimal) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than Byte.MinValue or greater than Byte.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is

to call either the Decimal.ToByte method or the Convert.ToByte method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

None. This conversion is not supported.

Implements

ToChar(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

None. This conversion is not supported.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.IConvertible.To Decimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, unchanged.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call either the Decimal.ToDouble method or the Convert.ToDouble method.

Because a Double has fewer significant digits than a Decimal, this operation may produce round-off errors.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

```
C#
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to a Int16.

Implements

ToInt16(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than Int16.MinValue or greater than Int16.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is

to call either the Decimal.ToInt16 method or the Convert.ToInt16 method.

The Decimal value is rounded toward zero to the nearest integer value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

The parameter is ignored.

Returns

Int32

The value of the current instance, converted to a Int32.

Implements

ToInt32(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than Int32.MinValue or greater than Int32.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is

to call either the Decimal.ToInt32 method or the Convert.ToInt32 method.

The Decimal value is rounded toward zero to the nearest integer value.

Applies to

Product	Versions

Decimal.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to a Int64.

Implements

ToInt64(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than Int64.MinValue or greater than Int64.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is

to call either the Decimal.ToInt64 method or the Convert.ToInt64 method.

Applies to

Product	Versions

Decimal.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to a SByte.

Implements

ToSByte(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than SByte.MinValue or greater than SByte.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call either the Decimal.ToSByte method or the Convert.ToSByte method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call either the Decimal.ToSingle method or the Convert.ToSingle method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The type to which to convert the value of this Decimal instance.

`provider` IFormatProvider

An IFormatProvider implementation that supplies culture-specific information about the format of the returned value.

Returns

Object

The value of the current instance, converted to a `type`.

Implements

ToType(Type, IFormatProvider)

Exceptions

ArgumentNullException

`type` is `null`.

InvalidCastException

The requested type conversion is not supported.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Collaborate with us on GitHub

Decimal.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than UInt16.MinValue or greater than UInt16.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call either the Decimal.ToUInt16 method or the Convert.ToUInt16 method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Decimal.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than UInt32.MinValue or greater than UInt32.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call either the Decimal.ToUInt32 method or the Convert.ToUInt32 method.

The Decimal value is rounded toward zero to the nearest integer value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Exceptions

OverflowException

The resulting integer value is less than UInt64.MinValue or greater than UInt64.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the Decimal instance is cast to an IConvertible interface. The recommended alternative is to call either the Decimal.ToUInt64 method or the Convert.ToUInt64 method.

The Decimal value is rounded toward zero to the nearest integer value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Decimal.IFloatingPoint<Decimal>.TryWriteExponentBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current exponent, in big-endian format, to a given span.

C#

```
bool IFloatingPoint<decimal>.TryWriteExponentBigEndian (Span<byte>
destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current exponent should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the exponent was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteExponentBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.INumber<Decimal>.MaxNumber(Decimal, Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static decimal INumber<decimal>.MaxNumber (decimal x, decimal y);
```

Parameters

x Decimal

The value to compare with `y`.

y Decimal

The value to compare with `x`.

Returns

Decimal

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.INumberBase<Decimal>.IsRealNumber(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<decimal>.IsRealNumber (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.INumberBase<Decimal>.IsSubnormal(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is subnormal.

C#

```
static bool INumberBase<decimal>.IsSubnormal (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is subnormal; otherwise, `false`.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.INumberBase<Decimal>.IsZero(Decimal) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<decimal>.IsZero (decimal value);
```

Parameters

`value` Decimal

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.INumberBase<Decimal>.MaxMagnitudeNumber Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

C#

```
static decimal INumberBase<decimal>.MaxMagnitudeNumber (decimal x, decimal y);
```

Parameters

x Decimal

The value to compare with `y`.

y Decimal

The value to compare with `x`.

Returns

Decimal

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.INumberBase<Decimal>.MinMagnitudeNumber Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

```
C#

static decimal INumberBase<decimal>.MinMagnitudeNumber (decimal x, decimal
y);
```

Parameters

x Decimal

The value to compare with `y`.

y Decimal

The value to compare with `x`.

Returns

Decimal

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.INumberBase<Decimal>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<decimal>.TryConvertToChecked<TOther> (decimal value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Decimal

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Decimal.INumberBase<Decimal>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<decimal>.TryConvertToSaturating<TOther> (decimal
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Decimal

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Decimal.IDeserializationCallback.OnDeserialization(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Runs when the deserialization of an object has been completed.

C#

```
void IDeserializationCallback.OnDeserialization (object sender);
```

Parameters

sender Object

The object that initiated the callback. The functionality for this parameter is not currently implemented.

Implements

OnDeserialization(Object)

Exceptions

SerializationException

The Decimal object contains invalid or corrupted data.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Decimal.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo with the data needed to serialize the target object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo to populate with data.

`context` StreamingContext

The destination (see StreamingContext) for this serialization.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Delegate Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a delegate, which is a data structure that refers to a static method or to a class instance and an instance method of that class.

```C#
public abstract class Delegate : ICloneable,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → Delegate

Derived Microsoft.Aspnet.Snapin.DialogProc
Microsoft.Aspnet.Snapin.PropSheetPageProc
Microsoft.Extensions.Caching.Memory.PostEvictionDelegate
Microsoft.Extensions.DependencyInjection.ObjectFactory
Microsoft.Extensions.DependencyInjection.ObjectFactory<T>
More...

Implements ICloneable , ISerializable

Remarks

The Delegate class is the base class for delegate types. However, only the system and compilers can derive explicitly from the Delegate class or from the MulticastDelegate class. It is also not permissible to derive a new type from a delegate type. The Delegate class is not considered a delegate type; it is a class used to derive delegate types.

Most languages implement a `delegate` keyword, and compilers for those languages are able to derive from the MulticastDelegate class; therefore, users should use the `delegate` keyword provided by the language.

Note

The common language runtime provides an `Invoke` method for each delegate type, with the same signature as the delegate. You do not have to call this method explicitly from C#, Visual Basic, or Visual C++, because the compilers call it automatically. The `Invoke` method is useful in **reflection** when you want to find the signature of the delegate type.

The common language runtime provides each delegate type with `BeginInvoke` and `EndInvoke` methods, to enable asynchronous invocation of the delegate. For more information about these methods, see Calling Synchronous Methods Asynchronously.

The declaration of a delegate type establishes a contract that specifies the signature of one or more methods. A delegate is an instance of a delegate type that has references to:

- An instance method of a type and a target object assignable to that type.
- An instance method of a type, with the hidden `this` parameter exposed in the formal parameter list. The delegate is said to be an open instance delegate.
- A static method.
- A static method and a target object assignable to the first parameter of the method. The delegate is said to be closed over its first argument.

For more information on delegate binding, see the CreateDelegate(Type, Object, MethodInfo, Boolean) method overload.

When a delegate represents an instance method closed over its first argument (the most common case), the delegate stores a reference to the method's entry point and a reference to an object, called the target, which is of a type assignable to the type that defined the method. When a delegate represents an open instance method, it stores a reference to the method's entry point. The delegate signature must include the hidden `this` parameter in its formal parameter list; in this case, the delegate does not have a reference to a target object, and a target object must be supplied when the delegate is invoked.

When a delegate represents a static method, the delegate stores a reference to the method's entry point. When a delegate represents a static method closed over its first argument, the delegate stores a reference to the method's entry point and a reference to a target object assignable to the type of the method's first argument. When the delegate is invoked, the first argument of the static method receives the target object. This first argument must be a reference type.

The invocation list of a delegate is an ordered set of delegates in which each element of the list invokes exactly one of the methods represented by the delegate. An invocation list can contain duplicate methods. During an invocation, methods are invoked in the order in which they appear in the invocation list. A delegate attempts to invoke every method in its invocation list; duplicates are invoked once for each time they appear in the invocation list. Delegates are immutable; once created, the invocation list of a delegate does not change.

Delegates are referred to as multicast, or combinable, because a delegate can invoke one or more methods and can be used in combining operations.

Combining operations, such as Combine and Remove, do not alter existing delegates. Instead, such an operation returns a new delegate that contains the results of the operation, an unchanged delegate, or `null`. A combining operation returns `null` when the result of the operation is a delegate that does not reference at least one method. A combining operation returns an unchanged delegate when the requested operation has no effect.

> **Note**
>
> Managed languages use the **Combine** and **Remove** methods to implement delegate operations. Examples include the `AddHandler` and `RemoveHandler` statements in Visual Basic and the `+=` and `-=` operators on delegate types in C#.

Starting with the .NET Framework 4, generic delegate types can have variant type parameters. Contravariant type parameters can be used as parameter types of the delegate, and a covariant type parameter can be used as the return type. This feature allows generic delegate types that are constructed from the same generic type definition to be assignment-compatible if their type arguments are reference types with an inheritance relationship, as explained in Covariance and Contravariance.

> **Note**
>
> Generic delegates that are assignment-compatible because of variance are not necessarily combinable. To be combinable, the types must match exactly. For example, suppose that a class named `Derived` is derived from a class named `Base`. A delegate of type `Action<Base>` (`Action(Of Base)` in Visual Basic) can be assigned to a variable of type `Action<Derived>`, but the two delegates cannot be combined because the types do not match exactly.

If an invoked method throws an exception, the method stops executing, the exception is passed back to the caller of the delegate, and remaining methods in the invocation list are not invoked. Catching the exception in the caller does not alter this behavior.

When the signature of the methods invoked by a delegate includes a return value, the delegate returns the return value of the last element in the invocation list. When the signature includes a parameter that is passed by reference, the final value of the parameter is the result of every method in the invocation list executing sequentially and updating the parameter's value.

The closest equivalent of a delegate in C is a function pointer. A delegate can represent a static method or an instance method. When the delegate represents an instance method, the delegate stores not only a reference to the method's entry point, but also a reference to the class instance. Unlike function pointers, delegates are object oriented and type safe.

For examples, see Supplemental API remarks for System.Delegate.CreateDelegate.

Constructors

Expand table

Delegate(Object, String)	Initializes a delegate that invokes the specified instance method on the specified class instance.
Delegate(Type, String)	Initializes a delegate that invokes the specified static method from the specified class.

Properties

Expand table

Method	Gets the method represented by the delegate.
Target	Gets the class instance on which the current delegate invokes the instance method.

Methods

Expand table

Clone()	Creates a shallow copy of the delegate.

Combine(Delegate, Delegate)	Concatenates the invocation lists of two delegates.
Combine(Delegate[])	Concatenates the invocation lists of an array of delegates.
CombineImpl(Delegate)	Concatenates the invocation lists of the specified multicast (combinable) delegate and the current multicast (combinable) delegate.
CreateDelegate(Type, MethodInfo)	Creates a delegate of the specified type to represent the specified method.
CreateDelegate(Type, MethodInfo, Boolean)	Creates a delegate of the specified type to represent the specified static method, with the specified behavior on failure to bind.
CreateDelegate(Type, Object, MethodInfo)	Creates a delegate of the specified type that represents the specified static or instance method, with the specified first argument.
CreateDelegate(Type, Object, MethodInfo, Boolean)	Creates a delegate of the specified type that represents the specified static or instance method, with the specified first argument and the specified behavior on failure to bind.
CreateDelegate(Type, Object, String)	Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance.
CreateDelegate(Type, Object, String, Boolean)	Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance with the specified case-sensitivity.
CreateDelegate(Type, Object, String, Boolean, Boolean)	Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance, with the specified case-sensitivity and the specified behavior on failure to bind.
CreateDelegate(Type, Type, String)	Creates a delegate of the specified type that represents the specified static method of the specified class.
CreateDelegate(Type, Type, String, Boolean)	Creates a delegate of the specified type that represents the specified static method of the specified class, with the specified case-sensitivity.
CreateDelegate(Type, Type, String, Boolean, Boolean)	Creates a delegate of the specified type that represents the specified static method of the specified class, with the specified case-sensitivity and the specified behavior on failure to bind.
DynamicInvoke(Object[])	Dynamically invokes (late-bound) the method represented by the current delegate.
DynamicInvokeImpl(Object[])	Dynamically invokes (late-bound) the method represented by

	the current delegate.
Equals(Object)	Determines whether the specified object and the current delegate are of the same type and share the same targets, methods, and invocation list.
GetHashCode()	Returns a hash code for the delegate.
GetInvocationList()	Returns the invocation list of the delegate.
GetMethodImpl()	Gets the method represented by the current delegate.
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Not supported.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Remove(Delegate, Delegate)	Removes the last occurrence of the invocation list of a delegate from the invocation list of another delegate.
RemoveAll(Delegate, Delegate)	Removes all occurrences of the invocation list of a delegate from the invocation list of another delegate.
RemoveImpl(Delegate)	Removes the invocation list of a delegate from the invocation list of another delegate.
ToString()	Returns a string that represents the current object. (Inherited from Object)

Operators

Expand table

Equality(Delegate, Delegate)	Determines whether the specified delegates are equal.
Inequality(Delegate, Delegate)	Determines whether the specified delegates are not equal.

Extension Methods

Expand table

GetMethod	Gets an object that represents the method represented by the

Info(Delegate)	specified delegate.

Applies to

Delegate Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new delegate.

Overloads

Expand table

Delegate(Object, String)	Initializes a delegate that invokes the specified instance method on the specified class instance.
Delegate(Type, String)	Initializes a delegate that invokes the specified static method from the specified class.

Delegate(Object, String)

Initializes a delegate that invokes the specified instance method on the specified class instance.

C#

```
protected Delegate (object target, string method);
```

Parameters

target Object

The class instance on which the delegate invokes `method`.

method String

The name of the instance method that the delegate represents.

Exceptions

ArgumentNullException

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

There was an error binding to the target method.

Remarks

This constructor cannot be used in application code. To create a delegate by specifying the name of an instance method, use an overload of the CreateDelegate method that specifies a method name and a target object. For example, the CreateDelegate(Type, Object, String) method overload creates a delegate for an instance method with a specified name.

This constructor creates delegates for instance methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

See also

- Object
- String

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Delegate(Type, String)

Initializes a delegate that invokes the specified static method from the specified class.

```
C#

protected Delegate (Type target, string method);
```

Parameters

`target` Type

The Type representing the class that defines `method`.

`method` String

The name of the static method that the delegate represents.

Exceptions

ArgumentNullException

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`target` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`target` represents an open generic type.

Remarks

This constructor cannot be used in application code. To create a delegate by specifying the name of a static method, use an overload of the CreateDelegate method that specifies a method name but does not specify a target object. For example, the CreateDelegate(Type, Type, String) method overload creates a static delegate for a method with a specified name.

This constructor creates delegates for static methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

Delegate.Method Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the method represented by the delegate.

```
C#
public System.Reflection.MethodInfo Method { get; }
```

Property Value

MethodInfo

A MethodInfo describing the method represented by the delegate.

Exceptions

MemberAccessException

The caller does not have access to the method represented by the delegate (for example, if the method is private).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Delegate.Target Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the class instance on which the current delegate invokes the instance method.

```
C#
public object? Target { get; }
```

Property Value

Object

The object on which the current delegate invokes the instance method, if the delegate represents an instance method; `null` if the delegate represents a static method.

Remarks

An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

If the delegate invokes one or more instance methods, this property returns the target of the last instance method in the invocation list.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Delegate.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a shallow copy of the delegate.

C#

```
public virtual object Clone ();
```

Returns

Object

A shallow copy of the delegate.

Implements

Clone()

Remarks

The clone has the same Type, target, method, and invocation list as the original delegate.

A shallow copy creates a new instance of the same type as the original object, and then copies the nonstatic fields of the original object. If the field is a value type, a bit-by-bit copy of the field is performed. If the field is a reference type, the reference is copied but the referred object is not; therefore, the reference in the original object and the reference in the clone point to the same object. In contrast, a deep copy of an object duplicates everything directly or indirectly referenced by the fields in the object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Delegate.Combine Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Concatenates the invocation lists of the specified multicast (combinable) delegates.

Overloads

Expand table

Combine(Delegate[])	Concatenates the invocation lists of an array of delegates.
Combine(Delegate, Delegate)	Concatenates the invocation lists of two delegates.

Combine(Delegate[])

Concatenates the invocation lists of an array of delegates.

C#

```
public static Delegate? Combine (params Delegate?[]? delegates);
```

Parameters

delegates Delegate[]

The array of delegates to combine.

Returns

Delegate

A new delegate with an invocation list that concatenates the invocation lists of the delegates in the `delegates` array. Returns `null` if `delegates` is `null`, if `delegates` contains zero elements, or if every entry in `delegates` is `null`.

Exceptions

ArgumentException

Not all the non-null entries in `delegates` are instances of the same delegate type.

Remarks

If the `delegates` array contains entries that are `null`, those entries are ignored.

The invocation list can contain duplicate entries; that is, entries that refer to the same method on the same object.

> **Note**
>
> Generic delegates that are assignment-compatible because of variance are not necessarily combinable. To be combinable, the types must match exactly. For example, suppose that a class named `Derived` is derived from a class named `Base`. A delegate of type `Action<Base>` (`Action(Of Base)` in Visual Basic) can be assigned to a variable of type `Action<Derived>`, as explained in **Covariance and Contravariance**, but the two delegates cannot be combined because the types do not match exactly.

Combine is useful for creating event handlers that call multiple methods each time an event occurs.

- CombineImpl(Delegate)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Combine(Delegate, Delegate)

Concatenates the invocation lists of two delegates.

C#

```
public static Delegate? Combine (Delegate? a, Delegate? b);
```

Parameters

a Delegate

The delegate whose invocation list comes first.

b Delegate

The delegate whose invocation list comes last.

Returns

Delegate

A new delegate with an invocation list that concatenates the invocation lists of `a` and `b` in that order. Returns `a` if `b` is `null`, returns `b` if `a` is a null reference, and returns a null reference if both `a` and `b` are null references.

Exceptions

ArgumentException

Both `a` and `b` are not `null`, and `a` and `b` are not instances of the same delegate type.

Remarks

The invocation list can contain duplicate entries; that is, entries that refer to the same method on the same object.

> **Note**
>
> Generic delegates that are assignment-compatible because of variance are not necessarily combinable. To be combinable, the types must match exactly. For example, suppose that a class named `Derived` is derived from a class named `Base`. Delegate.CombineImpl(Delegate) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Concatenates the invocation lists of the specified multicast (combinable) delegate and the current multicast (combinable) delegate.

C#

```
protected virtual Delegate CombineImpl (Delegate? d);
```

Parameters

d Delegate

The multicast (combinable) delegate whose invocation list to append to the end of the invocation list of the current multicast (combinable) delegate.

Returns

Delegate

A new multicast (combinable) delegate with an invocation list that concatenates the invocation list of the current multicast (combinable) delegate and the invocation list of `d`, or the current multicast (combinable) delegate if `d` is `null`.

Exceptions

MulticastNotSupportedException

Always thrown.

Remarks

This method applies only if the current delegate is multicast (combinable).

The current implementation simply throws a MulticastNotSupportedException.

The invocation list can contain duplicate entries; that is, entries that refer to the same method on the same object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Delegate.CreateDelegate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a delegate of the specified type.

Overloads

Expand table

CreateDelegate(Type, Type, String, Boolean, Boolean)	Creates a delegate of the specified type that represents the specified static method of the specified class, with the specified case-sensitivity and the specified behavior on failure to bind.
CreateDelegate(Type, Type, String, Boolean)	Creates a delegate of the specified type that represents the specified static method of the specified class, with the specified case-sensitivity.
CreateDelegate(Type, Object, String, Boolean)	Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance with the specified case-sensitivity.
CreateDelegate(Type, Object, MethodInfo, Boolean)	Creates a delegate of the specified type that represents the specified static or instance method, with the specified first argument and the specified behavior on failure to bind.
CreateDelegate(Type, Object, String, Boolean, Boolean)	Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance, with the specified case-sensitivity and the specified behavior on failure to bind.
CreateDelegate(Type, MethodInfo, Boolean)	Creates a delegate of the specified type to represent the specified static method, with the specified behavior on failure to bind.
CreateDelegate(Type, Object, String)	Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance.
CreateDelegate(Type, Object, MethodInfo)	Creates a delegate of the specified type that represents the specified static or instance method, with the specified first

	argument.
CreateDelegate(Type, Type, String)	Creates a delegate of the specified type that represents the specified static method of the specified class.
CreateDelegate(Type, MethodInfo)	Creates a delegate of the specified type to represent the specified method.

CreateDelegate(Type, Type, String, Boolean, Boolean)

Creates a delegate of the specified type that represents the specified static method of the specified class, with the specified case-sensitivity and the specified behavior on failure to bind.

```
C#

public static Delegate? CreateDelegate (Type type, Type target, string
method, bool ignoreCase, bool throwOnBindFailure);
```

Parameters

`type` Type

The Type of delegate to create.

`target` Type

The Type representing the class that implements `method`.

`method` String

The name of the static method that the delegate is to represent.

`ignoreCase` Boolean

A Boolean indicating whether to ignore the case when comparing the name of the method.

`throwOnBindFailure` Boolean

`true` to throw an exception if `method` cannot be bound; otherwise, `false`.

Returns

Delegate

A delegate of the specified type that represents the specified static method of the specified class.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`target` is not a `RuntimeType`.

-or-

`target` is an open generic type. That is, its ContainsGenericParameters property is `true`.

-or-

`method` is not a `static` method (`Shared` method in Visual Basic).

-or-

`method` cannot be bound, for example because it cannot be found, and `throwOnBindFailure` is `true`.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

This method creates delegates for static methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

See also

- Type
- MulticastDelegate
- ReflectionPermission
- Object

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateDelegate(Type, Type, String, Boolean)

Creates a delegate of the specified type that represents the specified static method of the specified class, with the specified case-sensitivity.

C#

```
public static Delegate CreateDelegate (Type type, Type target, string
method, bool ignoreCase);
```

Parameters

type Type

The Type of delegate to create.

`target` Type

The Type representing the class that implements `method`.

`method` String

The name of the static method that the delegate is to represent.

`ignoreCase` Boolean

A Boolean indicating whether to ignore the case when comparing the name of the method.

Returns

Delegate

A delegate of the specified type that represents the specified static method of the specified class.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`target` is not a `RuntimeType`.

-or-

`target` is an open generic type. That is, its ContainsGenericParameters property is `true`.

-or-

`method` is not a `static` method (`Shared` method in Visual Basic).

-or-

`method` cannot be bound, for example because it cannot be found.

MissingMethodException
The `Invoke` method of `type` is not found.

MethodAccessException
The caller does not have the permissions necessary to access `method`.

Remarks

This method creates delegates for static methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

This method overload is equivalent to calling the CreateDelegate(Type, Type, String, Boolean, Boolean) method overload, specifying `true` for `throwOnBindFailure`.

Product	Versions
.NET Standard	2.0, 2.1

CreateDelegate(Type, Object, String, Boolean)

Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance with the specified case-sensitivity.

C#

```
public static Delegate CreateDelegate (Type type, object target, string
method, bool ignoreCase);
```

Parameters

`type` Type

The Type of delegate to create.

`target` Object

The class instance on which `method` is invoked.

`method` String

The name of the instance method that the delegate is to represent.

`ignoreCase` Boolean

A Boolean indicating whether to ignore the case when comparing the name of the method.

Returns

Delegate

A delegate of the specified type that represents the specified instance method to invoke on the specified class instance.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` is not an instance method.

-or-

`method` cannot be bound, for example because it cannot be found.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

This method creates delegates for instance methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

This method overload is equivalent to calling the CreateDelegate(Type, Object, String, Boolean, Boolean) method overload, specifying `true` for `throwOnBindFailure`.

See also

- Type
- MulticastDelegate
- ReflectionPermission

- Object

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateDelegate(Type, Object, MethodInfo, Boolean)

Creates a delegate of the specified type that represents the specified static or instance method, with the specified first argument and the specified behavior on failure to bind.

C#

```
public static Delegate? CreateDelegate (Type type, object? firstArgument,
System.Reflection.MethodInfo method, bool throwOnBindFailure);
```

Parameters

`type` Type

A Type representing the type of delegate to create.

`firstArgument` Object

An Object that is the first argument of the method the delegate represents. For instance methods, it must be compatible with the instance type.

`method` MethodInfo

The MethodInfo describing the static or instance method the delegate is to represent.

`throwOnBindFailure` Boolean

`true` to throw an exception if `method` cannot be bound; otherwise, `false`.

Returns

Delegate

A delegate of the specified type that represents the specified static or instance method, or `null` if `throwOnBindFailure` is `false` and the delegate cannot be bound to `method`.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` cannot be bound, and `throwOnBindFailure` is `true`.

-or-

`method` is not a `RuntimeMethodInfo`. See Runtime Types in Reflection.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

This method overload and the CreateDelegate(Type, Object, MethodInfo) method overload, which always throws on failure to bind, provide the most flexible way to create delegates. You can use them to create delegates for either static or instance methods, with or without a first argument.

> ⓘ **Note**
>
> If you do not supply a first argument, use the **CreateDelegate(Type, MethodInfo, Boolean)** method overload for better performance.

For more information and examples, see Supplemental API remarks for System.Delegate.CreateDelegate.

.NET Standard	2.0, 2.1

CreateDelegate(Type, Object, String, Boolean, Boolean)

Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance, with the specified case-sensitivity and the specified behavior on failure to bind.

```
C#
```

```
public static Delegate? CreateDelegate (Type type, object target, string
method, bool ignoreCase, bool throwOnBindFailure);
```

Parameters

`type` Type

The Type of delegate to create.

`target` Object

The class instance on which `method` is invoked.

`method` String

The name of the instance method that the delegate is to represent.

`ignoreCase` Boolean

A Boolean indicating whether to ignore the case when comparing the name of the method.

`throwOnBindFailure` Boolean

`true` to throw an exception if `method` cannot be bound; otherwise, `false`.

Returns

Delegate

A delegate of the specified type that represents the specified instance method to invoke on the specified class instance.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` is not an instance method.

-or-

`method` cannot be bound, for example because it cannot be found, and `throwOnBindFailure` is `true`.

MissingMethodException
The `Invoke` method of `type` is not found.

MethodAccessException
The caller does not have the permissions necessary to access `method`.

Remarks

This method creates delegates for instance methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.0, 2.1

CreateDelegate(Type, MethodInfo, Boolean)

Creates a delegate of the specified type to represent the specified static method, with the specified behavior on failure to bind.

```
C#

public static Delegate? CreateDelegate (Type type,
System.Reflection.MethodInfo method, bool throwOnBindFailure);
```

Parameters

`type` Type

The Type of delegate to create.

`method` MethodInfo

The MethodInfo describing the static or instance method the delegate is to represent.

`throwOnBindFailure` Boolean

`true` to throw an exception if `method` cannot be bound; otherwise, `false`.

Returns

Delegate

A delegate of the specified type to represent the specified static method.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` cannot be bound, and `throwOnBindFailure` is `true`.

-or-

`method` is not a `RuntimeMethodInfo`. See Runtime Types in Reflection.

MissingMethodException
The `Invoke` method of `type` is not found.

MethodAccessException
The caller does not have the permissions necessary to access `method`.

Remarks

This method overload can create open static method delegates and open instance method delegates - that is, delegates that expose the hidden first argument of instance methods. For a detailed explanation, see the more general CreateDelegate(Type, Object, MethodInfo, Boolean) method overload, which allows you to create all combinations of open or closed delegates for instance or static methods.

> **Note**
>
> This method overload should be used when the delegate is not closed over its first argument, because it is somewhat faster in that case.

For examples, see Supplemental API remarks for System.Delegate.CreateDelegate.

.NET Standard	2.0, 2.1

CreateDelegate(Type, Object, String)

Creates a delegate of the specified type that represents the specified instance method to invoke on the specified class instance.

C#

```
public static Delegate CreateDelegate (Type type, object target, string
method);
```

Parameters

`type` Type

The Type of delegate to create.

`target` Object

The class instance on which `method` is invoked.

`method` String

The name of the instance method that the delegate is to represent.

Returns

Delegate

A delegate of the specified type that represents the specified instance method to invoke on the specified class instance.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` is not an instance method.

-or-

`method` cannot be bound, for example because it cannot be found.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

This method creates delegates for instance methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

This method overload is equivalent to calling the CreateDelegate(Type, Object, String, Boolean, Boolean) method overload, specifying `false` for `ignoreCase` and `true` for `throwOnBindFailure`.

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateDelegate(Type, Object, MethodInfo)

Creates a delegate of the specified type that represents the specified static or instance method, with the specified first argument.

C#

```
public static Delegate CreateDelegate (Type type, object? firstArgument,
System.Reflection.MethodInfo method);
```

Parameters

`type` Type

The Type of delegate to create.

`firstArgument` Object

The object to which the delegate is bound, or `null` to treat `method` as `static` (`Shared` in Visual Basic).

`method` MethodInfo

The MethodInfo describing the static or instance method the delegate is to represent.

Returns

Delegate

A delegate of the specified type that represents the specified static or instance method.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` cannot be bound.

-or-

`method` is not a `RuntimeMethodInfo`. See Runtime Types in Reflection.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

Calling this method overload is equivalent to calling the CreateDelegate(Type, Object, MethodInfo, Boolean) method overload and specifying `true` for `throwOnBindFailure`. These two overloads provide the most flexible way to create delegates. You can use them to create delegates for either static or instance methods, and optionally to specify the first argument.

> ⓘ **Note**
>
> If you don't supply a first argument, use the **CreateDelegate(Type, MethodInfo)** method overload for better performance.

For more information about this API, see Supplemental API remarks for System.Delegate.CreateDelegate.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateDelegate(Type, Type, String)

Creates a delegate of the specified type that represents the specified static method of the specified class.

C#

```
public static Delegate CreateDelegate (Type type, Type target, string
method);
```

Parameters

type Type

The Type of delegate to create.

`target` Type

The Type representing the class that implements `method`.

`method` String

The name of the static method that the delegate is to represent.

Returns

Delegate

A delegate of the specified type that represents the specified static method of the specified class.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`target` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`target` is not a `RuntimeType`.

-or-

`target` is an open generic type. That is, its ContainsGenericParameters property is `true`.

-or-

`method` is not a `static` method (`Shared` method in Visual Basic).

-or-

`method` cannot be bound, for example because it cannot be found, and `throwOnBindFailure` is `true`.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

This method creates delegates for static methods only. An instance method is a method that is associated with an instance of a class; a static method is a method that is associated with the class itself.

This method overload is equivalent to calling the CreateDelegate(Type, Type, String, Boolean, Boolean) method overload, specifying `false` for `ignoreCase` and `true` for `throwOnBindFailure`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateDelegate(Type, MethodInfo)

Creates a delegate of the specified type to represent the specified method.

```
C#

public static Delegate CreateDelegate (Type type,
System.Reflection.MethodInfo method);
```

Parameters

`type` Type

The Type of delegate to create.

`method` MethodInfo

The MethodInfo describing the static or instance method the delegate is to represent.

Returns

Delegate

A delegate of the specified type to represent the specified method.

Exceptions

ArgumentNullException

`type` is `null`.

-or-

`method` is `null`.

ArgumentException

`type` does not inherit MulticastDelegate.

-or-

`type` is not a `RuntimeType`. See Runtime Types in Reflection.

-or-

`method` cannot be bound.

-or-

`method` is not a `RuntimeMethodInfo`. See Runtime Types in Reflection.

MissingMethodException

The `Invoke` method of `type` is not found.

MethodAccessException

The caller does not have the permissions necessary to access `method`.

Remarks

This overload can create delegates for static methods and open instance method delegates; that is, delegates that explicitly supply the hidden first argument of instance methods. For a detailed explanation, see the more general CreateDelegate(Type, Object, MethodInfo) method overload, which allows you to create all combinations of open or closed delegates for instance or static methods, and optionally to specify a first argument.

> **Note**
>
> This method overload should be used when the delegate is not closed over its first argument, because it is somewhat faster in that case.

For more information about this API, see Supplemental API remarks for System.Delegate.CreateDelegate.

Delegate.DynamicInvoke(Object[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Dynamically invokes (late-bound) the method represented by the current delegate.

C#

```
public object? DynamicInvoke (params object?[]? args);
```

Parameters

args Object[]

An array of objects that are the arguments to pass to the method represented by the current delegate.

-or-

`null`, if the method represented by the current delegate does not require arguments.

Returns

Object

The object returned by the method represented by the delegate.

Exceptions

TargetParameterCountException

The `args` array does not have the correct number of arguments.

ArgumentException

The elements of the `args` array do not match the signature of the delegate.

TargetInvocationException

The method represented by the delegate is an instance method and the target object is `null`.

-or-

One of the encapsulated methods throws an exception.

MemberAccessException
The caller does not have access to the method represented by the delegate (for example, if the method is private).

-or-

The number, order, or type of parameters listed in `args` is invalid.

Remarks

This method calls the DynamicInvokeImpl method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Delegate.DynamicInvokeImpl(Object[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Dynamically invokes (late-bound) the method represented by the current delegate.

C#

```
protected virtual object? DynamicInvokeImpl (object?[]? args);
```

Parameters

args Object[]

An array of objects that are the arguments to pass to the method represented by the current delegate.

-or-

`null`, if the method represented by the current delegate does not require arguments.

Returns

Object

The object returned by the method represented by the delegate.

Exceptions

TargetParameterCountException

The `args` array does not have the correct number of arguments.

ArgumentException

The elements of the `args` array do not match the signature of the delegate.

TargetInvocationException

The method represented by the delegate is an instance method and the target object is `null`.

-or-

One of the encapsulated methods throws an exception.

MemberAccessException
The caller does not have access to the method represented by the delegate (for example, if the method is private).

-or-

The number, order, or type of parameters listed in `args` is invalid.

Remarks

This method implements the DynamicInvoke method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Delegate.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified object and the current delegate are of the same type and share the same targets, methods, and invocation list.

```C#
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with the current delegate.

Returns

Boolean

`true` if `obj` and the current delegate have the same targets, methods, and invocation list; otherwise, `false`.

Exceptions

MemberAccessException

The caller does not have access to the method represented by the delegate (for example, if the method is private).

Remarks

If the two delegates are not of the same type, they are not considered equal.

The methods and targets are compared for equality as follows:

- If the two methods being compared are both static and are the same method on the same class, the methods are considered equal and the targets are also considered equal.
- If the two methods being compared are instance methods and are the same method on the same object, the methods are considered equal and the targets are also considered equal.
- Otherwise, the methods are not considered to be equal and the targets are also not considered to be equal.

Two invocation lists are considered identical only if they have the same order and the corresponding elements from the two lists represent the same method and target.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Delegate.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a hash code for the delegate.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A hash code for the delegate.

Remarks

The return value of this method must not be persisted for two reasons. First, the hash function of a class might be altered to generate a better distribution, rendering any values from the old hash function useless. Second, the default implementation of this class does not guarantee that the same value will be returned by different instances.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Delegate.GetInvocationList Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the invocation list of the delegate.

C#

```
public virtual Delegate[] GetInvocationList ();
```

Returns

Delegate[]

An array of delegates representing the invocation list of the current delegate.

Examples

The following example assigns three methods to a delegate. It then calls the GetInvocationList method to get a total count of the methods assigned to the delegate, to execute the delegates in reverse order, and to execute the methods whose name do not include the substring "File".

C#

```
using System;
using System.IO;
using System.Reflection;
using System.Windows.Forms;

public class Example
{
   public static void Main()
   {
      Action<String> outputMessage = null;
      outputMessage += Console.WriteLine;
      outputMessage += OutputToFile;
      outputMessage += ShowMessageBox;

//       Dim output1 As Action(Of String) = AddressOf Console.WriteLine
```

```
//       Dim output2 As Action(Of String) = AddressOf OutputToFile
//       Dim output3 As Action(Of String) = AddressOf MessageBox.Show
//
//       outputMessage = [Delegate].Combine( { output1, output2, output3 } )
      Console.WriteLine("Invocation list has {0} methods.",
                        outputMessage.GetInvocationList().Length);

      // Invoke delegates normally.
      outputMessage("Hello there!");
      Console.WriteLine("Press <Enter> to continue...");
      Console.ReadLine();

      // Invoke each delegate in the invocation list in reverse order.
      for (int ctr = outputMessage.GetInvocationList().Length - 1; ctr >= 0;
ctr--) {
         var outputMsg = outputMessage.GetInvocationList()[ctr];
         outputMsg.DynamicInvoke("Greetings and salutations!");
      }
      Console.WriteLine("Press <Enter> to continue...");
      Console.ReadLine();

      // Invoke each delegate that doesn't write to a file.
      for (int ctr = 0; ctr < outputMessage.GetInvocationList().Length;
ctr++) {
         var outputMsg = outputMessage.GetInvocationList()[ctr];
         if (! outputMsg.GetMethodInfo().Name.Contains("File"))
            outputMsg.DynamicInvoke( new String[] { "Hi!" } );
      }
   }

   private static void OutputToFile(String s)
   {
      var sw = new StreamWriter(@".\output.txt");
      sw.WriteLine(s);
      sw.Close();
   }

   private static void ShowMessageBox(String s)
   {
      MessageBox.Show(s);
   }
}
```

Remarks

Each delegate in the array represents exactly one method.

The order of the delegates in the array is the same order in which the current delegate invokes the methods that those delegates represent.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Delegate.GetMethodImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the method represented by the current delegate.

C#

```
protected virtual System.Reflection.MethodInfo GetMethodImpl ();
```

Returns

MethodInfo

A MethodInfo describing the method represented by the current delegate.

Exceptions

MemberAccessException

The caller does not have access to the method represented by the delegate (for example, if the method is private).

Remarks

This method implements the Method property.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Delegate.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Not supported.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public virtual void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

Not supported.

`context` StreamingContext

Not supported.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

NotSupportedException

This method is not supported.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Delegate.Remove(Delegate, Delegate) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Removes the last occurrence of the invocation list of a delegate from the invocation list of another delegate.

```
C#

public static Delegate? Remove (Delegate? source, Delegate? value);
```

Parameters

`source` Delegate

The delegate from which to remove the invocation list of `value`.

`value` Delegate

The delegate that supplies the invocation list to remove from the invocation list of `source`.

Returns

Delegate

A new delegate with an invocation list formed by taking the invocation list of `source` and removing the last occurrence of the invocation list of `value`, if the invocation list of `value` is found within the invocation list of `source`. Returns `source` if `value` is `null` or if the invocation list of `value` is not found within the invocation list of `source`. Returns a null reference if the invocation list of `value` is equal to the invocation list of `source` or if `source` is a null reference.

Exceptions

ArgumentException

The delegate types do not match.

MemberAccessException
The caller does not have access to the method represented by the delegate (for example, if the method is private).

Remarks

If the invocation list of `value` matches a contiguous set of elements in the invocation list of `source`, then the invocation list of `value` is said to occur within the invocation list of `source`. If the invocation list of `value` occurs more than once in the invocation list of `source`, the last occurrence is removed.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Delegate.RemoveAll(Delegate, Delegate) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Removes all occurrences of the invocation list of a delegate from the invocation list of another delegate.

C#

```
public static Delegate? RemoveAll (Delegate? source, Delegate? value);
```

Parameters

`source` Delegate

The delegate from which to remove the invocation list of `value`.

`value` Delegate

The delegate that supplies the invocation list to remove from the invocation list of `source`.

Returns

Delegate

A new delegate with an invocation list formed by taking the invocation list of `source` and removing all occurrences of the invocation list of `value`, if the invocation list of `value` is found within the invocation list of `source`. Returns `source` if `value` is `null` or if the invocation list of `value` is not found within the invocation list of `source`. Returns a null reference if the invocation list of `value` is equal to the invocation list of `source`, if `source` contains only a series of invocation lists that are equal to the invocation list of `value`, or if `source` is a null reference.

Exceptions

ArgumentException

The delegate types do not match.

MemberAccessException

The caller does not have access to the method represented by the delegate (for example, if the method is private).

Remarks

If the invocation list of `value` matches a contiguous set of elements in the invocation list of `source`, then the invocation list of `value` is said to occur within the invocation list of `source`. If the invocation list of `value` occurs more than once in the invocation list of `source`, all occurrences are removed.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Delegate.RemoveImpl(Delegate) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Removes the invocation list of a delegate from the invocation list of another delegate.

```
C#
protected virtual Delegate? RemoveImpl (Delegate d);
```

Parameters

d Delegate

The delegate that supplies the invocation list to remove from the invocation list of the current delegate.

Returns

Delegate

A new delegate with an invocation list formed by taking the invocation list of the current delegate and removing the invocation list of `value`, if the invocation list of `value` is found within the current delegate's invocation list. Returns the current delegate if `value` is `null` or if the invocation list of `value` is not found within the current delegate's invocation list. Returns `null` if the invocation list of `value` is equal to the current delegate's invocation list.

Exceptions

MemberAccessException

The caller does not have access to the method represented by the delegate (for example, if the method is private).

Remarks

If the invocation list of `value` matches a contiguous set of elements in the current delegate's invocation list, then the invocation list of `value` is said to occur within the current delegate's invocation list. If the invocation list of `value` occurs more than once in the current delegate's invocation list, the last occurrence is removed.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Delegate.Equality(Delegate, Delegate) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified delegates are equal.

C#

```
public static bool operator == (Delegate? d1, Delegate? d2);
```

Parameters

d1 Delegate

The first delegate to compare.

d2 Delegate

The second delegate to compare.

Returns

Boolean

`true` if `d1` is equal to `d2`; otherwise, `false`.

Remarks

Two delegates of the same type with the same targets, methods, and invocation lists are considered equal.

If the two delegates are not of the same type, they are not considered equal.

The methods and targets are compared for equality as follows:

- If the two methods being compared are both static and are the same method on the same class, the methods are considered equal and the targets are also

considered equal.

- If the two methods being compared are instance methods and are the same method on the same object, the methods are considered equal and the targets are also considered equal.
- Otherwise, the methods are not considered to be equal and the targets are also not considered to be equal.

Two invocation lists are considered identical if they have the same order and the corresponding elements from the two lists represent the same method and target.

The equivalent method for this operator is Delegate.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Delegate.Inequality(Delegate, Delegate) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified delegates are not equal.

```
C#
public static bool operator != (Delegate? d1, Delegate? d2);
```

Parameters

d1 Delegate

The first delegate to compare.

d2 Delegate

The second delegate to compare.

Returns

Boolean

`true` if `d1` is not equal to `d2`; otherwise, `false`.

Remarks

Two delegates are considered not equal if they are of different types, or have different methods, different targets, or different invocation lists.

If the two delegates are not of the same type, they are not considered equal.

The methods and targets are compared for equality as follows:

- If the two methods being compared are both static and are the same method on the same class, the methods are considered equal and the targets are also

considered equal.

- If the two methods being compared are instance methods and are the same method on the same object, the methods are considered equal and the targets are also considered equal.
- Otherwise, the methods are not considered to be equal and the targets are also not considered to be equal.

Two invocation lists are not equal if they have different sizes, if they are ordered differently, or if at least one element from one list represents a method or target that is different from that represented by its corresponding element in the other list.

The equivalent method for this operator is Delegate.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

DivideByZeroException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to divide an integral or Decimal value by zero.

C#

```
public class DivideByZeroException : ArithmeticException
```

Inheritance Object → Exception → SystemException → ArithmeticException → DivideByZeroException

Examples

The following example handles a DivideByZeroException exception in integer division.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int number1 = 3000;
      int number2 = 0;
      try {
         Console.WriteLine(number1 / number2);
      }
      catch (DivideByZeroException) {
         Console.WriteLine("Division of {0} by zero.", number1);
      }
   }
}
// The example displays the following output:
//        Division of 3000 by zero.
```

Remarks

Trying to divide an integer or Decimal number by zero throws a DivideByZeroException exception. To prevent the exception, ensure that the denominator in a division operation with integer or Decimal values is non-zero.

Dividing a floating-point value by zero doesn't throw an exception; it results in positive infinity, negative infinity, or not a number (NaN), according to the rules of IEEE 754 arithmetic. Because the following example uses floating-point division rather than integer division, the operation does not throw a DivideByZeroException exception.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int number1 = 3000;
      int number2 = 0;

      Console.WriteLine((double)number1 / number2);
   }
}
// The example displays the following output:
//        Infinity
```

For more information, see Single and Double.

The following Microsoft intermediate language (MSIL) instructions throw DivideByZeroException:

- div
- div.un
- rem
- rem.un

DivideByZeroException uses the HRESULT COR_E_DIVIDEBYZERO, which has the value 0x80020012.

For a list of initial property values for an instance of DivideByZeroException, see the DivideByZeroException constructors.

Constructors

Expand table

DivideByZeroException()	Initializes a new instance of the DivideByZeroException class.
DivideByZero Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the DivideByZeroException class with serialized data.
DivideByZeroException(String)	Initializes a new instance of the DivideByZeroException class with a specified error message.
DivideByZeroException(String, Exception)	Initializes a new instance of the DivideByZeroException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DivideByZeroException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the DivideByZeroException class.

Overloads

Expand table

DivideByZeroException()	Initializes a new instance of the DivideByZeroException class.
DivideByZeroException(String)	Initializes a new instance of the DivideByZeroException class with a specified error message.
DivideByZeroException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the DivideByZeroException class with serialized data.
DivideByZeroException(String, Exception)	Initializes a new instance of the DivideByZeroException class with a specified error message and a reference to the inner exception that is the cause of this exception.

DivideByZeroException()

Initializes a new instance of the DivideByZeroException class.

C#

```
public DivideByZeroException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to divide by zero." This message takes into account the current system culture.

The following table shows the initial property values for an instance of DivideByZeroException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DivideByZeroException(String)

Initializes a new instance of the DivideByZeroException class with a specified error message.

C#

```
public DivideByZeroException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of DivideByZeroException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

DivideByZeroException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the DivideByZeroException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected DivideByZeroException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DivideByZeroException(String, Exception)

Initializes a new instance of the DivideByZeroException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public DivideByZeroException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of DivideByZeroException.

Expand table

Property Type	Condition
InnerException	The inner exception reference.
Message	The error message string.

DllNotFoundException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.InteropServices.dll

The exception that is thrown when a DLL specified in a DLL import cannot be found.

C#

```
public class DllNotFoundException : TypeLoadException
```

Inheritance Object → Exception → SystemException → TypeLoadException → DllNotFoundException

Remarks

DllNotFoundException uses the HRESULT COR_E_DLLNOTFOUND, which has the value 0x80131524.

For a list of initial property values for an instance of DllNotFoundException, see the DllNotFoundException constructors.

The DllNotFoundException is thrown when a dynamic link library defined by the System.Runtime.InteropServices.DllImportAttribute attribute or a comparable language construct, such as the Visual Basic `Declare` statement, cannot be found. It is not thrown when the common language runtime is unable to load a .NET Framework assembly.

Note that the DllImportAttribute can specify the path to the directory in which the DLL resides. If a path is not specified, Windows uses the search order described in Dynamic-Link Library Search Order.

Constructors

Expand table

DllNotFoundException()	Initializes a new instance of the DllNotFoundException class

	with default properties.
DllNotFoundException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the DllNotFoundException class with serialized data.
DllNotFoundException(String)	Initializes a new instance of the DllNotFoundException class with a specified error message.
DllNotFoundException(String, Exception)	Initializes a new instance of the DllNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message for this exception. (Inherited from TypeLoadException)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)
TypeName	Gets the fully qualified name of the type that causes the exception. (Inherited from TypeLoadException)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the class name, method name, resource ID, and additional exception information. (Inherited from TypeLoadException)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Double Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a double-precision floating-point number.

C#

```
public readonly struct Double : IComparable<double>, IConvertible,
IEquatable<double>, IParsable<double>, ISpanParsable<double>,
IUtf8SpanParsable<double>,
System.Numerics.IAdditionOperators<double,double,double>,
System.Numerics.IAdditiveIdentity<double,double>,
System.Numerics.IBinaryFloatingPointIeee754<double>,
System.Numerics.IBinaryNumber<double>,
System.Numerics.IBitwiseOperators<double,double,double>,
System.Numerics.IComparisonOperators<double,double,bool>,
System.Numerics.IDecrementOperators<double>,
System.Numerics.IDivisionOperators<double,double,double>,
System.Numerics.IEqualityOperators<double,double,bool>,
System.Numerics.IExponentialFunctions<double>,

Remarks

For more information about this API, see Supplemental API remarks for Double.

Fields

Expand table

E	Represents the natural logarithmic base, specified by the constant, e.
Epsilon	Represents the smallest positive Double value that is greater than zero. This field is constant.
MaxValue	Represents the largest possible value of a Double. This field is constant.
MinValue	Represents the smallest possible value of a Double. This field is constant.
NaN	Represents a value that is not a number (`NaN`). This field is constant.
Negative Infinity	Represents negative infinity. This field is constant.
NegativeZero	Represents the number negative zero (-0).
Pi	Represents the ratio of the circumference of a circle to its diameter, specified by the constant, π.
PositiveInfinity	Represents positive infinity. This field is constant.
Tau	Represents the number of radians in one turn, specified by the constant, τ.

Methods

Expand table

Abs(Double)	Computes the absolute of a value.
Acos(Double)	Computes the arc-cosine of a value.
Acosh(Double)	Computes the hyperbolic arc-cosine of a value.
AcosPi(Double)	Computes the arc-cosine of a value and divides the result by `pi`.
Asin(Double)	Computes the arc-sine of a value.
Asinh(Double)	Computes the hyperbolic arc-sine of a value.
AsinPi(Double)	Computes the arc-sine of a value and divides the result by `pi`.
Atan(Double)	Computes the arc-tangent of a value.
Atan2(Double, Double)	Computes the arc-tangent of the quotient of two values.
Atan2Pi(Double, Double)	Computes the arc-tangent for the quotient of two values and divides the result by `pi`.
Atanh(Double)	Computes the hyperbolic arc-tangent of a value.
AtanPi(Double)	Computes the arc-tangent of a value and divides the result by pi.
BitDecrement(Double)	Decrements a value to the smallest value that compares less than a given value.
BitIncrement(Double)	Increments a value to the smallest value that compares greater than a given value.
Cbrt(Double)	Computes the cube-root of a value.
Ceiling(Double)	Computes the ceiling of a value.
Clamp(Double, Double, Double)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Double)	Compares this instance to a specified double-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified double-precision floating-point number.

CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.
CopySign(Double, Double)	Copies the sign of a value to the sign of another value.
Cos(Double)	Computes the cosine of a value.
Cosh(Double)	Computes the hyperbolic cosine of a value.
CosPi(Double)	Computes the cosine of a value that has been multipled by `pi`.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DegreesToRadians(Double)	Converts a given value from degrees to radians.
Equals(Double)	Returns a value indicating whether this instance and a specified Double object represent the same value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Exp(Double)	Computes `E` raised to a given power.
Exp10(Double)	Computes `10` raised to a given power.
Exp10M1(Double)	Computes `10` raised to a given power and subtracts one.
Exp2(Double)	Computes `2` raised to a given power.
Exp2M1(Double)	Computes `2` raised to a given power and subtracts one.
ExpM1(Double)	Computes `E` raised to a given power and subtracts one.
Floor(Double)	Computes the floor of a value.
FusedMultiplyAdd(Double, Double, Double)	Computes the fused multiply-add of three values.
GetHashCode()	Returns the hash code for this instance.

GetTypeCode()	Returns the TypeCode for value type Double.
Hypot(Double, Double)	Computes the hypotenuse given two values representing the lengths of the shorter sides in a right-angled triangle.
Ieee754Remainder(Double, Double)	Computes the remainder of two values as specified by IEEE 754.
ILogB(Double)	Computes the integer logarithm of a value.
IsEvenInteger(Double)	Determines if a value represents an even integral number.
IsFinite(Double)	Determines whether the specified value is finite (zero, subnormal, or normal).
IsInfinity(Double)	Returns a value indicating whether the specified number evaluates to negative or positive infinity.
IsInteger(Double)	Determines if a value represents an integral value.
IsNaN(Double)	Returns a value that indicates whether the specified value is not a number (NaN).
IsNegative(Double)	Determines whether the specified value is negative.
IsNegativeInfinity(Double)	Returns a value indicating whether the specified number evaluates to negative infinity.
IsNormal(Double)	Determines whether the specified value is normal.
IsOddInteger(Double)	Determines if a value represents an odd integral number.
IsPositive(Double)	Determines if a value is positive.
IsPositiveInfinity(Double)	Returns a value indicating whether the specified number evaluates to positive infinity.
IsPow2(Double)	Determines if a value is a power of two.
IsRealNumber(Double)	Determines if a value represents a real number.
IsSubnormal(Double)	Determines whether the specified value is subnormal.
Lerp(Double, Double, Double)	Performs a linear interpolation between two values based on the given weight.
Log(Double)	Computes the natural (`base-E` logarithm of a value.
Log(Double, Double)	Computes the logarithm of a value in the specified base.
Log10(Double)	Computes the base-10 logarithm of a value.
Log10P1(Double)	Computes the base-10 logarithm of a value plus one.

Log2(Double)	Computes the log2 of a value.
Log2P1(Double)	Computes the base-2 logarithm of a value plus one.
LogP1(Double)	Computes the natural (`base-E`) logarithm of a value plus one.
Max(Double, Double)	Compares two values to compute which is greater.
MaxMagnitude(Double, Double)	Compares two values to compute which is greater.
MaxMagnitudeNumber(Double, Double)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
MaxNumber(Double, Double)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
Min(Double, Double)	Compares two values to compute which is lesser.
MinMagnitude(Double, Double)	Compares two values to compute which is lesser.
MinMagnitudeNumber(Double, Double)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
MinNumber(Double, Double)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts a character span that contains the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent.
Parse(String)	Converts the string representation of a number to its double-precision floating-point number equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its double-precision floating-point number equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its double-precision floating-point

	number equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent.
Pow(Double, Double)	Computes a value raised to a given power.
RadiansToDegrees(Double)	Converts a given value from radians to degrees.
ReciprocalEstimate(Double)	Computes an estimate of the reciprocal of a value.
ReciprocalSqrtEstimate(Double)	Computes an estimate of the reciprocal square root of a value.
RootN(Double, Int32)	Computes the n-th root of a value.
Round(Double)	Rounds a value to the nearest integer using the default rounding mode (ToEven).
Round(Double, Int32)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Double, Int32, MidpointRounding)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Double, MidpointRounding)	Rounds a value to the nearest integer using the specified rounding mode.
ScaleB(Double, Int32)	Computes the product of a value and its base-radix raised to the specified power.
Sign(Double)	Computes the sign of a value.
Sin(Double)	Computes the sine of a value.
SinCos(Double)	Computes the sine and cosine of a value.
SinCosPi(Double)	Computes the sine and cosine of a value.
Sinh(Double)	Computes the hyperbolic sine of a value.
SinPi(Double)	Computes the sine of a value that has been multiplied by `pi`.
Sqrt(Double)	Computes the square-root of a value.
Tan(Double)	Computes the tangent of a value.
Tanh(Double)	Computes the hyperbolic tangent of a value.
TanPi(Double)	Computes the tangent of a value that has been multipled by `pi`.

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
Truncate(Double)	Truncates a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current double instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, Double)	Tries to convert a UTF-8 character span containing the string representation of a number to its double-precision floating-point number equivalent.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Double)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Double)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Double)	Converts the span representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Double)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Double)	Converts a character span containing the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Double)	Converts the string representation of a number to its double-precision floating-point number equivalent. A

	return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, Double)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, Double)	Converts the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Operators

Expand table

Equality(Double, Double)	Returns a value that indicates whether two specified Double values are equal.
GreaterThan(Double, Double)	Returns a value that indicates whether a specified Double value is greater than another specified Double value.
GreaterThan OrEqual(Double, Double)	Returns a value that indicates whether a specified Double value is greater than or equal to another specified Double value.
Inequality(Double, Double)	Returns a value that indicates whether two specified Double values are not equal.
LessThan(Double, Double)	Returns a value that indicates whether a specified Double value is less than another specified Double value.
LessThanOrEqual(Double, Double)	Returns a value that indicates whether a specified Double value is less than or equal to another specified Double value.

Explicit Interface Implementations

Expand table

IAddition Operators<Double,Double,Double>.Addition(Double, Double)	Adds two values together to compute their sum.
IAdditiveIdentity<Double,Double>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryNumber<Double>.AllBitsSet	Gets an instance of the binary type in which all bits are set.

IBitwiseOperators<Double,Double,Double>.BitwiseAnd(Double, Double)	Computes the bitwise-and of two values.
IBitwiseOperators<Double,Double,Double>.BitwiseOr(Double, Double)	Computes the bitwise-or of two values.
IBitwiseOperators<Double,Double,Double>.ExclusiveOr(Double, Double)	Computes the exclusive-or of two values.
IBitwiseOperators<Double,Double,Double>.OnesComplement(Double)	Computes the ones-complement representation of a given value.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).

IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<Double>.Decrement(Double)	Decrements a value.
IDivisionOperators<Double,Double,Double>.Division(Double, Double)	Divides one value by another to compute their quotient.
IFloatingPoint<Double>.GetExponentByteCount()	Gets the number of bytes that will be written as part of TryWriteExponentLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Double>.GetExponentShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current exponent.
IFloatingPoint<Double>.GetSignificandBitLength()	Gets the length, in bits, of the current significand.
IFloatingPoint<Double>.GetSignificandByteCount()	Gets the number of bytes that will be written as part of TryWriteSignificandLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Double>.TryWriteExponentBigEndian(Span<Byte>, Int32)	Tries to write the current exponent, in big-endian format, to a given span.
IFloatingPoint<Double>.TryWriteExponentLittleEndian(Span<Byte>, Int32)	Tries to write the current exponent, in little-endian format, to a given span.
IFloatingPoint<Double>.TryWriteSignificandBigEndian(Span<Byte>, Int32)	Tries to write the current significand, in big-endian format, to a given span.
IFloatingPoint<Double>.TryWriteSignificandLittleEndian(Span<Byte>, Int32)	Tries to write the current significand, in little-endian format, to a given span.
IFloatingPointConstants<Double>.E	Gets the mathematical constant `e`.
IFloatingPointConstants<Double>.Pi	Gets the mathematical constant `pi`.

IFloatingPointConstants<Double>.Tau	Gets the mathematical constant `tau`.
IFloatingPointIeee754<Double>.Epsilon	Gets the smallest value such that can be added to `0` that does not result in `0`.
IFloatingPointIeee754<Double>.NaN	Gets a value that represents `NaN`.
IFloatingPointIeee754<Double>.NegativeInfinity	Gets a value that represents negative `infinity`.
IFloatingPointIeee754<Double>.NegativeZero	Gets a value that represents negative `zero`.
IFloatingPointIeee754<Double>.PositiveInfinity	Gets a value that represents positive `infinity`.
IIncrementOperators<Double>.Increment(Double)	Increments a value.
IMinMaxValue<Double>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Double>.MinValue	Gets the minimum value of the current type.
IModulus Operators<Double,Double,Double>.Modulus(Double, Double)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Double,Double>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiply Operators<Double,Double,Double>.Multiply(Double, Double)	Multiplies two values together to compute their product.
INumberBase<Double>.IsCanonical(Double)	Determines if a value is in its canonical representation.
INumberBase<Double>.IsComplexNumber(Double)	Determines if a value represents a complex number.
INumberBase<Double>.IsImaginaryNumber(Double)	Determines if a value represents a pure imaginary number.
INumberBase<Double>.IsZero(Double)	Determines if a value is zero.
INumberBase<Double>.One	Gets the value `1` for the type.
INumberBase<Double>.Radix	Gets the radix, or base, for the type.

INumberBase<Double>.TryConvertFromChecked<TOther>(TOther, Double)	
INumberBase<Double>.TryConvertFromSaturating<TOther>(TOther, Double)	
INumberBase<Double>.TryConvertFromTruncating<TOther>(TOther, Double)	
INumberBase<Double>.TryConvertToChecked<TOther>(Double, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Double>.TryConvertToSaturating<TOther>(Double, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Double>.TryConvertToTruncating<TOther>(Double, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Double>.Zero	Gets the value `0` for the type.
ISignedNumber<Double>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<Double,Double,Double>.Subtraction(Double, Double)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Double,Double>.UnaryNegation(Double)	Computes the unary negation of a value.
IUnaryPlusOperators<Double,Double>.UnaryPlus(Double)	Computes the unary plus of a value.

Applies to

Product	Versions

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Double.E Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the natural logarithmic base, specified by the constant, e.

C#

```
public const double E = 2.7182818284590451;
```

Field Value

***Value** = 2.7182818284590451*

Double

Remarks

Euler's number is approximately 2.7182818284590452354.

Applies to

Product	Versions
.NET	7, 8, 9

Double.Epsilon Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest positive Double value that is greater than zero. This field is constant.

C#

```
public const double Epsilon = 4.94065645841247E-324;
```

Field Value

Value = 4.94065645841247E-324

Double

Remarks

For more information about this API, see Supplemental API remarks for Double.Epsilon.

Applies to

Double.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of a Double. This field is constant.

C#

```
public const double MaxValue = 1.7976931348623157E+308;
```

Field Value

***Value** = 1.7976931348623157E+308*

Double

Examples

The following code example illustrates the use of Double.MaxValue:

C#

```
public class Temperature {
    public static double MinValue {
        get {
            return Double.MinValue;
        }
    }

    public static double MaxValue {
        get {
            return Double.MaxValue;
        }
    }

    // The value holder
    protected double m_value;

    public double Value {
        get {
            return m_value;
        }
```

```
        set {
            m_value = value;
        }
    }

    public double Celsius {
        get {
            return (m_value-32.0)/1.8;
        }
        set {
            m_value = 1.8*value+32.0;
        }
    }
}
```

Remarks

The value of this constant is positive 1.7976931348623157E+308.

The result of an operation that exceeds Double.MaxValue is Double.PositiveInfinity. In the following example, Double.PositiveInfinity results from addition, multiplication, and exponentiation operations when the result exceeds Double.MaxValue.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double result1 = 7.997e307 + 9.985e307;
      Console.WriteLine("{0} (Positive Infinity: {1})",
                        result1, Double.IsPositiveInfinity(result1));

      double result2 = 1.5935e250 * 7.948e110;
      Console.WriteLine("{0} (Positive Infinity: {1})",
                        result2, Double.IsPositiveInfinity(result2));

      double result3 = Math.Pow(1.256e100, 1.34e20);
      Console.WriteLine("{0} (Positive Infinity: {1})",
                        result3, Double.IsPositiveInfinity(result3));
   }
}
// The example displays the following output:
//    Infinity (Positive Infinity: True)
//    Infinity (Positive Infinity: True)
//    Infinity (Positive Infinity: True)
```

Applies to

Product	Versions

Double.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of a Double. This field is constant.

C#

```
public const double MinValue = -1.7976931348623157E+308;
```

Field Value

Value* = *-1.7976931348623157E+308

Double

Examples

The following code example illustrates the use of Double.MinValue:

C#

```
public class Temperature {
    public static double MinValue {
        get {
            return Double.MinValue;
        }
    }

    public static double MaxValue {
        get {
            return Double.MaxValue;
        }
    }

    // The value holder
    protected double m_value;

    public double Value {
        get {
            return m_value;
        }
```

```
        set {
            m_value = value;
        }
    }

    public double Celsius {
        get {
            return (m_value-32.0)/1.8;
        }
        set {
            m_value = 1.8*value+32.0;
        }
    }
}
```

Remarks

The value of this constant is negative 1.7976931348623157E+308.

The result of an operation that is less than Double.MinValue is Double.NegativeInfinity. In the following example, Double.NegativeInfinity results from subtraction and multiplication operations when the result is less than Double.MinValue.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double result1 = -7.997e307 + -9.985e307;
      Console.WriteLine("{0} (Negative Infinity: {1})",
                        result1, Double.IsNegativeInfinity(result1));

      double result2 = -1.5935e250 * 7.948e110;
      Console.WriteLine("{0} (Negative Infinity: {1})",
                        result2, Double.IsNegativeInfinity(result2));
   }
}
// The example displays the following output:
//    -Infinity (Negative Infinity: True)
//    -Infinity (Negative Infinity: True)
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.NaN Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value that is not a number (`NaN`). This field is constant.

C#

```
public const double NaN = NaN;
```

Field Value

Value* = *NaN

Double

Examples

The following example illustrates the use of NaN:

C#

```
Double zero = 0;

// This condition will return false.
if ((0 / zero) == Double.NaN)
   Console.WriteLine("0 / 0 can be tested with Double.NaN.");
else
   Console.WriteLine("0 / 0 cannot be tested with Double.NaN; use
Double.IsNan() instead.");
```

Remarks

A method or operator returns NaN when the result of an operation is undefined. For example, the result of dividing zero by zero is NaN, as the following example shows. (But note that dividing a non-zero number by zero returns either PositiveInfinity or NegativeInfinity, depending on the sign of the divisor.)

C#

```
double zero = 0.0;
Console.WriteLine("{0} / {1} = {2}", zero, zero, zero/zero);
// The example displays the following output:
//         0 / 0 = NaN
```

In addition, a method call with a NaN value or an operation on a NaN value returns NaN, as the following example shows.

C#

```
double nan1 = Double.NaN;

Console.WriteLine("{0} + {1} = {2}", 3, nan1, 3 + nan1);
Console.WriteLine("Abs({0}) = {1}", nan1, Math.Abs(nan1));
// The example displays the following output:
//       3 + NaN = NaN
//       Abs(NaN) = NaN
```

Use the IsNaN method to determine whether a value is not a number. The Equality operator considers two NaN values to be unequal to one another. In general, Double operators cannot be used to compare Double.NaN with other Double values, although comparison methods (such as Equals and CompareTo) can. The following example illustrates the difference in behavior between Double comparison operators and methods.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("NaN == NaN: {0}", Double.NaN == Double.NaN);
      Console.WriteLine("NaN != NaN: {0}", Double.NaN != Double.NaN);
      Console.WriteLine("NaN.Equals(NaN): {0}",
Double.NaN.Equals(Double.NaN));
      Console.WriteLine("! NaN.Equals(NaN): {0}", !
Double.NaN.Equals(Double.NaN));
      Console.WriteLine("IsNaN: {0}", Double.IsNaN(Double.NaN));

      Console.WriteLine("\nNaN > NaN: {0}", Double.NaN > Double.NaN);
      Console.WriteLine("NaN >= NaN: {0}", Double.NaN >= Double.NaN);
      Console.WriteLine("NaN < NaN: {0}", Double.NaN < Double.NaN);
      Console.WriteLine("NaN < 100.0: {0}", Double.NaN < 100.0);
      Console.WriteLine("NaN <= 100.0: {0}", Double.NaN <= 100.0);
      Console.WriteLine("NaN >= 100.0: {0}", Double.NaN > 100.0);
```

```
        Console.WriteLine("NaN.CompareTo(NaN): {0}",
Double.NaN.CompareTo(Double.NaN));
        Console.WriteLine("NaN.CompareTo(100.0): {0}",
Double.NaN.CompareTo(100.0));
        Console.WriteLine("(100.0).CompareTo(Double.NaN): {0}",
(100.0).CompareTo(Double.NaN));
    }
}
// The example displays the following output:
//       NaN == NaN: False
//       NaN != NaN: True
//       NaN.Equals(NaN): True
//       ! NaN.Equals(NaN): False
//       IsNaN: True
//
//       NaN > NaN: False
//       NaN >= NaN: False
//       NaN < NaN: False
//       NaN < 100.0: False
//       NaN <= 100.0: False
//       NaN >= 100.0: False
//       NaN.CompareTo(NaN): 0
//       NaN.CompareTo(100.0): -1
//       (100.0).CompareTo(Double.NaN): 1
```

Applies to

Product	Versions

Double.NegativeInfinity Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents negative infinity. This field is constant.

C#

```
public const double NegativeInfinity = -Infinity;
```

Field Value

Value* = *-Infinity

Double

Examples

The following code example illustrates the use of NegativeInfinity:

C#

```
// This will equal Infinity.
Console.WriteLine("10.0 minus NegativeInfinity equals {0}.", (10.0 -
Double.NegativeInfinity).ToString());
```

Remarks

The value of this constant is the result of dividing a negative number by zero.

This constant is returned when the result of an operation is less than Double.MinValue.

Use IsNegativeInfinity to determine whether a value evaluates to negative infinity.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.Pi Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the ratio of the circumference of a circle to its diameter, specified by the constant, π.

```
C#
public const double Pi = 3.1415926535897931;
```

Field Value

Value = 3.1415926535897931

Double

Remarks

Pi is approximately 3.1415926535897932385.

Applies to

Product	Versions
.NET	7, 8, 9

Double.PositiveInfinity Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents positive infinity. This field is constant.

```
C#

public const double PositiveInfinity = Infinity;
```

Field Value

Value* = *Infinity

Double

Examples

The following code example illustrates the use of PositiveInfinity:

```
C#

// This will equal Infinity.
Console.WriteLine("PositiveInfinity plus 10.0 equals {0}.",
(Double.PositiveInfinity + 10.0).ToString());
```

Remarks

The value of this constant is the result of dividing a positive number by zero.

This constant is returned when the result of an operation is greater than Double.MaxValue.

Use IsPositiveInfinity to determine whether a value evaluates to positive infinity.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.Tau Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of radians in one turn, specified by the constant, τ.

C#

```
public const double Tau = 6.2831853071795862;
```

Field Value

Value* = *6.2831853071795862

Double

Remarks

Tau is approximately 6.2831853071795864769.

Double.Abs(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static double Abs (double value);
```

Parameters

`value` Double

The value for which to get its absolute.

Returns

Double

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Acos(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-cosine of a value.

C#

```
public static double Acos (double x);
```

Parameters

x Double

The value, in radians, whose arc-cosine is to be computed.

Returns

Double

The arc-cosine of `x`.

Implements

Acos(TSelf)

Remarks

This computes `arccos(x)` in the interval `[+0, +π]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Acosh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic arc-cosine of a value.

C#

```
public static double Acosh (double x);
```

Parameters

x Double

The value, in radians, whose hyperbolic arc-cosine is to be computed.

Returns

Double

The hyperbolic arc-cosine of `x`.

Implements

Acosh(TSelf)

Applies to

Double.AcosPi(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-cosine of a value and divides the result by `pi`.

```
C#
public static double AcosPi (double x);
```

Parameters

x Double

The value whose arc-cosine is to be computed.

Returns

Double

The arc-cosine of `x`, divided by `pi`.

Implements

AcosPi(TSelf)

Remarks

This computes `arccos(x) / π` in the interval `[-0.5, +0.5]`.

Applies to

Product	Versions
.NET	7, 8, 9

Double.Asin(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-sine of a value.

C#

```
public static double Asin (double x);
```

Parameters

x Double

The value, in radians, whose arc-sine is to be computed.

Returns

Double

The arc-sine of `x`.

Implements

Asin(TSelf)

Remarks

This computes `arcsin(x)` in the interval `[-π / 2, +π / 2]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Double.Atan(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of a value.

C#

```
public static double Atan (double x);
```

Parameters

x Double

The value, in radians, whose arc-tangent is to be computed.

Returns

Double

The arc-tangent of `x`.

Implements

Atan(TSelf)

Remarks

This computes `arctan(x)` in the interval `[-π / 2, +π / 2]` radians.

Applies to

Product	Versions

Double.Atan2(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of the quotient of two values.

```
C#
public static double Atan2 (double y, double x);
```

Parameters

y Double

The y-coordinate of a point.

x Double

The x-coordinate of a point.

Returns

Double

The arc-tangent of `y` divided-by `x`.

Implements

Atan2(TSelf, TSelf)

Remarks

This computes `arctan(y / x)` in the interval `[-π, +π]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Atan2Pi(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent for the quotient of two values and divides the result by `pi`.

```
C#
public static double Atan2Pi (double y, double x);
```

Parameters

y Double

The y-coordinate of a point.

x Double

The x-coordinate of a point.

Returns

Double

The arc-tangent of `y` divided-by `x`, divided by `pi`.

Implements

Atan2Pi(TSelf, TSelf)

Remarks

This computes `arctan(y / x) / π` in the interval `[-1, +1]`.

Applies to

Product	Versions
.NET	7, 8, 9

Double.BitDecrement(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value to the smallest value that compares less than a given value.

C#

```
public static double BitDecrement (double x);
```

Parameters

x Double

The value to be bitwise decremented.

Returns

Double

The smallest value that compares less than `x`.

Implements

BitDecrement(TSelf)

Applies to

Double.BitIncrement(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value to the smallest value that compares greater than a given value.

C#

```
public static double BitIncrement (double x);
```

Parameters

x Double

The value to be bitwise incremented.

Returns

Double

The smallest value that compares greater than `x`.

Implements

BitIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Cbrt(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cube-root of a value.

```
C#
public static double Cbrt (double x);
```

Parameters

x Double

The value whose cube-root is to be computed.

Returns

Double

The cube-root of `x`.

Implements

Cbrt(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Ceiling(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ceiling of a value.

C#

```
public static double Ceiling (double x);
```

Parameters

x Double

The value whose ceiling is to be computed.

Returns

Double

The ceiling of `x`.

Implements

Ceiling(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Clamp(Double, Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static double Clamp (double value, double min, double max);
```

Parameters

`value` Double

The value to clamp.

`min` Double

The inclusive minimum to which `value` should clamp.

`max` Double

The inclusive maximum to which `value` should clamp.

Returns

Double

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or Double object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object or Double object.

Overloads

Expand table

CompareTo(Double)	Compares this instance to a specified double-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified double-precision floating-point number.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.

CompareTo(Double)

Compares this instance to a specified double-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified double-precision floating-point number.

C#

```
public int CompareTo (double value);
```

Parameters

`value` Double

A double-precision floating-point number to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`, or this instance is not a number (NaN) and `value` is a number.
Zero	This instance is equal to `value`, or both this instance and `value` are not a number (NaN), PositiveInfinity, or NegativeInfinity.
Greater than zero	This instance is greater than `value`, or this instance is a number and `value` is not a number (NaN).

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";
```

```
    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;
    Int16    c1 = -2,    c2 = 2;
    Int32    d1 = 3,     d2 = 3;
    Int64    e1 = 4,     e2 = -4;
    Decimal  f1 = -5.5m, f2 = 5.5m;
    Single   g1 = 6.6f,  g2 = 6.6f;
    Double   h1 = 7.7d,  h2 = -7.7d;
    Char     i1 = 'A',   i2 = 'A';
    String   j1 = "abc", j2 = "abc";
    DateTime k1 = now,   k2 = now;
    TimeSpan l1 = tsX,   l2 = tsX;
    Version  m1 = versX, m2 = new Version("2.0");
    Guid     n1 = guidX, n2 = guidX;

// The following types are not CLS-compliant.
    SByte    w1 = 8,     w2 = 8;

        Show("UInt16:   ", x1, x2, x1.CompareTo(x2),
x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
```

```
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Value	Description
A negative integer	This instance is less than `value`, or this instance is not a number (NaN) and `value` is a number.
Zero	This instance is equal to `value`, or this instance and `value` are both `Double.NaN`, PositiveInfinity, or NegativeInfinity
A positive integer	This instance is greater than `value`, OR this instance is a number and `value` is not a number (NaN), OR `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a Double.

Examples

The following code example illustrates the use of `CompareTo` in the context of `Double`.

C#

```
obj1 = (Double)450;

if (a.CompareTo(obj1) < 0)
   Console.WriteLine("{0} is less than {1}.", a.ToString(),
obj1.ToString());

if (a.CompareTo(obj1) > 0)
   Console.WriteLine("{0} is greater than {1}.", a.ToString(),
obj1.ToString());

if (a.CompareTo(obj1) == 0)
   Console.WriteLine("{0} equals {1}.", a.ToString(), obj1.ToString());
```

Remarks

For more information about this API, see Double.CompareTo.

Double.CopySign(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
public static double CopySign (double value, double sign);
```

Parameters

`value` Double

The value whose magnitude is used in the result.

`sign` Double

The value whose sign is used in the result.

Returns

Double

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Cos(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cosine of a value.

```
C#
public static double Cos (double x);
```

Parameters

x Double

The value, in radians, whose cosine is to be computed.

Returns

Double

The cosine of `x`.

Implements

Cos(TSelf)

Remarks

This computes `cos(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Cosh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic cosine of a value.

C#

```
public static double Cosh (double x);
```

Parameters

x Double

The value, in radians, whose hyperbolic cosine is to be computed.

Returns

Double

The hyperbolic cosine of `x`.

Implements

Cosh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.CosPi(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cosine of a value that has been multipled by `pi`.

```
C#
public static double CosPi (double x);
```

Parameters

x Double

The value, in half-revolutions, whose cosine is to be computed.

Returns

Double

The cosine of `x` multiplied-by `pi`.

Implements

CosPi(TSelf)

Remarks

This computes `cos(x * π)`.

Applies to

Product	Versions
.NET	7, 8, 9

Double.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static double CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Double

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Double.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static double CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Double

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

```
C#

public static double CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Double

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.DegreesToRadians(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a given value from degrees to radians.

C#

```
public static double DegreesToRadians (double degrees);
```

Parameters

`degrees` Double

The value to convert to radians.

Returns

Double

The value of `degrees` converted to radians.

Implements

DegreesToRadians(TSelf)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Double.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two instances of Double represent the same value.

Overloads

Expand table

Equals(Double)	Returns a value indicating whether this instance and a specified Double object represent the same value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(Double)

Returns a value indicating whether this instance and a specified Double object represent the same value.

```
C#

public bool Equals (double obj);
```

Parameters

obj Double

A Double object to compare to this instance.

Returns

Boolean

`true` if `obj` is equal to this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

For more information about this API, see Supplemental API remarks for Double.Equals.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Object) method overloads. If an implicit conversion between the `obj` argument and a Double is defined and the argument is not typed as an Object, compilers may perform an implicit conversion and call the Equals(Double) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a Double value. The following example illustrates the difference in behavior between the two method overloads. In the case of all primitive numeric types except for Decimal and in C#, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Double) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static double value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,16}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,18}", value.Equals(int1));
      TestObjectForEquality(int1);

      long long1 = 112;
      Console.WriteLine("value = long1: {0,17}", value.Equals(long1));
```

```
        TestObjectForEquality(long1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,16}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,18}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,17}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        float sng1 = 112;
        Console.WriteLine("value = sng1: {0,19}", value.Equals(sng1));
        TestObjectForEquality(sng1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (Double) = 112 (Byte): False
//
//       value = short1:             True
//       112 (Double) = 112 (Int16): False
//
//       value = int1:               True
//       112 (Double) = 112 (Int32): False
//
//       value = long1:              True
//       112 (Double) = 112 (Int64): False
//
//       value = sbyte1:             True
//       112 (Double) = 112 (SByte): False
//
//       value = ushort1:             True
//       112 (Double) = 112 (UInt16): False
//
```

```
//       value = uint1:                True
//       112 (Double) = 112 (UInt32): False
//
//       value = ulong1:               True
//       112 (Double) = 112 (UInt64): False
//
//       value = dec1:                  False
//       112 (Double) = 112 (Decimal): False
//
//       value = sng1:                 True
//       112 (Double) = 112 (Single): False
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is an instance of Double and equals the value of this instance; otherwise, `false`.

Remarks

The Equals method should be used with caution, because two apparently equivalent values can be unequal due to the differing precision of the two values. The following example reports that the Double value .3333 and the Double returned by dividing 1 by 3 are unequal.

```C#
// Initialize two doubles with apparently identical values
double double1 = .33333;
object double2 = (double) 1/3;
// Compare them for equality
Console.WriteLine(double1.Equals(double2));    // displays false
```

For alternatives to calling the Equals method, see the documentation for the Equals(Double) overload.

> **Note**
>
> Because **Epsilon** defines the minimum expression of a positive value whose range is near zero, the margin of difference between two similar values must be greater than **Epsilon**. Typically, it is many times greater than **Epsilon**.

The precision of floating-point numbers beyond the documented precision is specific to the implementation and version of the .NET Framework. Consequently, a comparison of two particular numbers might change between versions of the .NET Framework because the precision of the numbers' internal representation might change.

If two Double.NaN values are tested for equality by calling the Equals method, the method returns `true`. However, if two NaN values are tested for equality by using the equality operator, the operator returns `false`. When you want to determine

whether the value of a Double is not a number (NaN), an alternative is to call the IsNaN method.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Object) method overloads. If an implicit conversion between the `obj` argument and a Double is defined and the argument is not typed as an Object, compilers may perform an implicit conversion and call the Equals(Double) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a Double value. The following example illustrates the difference in behavior between the two method overloads. In the case of all primitive numeric types except for Decimal and in C#, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Double) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static double value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,16}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,18}", value.Equals(int1));
      TestObjectForEquality(int1);

      long long1 = 112;
      Console.WriteLine("value = long1: {0,17}", value.Equals(long1));
      TestObjectForEquality(long1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,16}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);

      ushort ushort1 = 112;
```

```
        Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,18}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,17}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        float sng1 = 112;
        Console.WriteLine("value = sng1: {0,19}", value.Equals(sng1));
        TestObjectForEquality(sng1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (Double) = 112 (Byte): False
//
//       value = short1:             True
//       112 (Double) = 112 (Int16): False
//
//       value = int1:               True
//       112 (Double) = 112 (Int32): False
//
//       value = long1:              True
//       112 (Double) = 112 (Int64): False
//
//       value = sbyte1:             True
//       112 (Double) = 112 (SByte): False
//
//       value = ushort1:             True
//       112 (Double) = 112 (UInt16): False
//
//       value = uint1:               True
//       112 (Double) = 112 (UInt32): False
//
//       value = ulong1:              True
//       112 (Double) = 112 (UInt64): False
//
//       value = dec1:                 False
```

```
//       112 (Double) = 112 (Decimal): False
//
//       value = sng1:                 True
//       112 (Double) = 112 (Single): False
```

Double.Exp(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `E` raised to a given power.

```
C#
public static double Exp (double x);
```

Parameters

x Double

The power to which `E` is raised.

Returns

Double

`E` raised to the power of `x`.

Implements

Exp(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Exp10(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `10` raised to a given power.

```
C#
public static double Exp10 (double x);
```

Parameters

x Double

The power to which `10` is raised.

Returns

Double

10^x

Implements

Exp10(TSelf)

Applies to

Double.Exp10M1(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `10` raised to a given power and subtracts one.

```
C#
public static double Exp10M1 (double x);
```

Parameters

x Double

The power to which `10` is raised.

Returns

Double

`10ˣ - 1`

Implements

Exp10M1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Exp2(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `2` raised to a given power.

```
C#
public static double Exp2 (double x);
```

Parameters

x Double

The power to which `2` is raised.

Returns

Double

2^x

Implements

Exp2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Floor(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the floor of a value.

C#

```
public static double Floor (double x);
```

Parameters

x Double

The value whose floor is to be computed.

Returns

Double

The floor of `x`.

Implements

Floor(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.FusedMultiplyAdd(Double, Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the fused multiply-add of three values.

```
C#

public static double FusedMultiplyAdd (double left, double right, double
addend);
```

Parameters

`left` Double

The value which `right` multiplies.

`right` Double

The value which multiplies `left`.

`addend` Double

The value that is added to the product of `left` and `right`.

Returns

Double

The result of `left` times `right` plus `addend` computed as one ternary operation.

Implements

FusedMultiplyAdd(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Double.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Double.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Double.Hypot(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hypotenuse given two values representing the lengths of the shorter sides in a right-angled triangle.

```
C#
public static double Hypot (double x, double y);
```

Parameters

x Double

The value to square and add to `y`.

y Double

The value to square and add to `x`.

Returns

Double

The square root of `x`-squared plus `y`-squared.

Implements

Hypot(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Ieee754Remainder(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the remainder of two values as specified by IEEE 754.

```
C#
public static double Ieee754Remainder (double left, double right);
```

Parameters

`left` Double

The value which `right` divides.

`right` Double

The value which divides `left`.

Returns

Double

The remainder of `left` divided-by `right` as specified by IEEE 754.

Implements

Ieee754Remainder(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.ILogB(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the integer logarithm of a value.

C#

```
public static int ILogB (double x);
```

Parameters

x Double

The value whose integer logarithm is to be computed.

Returns

Int32

The integer logarithm of `x`.

Implements

ILogB(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Double.IsEvenInteger(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (double value);
```

Parameters

value Double

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Double.IsFinite(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is finite (zero, subnormal, or normal).

C#

```
public static bool IsFinite (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if the value is finite (zero, subnormal or normal); `false` otherwise.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Double.IsInfinity(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to negative or positive infinity.

```C#
public static bool IsInfinity (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if `d` evaluates to PositiveInfinity or NegativeInfinity; otherwise, `false`.

Implements

IsInfinity(TSelf)

Examples

The following code example illustrates the use of IsInfinity:

```C#
// This will return "true".
Console.WriteLine("IsInfinity(3.0 / 0) == {0}.", Double.IsInfinity(3.0 / 0)
? "true" : "false");
```

Remarks

Floating-point operations return PositiveInfinity or NegativeInfinity to signal an overflow condition.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.IsInteger(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral value.

```
C#
public static bool IsInteger (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` and `3.0` will return `true` while `2.2` and `3.3` will return `false`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Double.IsNaN(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the specified value is not a number (NaN).

C#

```
public static bool IsNaN (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if `d` evaluates to NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Examples

The following code example illustrates the use of IsNaN:

C#

```
// This will return true.
if (Double.IsNaN(0 / zero))
   Console.WriteLine("Double.IsNan() can determine whether a value is not-a-
number.");
```

Remarks

Floating-point operations return NaN to signal that result of the operation is undefined. For example, dividing 0.0 by 0.0 results in NaN.

> **Note**
>
> IsNaN returns `false` if a Double value is either PositiveInfinity or NegativeInfinity. To test for these values, use the IsInfinity, IsPositiveInfinity, and IsNegativeInfinity methods.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.IsNegative(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is negative.

C#

```
public static bool IsNegative (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if the value is negative; `false` otherwise.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Double.IsNegativeInfinity(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to negative infinity.

C#

```
public static bool IsNegativeInfinity (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if `d` evaluates to NegativeInfinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Examples

The following code example illustrates the use of IsNegativeInfinity:

C#

```
// This will return "true".
Console.WriteLine("IsNegativeInfinity(-5.0 / 0) == {0}.",
Double.IsNegativeInfinity(-5.0 / 0) ? "true" : "false");
```

C#

```
if (d > Double.MaxValue)
   Console.WriteLine("Your number is bigger than a double.");
```

C#

```
// This will equal Infinity.
Console.WriteLine("10.0 minus NegativeInfinity equals {0}.", (10.0 -
Double.NegativeInfinity).ToString());
```

Remarks

Floating-point operations return NegativeInfinity to signal an overflow condition.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.IsNormal(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is normal.

C#

```
public static bool IsNormal (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if the value is normal; `false` otherwise.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Double.IsOddInteger(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (double value);
```

Parameters

value Double

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IsPositive(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IsPositiveInfinity(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to positive infinity.

C#

```
public static bool IsPositiveInfinity (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if `d` evaluates to PositiveInfinity; otherwise, `false`.

Implements

IsPositiveInfinity(TSelf)

Examples

The following code example illustrates the use of IsPositiveInfinity:

C#

```
// This will return "true".
Console.WriteLine("IsPositiveInfinity(4.0 / 0) == {0}.",
Double.IsPositiveInfinity(4.0 / 0) ? "true" : "false");
```

Remarks

Floating-point operations return PositiveInfinity to signal an overflow condition.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IsPow2(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IsRealNumber(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
public static bool IsRealNumber (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Remarks

This function returns `true` for a complex number `a + bi` where `b` is zero.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IsSubnormal(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is subnormal.

C#

```
public static bool IsSubnormal (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Boolean

`true` if the value is subnormal; `false` otherwise.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Double.Lerp(Double, Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Performs a linear interpolation between two values based on the given weight.

C#

```
public static double Lerp (double value1, double value2, double amount);
```

Parameters

`value1` Double

The first value, which is intended to be the lower bound.

`value2` Double

The second value, which is intended to be the upper bound.

`amount` Double

A value, intended to be between 0 and 1, that indicates the weight of the interpolation.

Returns

Double

The interpolated value.

Implements

Lerp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Double.Log Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Log(Double, Double)	Computes the logarithm of a value in the specified base.
Log(Double)	Computes the natural (`base-E` logarithm of a value.

Log(Double, Double)

Computes the logarithm of a value in the specified base.

C#

```
public static double Log (double x, double newBase);
```

Parameters

x Double

The value whose logarithm is to be computed.

newBase Double

The base in which the logarithm is to be computed.

Returns

Double

The base-`newBase` logarithm of `x`.

Implements

Log(TSelf, TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Log(Double)

Computes the natural (`base-E` logarithm of a value.

```
C#
public static double Log (double x);
```

Parameters

x Double

The value whose natural logarithm is to be computed.

Returns

Double

The natural logarithm of `x`.

Implements

Log(TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Double.Log10P1(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the base-10 logarithm of a value plus one.

C#

```
public static double Log10P1 (double x);
```

Parameters

x Double

The value to which one is added before computing the base-10 logarithm.

Returns

Double

$\log_{10}(x + 1)$

Implements

Log10P1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Max(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static double Max (double x, double y);
```

Parameters

x Double

The value to compare with `y`.

y Double

The value to compare with `x`.

Returns

Double

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf>, this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Double.MaxMagnitude(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static double MaxMagnitude (double x, double y);
```

Parameters

x Double

The value to compare with `y`.

y Double

The value to compare with `x`.

Returns

Double

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf>, this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.MaxMagnitudeNumber(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#
public static double MaxMagnitudeNumber (double x, double y);
```

Parameters

x Double

The value to compare with `y`.

y Double

The value to compare with `x`.

Returns

Double

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitudeNumber` function. This requires NaN inputs to not be propagated back

to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Double.Min(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static double Min (double x, double y);
```

Parameters

x Double

The value to compare with `y`.

y Double

The value to compare with `x`.

Returns

Double

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf>, this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Double.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its double-precision floating-point number equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts a character span that contains the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its double-precision floating-point number equivalent.
Parse(String)	Converts the string representation of a number to its double-precision floating-point number equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its double-precision floating-point number equivalent.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent.

```
C#

public static double Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicate the style elements that can be present in `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Double

A double-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a numeric value.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example illustrates the use of the Parse(String, NumberStyles, IFormatProvider) method to assign several string representations of temperature values to a `Temperature` object.

C#

```
using System;
using System.Globalization;

public class Temperature
{
   // Parses the temperature from a string. Temperature scale is
   // indicated by 'F (for Fahrenheit) or 'C (for Celsius) at the end
   // of the string.
   public static Temperature Parse(string s, NumberStyles styles,
                                   IFormatProvider provider)
   {
      Temperature temp = new Temperature();

      if (s.TrimEnd(null).EndsWith("'F"))
      {
         temp.Value = Double.Parse(s.Remove(s.LastIndexOf((char)39), 2),
                                   styles, provider);
      }
      else
      {
```

```
         if (s.TrimEnd(null).EndsWith("'C"))
            temp.Celsius = Double.Parse(s.Remove(s.LastIndexOf((char)39),
2),
                                        styles, provider);
         else
            temp.Value = Double.Parse(s, styles, provider);
      }
      return temp;
   }

   // Declare private constructor so Temperature so only Parse method can
   // create a new instance
   private Temperature()   {}

   protected double m_value;

   public double Value
   {
      get { return m_value; }
      private set { m_value = value; }
   }

   public double Celsius
   {
      get { return (m_value - 32) / 1.8; }
      private set { m_value = value * 1.8 + 32; }
   }

   public double Fahrenheit
   {
      get {return m_value; }
   }
}

public class TestTemperature
{
   public static void Main()
   {
      string value;
      NumberStyles styles;
      IFormatProvider provider;
      Temperature temp;

      value = "25,3'C";
      styles = NumberStyles.Float;
      provider = CultureInfo.CreateSpecificCulture("fr-FR");
      temp = Temperature.Parse(value, styles, provider);
      Console.WriteLine("{0} degrees Fahrenheit equals {1} degrees
Celsius.",
                        temp.Fahrenheit, temp.Celsius);

      value = " (40) 'C";
      styles = NumberStyles.AllowLeadingWhite |
NumberStyles.AllowTrailingWhite
               | NumberStyles.AllowParentheses;
```

```
      provider = NumberFormatInfo.InvariantInfo;
      temp = Temperature.Parse(value, styles, provider);
      Console.WriteLine("{0} degrees Fahrenheit equals {1} degrees
Celsius.",
                        temp.Fahrenheit, temp.Celsius);

      value = "5,778E03'C";      // Approximate surface temperature of
the Sun
      styles = NumberStyles.AllowDecimalPoint |
NumberStyles.AllowThousands |
               NumberStyles.AllowExponent;
      provider = CultureInfo.CreateSpecificCulture("en-GB");
      temp = Temperature.Parse(value, styles, provider);
      Console.WriteLine("{0} degrees Fahrenheit equals {1} degrees
Celsius.",
                        temp.Fahrenheit.ToString("N"),
temp.Celsius.ToString("N"));
   }
}
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The `style` parameter defines the style elements (such as white space, thousands separators, and currency symbols) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- AllowHexSpecifier
- HexNumber

The `s` parameter can contain NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, or NumberFormatInfo.NaNSymbol for the culture specified by `provider`. Depending on the value of `style`, it can also take the form:

[*ws*] [*$*] [*sign*][*integral-digits*,]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Elements framed in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white-space characters. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	A negative sign symbol (-) or a positive sign symbol (+). The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
,	A culture-specific group separator. The current culture's group separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

Note

Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Double type. The remaining System.Globalization.NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles flags affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in `s` in addition to digits
None	The *integral-digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation. This flag by itself supports values in the form *digits*E*digits*; additional flags are needed to successfully parse strings with such elements as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The thousands separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, thousands separator (,) and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that supplies culture-specific information used in interpreting the format of `s`. Typically, it is a NumberFormatInfo

or CultureInfo object. If `provider` is `null` or a NumberFormatInfo cannot be obtained, the formatting information for the current system culture is used.

Ordinarily, if you pass the Double.Parse method a string that is created by calling the Double.ToString method, the original Double value is returned. However, because of a loss of precision, the values may not be equal. In addition, attempting to parse the string representation of either MinValue or Double.MaxValue fails to round-trip. On .NET Framework and .NET Core 2.2 and previous versions, it throws an OverflowException. On .NET Core 3.0 and later versions, it returns Double.NegativeInfinity if you attempt to parse MinValue or Double.PositiveInfinity if you attempt to parse MaxValue. The following example provides an illustration.

C#

```
   string value;

   value = Double.MinValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   value = Double.MaxValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   // Format without the default precision.
   value = Double.MinValue.ToString("G17");
   try
   {
       Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException)
   {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the Double type.
//    1.79769313486232E+308 is outside the range of the Double type.
//    -1.79769313486232E+308
```

On .NET Framework and .NET Core 2.2 and earlier versions, if `s` is out of range of the Double data type, the Parse(String, NumberStyles, IFormatProvider) method throws an OverflowException.

On .NET Core 3.0 and later versions, no exception is thrown when `s` is out of range of the Double data type. In most cases, the Parse(String, NumberStyles, IFormatProvider) method will return Double.PositiveInfinity or Double.NegativeInfinity. However, there is a small set of values that are considered to be closer to the maximum or minimum values of Double than to positive or negative infinity. In those cases, the method returns Double.MaxValue or Double.MinValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts a character span that contains the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent.

```C#
public static double Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A character span that contains the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicate the style elements that can be present in `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Double

A double-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Exceptions

FormatException

`s` does not represent a numeric value.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

If `s` is out of range of the Double data type, the method returns Double.NegativeInfinity if `s` is less than Double.MinValue and Double.PositiveInfinity if `s` is greater than Double.MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static double Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Double

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its double-precision floating-point number equivalent.

C#

```
public static double Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Double

A double-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to a Double value.

C#

```
protected void OkToDouble_Click(object sender, EventArgs e)
{
    string locale;
    double number;
    CultureInfo culture;
```

```
    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;

    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = Double.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
        return;
    }
    catch (OverflowException)
    {
        return;
    }
    // Output number to label on web form
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

This overload of the Parse(String, IFormatProvider) method is typically used to convert text that can be formatted in a variety of ways to a Double value. For example, it can be used to convert the text that is entered by a user into an HTML text box to a numeric value.

The `s` parameter is interpreted using a combination of the NumberStyles.Float and NumberStyles.AllowThousands flags. The `s` parameter can contain NumberFormatInfo.PositiveInfinitySymbol,

NumberFormatInfo.NegativeInfinitySymbol, or NumberFormatInfo.NaNSymbol for the culture specified by `provider`, or it can contain a string of the form:

[*ws*][*sign*]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Optional elements are framed in square brackets ([and]). Elements that contain the term "digits" consist of a series of numeric characters ranging from 0 to 9.

Expand table

Element	Description
ws	A series of white-space characters.
sign	A negative sign symbol (-) or a positive sign symbol (+).
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. Runs of *integral-digits* can be partitioned by a group-separator symbol. For example, in some cultures a comma (,) separates groups of thousands. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
.	A culture-specific decimal point symbol.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

For more information about numeric formats, see the Formatting Types topic.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that supplies culture-specific information used in interpreting the format of `s`. Typically, it is a NumberFormatInfo or CultureInfo object. If `provider` is `null` or a NumberFormatInfo cannot be obtained, the formatting information for the current system culture is used.

Ordinarily, if you pass the Double.Parse method a string that is created by calling the Double.ToString method, the original Double value is returned. However, because of a loss of precision, the values may not be equal. In addition, attempting to parse the string representation of either Double.MinValue or Double.MaxValue fails to round-trip. On .NET Framework and .NET Core 2.2 and previous versions, it throws an OverflowException. On .NET Core 3.0 and later versions, it returns

Double.NegativeInfinity if you attempt to parse MinValue or Double.PositiveInfinity if you attempt to parse MaxValue. The following example provides an illustration.

C#

```
   string value;

   value = Double.MinValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   value = Double.MaxValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   // Format without the default precision.
   value = Double.MinValue.ToString("G17");
   try
   {
       Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException)
   {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the Double type.
//    1.79769313486232E+308 is outside the range of the Double type.
//    -1.79769313486232E+308
```

On .NET Framework and .NET Core 2.2 and earlier versions, if `s` is out of range of the Double data type, the Parse(String, IFormatProvider) method throws an OverflowException.

On .NET Core 3.0 and later versions, no exception is thrown when `s` is out of range of the Double data type. In most cases, the Parse(String, IFormatProvider) method will return Double.PositiveInfinity or Double.NegativeInfinity. However, there is a small set of values that are considered to be closer to the maximum or minimum

values of Double than to positive or negative infinity. In those cases, the method returns Double.MaxValue or Double.MinValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

UWP	10.0

Parse(String)

Converts the string representation of a number to its double-precision floating-point number equivalent.

C#

```
public static double Parse (string s);
```

Parameters

`s` String

A string that contains a number to convert.

Returns

Double

A double-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

Examples

The following example illustrates the use of the Parse(String) method.

C#

```
public class Temperature {
    // Parses the temperature from a string in form
    // [ws][sign]digits['F|'C][ws]
    public static Temperature Parse(string s) {
        Temperature temp = new Temperature();

        if( s.TrimEnd(null).EndsWith("'F") ) {
            temp.Value = Double.Parse( s.Remove(s.LastIndexOf('\''), 2)
);
        }
        else if( s.TrimEnd(null).EndsWith("'C") ) {
            temp.Celsius = Double.Parse( s.Remove(s.LastIndexOf('\''), 2)
);
        }
        else {
            temp.Value = Double.Parse(s);
        }
```

```
        return temp;
    }

    // The value holder
    protected double m_value;

    public double Value {
        get {
            return m_value;
        }
        set {
            m_value = value;
        }
    }

    public double Celsius {
        get {
            return (m_value-32.0)/1.8;
        }
        set {
            m_value = 1.8*value+32.0;
        }
    }
}
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The `s` parameter can contain the current culture's NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, NumberFormatInfo.NaNSymbol, or a string of the form:

[*ws*][*sign*][*integral-digits*[,]]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white-space characters.

Element	Description
sign	A negative sign symbol (-) or a positive sign symbol (+). Only a leading sign can be used.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. Runs of *integral-digits* can be partitioned by a group-separator symbol. For example, in some cultures a comma (,) separates groups of thousands. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
,	A culture-specific thousands separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

The `s` parameter is interpreted using a combination of the NumberStyles.Float and NumberStyles.AllowThousands flags. This means that white space and thousands separators are allowed, for example, while currency symbols are not. For finer control over which style elements are permitted in `s` for the parse operation to succeed, call the Double.Parse(String, NumberStyles) or the Double.Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is interpreted using the formatting information in a NumberFormatInfo object that is initialized for the current culture. For more information, see CurrentInfo. To parse a string using the formatting information of some other culture, call the Double.Parse(String, IFormatProvider) or Double.Parse(String, NumberStyles, IFormatProvider) method.

Ordinarily, if you pass the Double.Parse method a string that is created by calling the Double.ToString method, the original Double value is returned. However, on .NET Framework and on .NET Core 2.2 and earlier versions, the values may not be equal because of a loss of precision. In addition, attempting to parse the string representation of either Double.MinValue or Double.MaxValue fails to round-trip. On .NET Framework and .NET Core 2.2 and previous versions, it throws an OverflowException. The following example provides an illustration.

```
C#
```

```
   string value;

   value = Double.MinValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   value = Double.MaxValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   // Format without the default precision.
   value = Double.MinValue.ToString("G17");
   try
   {
       Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException)
   {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the Double type.
//    1.79769313486232E+308 is outside the range of the Double type.
//    -1.79769313486232E+308
```

On .NET Framework and .NET Core 2.2 and earlier versions, if `s` is out of range of the Double data type, the Parse(String) method throws an OverflowException.

On .NET Core 3.0 and later versions, no exception is thrown when `s` is out of range of the Double data type. In most cases, the method will return Double.PositiveInfinity or Double.NegativeInfinity. However, there is a small set of values that are considered to be closer to the maximum or minimum values of Double than to positive or negative infinity. In those cases, the method returns Double.MaxValue or Double.MinValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group

separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

UWP	10.0

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static double Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Double

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static double Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Double

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its double-precision floating-point number equivalent.

```
C#

public static double Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicate the style elements that can be present in `s`. A typical value to specify is a combination of Float combined with AllowThousands.

Returns

Double

A double-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number that is less than Double.MinValue or greater than Double.MaxValue.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` includes the AllowHexSpecifier value.

Examples

The following example uses the Parse(String, NumberStyles) method to parse the string representations of Double values using the en-US culture.

C#

```
public static void Main()
{
   // Set current thread culture to en-US.
   Thread.CurrentThread.CurrentCulture =
CultureInfo.CreateSpecificCulture("en-US");

   string value;
   NumberStyles styles;

   // Parse a string in exponential notation with only the AllowExponent
flag.
   value = "-1.063E-02";
   styles = NumberStyles.AllowExponent;
   ShowNumericValue(value, styles);

   // Parse a string in exponential notation
   // with the AllowExponent and Number flags.
   styles = NumberStyles.AllowExponent | NumberStyles.Number;
   ShowNumericValue(value, styles);

   // Parse a currency value with leading and trailing white space, and
   // white space after the U.S. currency symbol.
   value = " $ 6,164.3299  ";
   styles = NumberStyles.Number | NumberStyles.AllowCurrencySymbol;
   ShowNumericValue(value, styles);

   // Parse negative value with thousands separator and decimal.
```

```
   value = "(4,320.64)";
   styles = NumberStyles.AllowParentheses |
NumberStyles.AllowTrailingSign |
            NumberStyles.Float;
   ShowNumericValue(value, styles);

   styles = NumberStyles.AllowParentheses |
NumberStyles.AllowTrailingSign |
            NumberStyles.Float | NumberStyles.AllowThousands;
   ShowNumericValue(value, styles);
}

private static void ShowNumericValue(string value, NumberStyles styles)
{
   double number;
   try
   {
      number = Double.Parse(value, styles);
      Console.WriteLine("Converted '{0}' using {1} to {2}.",
                        value, styles.ToString(), number);
   }
   catch (FormatException)
   {
      Console.WriteLine("Unable to parse '{0}' with styles {1}.",
                        value, styles.ToString());
   }
   Console.WriteLine();
}
// The example displays the following output to the console:
//    Unable to parse '-1.063E-02' with styles AllowExponent.
//
//    Converted '-1.063E-02' using AllowTrailingSign, AllowThousands,
Float to -0.01063.
//
//    Converted ' $ 6,164.3299  ' using Number, AllowCurrencySymbol to
6164.3299.
//
//    Unable to parse '(4,320.64)' with styles AllowTrailingSign,
AllowParentheses, Float.
//
//    Converted '(4,320.64)' using AllowTrailingSign, AllowParentheses,
AllowThousands, Float to -4320.64.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The `style` parameter defines the style elements (such as white space, thousands separators, and currency symbols) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- AllowHexSpecifier
- HexNumber

The `s` parameter can contain the current culture's NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, or NumberFormatInfo.NaNSymbol. Depending on the value of `style`, it can also take the form:

[*ws*][*$*][*sign*][*integral-digits*[,]]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white-space characters. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	A negative sign symbol (-) or a positive sign symbol (+). The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
,	A culture-specific group separator. The current culture's group separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands

Element	Description
	flag
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Double type. The remaining System.Globalization.NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles flags affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in `s` in addition to digits
None	The *integral-digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation. This flag by itself supports values in the form *digits*E*digits*; additional flags are needed to successfully parse strings with such elements as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.

NumberStyles value	Elements permitted in `s` in addition to digits
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The thousands separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, thousands separator (,) and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see CurrentInfo.

Ordinarily, if you pass the Double.Parse method a string that is created by calling the Double.ToString method, the original Double value is returned. However, because of a loss of precision, the values may not be equal. In addition, attempting to parse the string representation of either Double.MinValue or Double.MaxValue fails to round-trip. On .NET Framework and .NET Core 2.2 and previous versions, it throws an OverflowException. On .NET Core 3.0 and later versions, it returns Double.NegativeInfinity if you attempt to parse MinValue or Double.PositiveInfinity if you attempt to parse MaxValue. The following example provides an illustration.

C#

```
   string value;

   value = Double.MinValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }
```

```
   value = Double.MaxValue.ToString();
   try {
      Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException) {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }

   // Format without the default precision.
   value = Double.MinValue.ToString("G17");
   try
   {
       Console.WriteLine(Double.Parse(value));
   }
   catch (OverflowException)
   {
      Console.WriteLine($"{value} is outside the range of the Double
type.");
   }
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the Double type.
//    1.79769313486232E+308 is outside the range of the Double type.
//    -1.79769313486232E+308
```

On .NET Framework and .NET Core 2.2 and earlier versions, if `s` is out of range of the Double data type, the Parse(String, NumberStyles) method throws an OverflowException.

On .NET Core 3.0 and later versions, no exception is thrown when `s` is out of range of the Double data type. In most cases, the Parse(String, NumberStyles) method will return Double.PositiveInfinity or Double.NegativeInfinity. However, there is a small set of values that are considered to be closer to the maximum or minimum values of Double than to positive or negative infinity. In those cases, the method returns Double.MaxValue or Double.MinValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Double.Pow(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes a value raised to a given power.

```
C#
public static double Pow (double x, double y);
```

Parameters

x Double

The value which is raised to the power of `x`.

y Double

The power to which `x` is raised.

Returns

Double

`x` raised to the power of `y`.

Implements

Pow(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.RadiansToDegrees(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a given value from radians to degrees.

C#

```
public static double RadiansToDegrees (double radians);
```

Parameters

`radians` Double

The value to convert to degrees.

Returns

Double

The value of `radians` converted to degrees.

Implements

RadiansToDegrees(TSelf)

Applies to

Product	Versions
.NET	8, 9

Double.ReciprocalEstimate(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes an estimate of the reciprocal of a value.

C#

```
public static double ReciprocalEstimate (double x);
```

Parameters

x Double

The value whose estimate of the reciprocal is to be computed.

Returns

Double

An estimate of the reciprocal of `x`.

Implements

ReciprocalEstimate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.RootN(Double, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the n-th root of a value.

```
C#
public static double RootN (double x, int n);
```

Parameters

x Double

The value whose `n`-th root is to be computed.

n Int32

The degree of the root to be computed.

Returns

Double

The `n`-th root of `x`.

Implements

RootN(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Double.Round Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Round(Double)	Rounds a value to the nearest integer using the default rounding mode (ToEven).
Round(Double, Int32)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Double, MidpointRounding)	Rounds a value to the nearest integer using the specified rounding mode.
Round(Double, Int32, MidpointRounding)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

Round(Double)

Rounds a value to the nearest integer using the default rounding mode (ToEven).

C#

```
public static double Round (double x);
```

Parameters

x Double

The value to round.

Returns

Double

The result of rounding `x` to the nearest integer using the default rounding mode.

Implements

Round(TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Double, Int32)

Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

C#

```
public static double Round (double x, int digits);
```

Parameters

`x` Double

The value to round.

`digits` Int32

The number of fractional digits to which `x` should be rounded.

Returns

Double

The result of rounding `x` to `digits` fractional-digits using the default rounding mode.

Implements

Round(TSelf, Int32)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Double, MidpointRounding)

Rounds a value to the nearest integer using the specified rounding mode.

C#

```
public static double Round (double x, MidpointRounding mode);
```

Parameters

`x` Double

The value to round.

`mode` MidpointRounding

The mode under which `x` should be rounded.

Returns

Double

The result of rounding `x` to the nearest integer using `mode`.

Implements

Round(TSelf, MidpointRounding)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Double, Int32, MidpointRounding)

Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

```
C#

public static double Round (double x, int digits, MidpointRounding mode);
```

Parameters

`x` Double

The value to round.

`digits` Int32

The number of fractional digits to which `x` should be rounded.

`mode` MidpointRounding

The mode under which `x` should be rounded.

Returns

Double

The result of rounding `x` to `digits` fractional-digits using `mode`.

Implements

Round(TSelf, Int32, MidpointRounding)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Double.ScaleB(Double, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the product of a value and its base-radix raised to the specified power.

C#

```
public static double ScaleB (double x, int n);
```

Parameters

x Double

The value which base-radix raised to the power of `n` multiplies.

n Int32

The value to which base-radix is raised before multipliying `x`.

Returns

Double

The product of `x` and base-radix raised to the power of `n`.

Implements

ScaleB(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Sign(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (double value);
```

Parameters

`value` Double

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Sin(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine of a value.

```
C#
public static double Sin (double x);
```

Parameters

x Double

The value, in radians, whose sine is to be computed.

Returns

Double

The sine of `x`.

Implements

Sin(TSelf)

Remarks

This computes `sin(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.SinCos(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine and cosine of a value.

```
C#
public static (double Sin, double Cos) SinCos (double x);
```

Parameters

x Double

The value, in radians, whose sine and cosine are to be computed.

Returns

ValueTuple<Double,Double>

The sine and cosine of `x`.

Implements

SinCos(TSelf)

Remarks

This computes `(sin(x), cos(x))`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.SinCosPi(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine and cosine of a value.

C#

```
public static (double SinPi, double CosPi) SinCosPi (double x);
```

Parameters

x Double

The value, in radians, whose sine and cosine are to be computed.

Returns

ValueTuple<Double,Double>

The sine and cosine of `x`.

Implements

SinCosPi(TSelf)

Remarks

This computes `(sin(x), cos(x))`.

Applies to

Product	Versions
.NET	7, 8, 9

Double.Sinh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic sine of a value.

C#

```
public static double Sinh (double x);
```

Parameters

x Double

The value, in radians, whose hyperbolic sine is to be computed.

Returns

Double

The hyperbolic sine of `x`.

Implements

Sinh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.SinPi(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine of a value that has been multiplied by `pi`.

C#

```
public static double SinPi (double x);
```

Parameters

x Double

The value, in half-revolutions, that is multipled by `pi` before computing its sine.

Returns

Double

The sine of `x` multiplied-by `pi`.

Implements

SinPi(TSelf)

Remarks

This computes `sin(x * π)`.

Applies to

Product	Versions
.NET	7, 8, 9

Double.Sqrt(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the square-root of a value.

C#

```
public static double Sqrt (double x);
```

Parameters

x Double

The value whose square-root is to be computed.

Returns

Double

The square-root of `x`.

Implements

Sqrt(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Tan(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the tangent of a value.

```
C#
public static double Tan (double x);
```

Parameters

x Double

The value, in radians, whose tangent is to be computed.

Returns

Double

The tangent of `x`.

Implements

Tan(TSelf)

Remarks

This computes `tan(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.Tanh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic tangent of a value.

C#

```
public static double Tanh (double x);
```

Parameters

x Double

The value, in radians, whose hyperbolic tangent is to be computed.

Returns

Double

The hyperbolic tangent of `x`.

Implements

Tanh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance.

Examples

The following example uses the default Double.ToString() method to display the string representations of a number of Double values.

C#

```
double number;

number = 1.6E20;
// Displays 1.6E+20.
Console.WriteLine(number.ToString());

number = 1.6E2;
// Displays 160.
Console.WriteLine(number.ToString());

number = -3.541;
// Displays -3.541.
Console.WriteLine(number.ToString());

number = -1502345222199E-07;
// Displays -150234.5222199.
Console.WriteLine(number.ToString());

number = -150234522219901995 74E-09;
// Displays -15023452221.9902.
Console.WriteLine(number.ToString());

number = .60344;
// Displays 0.60344.
Console.WriteLine(number.ToString());

number = .000000001;
// Displays 1E-09.
Console.WriteLine(number.ToString());
```

The following example illustrates the use of ToString.

C#

```
bool done = false;
string inp;
do {
   Console.Write("Enter a real number: ");
   inp = Console.ReadLine();
   try {
      d = Double.Parse(inp);
      Console.WriteLine("You entered {0}.", d.ToString());
      done = true;
   }
```

```
    catch (FormatException) {
       Console.WriteLine("You did not enter a number.");
    }
    catch (ArgumentNullException) {
       Console.WriteLine("You did not supply any input.");
    }
    catch (OverflowException) {
        Console.WriteLine("The value you entered, {0}, is out of range.",
inp);
    }
} while (!done);
```

Remarks

The ToString() method formats a Double value in the default ("G", or general) format of the current culture. If you want to specify a different format, precision, or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format or precision	Default (current) culture	ToString(String)
A specific format or precision	A specific culture	ToString(String, IFormatProvider)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or a string of the form:

[sign]integral-digits[.[fractional-digits]][E[sign]exponential-digits]

Optional elements are framed in square brackets ([and]). Elements that contain the term "digits" consist of a series of numeric characters ranging from 0 to 9. The elements listed in the following table are supported.

Expand table

Element	Description
sign	A negative sign or positive sign symbol.
integral-digits	A series of digits specifying the integral part of the number. Integral-digits can be absent if there are fractional-digits.
'.'	A culture-specific decimal point symbol.

Element	Description
fractional-digits	A series of digits specifying the fractional part of the number.
'E'	An uppercase character 'E', indicating exponential (scientific) notation.
exponential-digits	A series of digits specifying an exponent.

Some examples of the return value are "100", "-123,456,789", "123.45E+6", "500", "3.1416", "600", "-0.123", and "-Infinity".

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

```
C#

public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example displays the string representation of two Double values using CultureInfo objects that represent several different cultures.

```
C#

double value;

value = -16325.62015;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));

value = 16034.125E21;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
```

```
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));
// This example displays the following output to the console:
//       -16325.62015
//       -16325.62015
//       -16325,62015
//       1.6034125E+25
//       1.6034125E+25
//       1,6034125E+25
```

The following example illustrates the use of ToString, taking a String and an IFormatProvider as parameters.

C#

```
public class Temperature : IFormattable {
    // IFormattable.ToString implementation.
    public string ToString(string format, IFormatProvider provider) {
        if( format != null ) {
            if( format.Equals("F") ) {
                return String.Format("{0}'F", this.Value.ToString());
            }
            if( format.Equals("C") ) {
                return String.Format("{0}'C", this.Celsius.ToString());
            }
        }

        return m_value.ToString(format, provider);
    }

    // The value holder
    protected double m_value;

    public double Value {
        get {
            return m_value;
        }
        set {
            m_value = value;
        }
    }

    public double Celsius {
        get {
            return (m_value-32.0)/1.8;
        }
        set {
            m_value = 1.8*value+32.0;
        }
```

```
    }
}
```

Remarks

The ToString(IFormatProvider) method formats a Double value in the default ("G", or general) format of a specified culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current)	ToString()
A specific format or precision	Default (current) culture	ToString(String)
A specific format or precision	A specific culture	ToString(String, IFormatProvider)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or a string of the form:

[sign]integral-digits[.[fractional-digits]][E[sign]exponential-digits]

Optional elements are framed in square brackets ([and]). Elements that contain the term "digits" consist of a series of numeric characters ranging from 0 to 9. The elements listed in the following table are supported.

Expand table

Element	Description
sign	A negative sign or positive sign symbol.
integral-digits	A series of digits specifying the integral part of the number. Integral-digits can be absent if there are fractional-digits.
'.'	A culture-specific decimal point symbol.
fractional-digits	A series of digits specifying the fractional part of the number.
'*E*'	An uppercase character 'E', indicating exponential (scientific) notation.
exponential-digits	A series of digits specifying an exponent.

Some examples of the return value are "100", "-123,456,789", "123.45E+6", "500", "3.1416", "600", "-0.123", and "-Infinity".

This instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a CultureInfo object or a NumberFormatInfo object. The `provider` parameter supplies culture-specific information used in formatting. If `provider` is `null`, the return value is formatted using the NumberFormatInfo object for the current culture.

UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid.

Examples

The following example defines a numeric value and formats it as a currency value by using the "C" standard numeric format string and as a numeric value to three decimal places by using the "N" standard numeric format string. The result strings are formatted by using the conventions of the en-US culture. For more information on numeric format strings, see Standard Numeric Format Strings and Custom Numeric Format Strings.

```
C#

using System;

public class Example
{
   public static void Main()
   {
      float number = 1764.3789m;

      // Format as a currency value.
      Console.WriteLine(number.ToString("C"));
```

```
      // Format as a numeric value with 3 decimal places.
      Console.WriteLine(number.ToString("N3"));
   }
}
// The example displays the following output:
//       $1,764.38
//       1,764.379
```

The following example displays several Double values using the supported standard numeric format specifiers together with three custom numeric format strings. One of those custom format strings illustrates how to pad a Single value with leading zeros. In addition, the example uses precision specifiers with each standard format specifier except for "R". The values of the precision specifiers range from 0 to 3. To convert the numeric values to strings, the example uses the formatting conventions of the en-US culture.

C#

```
double[] numbers= {1054.32179, -195489100.8377, 1.0437E21,
                   -1.0573e-05};
string[] specifiers = { "C", "E", "e", "F", "G", "N", "P",
                        "R", "#,000.000", "0.###E-000",
                        "000,000,000,000.00###" };
foreach (double number in numbers)
{
   Console.WriteLine("Formatting of {0}:", number);
   foreach (string specifier in specifiers) {
      Console.WriteLine("   {0,-22} {1}",
                        specifier + ":", number.ToString(specifier));
      // Add precision specifiers from 0 to 3.
      if (specifier.Length == 1 & ! specifier.Equals("R")) {
         for (int precision = 0; precision <= 3; precision++) {
            string pSpecifier = String.Format("{0}{1}", specifier,
precision);
            Console.WriteLine("   {0,-22} {1}",
                              pSpecifier + ":",
number.ToString(pSpecifier));
         }
         Console.WriteLine();
      }
   }
   Console.WriteLine();
}
// The example displays the following output to the console:
//       Formatting of 1054.32179:
//          C:                     $1,054.32
//          C0:                    $1,054
//          C1:                    $1,054.3
//          C2:                    $1,054.32
//          C3:                    $1,054.322
//
```

```

Remarks

The ToString(String) method formats a Double value in a specified format by using the conventions of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format or precision	A specific culture	ToString(String, IFormatProvider)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or the string representation of a number, as specified by `format`.

The `format` parameter can be any valid standard numeric format specifier except for D and X, as well as any combination of custom numeric format specifiers. If `format` is `null` or an empty string, the return value is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

By default, the return value only contains 15 digits of precision although a maximum of 17 digits is maintained internally. If the value of this instance has greater than 15 digits, ToString returns PositiveInfinitySymbol or NegativeInfinitySymbol instead of the expected number. If you require more precision, specify `format` with the "G17" format specification, which always returns 17 digits of precision, or "R", which returns 15 digits if the number can be represented with that precision or 17 digits if the number can only be represented with maximum precision.

Notes to Callers

In some cases, Double values formatted with the "R" standard numeric format string do not successfully round-trip if compiled using the `/platform:x64` or `/platform:anycpu` switches and run on 64-bit systems. To work around this problem, you can format Double values by using the "G17" standard numeric format string. The following example uses the "R" format string with a Double value that does not round-trip successfully, and also uses the "G17" format string to successfully round-trip the original value.

C#

```
using System;

public class Example
{
   static void Main(string[] args)
   {
      Console.WriteLine("Attempting to round-trip a Double with 'R':");
      double initialValue = 0.6822871999174;
      string valueString = initialValue.ToString("R");
      double roundTripped = double.Parse(valueString);
      Console.WriteLine("{0:R} = {1:R}: {2}\n",
                        initialValue, roundTripped,
initialValue.Equals(roundTripped));

      Console.WriteLine("Attempting to round-trip a Double with 'G17':");
      string valueString17 = initialValue.ToString("G17");
      double roundTripped17 = double.Parse(valueString17);
      Console.WriteLine("{0:R} = {1:R}: {2}\n",
                        initialValue, roundTripped17,
initialValue.Equals(roundTripped17));
   }
}
```

```
// If compiled to an application that targets anycpu or x64 and run on an
x64 system,
// the example displays the following output:
//       Attempting to round-trip a Double with 'R':
//       0.6822871999174 = 0.68228719991740006: False
//
//       Attempting to round-trip a Double with 'G17':
//       0.6822871999174 = 0.6822871999174: True
```

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Examples

The following example displays a Double value using each of the supported standard numeric format specifiers for several different cultures.

C#

```
double value = 16325.62901;
string specifier;
CultureInfo culture;

// Use standard numeric format specifiers.
specifier = "G";
culture = CultureInfo.CreateSpecificCulture("eu-ES");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325,62901
Console.WriteLine(value.ToString(specifier,
CultureInfo.InvariantCulture));
// Displays:    16325.62901

specifier = "C";
culture = CultureInfo.CreateSpecificCulture("en-US");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    $16,325.63
culture = CultureInfo.CreateSpecificCulture("en-GB");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    £16,325.63

specifier = "E04";
culture = CultureInfo.CreateSpecificCulture("sv-SE");
```

```
Console.WriteLine(value.ToString(specifier, culture));
// Displays: 1,6326E+004
 culture = CultureInfo.CreateSpecificCulture("en-NZ");
 Console.WriteLine(value.ToString(specifier, culture));
// Displays:    1.6326E+004

specifier = "F";
culture = CultureInfo.CreateSpecificCulture("fr-FR");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325,63
culture = CultureInfo.CreateSpecificCulture("en-CA");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325.63

specifier = "N";
culture = CultureInfo.CreateSpecificCulture("es-ES");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16.325,63
culture = CultureInfo.CreateSpecificCulture("fr-CA");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16 325,63

specifier = "P";
culture = CultureInfo.InvariantCulture;
Console.WriteLine((value/10000).ToString(specifier, culture));
// Displays:    163.26 %
culture = CultureInfo.CreateSpecificCulture("ar-EG");
Console.WriteLine((value/10000).ToString(specifier, culture));
// Displays:    163.256 %
```

The following example illustrates the use of ToString, taking a String and an IFormatProvider as parameters.

C#

```
public class Temperature : IFormattable {
    // IFormattable.ToString implementation.
    public string ToString(string format, IFormatProvider provider) {
        if( format != null ) {
            if( format.Equals("F") ) {
                return String.Format("{0}'F", this.Value.ToString());
            }
            if( format.Equals("C") ) {
                return String.Format("{0}'C", this.Celsius.ToString());
            }
        }

        return m_value.ToString(format, provider);
    }

    // The value holder
    protected double m_value;
```

```
    public double Value {
        get {
            return m_value;
        }
        set {
            m_value = value;
        }
    }

    public double Celsius {
        get {
            return (m_value-32.0)/1.8;
        }
        set {
            m_value = 1.8*value+32.0;
        }
    }
}
```

Remarks

The ToString(String, IFormatProvider) method formats a Double value in a specified format of a specified culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format or precision	Default (current) culture	ToString(String)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or the string representation of a number, as specified by `format`.

The `format` parameter can be any valid standard numeric format specifier except for D and X, as well as any combination of custom numeric format specifiers. If `format` is `null` or an empty string, the return value for this instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a CultureInfo object or a NumberFormatInfo object. The `provider` parameter supplies culture-specific information used in formatting. If `provider` is `null`, the return value is formatted using the NumberFormatInfo object for the current culture.

By default, the return value only contains 15 digits of precision although a maximum of 17 digits is maintained internally. If the value of this instance has greater than 15 digits, ToString returns PositiveInfinitySymbol or NegativeInfinitySymbol instead of the expected number. If you require more precision, specify `format` with the "G17" format specification, which always returns 17 digits of precision, or "R", which returns 15 digits if the number can be represented with that precision or 17 digits if the number can only be represented with maximum precision.

Notes to Callers

In some cases, Double values formatted with the "R" standard numeric format string do not successfully round-trip if compiled using the `/platform:x64` or `/platform:anycpu` switches and run on 64-bit systems. To work around this problem, you can format Double values by using the "G17" standard numeric format string. The following example uses the "R" format string with a Double value that does not round-trip successfully, and also uses the "G17" format string to successfully round-trip the original value.

C#

```
using System;
using System.Globalization;

public class Example
{
   static void Main(string[] args)
   {
      Console.WriteLine("Attempting to round-trip a Double with 'R':");
      double initialValue = 0.6822871999174;
      string valueString = initialValue.ToString("R",

CultureInfo.InvariantCulture);
      double roundTripped = double.Parse(valueString,
                                         CultureInfo.InvariantCulture);
```

```
      Console.WriteLine("{0:R} = {1:R}: {2}\n",
                        initialValue, roundTripped,
initialValue.Equals(roundTripped));

      Console.WriteLine("Attempting to round-trip a Double with 'G17':");
      string valueString17 = initialValue.ToString("G17",

CultureInfo.InvariantCulture);
      double roundTripped17 = double.Parse(valueString17,
                                           CultureInfo.InvariantCulture);
      Console.WriteLine("{0:R} = {1:R}: {2}\n",
                        initialValue, roundTripped17,
initialValue.Equals(roundTripped17));
      // If compiled to an application that targets anycpu or x64 and run
on an x64 system,
      // the example displays the following output:
      //       Attempting to round-trip a Double with 'R':
      //       0.6822871999174 = 0.68228719991740006: False
      //
      //       Attempting to round-trip a Double with 'G17':
      //       0.6822871999174 = 0.6822871999174: True
   }
}
```

Double.Truncate(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Truncates a value.

C#

```
public static double Truncate (double x);
```

Parameters

x Double

The value to truncate.

Returns

Double

The truncation of `x`.

Implements

Truncate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current double instance into the provided span of characters.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current double instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

```
C#
```

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Double.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, IFormatProvider, Double)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, Double)	Converts the span representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Double)	Converts the string representation of a number to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Double)	Tries to parse a span of UTF-8 characters into a value.
TryParse(String, IFormatProvider, Double)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Double)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Double)	Tries to convert a UTF-8 character span containing the string representation of a number to its double-precision floating-point number equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider,	Converts a character span containing the string representation of a number in a specified style and

Double)	culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Double)	Converts the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

TryParse(ReadOnlySpan<Char>, IFormatProvider, Double)

Tries to parse a span of characters into a value.

```C#
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out double result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

result Double

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, Double)

Converts the span representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, out double result);
```

Parameters

`s` ReadOnlySpan<Char>

A character span that contains the string representation of the number to convert.

`result` Double

When this method returns, contains the double-precision floating-point number equivalent of the numeric value or symbol contained in `s` parameter, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or empty, or is not in a format compliant with `style`. The conversion also fails if `style` is not a valid combination of NumberStyles enumerated constants. If `s` is a valid number less than Double.MinValue, `result` is NegativeInfinity. If `s` is a valid number greater than Double.MaxValue, `result` is PositiveInfinity. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Double)

Converts the string representation of a number to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, out double result);
```

Parameters

`s` String

A string containing a number to convert.

`result` Double

When this method returns, contains the double-precision floating-point number equivalent of the `s` parameter, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty or is not a number in a valid format. It also fails on .NET Framework and .NET Core 2.2 and earlier versions

if `s` represents a number less than Double.MinValue or greater than Double.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example uses the TryParse(String, Double) method to convert the string representations of numeric values to Double values. It assumes that en-US is the current culture.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] values = { "1,643.57", "$1,643.57", "-1.643e6",
                          "-168934617882109132", "123AE6",
                          null, String.Empty, "ABCDEF" };
      double number;

      foreach (var value in values) {
         if (Double.TryParse(value, out number))
            Console.WriteLine("'{0}' --> {1}", value, number);
         else
            Console.WriteLine("Unable to parse '{0}'.", value);
      }
   }
}
// The example displays the following output:
//       '1,643.57' --> 1643.57
//       Unable to parse '$1,643.57'.
//       '-1.643e6' --> -1643000
//       '-168934617882109132' --> -1.68934617882109E+17
//       Unable to parse '123AE6'.
//       Unable to parse ''.
//       Unable to parse ''.
//       Unable to parse 'ABCDEF'.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

This overload differs from the Double.Parse(String) method by returning a Boolean value that indicates whether the parse operation succeeded instead of returning the parsed numeric value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `s` parameter can contain the current culture's NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, NumberFormatInfo.NaNSymbol (the string comparison is case-sensitive), or a string of the form:

[ws][sign][integral-digits,]integral-digits[.[fractional-digits]][e[sign]exponential-digits][ws]

Elements in square brackets are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white-space characters.
sign	A negative sign or positive sign symbol.
integral-digits	A series of numeric characters ranging from 0 to 9 that specify the integral part of the number. Integral-digits can be absent if there are fractional-digits.
,	A culture-specific group separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A series of numeric characters ranging from 0 to 9 that specify the fractional part of the number.
E	An uppercase or lowercase character 'e', that indicates exponential (scientific) notation.
exponential-digits	A series of numeric characters ranging from 0 to 9 that specify an exponent.

For more information about numeric formats, see Formatting Types.

The `s` parameter is interpreted by using a combination of the NumberStyles.Float and NumberStyles.AllowThousands flags. This means that white space and thousands separators are allowed but currency symbols are not. To explicitly define the elements (such as currency symbols, thousands separators, and white space) that can be present in `s`, use the Double.TryParse(String, NumberStyles, IFormatProvider, Double) method overload.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse a string using the formatting information of some other specified culture, use the Double.TryParse(String, NumberStyles, IFormatProvider, Double) method overload.

Ordinarily, if you pass the Double.TryParse method a string that is created by calling the Double.ToString method, the original Double value is returned. However, because of a loss of precision, the values may not be equal. In addition, attempting to parse the string representation of either Double.MinValue or Double.MaxValue fails to round-trip. On .NET Framework and .NET Core 2.2 and previous versions, it throws an OverflowException. On .NET Core 3.0 and later versions, it returns Double.NegativeInfinity if you attempt to parse MinValue or Double.PositiveInfinity if you attempt to parse MaxValue. The following example provides an illustration.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string value;
      double number;

      value = Double.MinValue.ToString();
      if (Double.TryParse(value, out number))
         Console.WriteLine(number);
      else
         Console.WriteLine("{0} is outside the range of a Double.",
                           value);

      value = Double.MaxValue.ToString();
      if (Double.TryParse(value, out number))
         Console.WriteLine(number);
      else
         Console.WriteLine("{0} is outside the range of a Double.",
                           value);
```

```
    }
}
// The example displays the following output:
//    -1.79769313486232E+308 is outside the range of the Double type.
//    1.79769313486232E+308 is outside the range of the Double type.
```

On .NET Framework and .NET Core 2.2 and earlier versions, if `s` is out of range of the Double data type, the TryParse(String, Double) method throws an OverflowException.

On .NET Core 3.0 and later versions, no exception is thrown when `s` is out of range of the Double data type. In most cases, the TryParse(String, Double) method calculates a result of Double.PositiveInfinity or Double.NegativeInfinity. However, there is a small set of values that are considered to be closer to the maximum or minimum values of Double than to positive or negative infinity. In those cases, the method calculates a result of Double.MaxValue or Double.MinValue.

If a separator is encountered in the `s` parameter during a parse operation, and the decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Double)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out double result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Double

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, IFormatProvider, Double)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
double result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Double

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Double)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
double result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Double

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, Double)

Tries to convert a UTF-8 character span containing the string representation of a number to its double-precision floating-point number equivalent.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text, out double
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A read-only UTF-8 character span that contains the number to convert.

`result` Double

When this method returns, contains a double-precision floating-point number equivalent of the numeric value or symbol contained in `utf8Text` if the conversion succeeded or zero if the conversion failed. The conversion fails if the `utf8Text` is Empty or is not in a valid format. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Double)

Converts a character span containing the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
```

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
double result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only character span that contains the number to convert.

`style` NumberStyles

A bitwise combination of NumberStyles values that indicates the permitted format of `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Double

When this method returns and if the conversion succeeded, contains a double-precision floating-point number equivalent of the numeric value or symbol contained in `s`. Contains zero if the conversion failed. The conversion fails if the `s` parameter is `null`, an empty character span, or not a number in a format compliant with `style`. If `s` is a valid number less than Double.MinValue, `result` is NegativeInfinity. If `s` is a valid number greater than Double.MaxValue, `result` is PositiveInfinity. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Double)

Converts the string representation of a number in a specified style and culture-specific format to its double-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out double result);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of NumberStyles values that indicates the permitted format of `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information about `s`.

`result` Double

When this method returns, contains a double-precision floating-point number equivalent of the numeric value or symbol contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty or is not in a format compliant with `style`, or if `style` is not a valid combination of NumberStyles enumeration constants. It also fails on .NET

Framework or .NET Core 2.2 and earlier versions if `s` represents a number less than SByte.MinValue or greater than SByte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` includes the AllowHexSpecifier value.

Examples

The following example demonstrates the use of the Double.TryParse(String, NumberStyles, IFormatProvider, Double) method to parse the string representation of numbers that have a particular style and are formatted using the conventions of a particular culture.

C#

```
string value;
NumberStyles style;
CultureInfo culture;
double number;

// Parse currency value using en-GB culture.
value = "£1,097.63";
style = NumberStyles.Number | NumberStyles.AllowCurrencySymbol;
culture = CultureInfo.CreateSpecificCulture("en-GB");
if (Double.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Converted '£1,097.63' to 1097.63.

value = "1345,978";
style = NumberStyles.AllowDecimalPoint;
culture = CultureInfo.CreateSpecificCulture("fr-FR");
```

```
if (Double.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Converted '1345,978' to 1345.978.

value = "1.345,978";
style = NumberStyles.AllowDecimalPoint | NumberStyles.AllowThousands;
culture = CultureInfo.CreateSpecificCulture("es-ES");
if (Double.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Converted '1.345,978' to 1345.978.

value = "1 345,978";
if (Double.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// Displays:
//       Unable to convert '1 345,978'.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The TryParse method is like the Parse(String, NumberStyles, IFormatProvider) method, except this method does not throw an exception if the conversion fails. If the conversion succeeds, the return value is `true` and the `result` parameter is set to the outcome of the conversion. If the conversion fails, the return value is `false` and the `result` parameter is set to zero. This eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `style` parameter defines the allowable format of the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- NumberStyles.AllowHexSpecifier
- NumberStyles.HexNumber

The `s` parameter can contain NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, or NumberFormatInfo.NaNSymbol for the culture indicated by `provider`. In addition, depending on the value of `style`, the `s` parameter may include the following elements:

[ws] [$] [sign][integral-digits,]integral-digits[.fractional-digits][e[sign]exponential-digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag. It can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern or NumberFormatInfo.CurrencyPositivePattern properties of the NumberFormatInfo object returned by the IFormatProvider.GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. Integral-digits can be absent if there are fractional-digits.
,	A culture-specific thousands separator symbol. The current culture's thousands separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.

Element	Description
e	The e or E character, which indicates that `s` can represent a number using exponential notation. The `s` parameter can represent a number in exponential notation if style includes the NumberStyles.AllowExponent flag.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Double type. The remaining System.Globalization.NumberStyles members control elements that may be but are not required to be present in the input string. The following table indicates how individual NumberStyles flags affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in s in addition to digits
None	The *integral-digits* element only.
AllowDecimalPoint	The . and *fractional-digits* elements.
AllowExponent	The `s` parameter can also use exponential notation. This flag by itself supports values in the form *integral-digits*E*exponential-digits*; additional flags are needed to successfully parse strings in exponential notation with such elements as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The , element.

NumberStyles value	Elements permitted in s in addition to digits
AllowCurrencySymbol	The *$* element.
Currency	All. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the . symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, thousands separator (*,*), and decimal point (.) elements.
Any	All styles, except `s` cannot represent a hexadecimal number.

The `provider` parameter is a IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null` or a NumberFormatInfo object cannot be obtained, the format information for the current culture is used.

The conversion fails if the `s` parameter is `null` or not a numeric value, the `provider` parameter does not yield a NumberFormatInfo object, or the `style` parameter is not a combination of bit flags from the NumberStyles enumeration.

Ordinarily, if you pass the Double.TryParse method a string that is created by calling the Double.ToString method, the original Double value is returned. However, because of a loss of precision, the values may not be equal. In addition, attempting to parse the string representation of either Double.MinValue or Double.MaxValue fails to round-trip. On .NET Framework and .NET Core 2.2 and previous versions, it throws an OverflowException. On .NET Core 3.0 and later versions, it returns Double.NegativeInfinity if you attempt to parse MinValue or Double.PositiveInfinity if you attempt to parse MaxValue. The following example provides an illustration.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string value;
      double number;

      value = Double.MinValue.ToString();
      if (Double.TryParse(value, out number))
         Console.WriteLine(number);
```

```
        else
           Console.WriteLine("{0} is outside the range of a Double.",
                             value);

        value = Double.MaxValue.ToString();
        if (Double.TryParse(value, out number))
           Console.WriteLine(number);
        else
           Console.WriteLine("{0} is outside the range of a Double.",
                             value);
     }
  }
  // The example displays the following output:
  //    -1.79769313486232E+308 is outside the range of the Double type.
  //    1.79769313486232E+308 is outside the range of the Double type.
```

On .NET Framework and .NET Core 2.2 and earlier versions, if `s` is out of range of the Double data type, the Double.TryParse(String, NumberStyles, IFormatProvider, Double) method throws an OverflowException.

On .NET Core 3.0 and later versions, no exception is thrown when `s` is out of range of the Double data type. In most cases, the Double.TryParse(String, NumberStyles, IFormatProvider, Double) method calculates a result of Double.PositiveInfinity or Double.NegativeInfinity. However, there is a small set of values that are considered to be closer to the maximum or minimum values of Double than to positive or negative infinity. In those cases, the method calculates a result of Double.MaxValue or Double.MinValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Double.Equality(Double, Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two specified Double values are equal.

```
C#
public static bool operator == (double left, double right);
```

Parameters

`left` Double

The first value to compare.

`right` Double

The second value to compare.

Returns

Boolean

`true` if `left` and `right` are equal; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Remarks

The Equality method defines the equality operator for Double values.

If two Double.NaN values are tested for equality by using the equality operator, the result is `false`; two Double.NaN values are not considered equal. If they are tested for

equality by calling the Equals method, the result is `true`. When you want to determine whether the value of a Double is not a number (NaN), an alternative is to call the IsNaN method.

Applies to

Product	Versions

Double.GreaterThan(Double, Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Double value is greater than another specified Double value.

```
C#
public static bool operator > (double left, double right);
```

Parameters

`left` Double

The first value to compare.

`right` Double

The second value to compare.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Remarks

The GreaterThan method defines the operation of the greater-than operator for Double values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.GreaterThanOrEqual(Double, Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Double value is greater than or equal to another specified Double value.

```
C#

public static bool operator >= (double left, double right);
```

Parameters

`left` Double

The first value to compare.

`right` Double

The second value to compare.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Remarks

The GreaterThanOrEqual method defines the operation of the greater-than-or-equal operator for Double values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.Inequality(Double, Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two specified Double values are not equal.

```
C#
public static bool operator != (double left, double right);
```

Parameters

`left` Double

The first value to compare.

`right` Double

The second value to compare.

Returns

Boolean

`true` if `left` and `right` are not equal; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Remarks

The Inequality method defines the inequality operator for Double values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.LessThan(Double, Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Double value is less than another specified Double value.

```
C#
public static bool operator < (double left, double right);
```

Parameters

`left` Double

The first value to compare.

`right` Double

The second value to compare.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Remarks

The LessThan method defines the operation of the less-than operator for Double values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.LessThanOrEqual(Double, Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Double value is less than or equal to another specified Double value.

```
C#
public static bool operator <= (double left, double right);
```

Parameters

`left` Double

The first value to compare.

`right` Double

The second value to compare.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Remarks

The LessThanOrEqual method defines the operation of the less-than-or-equal operator for Double values.

Applies to

Product	Versions

Double.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

This conversion is not supported. No value is returned.

Implements

ToChar(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions

Double.IConvertible.To Double(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, unchanged.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToSByte(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to which to convert this Double value.

provider IFormatProvider

An IFormatProvider implementation that supplies culture-specific information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Double.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt16(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Double.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt32(Double) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Double.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Double instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt64(Double) method.

Applies to

Product	Versions

Double.IAdditionOperators<Double,Double,Double>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static double IAdditionOperators<double,double,double>.operator + (double
left, double right);
```

Parameters

`left` Double

The value to which `right` is added.

`right` Double

The value that's added to `left`.

Returns

Double

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Double.IBitwiseOperators<Double,Double,Double>.BitwiseAnd Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static double IBitwiseOperators<double,double,double>.operator & (double
left, double right);
```

Parameters

`left` Double

The value to `and` with `right`.

`right` Double

The value to `and` with `left`.

Returns

Double

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Double.IBitwiseOperators<Double,Double,Double>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static double IBitwiseOperators<double,double,double>.operator | (double
left, double right);
```

Parameters

`left` Double

The value to `or` with `right`.

`right` Double

The value to `or` with `left`.

Returns

Double

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IBitwiseOperators<Double,Double,Double>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static double IBitwiseOperators<double,double,double>.operator ^ (double
left, double right);
```

Parameters

`left` Double

The value to xor with `right`.

`right` Double

The value to xor with `left`.

Returns

Double

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IBitwise Operators<Double,Double,Double>.OnesComplement Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#

static double IBitwiseOperators<double,double,double>.operator ~ (double
value);
```

Parameters

`value` Double

The value for which to compute the ones-complement.

Returns

Double

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IDecrementOperators<Double>.Decrement(Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static double IDecrementOperators<double>.operator -- (double value);
```

Parameters

`value` Double

The value to decrement.

Returns

Double

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Double.IDivisionOperators<Double,Double,Double>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static double IDivisionOperators<double,double,double>.operator / (double
left, double right);
```

Parameters

`left` Double

The value that `right` divides.

`right` Double

The value that divides `left`.

Returns

Double

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IFloatingPoint<Double>.TryWriteExponentBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current exponent, in big-endian format, to a given span.

```
C#

bool IFloatingPoint<double>.TryWriteExponentBigEndian (Span<byte>
destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current exponent should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the exponent was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteExponentBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Double.IFloatingPoint<Double>.TryWriteSignificandBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current significand, in big-endian format, to a given span.

C#

```
bool IFloatingPoint<double>.TryWriteSignificandBigEndian (Span<byte>
destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current significand should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the significand was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteSignificandBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Double.IFloatingPoint<Double>.TryWriteSignificandLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current significand, in little-endian format, to a given span.

C#

```
bool IFloatingPoint<double>.TryWriteSignificandLittleEndian (Span<byte>
destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current significand should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the significand was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteSignificandLittleEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Double.IFloatingPoint Constants<Double>.E Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the mathematical constant `e`.

```
C#

static double System.Numerics.IFloatingPointConstants<System.Double>.E {
get; }
```

Property Value

Double

Implements

E

Applies to

Product	Versions
.NET	7, 8, 9

Double.IFloatingPoint Constants<Double>.Pi Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the mathematical constant `pi`.

C#

```
static double System.Numerics.IFloatingPointConstants<System.Double>.Pi {
get; }
```

Property Value

Double

Implements

Pi

Applies to

Product	Versions
.NET	7, 8, 9

Double.IFloatingPoint Constants<Double>.Tau Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the mathematical constant `tau`.

C#

```
static double System.Numerics.IFloatingPointConstants<System.Double>.Tau {
get; }
```

Property Value

Double

Implements

Tau

Applies to

Product	Versions
.NET	7, 8, 9

Double.IFloatingPoint Ieee754<Double>.Epsilon Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the smallest value such that can be added to `0` that does not result in `0`.

```
C#

static double System.Numerics.IFloatingPointIeee754<System.Double>.Epsilon {
get; }
```

Property Value

Double

Implements

Epsilon

Applies to

Product	Versions
.NET	7, 8, 9

Double.IFloatingPoint Ieee754<Double>.NaN Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that represents `NaN`.

C#

```
static double System.Numerics.IFloatingPointIeee754<System.Double>.NaN {
get; }
```

Property Value

Double

Implements

NaN

Applies to

Product	Versions
.NET	7, 8, 9

Double.IIncrementOperators<Double>.Increment(Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static double IIncrementOperators<double>.operator ++ (double value);
```

Parameters

`value` Double

The value to increment.

Returns

Double

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IModulus Operators<Double,Double,Double>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static double IModulusOperators<double,double,double>.operator % (double
left, double right);
```

Parameters

`left` Double

The value that `right` divides.

`right` Double

The value that divides `left`.

Returns

Double

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IMultiplyOperators<Double,Double,Double>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static double IMultiplyOperators<double,double,double>.operator * (double
left, double right);
```

Parameters

`left` Double

The value that `right` multiplies.

`right` Double

The value that multiplies `left`.

Returns

Double

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.INumberBase<Double>.IsCanonical(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<double>.IsCanonical (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.INumberBase<Double>.IsComplexNumber(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<double>.IsComplexNumber (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.INumberBase<Double>.IsImaginaryNumber(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<double>.IsImaginaryNumber (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.INumberBase<Double>.IsZero(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<double>.IsZero (double value);
```

Parameters

`value` Double

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.INumberBase<Double>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<double>.TryConvertToChecked<TOther> (double value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Double

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Double.INumberBase<Double>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<double>.TryConvertToSaturating<TOther> (double value, out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Double

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.ISubtraction Operators<Double,Double,Double>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static double ISubtractionOperators<double,double,double>.operator - (double
left, double right);
```

Parameters

`left` Double

The value from which `right` is subtracted.

`right` Double

The value that's subtracted from `left`.

Returns

Double

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IUnaryNegationOperators<Double,Double>.UnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#

static double IUnaryNegationOperators<double,double>.operator - (double
value);
```

Parameters

`value` Double

The value for which to compute the unary negation.

Returns

Double

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Double.IUnaryPlusOperators<Double,Double>.UnaryPlus(Double) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static double IUnaryPlusOperators<double,double>.operator + (double value);
```

Parameters

`value` Double

The value for which to compute the unary plus.

Returns

Double

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

DuplicateWaitObjectException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an object appears more than once in an array of synchronization objects.

C#

```
public class DuplicateWaitObjectException : ArgumentException
```

Inheritance Object → Exception → SystemException → ArgumentException → DuplicateWaitObjectException

Remarks

The common language runtime provides a thread synchronization mechanism based on synchronization objects waiting for execution in an array of WaitHandle objects. If the array of WaitHandle objects passed to WaitAll or WaitAny contains any duplicate operating system handles, DuplicateWaitObjectException is thrown. For more information, see WaitHandle.

DuplicateWaitObjectException uses the HRESULT COR_E_DUPLICATEWAITOBJECT, which has the value 0x80131529.

For a list of initial property values for an instance of DuplicateWaitObjectException, see the DuplicateWaitObjectException constructors.

> **Note**
>
> This exception is not included in **.NET for Windows Store apps** or the **Portable Class Library**, but it is thrown by some members that are. To catch the exception in that case, write a `catch` statement for **ArgumentException** instead.

Constructors

Expand table

DuplicateWaitObjectException()	Initializes a new instance of the DuplicateWaitObjectException class.
DuplicateWaitObject Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the DuplicateWaitObjectException class with serialized data.
DuplicateWaitObject Exception(String)	Initializes a new instance of the DuplicateWaitObjectException class with the name of the parameter that causes this exception.
DuplicateWaitObject Exception(String, Exception)	Initializes a new instance of the DuplicateWaitObjectException class with a specified error message and a reference to the inner exception that is the cause of this exception.
DuplicateWaitObject Exception(String, String)	Initializes a new instance of the DuplicateWaitObjectException class with a specified error message and the name of the parameter that causes this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message and the parameter name, or only the error message if no parameter name is set. (Inherited from ArgumentException)

ParamName	Gets the name of the parameter that causes this exception. (Inherited from ArgumentException)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the parameter name and additional exception information. (Inherited from ArgumentException)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions

DuplicateWaitObjectException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the DuplicateWaitObjectException class.

Overloads

Expand table

DuplicateWaitObjectException()	Initializes a new instance of the DuplicateWaitObjectException class.
DuplicateWaitObjectException(String)	Initializes a new instance of the DuplicateWaitObjectException class with the name of the parameter that causes this exception.
DuplicateWaitObjectException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the DuplicateWaitObjectException class with serialized data.
DuplicateWaitObjectException(String, Exception)	Initializes a new instance of the DuplicateWaitObjectException class with a specified error message and a reference to the inner exception that is the cause of this exception.
DuplicateWaitObjectException(String, String)	Initializes a new instance of the DuplicateWaitObjectException class with a specified error message and the name of the parameter that causes this exception.

DuplicateWaitObjectException()

Initializes a new instance of the DuplicateWaitObjectException class.

C#

```
public DuplicateWaitObjectException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Duplicate objects in argument." This message takes into account the current system culture.

The following table shows the initial property values for an instance of DuplicateWaitObjectException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DuplicateWaitObjectException(String)

Initializes a new instance of the DuplicateWaitObjectException class with the name of the parameter that causes this exception.

C#

```
public DuplicateWaitObjectException (string? parameterName);
```

Parameters

`parameterName` String

The name of the parameter that caused the exception.

Remarks

The content of `parameterName` is intended to be understood by humans.

The following table shows the initial property values for an instance of DuplicateWaitObjectException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.
ParamName	The parameter name string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DuplicateWaitObjectException(SerializationInfo, StreamingContext)

⊗ Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the DuplicateWaitObjectException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected DuplicateWaitObjectException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DuplicateWaitObjectException(String, Exception) *(Obsolete)*

Initializes a new instance of the DuplicateWaitObjectException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public DuplicateWaitObjectException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed to this constructor.

The following table shows the initial property values for an instance of DuplicateWaitObjectException.

Expand table

Property	Value
InnerException	The exception specified by `innerException`.

Property	Value
Message	The error message string specified by `message`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

DuplicateWaitObjectException(String, String)

Initializes a new instance of the DuplicateWaitObjectException class with a specified error message and the name of the parameter that causes this exception.

C#

```
public DuplicateWaitObjectException (string? parameterName, string?
message);
```

Parameters

`parameterName` String

The name of the parameter that caused the exception.

`message` String

The message that describes the error.

Remarks

The content of the `parameterName` and `message` parameters is intended to be understood by humans. The caller of this constructor is required to ensure that these strings have been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The

InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of DuplicateWaitObjectException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic)
Message	The error message string.
ParamName	The parameter name string.

EntryPointNotFoundException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt to load a class fails due to the absence of an entry method.

```
C#

public class EntryPointNotFoundException : TypeLoadException
```

Inheritance Object → Exception → SystemException → TypeLoadException → EntryPointNotFoundException

Remarks

An EntryPointNotFoundException exception is thrown when the common language runtime is unable to load an assembly because it cannot identify the assembly's entry point. This exception can be thrown under the following conditions:

- The common language runtime is unable to locate an application entry point (typically a `Main` method) in an executable assembly. The application entry point must be a global or `static` method that has either no parameters or a string array as its only parameter. The entry point can return `void`, or it can return an Int32 or UInt32 exit code. An application assembly cannot define more than one entry point.

- The call to a function in a Windows DLL cannot be resolved because the function cannot be found. In the following example, an EntryPointNotFoundException exception is thrown because User32.dll does not include a function named `GetMyNumber`.

  ```
  C#

  using System;
  using System.Runtime.InteropServices;
  ```

```
public class Example
{
   [DllImport("user32.dll")]
   public static extern int GetMyNumber();

   public static void Main()
   {
      try {
         int number = GetMyNumber();
      }
      catch (EntryPointNotFoundException e) {
         Console.WriteLine("{0}:\n   {1}", e.GetType().Name,
                           e.Message);
      }
   }
}
// The example displays the following output:
//    EntryPointNotFoundException:
//       Unable to find an entry point named 'GetMyNumber' in DLL
'User32.dll'.
```

- The call to a function in a Windows DLL cannot be resolved because the name used in the method call does not match a name found in the assembly. Frequently, this occurs because the DllImportAttribute.ExactSpelling field is either implicitly or explicitly set to `true`, the called method includes one or more string parameters and has both an ANSI and a Unicode version, and the name used in the method call does not correspond to the name of this ANSI or Unicode version. The following example provides an illustration by attempting to call the Windows `MessageBox` function in User32.dll. Because the first method definition specifies CharSet.Unicode for string marshaling, the common language looks for the wide-character version of the function, `MessageBoxW`, instead of the name used in the method call, `MessageBox`. The second method definition corrects this problem by calling the `MessageBoxW` instead of the `MessageBox` function.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
   [DllImport("user32.dll", CharSet = CharSet.Unicode, ExactSpelling =
true )]
   public static extern int MessageBox(IntPtr hwnd, String text, String
caption, uint type);

   [DllImport("user32.dll", CharSet = CharSet.Unicode, ExactSpelling =
true )]
```

```
   public static extern int MessageBoxW(IntPtr hwnd, String text,
String caption, uint type);

   public static void Main()
   {
      try {
         MessageBox(new IntPtr(0), "Calling the MessageBox Function",
"Example", 0);
      }
      catch (EntryPointNotFoundException e) {
         Console.WriteLine("{0}:\n   {1}", e.GetType().Name,
                           e.Message);
      }

      try {
         MessageBoxW(new IntPtr(0), "Calling the MessageBox Function",
"Example", 0);
      }
      catch (EntryPointNotFoundException e) {
         Console.WriteLine("{0}:\n   {1}", e.GetType().Name,
                           e.Message);
      }
   }
}
```

- You are trying to call a function in a dynamic link library by its simple name rather than its decorated name. Typically, the C++ compiler generates a decorated name for DLL functions. For example, the following C++ code defines a function named `Double` in a library named TestDll.dll.

```
C++

__declspec(dllexport) int Double(int number)
{
    return number * 2;
}
```

When the code in the following example tries to call the function, an EntryPointNotFoundException exception is thrown because the `Double` function cannot be found.

```
C#

using System;
using System.Runtime.InteropServices;

public class Example
{
   [DllImport("TestDll.dll")]
   public static extern int Double(int number);
```

```
    public static void Main()
    {
        Console.WriteLine(Double(10));
    }
}
// The example displays the following output:
//    Unhandled Exception: System.EntryPointNotFoundException: Unable
to find
//    an entry point named 'Double' in DLL '.\TestDll.dll'.
//       at Example.Double(Int32 number)
//       at Example.Main()
```

However, if the function is called by using its decorated name (in this case, `?Double@@YAHH@Z`), the function call succeeds, as the following example shows.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
    [DllImport("TestDll.dll", EntryPoint = "?Double@@YAHH@Z")]
    public static extern int Double(int number);

    public static void Main()
    {
        Console.WriteLine(Double(10));
    }
}
// The example displays the following output:
//    20
```

You can find the decorated names of functions exported by a DLL by using a utility such as Dumpbin.exe.

- You are attempting to call a method in a managed assembly as if it were an unmanaged dynamic link library. To see this in action, compile the following example to an assembly named StringUtilities.dll.

C#

```
using System;

public static class StringUtilities
{
    public static String SayGoodMorning(String name)
    {
        return String.Format("A top of the morning to you, {0}!", name);
```

```
    }
}
```

Then compile and execute the following example, which attempts to call the `StringUtilities.SayGoodMorning` method in the StringUtilities.dll dynamic link library as if it were unmanaged code. The result is an EntryPointNotFoundException exception.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
   [DllImport("StringUtilities.dll", CharSet = CharSet.Unicode )]
   public static extern String SayGoodMorning(String name);

   public static void Main()
   {
      Console.WriteLine(SayGoodMorning("Dakota"));
   }
}
// The example displays the following output:
//    Unhandled Exception: System.EntryPointNotFoundException: Unable
to find an entry point
//    named 'GoodMorning' in DLL 'StringUtilities.dll'.
//       at Example.GoodMorning(String& name)
//       at Example.Main()
```

To eliminate the exception, add a reference to the managed assembly and access the `StringUtilities.SayGoodMorning` method just as you would access any other method in managed code, as the following example does.

C#

```
using System;

public class Example
{
   public static void Main()
   {
       Console.WriteLine(StringUtilities.SayGoodMorning("Dakota"));
   }
}
// The example displays the following output:
//        A top of the morning to you, Dakota!
```

- You are trying to call a method in a COM DLL as if it were a Windows DLL. To access a COM DLL, select the **Add Reference** option in Visual Studio to add a reference to the project, and then select the type library from the **COM** tab.

For a list of initial property values for an instance of EntryPointNotFoundException, see the EntryPointNotFoundException constructors.

Constructors

Expand table

EntryPointNotFoundException()	Initializes a new instance of the EntryPointNotFoundException class.
EntryPointNotFound Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the EntryPointNotFoundException class with serialized data.
EntryPointNotFound Exception(String)	Initializes a new instance of the EntryPointNotFoundException class with a specified error message.
EntryPointNotFoundException(String, Exception)	Initializes a new instance of the EntryPointNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

EntryPointNotFoundException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the EntryPointNotFoundException class.

Overloads

Expand table

EntryPointNotFoundException()	Initializes a new instance of the EntryPointNotFoundException class.
EntryPointNotFoundException(String)	Initializes a new instance of the EntryPointNotFoundException class with a specified error message.
EntryPointNotFoundException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the EntryPointNotFoundException class with serialized data.
EntryPointNotFoundException(String, Exception)	Initializes a new instance of the EntryPointNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

EntryPointNotFoundException()

Initializes a new instance of the EntryPointNotFoundException class.

C#

```
public EntryPointNotFoundException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Entry point was not found." This message takes into account the current system culture.

The following table shows the initial property values for an instance of EntryPointNotFoundException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

EntryPointNotFoundException(String)

Initializes a new instance of the EntryPointNotFoundException class with a specified error message.

C#

```
public EntryPointNotFoundException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Remarks

The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of EntryPointNotFoundException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

.NET Standard	2.0, 2.1

EntryPointNotFoundException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the EntryPointNotFoundException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected EntryPointNotFoundException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

EntryPointNotFoundException(String, Exception)

Initializes a new instance of the EntryPointNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public EntryPointNotFoundException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

Enum Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides the base class for enumerations.

C#

```
public abstract class Enum : ValueType, IComparable, IConvertible,
ISpanFormattable
```

Inheritance Object → ValueType → Enum

Derived Accessibility.AnnoScope
Microsoft.Aspnet.Snapin.MMC_CONTROL_TYPE
Microsoft.CSharp.ErrorLevel
Microsoft.CSharp.RuntimeBinder.CSharpArgumentInfoFlags
Microsoft.CSharp.RuntimeBinder.CSharpBinderFlags
More...

Implements IComparable , IConvertible , IFormattable , ISpanFormattable

Remarks

For more information about this API, see Supplemental API remarks for Enum.

Constructors

Expand table

Enum()	Initializes a new instance of the Enum class.

Methods

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Format(Type, Object, String)	Converts the specified value of a specified enumerated type to its equivalent string representation according to the specified format.
GetHashCode()	Returns the hash code for the value of this instance.
GetName(Type, Object)	Retrieves the name of the constant in the specified enumeration that has the specified value.
GetName<TEnum>(TEnum)	Retrieves the name of the constant in the specified enumeration type that has the specified value.
GetNames(Type)	Retrieves an array of the names of the constants in a specified enumeration.
GetNames<TEnum>()	Retrieves an array of the names of the constants in a specified enumeration type.
GetType()	Gets the Type of the current instance. (Inherited from Object)
GetTypeCode()	Returns the type code of the underlying type of this enumeration member.
GetUnderlyingType(Type)	Returns the underlying type of the specified enumeration.
GetValues(Type)	Retrieves an array of the values of the constants in a specified enumeration.
GetValues<TEnum>()	Retrieves an array of the values of the constants in a specified enumeration type.
GetValuesAsUnderlyingType(Type)	Retrieves an array of the values of the underlying type constants in a specified enumeration.
GetValuesAsUnderlyingType<TEnum>()	Retrieves an array of the values of the underlying type constants in a specified enumeration type.
HasFlag(Enum)	Determines whether one or more bit fields are set in the current instance.
IsDefined(Type, Object)	Returns a Boolean telling whether a given integral value, or its name as a string, exists in a specified enumeration.

IsDefined<TEnum>(TEnum)	Returns a boolean telling whether a given integral value, or its name as a string, exists in a specified enumeration.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Parse(Type, ReadOnlySpan<Char>)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
Parse(Type, ReadOnlySpan<Char>, Boolean)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse(Type, String)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
Parse(Type, String, Boolean)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse<TEnum>(ReadOnlySpan<Char>)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object.
Parse<TEnum>(ReadOnlySpan<Char>, Boolean)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse<TEnum>(String)	Converts the string representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object.
Parse<TEnum>(String, Boolean)	Converts the string representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
ToObject(Type, Byte)	Converts the specified 8-bit unsigned integer to an enumeration member.
ToObject(Type, Int16)	Converts the specified 16-bit signed integer to an enumeration member.
ToObject(Type, Int32)	Converts the specified 32-bit signed integer to an enumeration member.

ToObject(Type, Int64)	Converts the specified 64-bit signed integer to an enumeration member.
ToObject(Type, Object)	Converts the specified object with an integer value to an enumeration member.
ToObject(Type, SByte)	Converts the specified 8-bit signed integer value to an enumeration member.
ToObject(Type, UInt16)	Converts the specified 16-bit unsigned integer value to an enumeration member.
ToObject(Type, UInt32)	Converts the specified 32-bit unsigned integer value to an enumeration member.
ToObject(Type, UInt64)	Converts the specified 64-bit unsigned integer value to an enumeration member.
ToString()	Converts the value of this instance to its equivalent string representation.
ToString(IFormatProvider)	**Obsolete.** This method overload is obsolete; use ToString().
ToString(String)	Converts the value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormat Provider)	**Obsolete.** This method overload is obsolete; use ToString(String).
TryFormat<TEnum>(TEnum, Span<Char>, Int32, ReadOnly Span<Char>)	Tries to format the value of the enumerated type instance into the provided span of characters.
TryParse(Type, ReadOnly Span<Char>, Boolean, Object)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
TryParse(Type, ReadOnly Span<Char>, Object)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse(Type, String, Boolean, Object)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse(Type, String, Object)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

TryParse<TEnum>(ReadOnlySpan<Char>, Boolean, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-sensitive. The return value indicates whether the conversion succeeded.
TryParse<TEnum>(ReadOnlySpan<Char>, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse<TEnum>(String, Boolean, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-sensitive. The return value indicates whether the conversion succeeded.
TryParse<TEnum>(String, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. The return value indicates whether the conversion succeeded.

Explicit Interface Implementations

Expand table

IConvertible.ToBoolean(IFormatProvider)	Converts the current value to a Boolean value based on the underlying type.
IConvertible.ToByte(IFormatProvider)	Converts the current value to an 8-bit unsigned integer based on the underlying type.
IConvertible.ToChar(IFormatProvider)	Converts the current value to a Unicode character based on the underlying type.
IConvertible.ToDateTime(IFormatProvider)	Converts the current value to a DateTime based on the underlying type.
IConvertible.ToDecimal(IFormatProvider)	Converts the current value to a Decimal based on the underlying type.
IConvertible.ToDouble(IFormatProvider)	Converts the current value to a double-precision floating point number based on the underlying type.
IConvertible.ToInt16(IFormatProvider)	Converts the current value to a 16-bit signed integer based on the underlying type.

IConvertible.ToInt32(IFormatProvider)	Converts the current value to a 32-bit signed integer based on the underlying type.
IConvertible.ToInt64(IFormatProvider)	Converts the current value to a 64-bit signed integer based on the underlying type.
IConvertible.ToSByte(IFormatProvider)	Converts the current value to an 8-bit signed integer based on the underlying type.
IConvertible.ToSingle(IFormatProvider)	Converts the current value to a single-precision floating-point number based on the underlying type.
IConvertible.ToType(Type, IFormatProvider)	Converts the current value to a specified type based on the underlying type.
IConvertible.ToUInt16(IFormatProvider)	Converts the current value to a 16-bit unsigned integer based on the underlying type.
IConvertible.ToUInt32(IFormatProvider)	Converts the current value to a 32-bit unsigned integer based on the underlying type.
IConvertible.ToUInt64(IFormatProvider)	Converts the current value to a 64-bit unsigned integer based on the underlying type.
ISpanFormattable.TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the enum into the provided span of characters.

Enum Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Enum class.

C#

```
protected Enum ();
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object and returns an indication of their relative values.

```
C#
public int CompareTo (object? target);
```

Parameters

target Object

An object to compare, or `null`.

Returns

Int32

A signed number that indicates the relative values of this instance and `target`.

Expand table

Value	Meaning
Less than zero	The value of this instance is less than the value of `target`.
Zero	The value of this instance is equal to the value of `target`.
Greater than zero	The value of this instance is greater than the value of `target`, or `target` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`target` and this instance are not the same type.

InvalidOperationException

This instance is not type SByte, Int16, Int32, Int64, Byte, UInt16, UInt32, or UInt64.

NullReferenceException

This instance is null.

Examples

The following example illustrates the use of `CompareTo` in the context of `Enum`.

C#

```
using System;

public class CompareToTest {
    enum VehicleDoors { Motorbike = 0, Sportscar = 2, Sedan = 4, Hatchback =
5 };

    public static void Main() {
        VehicleDoors myVeh = VehicleDoors.Sportscar;
        VehicleDoors yourVeh = VehicleDoors.Motorbike;
        VehicleDoors otherVeh = VehicleDoors.Sedan;

        Console.WriteLine("Does a {0} have more doors than a {1}?", myVeh,
yourVeh);
        Console.WriteLine( "{0}{1}", myVeh.CompareTo(yourVeh) > 0 ? "Yes" :
"No", Environment.NewLine );

        Console.WriteLine("Does a {0} have more doors than a {1}?", myVeh,
otherVeh);
        Console.WriteLine( "{0}", myVeh.CompareTo(otherVeh) > 0 ? "Yes" :
"No" );
    }
}
// The example displays the following output:
//       Does a Sportscar have more doors than a Motorbike?
//       Yes
//
//       Does a Sportscar have more doors than a Sedan?
//       No
```

Applies to

Product	Versions

Enum.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance, or `null`.

Returns

Boolean

`true` if `obj` is an enumeration value of the same type and with the same underlying value as this instance; otherwise, `false`.

Examples

The following example illustrates the use of the Equals method.

C#

```
using System;

public class EqualsTest {
    enum Colors { Red, Green, Blue, Yellow };
    enum Mammals { Cat, Dog, Horse, Dolphin };

    public static void Main() {
        Mammals myPet = Mammals.Cat;
        Colors myColor = Colors.Red;
        Mammals yourPet = Mammals.Dog;
        Colors yourColor = Colors.Red;
```

```
        Console.WriteLine("My favorite animal is a {0}", myPet);
        Console.WriteLine("Your favorite animal is a {0}", yourPet);
        Console.WriteLine("Do we like the same animal? {0}",
myPet.Equals(yourPet) ? "Yes" : "No");

        Console.WriteLine();
        Console.WriteLine("My favorite color is {0}", myColor);
        Console.WriteLine("Your favorite color is {0}", yourColor);
        Console.WriteLine("Do we like the same color? {0}",
myColor.Equals(yourColor) ? "Yes" : "No");

        Console.WriteLine();
        Console.WriteLine("The value of my color ({0}) is {1}", myColor,
Enum.Format(typeof(Colors), myColor, "d"));
        Console.WriteLine("The value of my pet (a {0}) is {1}", myPet,
Enum.Format(typeof(Mammals), myPet, "d"));
        Console.WriteLine("Even though they have the same value, are they
equal? {0}",
                    myColor.Equals(myPet) ? "Yes" : "No");
    }
}
// The example displays the following output:
//    My favorite animal is a Cat
//    Your favorite animal is a Dog
//    Do we like the same animal? No
//
//    My favorite color is Red
//    Your favorite color is Red
//    Do we like the same color? Yes
//
//    The value of my color (Red) is 0
//    The value of my pet (a Cat) is 0
//    Even though they have the same value, are they equal? No
```

The following example defines two enumeration types, `SledDog` and `WorkDog`. The `SledDog` enumeration has two members, `SledDog.AlaskanMalamute` and `SledDog.Malamute`, that have the same underlying value. The call to the Equals method indicates that these values are equal because their underlying values are the same. The `SledDog.Malamute` and `WorkDog.Newfoundland` members have the same underlying value, although they represent different enumeration types. A call to the Equals method indicates that these values are not equal.

C#

```
using System;

public enum SledDog { Unknown=0, AlaskanMalamute=1, Malamute=1,
                      Husky=2, SiberianHusky=2 };

public enum WorkDog { Unknown=0, Newfoundland=1, GreatPyrennes=2 };
```

```
public class Example
{
   public static void Main()
   {
      SledDog dog1 = SledDog.Malamute;
      SledDog dog2 = SledDog.AlaskanMalamute;
      WorkDog dog3 = WorkDog.Newfoundland;

      Console.WriteLine("{0:F} ({0:D}) = {1:F} ({1:D}): {2}",
                        dog1, dog2, dog1.Equals(dog2));
      Console.WriteLine("{0:F} ({0:D}) = {1:F} ({1:D}): {2}",
                        dog1, dog3, dog1.Equals(dog3));
   }
}
// The example displays the following output:
//       Malamute (1) = Malamute (1): True
//       Malamute (1) = Newfoundland (1): False
```

Remarks

The Enum.Equals(Object) method overrides ValueType.Equals(Object) to define how enumeration members are evaluated for equality.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.Format(Type, Object, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified value of a specified enumerated type to its equivalent string representation according to the specified format.

C#

```
public static string Format (Type enumType, object value, string format);
```

Parameters

`enumType` Type

The enumeration type of the value to convert.

`value` Object

The value to convert.

`format` String

The output format to use.

Returns

String

A string representation of `value`.

Exceptions

ArgumentNullException

The `enumType`, `value`, or `format` parameter is `null`.

ArgumentException

The `enumType` parameter is not an Enum type.

-or-

The `value` is from an enumeration that differs in type from `enumType`.

-or-

The type of `value` is not an underlying type of `enumType`.

FormatException

The `format` parameter contains an invalid value.

InvalidOperationException

`format` equals "X", but the enumeration type is unknown.

-or-

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Examples

The following example illustrates the use of `Format` in the context of `Enum`.

C#

```
using System;

enum Colors { Red, Green, Blue, Yellow };

public class FormatTest {
    public static void Main() {
        Colors myColor = Colors.Blue;

        Console.WriteLine("My favorite color is {0}.", myColor);
        Console.WriteLine("The value of my favorite color is {0}.",
Enum.Format(typeof(Colors), myColor, "d"));
        Console.WriteLine("The hex value of my favorite color is {0}.",
Enum.Format(typeof(Colors), myColor, "x"));
    }
}
// The example displays the following output:
//    My favorite color is Blue.
//    The value of my favorite color is 2.
//    The hex value of my favorite color is 00000002.
```

Remarks

The following table shows the valid values for the `format` parameter.

Expand table

Format	Description
"G" or "g"	If `value` is equal to a named enumerated constant, the name of that constant is returned; otherwise, the decimal equivalent of `value` is returned. For example, suppose the only enumerated constant is named Red, and its value is 1. If `value` is specified as 1, this format returns "Red". However, if `value` is specified as 2, this format returns "2". -or- If the FlagsAttribute custom attribute is applied to the enumeration, `value` is treated as a bit field that contains one or more flags that consist of one or more bits. If `value` is equal to a combination of named enumerated constants, a delimiter-separated list of the names of those constants is returned. `value` is searched for flags, going from the flag with the largest value to the smallest value. For each flag that corresponds to a bit field in `value`, the name of the constant is concatenated to the delimiter-separated list. The value of that flag is then excluded from further consideration, and the search continues for the next flag. If `value` is not equal to a combination of named enumerated constants, the decimal equivalent of `value` is returned.
"X" or "x"	Represents `value` in hexadecimal format without a leading "0x".
"D" or "d"	Represents `value` in decimal form.
"F" or "f"	Behaves identically to "G" or "g", except that the FlagsAttribute is not required to be present on the Enum declaration.

Applies to

Enum.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the value of this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.GetName Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetName(Type, Object)	Retrieves the name of the constant in the specified enumeration that has the specified value.
GetName<TEnum>(TEnum)	Retrieves the name of the constant in the specified enumeration type that has the specified value.

GetName(Type, Object)

Retrieves the name of the constant in the specified enumeration that has the specified value.

C#

```
public static string? GetName (Type enumType, object value);
```

Parameters

`enumType` Type

An enumeration type.

`value` Object

The value of a particular enumerated constant in terms of its underlying type.

Returns

String

A string containing the name of the enumerated constant in `enumType` whose value is `value`; or `null` if no such constant is found.

Exceptions

ArgumentNullException

`enumType` or `value` is `null`.

ArgumentException

`enumType` is not an Enum.

-or-

`value` is neither of type `enumType` nor does it have the same underlying type as `enumType`.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Examples

The following example illustrates the use of `GetName`.

C#

```
using System;

public class GetNameTest {
    enum Colors { Red, Green, Blue, Yellow };
    enum Styles { Plaid, Striped, Tartan, Corduroy };

    public static void Main() {

        Console.WriteLine("The 4th value of the Colors Enum is {0}",
Enum.GetName(typeof(Colors), 3));
        Console.WriteLine("The 4th value of the Styles Enum is {0}",
Enum.GetName(typeof(Styles), 3));
    }
}
// The example displays the following output:
//       The 4th value of the Colors Enum is Yellow
//       The 4th value of the Styles Enum is Corduroy
```

Remarks

If multiple enumeration members have the same underlying value, the GetName method guarantees that it will return the name of one of those enumeration members. However, it does not guarantee that it will always return the name of the same enumeration member. As a result, when multiple enumeration members have the same value, your application code should never depend on the method returning a particular member's name.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetName<TEnum>(TEnum)

Retrieves the name of the constant in the specified enumeration type that has the specified value.

C#

```
public static string? GetName<TEnum> (TEnum value) where TEnum : struct;
```

Type Parameters

`TEnum`

The type of the enumeration.

Parameters

`value` TEnum

The value of a particular enumerated constant in terms of its underlying type.

Returns

String

A string containing the name of the enumerated constant in `TEnum` whose value is `value`; or `null` if no such constant is found.

Exceptions

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Applies to

Enum.GetNames Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetNames(Type)	Retrieves an array of the names of the constants in a specified enumeration.
GetNames<TEnum>()	Retrieves an array of the names of the constants in a specified enumeration type.

GetNames(Type)

Retrieves an array of the names of the constants in a specified enumeration.

C#

```
public static string[] GetNames (Type enumType);
```

Parameters

enumType Type

An enumeration type.

Returns

String[]

A string array of the names of the constants in `enumType`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` parameter is not an Enum.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Examples

The following example illustrates the use of the GetNames method.

C#

```
using System;

public class GetNamesTest {
    enum Colors { Red, Green, Blue, Yellow };
    enum Styles { Plaid, Striped, Tartan, Corduroy };

    public static void Main() {

        Console.WriteLine("The members of the Colors enum are:");
        foreach(string s in Enum.GetNames(typeof(Colors)))
            Console.WriteLine(s);

        Console.WriteLine();

        Console.WriteLine("The members of the Styles enum are:");
        foreach(string s in Enum.GetNames(typeof(Styles)))
            Console.WriteLine(s);
    }
}
// The example displays the following output:
//       The members of the Colors enum are:
//       Red
//       Green
//       Blue
//       Yellow
//
//       The members of the Styles enum are:
//       Plaid
//       Striped
//       Tartan
//       Corduroy
```

Remarks

The elements of the return value array are sorted by the binary values of the enumerated constants (that is, by their unsigned magnitude). The following example provides displays information about the array returned by the GetNames method for an enumeration that includes a negative, zero, and a positive value.

C#

```
using System;

enum SignMagnitude { Negative = -1, Zero = 0, Positive = 1 };

public class Example
{
   public static void Main()
   {
      foreach (var name in Enum.GetNames(typeof(SignMagnitude))) {
         Console.WriteLine("{0,3:D}     0x{0:X}     {1}",
                           Enum.Parse(typeof(SignMagnitude), name),
                           name);
}   }
}
// The example displays the following output:
//          0     0x00000000     Zero
//          1     0x00000001     Positive
//         -1     0xFFFFFFFF     Negative
```

If there are enumerated constants with same value, the order of their corresponding names is unspecified.

Applies to

UWP	10.0

GetNames<TEnum>()

Retrieves an array of the names of the constants in a specified enumeration type.

```
C#

public static string[] GetNames<TEnum> () where TEnum : struct;
```

Type Parameters

`TEnum`

The type of the enumeration.

Returns

String[]

A string array of the names of the constants in `TEnum`.

Exceptions

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Enum.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the type code of the underlying type of this enumeration member.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The type code of the underlying type of this instance.

Implements

GetTypeCode()

Exceptions

InvalidOperationException

The enumeration type is unknown.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Enum.GetUnderlyingType(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the underlying type of the specified enumeration.

```
C#
public static Type GetUnderlyingType (Type enumType);
```

Parameters

enumType Type

The enumeration whose underlying type will be retrieved.

Returns

Type

The underlying type of `enumType`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

Examples

The following example calls the GetUnderlyingType method to display the underlying type of some enumeration members.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      Enum[] enumValues = { ConsoleColor.Red, DayOfWeek.Monday,
                            MidpointRounding.ToEven, PlatformID.Win32NT,
                            DateTimeKind.Utc, StringComparison.Ordinal };
      Console.WriteLine("{0,-10} {1, 18}   {2,15}\n",
                        "Member", "Enumeration", "Underlying Type");
      foreach (var enumValue in enumValues)
         DisplayEnumInfo(enumValue);
   }

   static void DisplayEnumInfo(Enum enumValue)
   {
      Type enumType = enumValue.GetType();
      Type underlyingType = Enum.GetUnderlyingType(enumType);
      Console.WriteLine("{0,-10} {1, 18}   {2,15}",
                        enumValue, enumType.Name, underlyingType.Name);
   }
}
// The example displays the following output:
//       Member            Enumeration   Underlying Type
//
//       Red              ConsoleColor             Int32
//       Monday              DayOfWeek             Int32
//       ToEven       MidpointRounding             Int32
//       Win32NT            PlatformID             Int32
//       Utc              DateTimeKind             Int32
//       Ordinal      StringComparison             Int32
```

Remarks

The Enum structure enables values to be represented as named constants. The data type of the enumeration's values is known as its underlying type. For example, the underlying type of the DayOfWeek enumeration, which consists of constants that represent each day of the week (DayOfWeek.Monday, DayOfWeek.Tuesday, and so on), is Int32.

Applies to

Enum.GetValues Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetValues(Type)	Retrieves an array of the values of the constants in a specified enumeration.
GetValues<TEnum>()	Retrieves an array of the values of the constants in a specified enumeration type.

GetValues(Type)

Retrieves an array of the values of the constants in a specified enumeration.

C#

```
public static Array GetValues (Type enumType);
```

Parameters

enumType Type

An enumeration type.

Returns

Array

An array that contains the values of the constants in `enumType`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

InvalidOperationException

The method is invoked by reflection in a reflection-only context,

-or-

`enumType` is a type from an assembly loaded in a reflection-only context.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Examples

The following example illustrates the use of GetValues.

C#

```
using System;

public class GetValuesTest {
    enum Colors { Red, Green, Blue, Yellow };
    enum Styles { Plaid = 0, Striped = 23, Tartan = 65, Corduroy = 78 };

    public static void Main() {

        Console.WriteLine("The values of the Colors Enum are:");
        foreach(int i in Enum.GetValues(typeof(Colors)))
            Console.WriteLine(i);

        Console.WriteLine();

        Console.WriteLine("The values of the Styles Enum are:");
        foreach(int i in Enum.GetValues(typeof(Styles)))
            Console.WriteLine(i);
    }
}
// The example produces the following output:
//       The values of the Colors Enum are:
//       0
//       1
//       2
//       3
//
//       The values of the Styles Enum are:
```

```
//        0
//        23
//        65
//        78
```

Remarks

The elements of the array are sorted by the binary values of the enumeration constants (that is, by their unsigned magnitude). The following example displays information about the array returned by the GetValues method for an enumeration that includes a negative value, zero, and a positive value.

```C#
using System;

enum SignMagnitude { Negative = -1, Zero = 0, Positive = 1 };

public class Example
{
   public static void Main()
   {
      foreach (var value in Enum.GetValues(typeof(SignMagnitude))) {
         Console.WriteLine("{0,3}     0x{0:X8}     {1}",
                           (int) value, ((SignMagnitude) value));
}   }
}
// The example displays the following output:
//          0     0x00000000     Zero
//          1     0x00000001     Positive
//         -1     0xFFFFFFFF     Negative
```

The GetValues method returns an array that contains a value for each member of the `enumType` enumeration. If multiple members have the same value, the returned array includes duplicate values. In this case, calling the GetName method with each value in the returned array does not restore the unique names assigned to members that have duplicate values. To retrieve all the names of enumeration members successfully, call the GetNames method.

The GetValues method cannot be invoked by using reflection in a reflection-only context. Instead, you can retrieve the value of all enumeration members by using the Type.GetFields method to get an array of FieldInfo objects that represent enumeration members and then call the FieldInfo.GetRawConstantValue method on each element of the array. The following example illustrates this technique. It requires that you define the following enumeration in an assembly named Enumerations.dll:

C#

```
[Flags] enum Pets { None=0, Dog=1, Cat=2, Rodent=4, Bird=8,
                    Fish=16, Reptile=32, Other=64 };
```

The assembly is loaded in a reflection-only context, a Type object that represents the `Pets` enumeration is instantiated, an array of FieldInfo objects is retrieved, and the field values are displayed to the console.

C#

```
using System;
using System.Reflection;

public class Example
{
   public static void Main()
   {
      Assembly assem =
Assembly.ReflectionOnlyLoadFrom(@".\Enumerations.dll");
      Type typ = assem.GetType("Pets");
      FieldInfo[] fields = typ.GetFields();

      foreach (var field in fields) {
         if (field.Name.Equals("value__")) continue;

         Console.WriteLine("{0,-9} {1}", field.Name + ":",
                                         field.GetRawConstantValue());
      }
   }
}
// The example displays the following output:
//       None:     0
//       Dog:      1
//       Cat:      2
//       Rodent:   4
//       Bird:     8
//       Fish:     16
//       Reptile:  32
//       Other:    64
```

GetValues<TEnum>()

Retrieves an array of the values of the constants in a specified enumeration type.

C#

```
public static TEnum[] GetValues<TEnum> () where TEnum : struct;
```

Type Parameters

`TEnum`

The type of the enumeration.

Returns

TEnum[]

An array that contains the values of the constants in `TEnum`.

Exceptions

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Enum.GetValuesAsUnderlyingType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetValuesAsUnderlyingType(Type)	Retrieves an array of the values of the underlying type constants in a specified enumeration.
GetValuesAsUnderlyingType<TEnum>()	Retrieves an array of the values of the underlying type constants in a specified enumeration type.

GetValuesAsUnderlyingType(Type)

Retrieves an array of the values of the underlying type constants in a specified enumeration.

C#

```
public static Array GetValuesAsUnderlyingType (Type enumType);
```

Parameters

enumType Type

An enumeration type.

Returns

Array

An array that contains the values of the underlying type constants in `enumType`.

Exceptions

ArgumentNullException

`enumType` is null.

ArgumentException

`enumType` is not an enumeration type.

Remarks

You can use this method to get enumeration values when it's hard to create an array of the enumeration type. For example, you might use this method for the MetadataLoadContext enumeration or on a platform where run-time code generation is not available.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

GetValuesAsUnderlyingType<TEnum>()

Retrieves an array of the values of the underlying type constants in a specified enumeration type.

C#

```
public static Array GetValuesAsUnderlyingType<TEnum> () where TEnum :
struct;
```

Type Parameters

`TEnum`

An enumeration type.

Returns

Array

An array that contains the values of the underlying type constants in `TEnum`.

Remarks

You can use this method to get enumeration values when it's hard to create an array of the enumeration type. For example, you might use this method for the MetadataLoadContext enumeration or on a platform where run-time code generation is not available.

Applies to

Enum.HasFlag(Enum) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one or more bit fields are set in the current instance.

```
C#
public bool HasFlag (Enum flag);
```

Parameters

`flag` Enum

An enumeration value.

Returns

Boolean

`true` if the bit field or bit fields that are set in `flag` are also set in the current instance; otherwise, `false`.

Exceptions

ArgumentException

`flag` is a different type than the current instance.

Examples

The following example defines an `DinnerItems` enumeration that reflects categories of items that a customer can order in a restaurant. The example tests whether the customer has ordered both an entrée and a beverage.

```
C#
```

```
using System;

[Flags] public enum DinnerItems {
   None = 0,
   Entree = 1,
   Appetizer = 2,
   Side = 4,
   Dessert = 8,
   Beverage = 16,
   BarBeverage = 32
}

public class Example
{
   public static void Main()
   {
      DinnerItems myOrder = DinnerItems.Appetizer | DinnerItems.Entree |
                            DinnerItems.Beverage | DinnerItems.Dessert;
      DinnerItems flagValue = DinnerItems.Entree | DinnerItems.Beverage;
      Console.WriteLine("{0} includes {1}: {2}",
                        myOrder, flagValue, myOrder.HasFlag(flagValue));
   }
}
// The example displays the following output:
//    Entree, Appetizer, Dessert, Beverage includes Entree, Beverage: True
```

Remarks

The HasFlag method returns the result of the following Boolean expression.

C#

```
(thisInstance & flag) == flag
```

If the underlying value of `flag` is zero, the method returns `true`. If this behavior is not desirable, you can use the Equals method to test for equality with zero and call HasFlag only if the underlying value of `flag` is non-zero, as the following example illustrates.

C#

```
using System;

[Flags] public enum Pets {
   None = 0,
   Dog = 1,
   Cat = 2,
   Bird = 4,
   Rabbit = 8,
```

```
    Other = 16
}

public class Example
{
    public static void Main()
    {
        Pets[] petsInFamilies = { Pets.None, Pets.Dog | Pets.Cat, Pets.Dog };
        int familiesWithoutPets = 0;
        int familiesWithDog = 0;

        foreach (var petsInFamily in petsInFamilies)
        {
            // Count families that have no pets.
            if (petsInFamily.Equals(Pets.None))
                familiesWithoutPets++;
            // Of families with pets, count families that have a dog.
            else if (petsInFamily.HasFlag(Pets.Dog))
                familiesWithDog++;
        }
        Console.WriteLine("{0} of {1} families in the sample have no pets.",
                          familiesWithoutPets, petsInFamilies.Length);
        Console.WriteLine("{0} of {1} families in the sample have a dog.",
                          familiesWithDog, petsInFamilies.Length);
    }
}
// The example displays the following output:
//       1 of 3 families in the sample have no pets.
//       2 of 3 families in the sample have a dog.
```

The HasFlag method is designed to be used with enumeration types that are marked with the FlagsAttribute attribute and can be used to determine whether multiple bit fields are set. For enumeration types that are not marked with the FlagsAttribute attribute, call either the Equals method or the CompareTo method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Enum.IsDefined Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

IsDefined(Type, Object)	Returns a Boolean telling whether a given integral value, or its name as a string, exists in a specified enumeration.
IsDefined<TEnum>(TEnum)	Returns a boolean telling whether a given integral value, or its name as a string, exists in a specified enumeration.

IsDefined(Type, Object)

Returns a Boolean telling whether a given integral value, or its name as a string, exists in a specified enumeration.

C#

```
public static bool IsDefined (Type enumType, object value);
```

Parameters

enumType Type

An enumeration type.

value Object

The value or name of a constant in `enumType`.

Returns

Boolean

`true` if a constant in `enumType` has a value equal to `value`; otherwise, `false`.

Exceptions

ArgumentNullException

`enumType` or `value` is `null`.

ArgumentException

`enumType` is not an `Enum`.

-or-

The type of `value` is an enumeration, but it is not an enumeration of type `enumType`.

-or-

The type of `value` is not an underlying type of `enumType`.

InvalidOperationException

`value` is not type SByte, Int16, Int32, Int64, Byte, UInt16, UInt32, or UInt64, or String.

Examples

The following example defines an enumeration named `PetType` that consists of individual bit fields. It then calls the IsDefined method with possible underlying enumeration values, string names, and composite values that result from setting multiple bit fields.

C#

```
using System;

[Flags] public enum PetType
{
   None = 0, Dog = 1, Cat = 2, Rodent = 4, Bird = 8, Reptile = 16, Other
= 32
};

public class Example
{
   public static void Main()
   {
      object value;

      // Call IsDefined with underlying integral value of member.
      value = 1;
```

```
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        // Call IsDefined with invalid underlying integral value.
        value = 64;
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        // Call IsDefined with string containing member name.
        value = "Rodent";
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        // Call IsDefined with a variable of type PetType.
        value = PetType.Dog;
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        value = PetType.Dog | PetType.Cat;
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        // Call IsDefined with uppercase member name.
        value = "None";
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        value = "NONE";
        Console.WriteLine("{0}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        // Call IsDefined with combined value
        value = PetType.Dog | PetType.Bird;
        Console.WriteLine("{0:D}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
        value = value.ToString();
        Console.WriteLine("{0:D}: {1}", value,
Enum.IsDefined(typeof(PetType), value));
    }
}
// The example displays the following output:
//       1: True
//       64: False
//       Rodent: True
//       Dog: True
//       Dog, Cat: False
//       None: True
//       NONE: False
//       9: False
//       Dog, Bird: False
```

Remarks

The `value` parameter can be any of the following:

- Any member of type `enumType`.
- A variable whose value is an enumeration member of type `enumType`.

- The string representation of the name of an enumeration member. The characters in the string must have the same case as the enumeration member name.
- A value of the underlying type of `enumType`.

If the constants in `enumType` define a set of bit fields and `value` contains the values, names, or underlying values of multiple bit fields, the IsDefined method returns `false`. In other words, for enumerations that define a set of bit fields, the method determines only whether a single bit field belongs to the enumeration. To determine whether multiple bit fields are set in an enumeration type that is tagged with the FlagsAttribute attribute, you can call the HasFlag method.

Notes to Callers

If `enumType` is an enumeration that is defined by using the FlagsAttribute attribute, the method returns `false` if multiple bit fields in `value` are set but `value` does not correspond to a composite enumeration value, or if `value` is a string concatenation of the names of multiple bit flags. In the following example, a `Pets` enumeration is defined with the FlagsAttribute attribute. The IsDefined(Type, Object) method returns `false` when you pass it an enumeration value that has two bit fields (`Pets.Dog` and `Pets.Cat`) set, and when you pass it the string representation of that enumeration value ("Dog, Cat").

C#

```
using System;

[Flags] public enum Pets {
      None = 0, Dog = 1, Cat = 2, Bird = 4,
      Rodent = 8, Other = 16 };

public class Example
{
   public static void Main()
   {
      Pets value = Pets.Dog | Pets.Cat;
      Console.WriteLine("{0:D} Exists: {1}",
                        value, Pets.IsDefined(typeof(Pets), value));
      string name = value.ToString();
      Console.WriteLine("{0} Exists: {1}",
                        name, Pets.IsDefined(typeof(Pets), name));
   }
}
// The example displays the following output:
```

```
//       3 Exists: False
//       Dog, Cat Exists: False
```

You can determine whether multiple bit fields are set by calling the HasFlag(Enum) method.

IsDefined<TEnum>(TEnum)

Returns a boolean telling whether a given integral value, or its name as a string, exists in a specified enumeration.

C#

```
public static bool IsDefined<TEnum> (TEnum value) where TEnum : struct;
```

Type Parameters

`TEnum`

The type of the enumeration.

Parameters

`value` TEnum

The value or name of a constant in `TEnum`.

Returns

Boolean

`true` if a given integral value, or its name as a string, exists in a specified enumeration; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Enum.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

Overloads

Expand table

Parse(Type, ReadOnlySpan<Char>)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
Parse(Type, String)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
Parse(Type, ReadOnlySpan<Char>, Boolean)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse(Type, String, Boolean)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse<TEnum>(String, Boolean)	Converts the string representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse<TEnum>(ReadOnlySpan<Char>, Boolean)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
Parse<TEnum>(ReadOnlySpan<Char>)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants specified by

	`TEnum` to an equivalent enumerated object.
Parse<TEnum>(String)	Converts the string representation of the name or numeric value of one or more enumerated constants specified by `TEnum` to an equivalent enumerated object.

Parse(Type, ReadOnlySpan<Char>)

Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

C#

```
public static object Parse (Type enumType, ReadOnlySpan<char> value);
```

Parameters

`enumType` Type

An enumeration type.

`value` ReadOnlySpan<Char>

A span containing the name or value to convert.

Returns

Object

An object of type `enumType` whose value is represented by `value`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

ArgumentException

`value` is either an empty string or only contains white space.

ArgumentException

`value` is a name, but not one of the named constants defined for the enumeration.

OverflowException

`value` is outside the range of the underlying type of `enumType`.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(Type, String)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

C#

```
public static object Parse (Type enumType, string value);
```

Parameters

`enumType` Type

An enumeration type.

`value` String

A string containing the name or value to convert.

Returns

Object

An object of type `enumType` whose value is represented by `value`.

Exceptions

ArgumentNullException

`enumType` or `value` is `null`.

ArgumentException

`enumType` is not an Enum.

-or-

`value` is either an empty string or only contains white space.

-or-

`value` is a name, but not one of the named constants defined for the enumeration.

OverflowException

`value` is outside the range of the underlying type of `enumType`.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Examples

The following example uses the Parse(Type, String) method to parse an array of strings that are created by calling the GetNames method. It also uses the Parse(Type, String) method to parse an enumeration value that consists of a bit field.

C#

```
using System;

public class ParseTest
{
    [Flags]
    enum Colors { Red = 1, Green = 2, Blue = 4, Yellow = 8 };

    public static void Main()
    {
        Console.WriteLine("The entries of the Colors enumeration are:");
        foreach (string colorName in Enum.GetNames(typeof(Colors)))
        {
            Console.WriteLine("{0} = {1:D}", colorName,
                                                Enum.Parse(typeof(Colors),
colorName));
        }
        Console.WriteLine();

        Colors orange = (Colors) Enum.Parse(typeof(Colors), "Red,
```

```
Yellow");
        Console.WriteLine("The orange value {0:D} has the combined
entries of {0}",
                          orange);
    }
}

/*
This code example produces the following results:

The entries of the Colors Enum are:
Red = 1
Green = 2
Blue = 4
Yellow = 8

The orange value 9 has the combined entries of Red, Yellow

*/
```

Remarks

The `value` parameter contains the string representation of an enumeration member's underlying value or named constant, or a list of named constants delimited by commas (,). One or more blank spaces can precede or follow each value, name, or comma in `value`. If `value` is a list, the return value is the value of the specified names combined with a bitwise `OR` operation.

If `value` is a name that does not correspond to a named constant of `enumType`, the method throws an ArgumentException. If `value` is the string representation of an integer that does not represent an underlying value of the `enumType` enumeration, the method returns an enumeration member whose underlying value is `value` converted to an integral type. If this behavior is undesirable, call the IsDefined method to ensure that a particular string representation of an integer is actually a member of `enumType`. The following example defines a `Colors` enumeration, calls the Parse(Type, String) method to convert strings to their corresponding enumeration values, and calls the IsDefined method to ensure that particular integral values are underlying values in the `Colors` enumeration.

C#

```
using System;

[Flags] enum Colors { None=0, Red = 1, Green = 2, Blue = 4 };

public class Example
```

```
{
   public static void Main()
   {
      string[] colorStrings = { "0", "2", "8", "blue", "Blue", "Yellow",
"Red, Green" };
      foreach (string colorString in colorStrings)
      {
         try {
            Colors colorValue = (Colors) Enum.Parse(typeof(Colors),
colorString);
            if (Enum.IsDefined(typeof(Colors), colorValue) |
colorValue.ToString().Contains(","))
               Console.WriteLine("Converted '{0}' to {1}.", colorString,
colorValue.ToString());
            else
               Console.WriteLine("{0} is not an underlying value of the
Colors enumeration.", colorString);
         }
         catch (ArgumentException) {
            Console.WriteLine("'{0}' is not a member of the Colors
enumeration.", colorString);
         }
      }
   }
}
// The example displays the following output:
//       Converted '0' to None.
//       Converted '2' to Green.
//       8 is not an underlying value of the Colors enumeration.
//       'blue' is not a member of the Colors enumeration.
//       Converted 'Blue' to Blue.
//       'Yellow' is not a member of the Colors enumeration.
//       Converted 'Red, Green' to Red, Green.
```

This operation is case-sensitive.

UWP	10.0

Parse(Type, ReadOnlySpan<Char>, Boolean)

Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.

C#

```
public static object Parse (Type enumType, ReadOnlySpan<char> value, bool
ignoreCase);
```

Parameters

`enumType` Type

An enumeration type.

`value` ReadOnlySpan<Char>

A span containing the name or value to convert.

`ignoreCase` Boolean

`true` to ignore case; `false` to regard case.

Returns

Object

An object of type `enumType` whose value is represented by `value`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

ArgumentException

`value` is either an empty string or only contains white space.

ArgumentException

`value` is a name, but not one of the named constants defined for the enumeration.

OverflowException

`value` is outside the range of the underlying type of `enumType`

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(Type, String, Boolean)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.

C#

```
public static object Parse (Type enumType, string value, bool
ignoreCase);
```

Parameters

`enumType` Type

An enumeration type.

`value` String

A string containing the name or value to convert.

`ignoreCase` Boolean

`true` to ignore case; `false` to regard case.

Returns

Object

An object of type `enumType` whose value is represented by `value`.

Exceptions

ArgumentNullException

`enumType` or `value` is `null`.

ArgumentException

`enumType` is not an Enum.

-or-

`value` is either an empty string ("") or only contains white space.

-or-

`value` is a name, but not one of the named constants defined for the enumeration.

OverflowException

`value` is outside the range of the underlying type of `enumType`.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Examples

The following example uses the Parse(Type, String, Boolean) method to parse an array of strings that are created by calling the GetNames method. It also uses the Parse(Type, String) method to parse an enumeration value that consists of a bit field.

C#

```
using System;
```

```
[Flags] enum Colors { None=0, Red = 1, Green = 2, Blue = 4 };

public class Example
{
   public static void Main()
   {
      string[] colorStrings = { "0", "2", "8", "blue", "Blue", "Yellow",
"Red, Green" };
      foreach (string colorString in colorStrings)
      {
         try {
            Colors colorValue = (Colors) Enum.Parse(typeof(Colors),
colorString, true);
            if (Enum.IsDefined(typeof(Colors), colorValue) |
colorValue.ToString().Contains(","))
               Console.WriteLine("Converted '{0}' to {1}.", colorString,
colorValue.ToString());
            else
               Console.WriteLine("{0} is not an underlying value of the
Colors enumeration.", colorString);
         }
         catch (ArgumentException) {
            Console.WriteLine("{0} is not a member of the Colors
enumeration.", colorString);
         }
      }
   }
}
// The example displays the following output:
//       Converted '0' to None.
//       Converted '2' to Green.
//       8 is not an underlying value of the Colors enumeration.
//       Converted 'blue' to Blue.
//       Converted 'Blue' to Blue.
//       Yellow is not a member of the Colors enumeration.
//       Converted 'Red, Green' to Red, Green.
```

Remarks

The `value` parameter contains the string representation of an enumeration member's underlying value or named constant, or a list of named constants delimited by commas (,). One or more blank spaces can precede or follow each value, name, or comma in `value`. If `value` is a list, the return value is the value of the specified names combined with a bitwise `OR` operation.

If `value` is a name that does not correspond to a named constant of `enumType`, the method throws an ArgumentException. If `value` is the string representation of an integer that does not represent an underlying value of the `enumType` enumeration, the method returns an enumeration member whose underlying value is `value`

converted to an integral type. If this behavior is undesirable, call the IsDefined method to ensure that a particular string representation of an integer is actually a member of `enumType`. The following example defines a `Colors` enumeration, calls the Parse(Type, String, Boolean) method to convert strings to their corresponding enumeration values, and calls the IsDefined method to ensure that particular integral values are underlying values in the `Colors` enumeration.

The `ignoreCase` parameter specifies whether this operation is case-sensitive.

Enum.ToObject Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified integer value to an enumeration member.

Overloads

Expand table

ToObject(Type, Int16)	Converts the specified 16-bit signed integer to an enumeration member.
ToObject(Type, Int32)	Converts the specified 32-bit signed integer to an enumeration member.
ToObject(Type, Int64)	Converts the specified 64-bit signed integer to an enumeration member.
ToObject(Type, Object)	Converts the specified object with an integer value to an enumeration member.
ToObject(Type, SByte)	Converts the specified 8-bit signed integer value to an enumeration member.
ToObject(Type, UInt16)	Converts the specified 16-bit unsigned integer value to an enumeration member.
ToObject(Type, UInt32)	Converts the specified 32-bit unsigned integer value to an enumeration member.
ToObject(Type, UInt64)	Converts the specified 64-bit unsigned integer value to an enumeration member.
ToObject(Type, Byte)	Converts the specified 8-bit unsigned integer to an enumeration member.

ToObject(Type, Int16)

Converts the specified 16-bit signed integer to an enumeration member.

```
C#
```

```
public static object ToObject (Type enumType, short value);
```

Parameters

`enumType` Type

The enumeration type to return.

`value` Int16

The value to convert to an enumeration member.

Returns

Object

An instance of the enumeration set to `value`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Remarks

The ToObject(Type, Int16) method converts `value` to an enumeration member whose underlying value is `value`. Note that the conversion succeeds even if value is outside the bounds of `enumType` members. To ensure that `value` is a valid underlying value of the `enumType` enumeration, pass it to the IsDefined method.

This conversion method returns a value of type Object. You can then cast it or convert it to an object of type `enumType`.

See also

- IsDefined(Type, Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToObject(Type, Int32)

Converts the specified 32-bit signed integer to an enumeration member.

```
C#

public static object ToObject (Type enumType, int value);
```

Parameters

`enumType` Type

The enumeration type to return.

`value` Int32

The value to convert to an enumeration member.

Returns

Object

An instance of the enumeration set to `value`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Remarks

The ToObject(Type, Int32) method converts `value` to an enumeration member whose underlying value is `value`. Note that the conversion succeeds even if value is outside the bounds of `enumType` members. To ensure that `value` is a valid underlying value of the `enumType` enumeration, pass it to the IsDefined method.

This conversion method returns a value of type Object. You can then cast it or convert it to an object of type `enumType`.

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToObject(Type, Int64)

Converts the specified 64-bit signed integer to an enumeration member.

C#

```
public static object ToObject (Type enumType, long value);
```

Parameters

enumType Type

The enumeration type to return.

`value` Int64

The value to convert to an enumeration member.

Returns

Object

An instance of the enumeration set to `value`.

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Remarks

The ToObject(Type, Int64) method converts `value` to an enumeration member whose underlying value is `value`. Note that the conversion succeeds even if value is outside the bounds of `enumType` members. To ensure that `value` is a valid underlying value of the `enumType` enumeration, pass it to the IsDefined method.

This conversion method returns a value of type Object. You can then cast it or convert it to an object of type `enumType`.

.NET Standard	2.0, 2.1

ToObject(Type, Object)

Converts the specified object with an integer value to an enumeration member.

```
C#
public static object ToObject (Type enumType, object value);
```

Parameters

`enumType` Type

The enumeration type to return.

`value` Object

The value convert to an enumeration member.

Returns

Object

An enumeration object whose value is `value`.

Exceptions

ArgumentNullException

`enumType` or `value` is `null`.

ArgumentException

`enumType` is not an Enum.

-or-

`value` is not type SByte, Int16, Int32, Int64, Byte, UInt16, UInt32, or UInt64.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Remarks

The ToObject(Type, Object) method converts the integral value `value` to an enumeration member whose underlying value is `value`. Note that the conversion succeeds even if value is outside the bounds of `enumType` members. To ensure that `value` is a valid underlying value of the `enumType` enumeration, pass it to the IsDefined method.

This conversion method returns a value of type Object. You can then cast it or convert it to an object of type `enumType`.

ToObject(Type, SByte)

> Important
>
> This API is not CLS-compliant.

Converts the specified 8-bit signed integer value to an enumeration member.

```
C#

[System.CLSCompliant(false)]
public static object ToObject (Type enumType, sbyte value);
```

Parameters

`enumType` Type

The enumeration type to return.

`value` SByte

The value to convert to an enumeration member.

Returns

Object

An instance of the enumeration set to `value`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Remarks

The ToObject(Type, SByte) method converts `value` to an enumeration member whose underlying value is `value`. Note that the conversion succeeds even if value is outside the bounds of `enumType` members. To ensure that `value` is a valid underlying value of the `enumType` enumeration, pass it to the IsDefined method.

ToObject(Type, UInt16)

> Important
>
> This API is not CLS-compliant.

Converts the specified 16-bit unsigned integer value to an enumeration member.

C#

```
[System.CLSCompliant(false)]
public static object ToObject (Type enumType, ushort value);
```

Parameters

`enumType` Type

The enumeration type to return.

`value` UInt16

The value to convert to an enumeration member.

Returns

Object

An instance of the enumeration set to `value`.

Attributes CLSCompliantAttribute

Exceptions

ArgumentNullException

`enumType` is `null`.

ArgumentException

`enumType` is not an Enum.

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Remarks

The ToObject(Type, UInt16) method converts `value` to an enumeration member whose underlying value is `value`. Note that the conversion succeeds even if value is outside the bounds of `enumType` members. To ensure that `value` is a valid underlying value of the `enumType` enumeration, pass it to the IsDefined method.

Enum.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to its equivalent string representation.

Overloads

Expand table

ToString(String, IFormatProvider)	**Obsolete.** This method overload is obsolete; use ToString(String).
ToString()	Converts the value of this instance to its equivalent string representation.
ToString(String)	Converts the value of this instance to its equivalent string representation using the specified format.
ToString(IFormatProvider)	**Obsolete.** This method overload is obsolete; use ToString().

ToString(String, IFormatProvider)

Caution

The provider argument is not used. Use ToString(String) instead.

This method overload is obsolete; use ToString(String).

C#

```
[System.Obsolete("The provider argument is not used. Use ToString(String) instead.")]
```

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A format specification.

`provider` IFormatProvider

(Obsolete.)

Returns

String

The string representation of the value of this instance as specified by `format`.

Implements

ToString(String, IFormatProvider)

Attributes ObsoleteAttribute

Exceptions

FormatException

`format` does not contain a valid format specification.

InvalidOperationException

`format` equals "X", but the enumeration type is unknown.

Remarks

The `format` parameter can be one of the following format strings: "G" or "g", "D" or "d", "X" or "x", and "F" or "f" (the format string is not case-sensitive). If `format` is `null` or an empty string (""), the general format specifier ("G") is used. For more information about the enumeration format strings and formatting enumeration values, see Enumeration Format Strings. For more information about formatting in general, see Formatting Types.

Specify only `format`; the `provider` parameter is obsolete.

See also

- Format(Type, Object, String)
- Formatting Types in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

ToString()

Converts the value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance.

Examples

The following example demonstrates converting an enumerated value to a string.

C#

```
using System;

public class EnumSample {
    enum Colors {Red = 1, Blue = 2};
```

```
    public static void Main() {
        Enum myColors = Colors.Red;
        Console.WriteLine("The value of this instance is '{0}'",
           myColors.ToString());
    }
}
/*
Output.
The value of this instance is 'Red'.
*/
```

Remarks

The return value is formatted with the general format specifier ("G"). That is, if the FlagsAttribute is not applied to this enumerated type and there is a named constant equal to the value of this instance, then the return value is a string containing the name of the constant. If the FlagsAttribute is applied and there is a combination of one or more named constants equal to the value of this instance, then the return value is a string containing a delimiter-separated list of the names of the constants. Otherwise, the return value is the string representation of the numeric value of this instance. For more information about formatting enumeration values, see Enumeration Format Strings. For more information about formatting in general, see Formatting Types.

Notes to Callers

If multiple enumeration members have the same underlying value and you attempt to retrieve the string representation of an enumeration member's name based on its underlying value, your code should not make any assumptions about which name the method will return. For example, the following enumeration defines two members, `Shade.Gray` and `Shade.Grey`, that have the same underlying value.

C#

```
enum Shade
{
    White = 0, Gray = 1, Grey = 1, Black = 2
}
```

The following method call attempts to retrieve the name of a member of the `Shade` enumeration whose underlying value is 1. The method can return either "Gray" or "Grey", and your code should not make any assumptions about which string will be returned.

```
C#
string shadeName = ((Shade) 1).ToString();
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the value of this instance to its equivalent string representation using the specified format.

```
C#
public string ToString (string? format);
```

Parameters

`format` String

A format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` contains an invalid specification.

InvalidOperationException

`format` equals "X", but the enumeration type is unknown.

Examples

The following example demonstrates how to convert an enumerated value to a string.

C#

```
// Sample for Enum.ToString(String)
using System;

class Sample
{
    enum Colors {Red, Green, Blue, Yellow = 12};

    public static void Main()
    {
    Colors myColor = Colors.Yellow;

    Console.WriteLine("Colors.Red = {0}", Colors.Red.ToString("d"));
    Console.WriteLine("Colors.Green = {0}", Colors.Green.ToString("d"));
    Console.WriteLine("Colors.Blue = {0}", Colors.Blue.ToString("d"));
    Console.WriteLine("Colors.Yellow = {0}",
Colors.Yellow.ToString("d"));

    Console.WriteLine("{0}myColor = Colors.Yellow{0}",
Environment.NewLine);

    Console.WriteLine("myColor.ToString(\"g\") = {0}",
myColor.ToString("g"));
    Console.WriteLine("myColor.ToString(\"G\") = {0}",
myColor.ToString("G"));

    Console.WriteLine("myColor.ToString(\"x\") = {0}",
myColor.ToString("x"));
    Console.WriteLine("myColor.ToString(\"X\") = {0}",
myColor.ToString("X"));

    Console.WriteLine("myColor.ToString(\"d\") = {0}",
myColor.ToString("d"));
```

```
    Console.WriteLine("myColor.ToString(\"D\") = {0}",
myColor.ToString("D"));

    Console.WriteLine("myColor.ToString(\"f\") = {0}",
myColor.ToString("f"));
    Console.WriteLine("myColor.ToString(\"F\") = {0}",
myColor.ToString("F"));
    }
}
/*
This example produces the following results:
Colors.Red = 0
Colors.Green = 1
Colors.Blue = 2
Colors.Yellow = 12

myColor = Colors.Yellow

myColor.ToString("g") = Yellow
myColor.ToString("G") = Yellow
myColor.ToString("x") = 0000000C
myColor.ToString("X") = 0000000C
myColor.ToString("d") = 12
myColor.ToString("D") = 12
myColor.ToString("f") = Yellow
myColor.ToString("F") = Yellow
*/
```

Remarks

The `format` parameter can be one of the following format strings: "G" or "g", "D" or "d", "X" or "x", and "F" or "f" (the format string is not case-sensitive). If `format` is `null` or an empty string (""), the general format specifier ("G") is used. For more information about the enumeration format strings and formatting enumeration values, see Enumeration Format Strings. For more information about formatting in general, see Formatting Types.

Notes to Callers

If multiple enumeration members have the same underlying value and you attempt to retrieve the string representation of an enumeration member's name based on its underlying value, your code should not make any assumptions about which name the method will return. For example, the following enumeration defines two members, `Shade.Gray` and `Shade.Grey`, that have the same underlying value.

```
C#
```

```
enum Shade
{
    White = 0, Gray = 1, Grey = 1, Black = 2
}
```

The following method call attempts to retrieve the name of a member of the `Shade` enumeration whose underlying value is 1. The method can return either "Gray" or "Grey", and your code should not make any assumptions about which string will be returned.

C#

```
string shadeName = ((Shade) 1).ToString("F");
```

Enum.TryFormat<TEnum> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the enumerated type instance into the provided span of characters.

C#

```
public static bool TryFormat<TEnum> (TEnum value, Span<char> destination,
out int charsWritten, ReadOnlySpan<char> format = default) where TEnum :
struct;
```

Type Parameters

TEnum

Parameters

value TEnum

destination Span<Char>

The span into which to write the instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

format ReadOnlySpan<Char>

A span containing the character that represents the standard format string that defines the acceptable format of destination. This value can be empty, or "g", "d", "f", or "x".

Returns

Boolean

`true` if the formatting was successful; otherwise, `false` if the destination span wasn't large enough to contain the formatted value.

Exceptions

FormatException

The format parameter contains an invalid value.

Applies to

Product	Versions
.NET	8, 9

Enum.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. The return value indicates whether the conversion succeeded.

Overloads

Expand table

TryParse(Type, ReadOnlySpan<Char>, Object)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse(Type, String, Object)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse(Type, ReadOnlySpan<Char>, Boolean, Object)	Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.
TryParse(Type, String, Boolean, Object)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse<TEnum>(ReadOnlySpan<Char>, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.
TryParse<TEnum>(String, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. The return value indicates whether the conversion succeeded.
TryParse<TEnum>(String, Boolean, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation

	is case-sensitive. The return value indicates whether the conversion succeeded.
TryParse<TEnum> (ReadOnlySpan<Char>, Boolean, TEnum)	Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-sensitive. The return value indicates whether the conversion succeeded.

TryParse(Type, ReadOnlySpan<Char>, Object)

Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

```
C#

public static bool TryParse (Type enumType, ReadOnlySpan<char> value, out
object? result);
```

Parameters

`enumType` Type

The enum type to use for parsing.

`value` ReadOnlySpan<Char>

The span representation of the name or numeric value of one or more enumerated constants.

`result` Object

When this method returns `true`, contains an enumeration constant that represents the parsed value.

Returns

Boolean

`true` if the conversion succeeded; `false` otherwise.

Exceptions

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(Type, String, Object)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

C#

```
public static bool TryParse (Type enumType, string? value, out object?
result);
```

Parameters

`enumType` Type

The enum type to use for parsing.

`value` String

The string representation of the name or numeric value of one or more enumerated constants.

`result` Object

When this method returns `true`, contains an enumeration constant that represents the parsed value.

Returns

Boolean

`true` if the conversion succeeded; `false` otherwise.

Exceptions

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(Type, ReadOnlySpan<Char>, Boolean, Object)

Converts the span of characters representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-insensitive.

C#

```
public static bool TryParse (Type enumType, ReadOnlySpan<char> value,
bool ignoreCase, out object? result);
```

Parameters

`enumType` Type

The enum type to use for parsing.

`value` ReadOnlySpan<Char>

The span representation of the name or numeric value of one or more enumerated constants.

`ignoreCase` Boolean

`true` to read `enumType` in case insensitive mode; `false` to read `enumType` in case sensitive mode.

`result` Object

When this method returns `true`, contains an enumeration constant that represents the parsed value.

Returns

Boolean

`true` if the conversion succeeded; `false` otherwise.

Exceptions

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(Type, String, Boolean, Object)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

C#

```
public static bool TryParse (Type enumType, string? value, bool
ignoreCase, out object? result);
```

Parameters

`enumType` Type

The enum type to use for parsing.

`value` String

The string representation of the name or numeric value of one or more enumerated constants.

`ignoreCase` Boolean

`true` to read `value` in case insensitive mode; `false` to read `value` in case sensitive mode.

`result` Object

When this method returns `true`, contains an enumeration constant that represents the parsed value.

Returns

Boolean

`true` if the conversion succeeded; `false` otherwise.

Exceptions

InvalidOperationException

.NET 8 and later versions: `enumType` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse<TEnum>(ReadOnlySpan<Char>, TEnum)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object.

C#

```
public static bool TryParse<TEnum> (ReadOnlySpan<char> value, out TEnum
result) where TEnum : struct;
```

Type Parameters

`TEnum`

The type of the `result` object.

Parameters

`value` ReadOnlySpan<Char>

The span representation of the name or numeric value of one or more enumerated constants.

`result` TEnum

When this method returns `true`, contains an enumeration constant that represents the parsed value.

Returns

Boolean

`true` if the conversion succeeded; `false` otherwise.

Exceptions

ArgumentException

`TEnum` is not an enumeration type.

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse<TEnum>(String, TEnum)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. The return value indicates whether the conversion succeeded.

C#

```
public static bool TryParse<TEnum> (string? value, out TEnum result)
where TEnum : struct;
```

Type Parameters

`TEnum`

The enumeration type to which to convert `value`.

Parameters

`value` String

The case-sensitive string representation of the enumeration name or underlying value to convert.

`result` TEnum

When this method returns, contains an object of type `TEnum` whose value is represented by `value` if the parse operation succeeds. If the parse operation fails, contains the default value of the underlying type of `TEnum`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `value` parameter was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`TEnum` is not an enumeration type.

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Examples

The following example defines a `Colors` enumeration, calls the TryParse<TEnum> (String, TEnum) method to convert strings to their corresponding enumeration values, and calls the IsDefined method to ensure that particular integral values are underlying values in the `Colors` enumeration.

C#

```
using System;

[Flags] enum Colors { None=0, Red = 1, Green = 2, Blue = 4 };
```

```
public class Example
{
   public static void Main()
   {
      string[] colorStrings = { "0", "2", "8", "blue", "Blue", "Yellow",
"Red, Green" };
      foreach (string colorString in colorStrings)
      {
         Colors colorValue;
         if (Enum.TryParse(colorString, out colorValue))
            if (Enum.IsDefined(typeof(Colors), colorValue) |
colorValue.ToString().Contains(","))
               Console.WriteLine("Converted '{0}' to {1}.", colorString,
colorValue.ToString());
            else
               Console.WriteLine("{0} is not an underlying value of the
Colors enumeration.", colorString);
         else
            Console.WriteLine("{0} is not a member of the Colors
enumeration.", colorString);
      }
   }
}
// The example displays the following output:
//       Converted '0' to None.
//       Converted '2' to Green.
//       8 is not an underlying value of the Colors enumeration.
//       blue is not a member of the Colors enumeration.
//       Converted 'Blue' to Blue.
//       Yellow is not a member of the Colors enumeration.
//       Converted 'Red, Green' to Red, Green.
```

Remarks

TryParse<TEnum>(String, TEnum) is identical to the Parse(Type, String) method, except that instead of throwing an exception, it returns `false` if the conversion fails. It eliminates the need for exception handling when parsing the string representation of an enumeration value.

The `value` parameter contains the string representation of an enumeration member's underlying value or named constant, or a list of named constants or underlying values delimited by commas (,). If `value` includes multiple named constants or values, one or more blank spaces can precede or follow each value, name, or comma in `value`. If `value` is a list, `result` reflects the value of the specified names or underlying values combined with a bitwise `OR` operation. If `value` is the string representation of the name of an enumeration value, the comparison of `value` with enumeration names is case-sensitive.

If `value` is a name that does not correspond to a named constant of `TEnum`, the method returns `false`. If `value` is the string representation of an integer that does not represent an underlying value of the `TEnum` enumeration, the method returns an enumeration member whose underlying value is `value` converted to an integral type. If this behavior is undesirable, call the IsDefined method to ensure that a particular string representation of an integer is actually a member of `TEnum`.

If the parse operation fails, the `result` parameter contains the default value of 0, which may not be a member of the underlying `TEnum` enumeration. If no values are assigned to the named constants in `TEnum`, the default is equal to the first member of the `TEnum`. Otherwise, the default is equal to the member in the enumeration with an assigned value of 0.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryParse<TEnum>(String, Boolean, TEnum)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-sensitive. The return value indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParse<TEnum> (string? value, bool ignoreCase, out
TEnum result) where TEnum : struct;
```

Type Parameters

`TEnum`

The enumeration type to which to convert `value`.

Parameters

`value` String

The string representation of the enumeration name or underlying value to convert.

`ignoreCase` Boolean

`true` to ignore case; `false` to consider case.

`result` TEnum

When this method returns, contains an object of type `TEnum` whose value is represented by `value` if the parse operation succeeds. If the parse operation fails, contains the default value of the underlying type of `TEnum`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the `value` parameter was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`TEnum` is not an enumeration type.

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Examples

The following example defines a `Colors` enumeration, calls the TryParse<TEnum> (String, Boolean, TEnum) method to convert strings to their corresponding

enumeration values, and calls the IsDefined method to ensure that particular integral values are underlying values in the `Colors` enumeration. The TryParse<TEnum> (String, Boolean, TEnum) method uses case-insensitive comparison when trying to convert the string representations of named constants to their equivalent enumeration values.

C#

```
using System;

[Flags] enum Colors { None=0, Red = 1, Green = 2, Blue = 4 };

public class Example
{
   public static void Main()
   {
      string[] colorStrings = { "0", "2", "8", "blue", "Blue", "Yellow",
"Red, Green" };
      foreach (string colorString in colorStrings)
      {
         Colors colorValue;
         if (Enum.TryParse(colorString, true, out colorValue))
            if (Enum.IsDefined(typeof(Colors), colorValue) |
colorValue.ToString().Contains(","))
               Console.WriteLine("Converted '{0}' to {1}.", colorString,
colorValue.ToString());
            else
               Console.WriteLine("{0} is not an underlying value of the
Colors enumeration.", colorString);
         else
            Console.WriteLine("{0} is not a member of the Colors
enumeration.", colorString);
      }
   }
}
// The example displays the following output:
//       Converted '0' to None.
//       Converted '2' to Green.
//       8 is not an underlying value of the Colors enumeration.
//       Converted 'blue' to Blue.
//       Converted 'Blue' to Blue.
//       Yellow is not a member of the Colors enumeration.
//       Converted 'Red, Green' to Red, Green.
```

Remarks

TryParse<TEnum>(String, Boolean, TEnum) is identical to the Parse(Type, String, Boolean) method, except that instead of throwing an exception, it returns `false` if

the conversion fails. It eliminates the need for exception handling when parsing the string representation of an enumeration value.

The `value` parameter contains the string representation of an enumeration member's underlying value or named constant, or a list of named constants or underlying values delimited by commas (,). If `value` includes multiple named constants or values, one or more blank spaces can precede or follow each value, name, or comma in `value`. If `value` is a list, `result` reflects the value of the specified names or underlying values combined with a bitwise `OR` operation. If `value` is the string representation of the name of an enumeration value, the comparison of `value` with enumeration names depends on the `ignoreCase` parameter. If `true`, the comparison is case-insensitive; if `false`, it is case-sensitive.

If `value` is a name that does not correspond to a named constant of `TEnum`, the method returns `false`. If `value` is the string representation of an integer that does not represent an underlying value of the `TEnum` enumeration, the method returns an enumeration member whose underlying value is `value` converted to an integral type. If this behavior is undesirable, call the IsDefined method to ensure that a particular string representation of an integer is actually a member of `TEnum`.

If the parse operation fails, the `result` parameter contains the default value of 0, which may not be a member of the underlying `TEnum` enumeration. If no values are assigned to the named constants in `TEnum`, the default is equal to the first member of the `TEnum`. Otherwise, the default is equal to the member in the enumeration with an assigned value of 0.

TryParse<TEnum>(ReadOnlySpan<Char>, Boolean, TEnum)

Converts the string representation of the name or numeric value of one or more enumerated constants to an equivalent enumerated object. A parameter specifies whether the operation is case-sensitive. The return value indicates whether the conversion succeeded.

```
C#

public static bool TryParse<TEnum> (ReadOnlySpan<char> value, bool
ignoreCase, out TEnum result) where TEnum : struct;
```

Type Parameters

`TEnum`

The type of the `result` object.

Parameters

`value` ReadOnlySpan<Char>

The span representation of the name or numeric value of one or more enumerated constants.

`ignoreCase` Boolean

`true` to ignore case; `false` to consider case.

`result` TEnum

When this method returns `true`, contains an enumeration constant that represents the parsed value.

Returns

Boolean

`true` if the conversion succeeded; `false` otherwise.

Exceptions

ArgumentException

`TEnum` is not an enumeration type.

InvalidOperationException

.NET 8 and later versions: `TEnum` is a Boolean-backed enumeration type.

Enum.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current value to a Boolean value based on the underlying type.

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Boolean

This member always throws an exception.

Implements

ToBoolean(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Remarks

Currently not implemented. Always throws an exception.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current value to an 8-bit unsigned integer based on the underlying type.

C#

```
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Byte

The converted value.

Implements

ToByte(IFormatProvider)

Remarks

Uses Convert to perform the conversion.

Applies to

Enum.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the current value to an 8-bit signed integer based on the underlying type.

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

SByte

The converted value.

Implements

ToSByte(IFormatProvider)

Remarks

Uses Convert to perform the conversion.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Enum.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current value to a single-precision floating-point number based on the underlying type.

```
C#

float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Single

This member always throws an exception.

Implements

ToSingle(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Remarks

Currently not implemented. Always throws an exception.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Enum.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current value to a specified type based on the underlying type.

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to convert to.

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

Object

The converted value.

Implements

ToType(Type, IFormatProvider)

Remarks

Uses Convert to perform the conversion.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Enum.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the current value to a 16-bit unsigned integer based on the underlying type.

```
C#
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt16

The converted value.

Implements

ToUInt16(IFormatProvider)

Remarks

Uses Convert to perform the conversion.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the current value to a 32-bit unsigned integer based on the underlying type.

```
C#
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt32

The converted value.

Implements

ToUInt32(IFormatProvider)

Remarks

Uses Convert to perform the conversion.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the current value to a 64-bit unsigned integer based on the underlying type.

```
C#
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

UInt64

The converted value.

Implements

ToUInt64(IFormatProvider)

Remarks

Uses Convert to perform the conversion.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Enum.ISpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the enum into the provided span of characters.

C#

```
bool ISpanFormattable.TryFormat (Span<char> destination, out int
charsWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in destination.

format ReadOnlySpan<Char>

The format specifier.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for destination. This parameter is ignored.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Environment Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides information about, and means to manipulate, the current environment and platform. This class cannot be inherited.

C#

```
public static class Environment
```

Inheritance Object → Environment

Examples

The following example displays a list of information about the current environment.

C#

```
// Sample for Environment class summary
using System;
using System.Collections;

class Sample
{
    public static void Main()
    {
        string str;
        string nl = Environment.NewLine;
        //
        Console.WriteLine();
        Console.WriteLine("-- Environment members --");

        //  Invoke this sample with an arbitrary set of command line
arguments.
        Console.WriteLine("CommandLine: {0}", Environment.CommandLine);

        string[] arguments = Environment.GetCommandLineArgs();
        Console.WriteLine("GetCommandLineArgs: {0}", String.Join(", ",
arguments));
```

```
        //  <-- Keep this information secure! -->
        Console.WriteLine("CurrentDirectory: {0}",
Environment.CurrentDirectory);

        Console.WriteLine("ExitCode: {0}", Environment.ExitCode);

        Console.WriteLine("HasShutdownStarted: {0}",
Environment.HasShutdownStarted);

        //  <-- Keep this information secure! -->
        Console.WriteLine("MachineName: {0}", Environment.MachineName);

        Console.WriteLine("NewLine: {0}  first line{0}  second line{0}
third line",
                              Environment.NewLine);

        Console.WriteLine("OSVersion: {0}",
Environment.OSVersion.ToString());

        Console.WriteLine("StackTrace: '{0}'", Environment.StackTrace);

        //  <-- Keep this information secure! -->
        Console.WriteLine("SystemDirectory: {0}",
Environment.SystemDirectory);

        Console.WriteLine("TickCount: {0}", Environment.TickCount);

        //  <-- Keep this information secure! -->
        Console.WriteLine("UserDomainName: {0}",
Environment.UserDomainName);

        Console.WriteLine("UserInteractive: {0}",
Environment.UserInteractive);

        //  <-- Keep this information secure! -->
        Console.WriteLine("UserName: {0}", Environment.UserName);

        Console.WriteLine("Version: {0}", Environment.Version.ToString());

        Console.WriteLine("WorkingSet: {0}", Environment.WorkingSet);

        //  No example for Exit(exitCode) because doing so would terminate
this example.

        //  <-- Keep this information secure! -->
        string query = "My system drive is %SystemDrive% and my system root
is %SystemRoot%";
        str = Environment.ExpandEnvironmentVariables(query);
        Console.WriteLine("ExpandEnvironmentVariables: {0}  {1}", nl, str);

        Console.WriteLine("GetEnvironmentVariable: {0}  My temporary
directory is {1}.", nl,
                               Environment.GetEnvironmentVariable("TEMP"));

        Console.WriteLine("GetEnvironmentVariables: ");
```

```
        IDictionary environmentVariables =
Environment.GetEnvironmentVariables();
        foreach (DictionaryEntry de in environmentVariables)
        {
            Console.WriteLine("  {0} = {1}", de.Key, de.Value);
        }

        Console.WriteLine("GetFolderPath: {0}",

Environment.GetFolderPath(Environment.SpecialFolder.System));

        string[] drives = Environment.GetLogicalDrives();
        Console.WriteLine("GetLogicalDrives: {0}", String.Join(", ",
drives));
    }
}
/*
This example produces results similar to the following:
(Any result that is lengthy or reveals information that should remain
secure has been omitted and marked "!---OMITTED---!".)

C:\>env0 ARBITRARY TEXT

-- Environment members --
CommandLine: env0 ARBITRARY TEXT
GetCommandLineArgs: env0, ARBITRARY, TEXT
CurrentDirectory: C:\Documents and Settings\!---OMITTED---!

```

```
*/
```

Remarks

Use the Environment class to retrieve information such as command-line arguments, the exit code, environment variable settings, contents of the call stack, time since last system boot, and the version of the common language runtime.

Properties

Expand table

CommandLine	Gets the command line for this process.
CurrentDirectory	Gets or sets the fully qualified path of the current working directory.
CurrentManagedThreadId	Gets a unique identifier for the current managed thread.
ExitCode	Gets or sets the exit code of the process.
HasShutdownStarted	Gets a value that indicates whether the current application domain is being unloaded or the common language runtime (CLR) is shutting down.
Is64BitOperatingSystem	Gets a value that indicates whether the current operating system is a 64-bit operating system.
Is64BitProcess	Gets a value that indicates whether the current process is a 64-bit process.
IsPrivilegedProcess	Gets a value that indicates whether the current process is authorized to perform security-relevant functions.
MachineName	Gets the NetBIOS name of this local computer.
NewLine	Gets the newline string defined for this environment.
OSVersion	Gets the current platform identifier and version number.
ProcessId	Gets the unique identifier for the current process.
ProcessorCount	Gets the number of processors available to the current process.
ProcessPath	Returns the path of the executable that started the currently executing process. Returns `null` when the path is not available.
StackTrace	Gets current stack trace information.

SystemDirectory	Gets the fully qualified path of the system directory.
SystemPageSize	Gets the number of bytes in the operating system's memory page.
TickCount	Gets the number of milliseconds elapsed since the system started.
TickCount64	Gets the number of milliseconds elapsed since the system started.
UserDomainName	Gets the network domain name associated with the current user.
UserInteractive	Gets a value indicating whether the current process is running in user interactive mode.
UserName	Gets the user name of the person who is associated with the current thread.
Version	Gets a version consisting of the major, minor, build, and revision numbers of the common language runtime.
WorkingSet	Gets the amount of physical memory mapped to the process context.

Methods

Expand table

Exit(Int32)	Terminates this process and returns an exit code to the operating system.
ExpandEnvironment Variables(String)	Replaces the name of each environment variable embedded in the specified string with the string equivalent of the value of the variable, then returns the resulting string.
FailFast(String)	Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message is included in error reporting to Microsoft. For Unix-like systems, the message, alongside the stack trace, is written to the standard error stream.
FailFast(String, Exception)	Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message and exception information is included in error reporting to Microsoft. For Unix-like systems, the message alongside the stack trace is written to the standard error stream.
GetCommandLineArgs()	Returns a string array containing the command-line arguments for the current process.

GetEnvironmentVariable(String)	Retrieves the value of an environment variable from the current process.
GetEnvironmentVariable(String, EnvironmentVariableTarget)	Retrieves the value of an environment variable from the current process or from the Windows operating system registry key for the current user or local machine.
GetEnvironmentVariables()	Retrieves all environment variable names and their values from the current process.
GetEnvironment Variables(EnvironmentVariable Target)	Retrieves all environment variable names and their values from the current process, or from the Windows operating system registry key for the current user or local machine.
GetFolder Path(Environment+SpecialFolder)	Gets the path to the specified system special folder.
GetFolder Path(Environment+SpecialFolder, Environment+SpecialFolderOption)	Gets the path to the specified system special folder using a specified option for accessing special folders.
GetLogicalDrives()	Returns an array of string containing the names of the logical drives on the current computer.
SetEnvironmentVariable(String, String)	Creates, modifies, or deletes an environment variable stored in the current process.
SetEnvironmentVariable(String, String, EnvironmentVariableTarget)	Creates, modifies, or deletes an environment variable stored in the current process or in the Windows operating system registry key reserved for the current user or local machine.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Environment.CommandLine Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the command line for this process.

C#

```
public static string CommandLine { get; }
```

Property Value

String

A string containing command-line arguments.

Examples

The following example displays its own command line.

C#

```
using System;

class Example
{
    public static void Main()
    {
       Console.WriteLine();
       //  Invoke this sample with an arbitrary set of command line
arguments.
       Console.WriteLine("CommandLine: {0}", Environment.CommandLine);
    }
}
// The example displays output like the following:
//       C:\>env0 ARBITRARY TEXT
//
//       CommandLine: env0 ARBITRARY TEXT
```

Remarks

This property provides access to the program name and any arguments specified on the command line when the current process was started.

The program name can include path information, but is not required to do so. Use the GetCommandLineArgs method to retrieve the command-line information parsed and stored in an array of strings.

The maximum size of the command-line buffer is not set to a specific number of characters; it varies depending on the Windows operating system that is running on the computer.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Environment.CurrentDirectory Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the fully qualified path of the current working directory.

C#

```
public static string CurrentDirectory { get; set; }
```

Property Value

String

The directory path.

Exceptions

ArgumentException

Attempted to set to an empty string ("").

ArgumentNullException

Attempted to set to `null`.

IOException

An I/O error occurred.

DirectoryNotFoundException

Attempted to set a local path that cannot be found.

SecurityException

The caller does not have the appropriate permission.

Examples

The following example demonstrates setting the CurrentDirectory property.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      if (Environment.OSVersion.Platform == PlatformID.Win32NT)
      {
         // Change the directory to %WINDIR%
         Environment.CurrentDirectory =
Environment.GetEnvironmentVariable("windir");
         DirectoryInfo info = new DirectoryInfo(".");

         Console.WriteLine("Directory Info:   " + info.FullName);
      }
      else
      {
         Console.WriteLine("This example runs on Windows only.");
      }
   }
}
// The example displays output like the following on a .NET implementation
running on Windows:
//        Directory Info:   C:\windows
// The example displays the following output on a .NET implementation on
Unix-based systems:
//        This example runs on Windows only.
```

Remarks

By definition, if this process starts in the root directory of a local or network drive, the value of this property is the drive name followed by a trailing slash (for example, "C:\"). If this process starts in a subdirectory, the value of this property is the drive and subdirectory path, without a trailing slash (for example, "C:\mySubDirectory").

Applies to

Environment.CurrentManagedThreadId Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a unique identifier for the current managed thread.

C#

```
public static int CurrentManagedThreadId { get; }
```

Property Value

Int32

A unique identifier for this managed thread.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Environment.ExitCode Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the exit code of the process.

C#

```
public static int ExitCode { get; set; }
```

Property Value

Int32

A 32-bit signed integer containing the exit code. The default value is 0 (zero), which indicates that the process completed successfully.

Examples

The following is a simple app named Double.exe that doubles an integer value passed to it as a command-line argument. The value assigns error codes to the ExitCode property to indicate error conditions. Note that you must add a reference to the System.Numerics.dll assembly to successfully compile the example.

C#

```
using System;
using System.Numerics;

public class Example
{
   private const int ERROR_BAD_ARGUMENTS = 0xA0;
   private const int ERROR_ARITHMETIC_OVERFLOW = 0x216;
   private const int ERROR_INVALID_COMMAND_LINE = 0x667;

   public static void Main()
   {
      string[] args = Environment.GetCommandLineArgs();
      if (args.Length == 1) {
```

```
            Environment.ExitCode = ERROR_INVALID_COMMAND_LINE;
        }
        else {
            BigInteger value = 0;
            if (BigInteger.TryParse(args[1], out value))
                if (value <= Int32.MinValue || value >= Int32.MaxValue)
                    Environment.ExitCode = ERROR_ARITHMETIC_OVERFLOW;
                else
                    Console.WriteLine("Result: {0}", value * 2);

            else
                Environment.ExitCode = ERROR_BAD_ARGUMENTS;
        }
    }
}
```

The example can then be invoked from a batch file such as the following, which makes its error codes accessible by using the `ERRORLEVEL` command.

```
@echo off
Double.exe %1
if errorlevel 1639 goto NoArg
if errorlevel 534 goto Overflow
if errorlevel 160 goto BadArg
if errorlevel 0 echo Completed Successfully
goto :EOF

:NoArg
echo Missing argument
goto :EOF

:Overflow
echo Arithmetic overflow
goto :EOF

:BadArg
echo Invalid argument
goto :EOF
```

The following shows some sample output produced by invoking the batch file.

```
>getdouble 123
Result: 246
Completed Successfully

>getdouble 5912323109093
Arithmetic overflow
```

```
>getdouble
Missing argument

>getdouble "a string"
Invalid argument
```

Note that code for Double.exe is identical in function to the following example, except that the former defines an entry point named `Main` that has no return value, whereas this example defines an entry point named `Main` that returns an integer.

C#

```
using System;
using System.Numerics;

public class Example
{
   private const int ERROR_SUCCESS = 0;
   private const int ERROR_BAD_ARGUMENTS = 0xA0;
   private const int ERROR_ARITHMETIC_OVERFLOW = 0x216;
   private const int ERROR_INVALID_COMMAND_LINE = 0x667;

   public static int Main()
   {
      string[] args = Environment.GetCommandLineArgs();
      if (args.Length == 1) {
         return ERROR_INVALID_COMMAND_LINE;
      }
      else {
         BigInteger value = 0;
         if (BigInteger.TryParse(args[1], out value))
            if (value <= Int32.MinValue || value >= Int32.MaxValue)
               return ERROR_ARITHMETIC_OVERFLOW;
            else
               Console.WriteLine("Result: {0}", value * 2);

         else
            return ERROR_BAD_ARGUMENTS;
      }
      return ERROR_SUCCESS;
   }
}
```

Remarks

If the `Main` method returns `void`, you can use this property to set the exit code that will be returned to the calling environment. If `Main` does not return `void`, this property is ignored. The initial value of this property is zero.

> ⚠ **Warning**
>
> The **ExitCode** property is a signed 32-bit integer. To prevent the property from returning a negative exit code, you should not use values greater than or equal to 0x80000000.

Use a non-zero number to indicate an error. In your application, you can define your own error codes in an enumeration, and return the appropriate error code based on the scenario. For example, return a value of 1 to indicate that the required file is not present and a value of 2 to indicate that the file is in the wrong format. For a list of exit codes used by the Windows operating system, see System Error Codes in the Windows documentation.

Environment.HasShutdownStarted Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current application domain is being unloaded or the common language runtime (CLR) is shutting down.

```
C#

public static bool HasShutdownStarted { get; }
```

Property Value

Boolean

`true` if the current application domain is being unloaded or the CLR is shutting down; otherwise, `false`.

Remarks

.NET Framework only: When the CLR unloads an application domain, it runs the finalizers on all objects that have a finalizer method in that application domain. When the CLR shuts down, it starts the finalizer thread on all objects that have a finalizer method. The HasShutdownStarted property returns `true` only after the finalizer thread has been started. When the property returns `true`, you can determine whether an application domain is being unloaded or the CLR itself is shutting down by calling the AppDomain.IsFinalizingForUnload method. This method returns `true` if finalizers are called because the application domain is unloading or `false` if the CLR is shutting down.

The HasShutdownStarted property returns `false` if the finalizer thread has not been started.

By using this property, you can determine whether to access static variables in your finalization code. If either an application domain or the CLR is shutting down, you cannot reliably access any object that has a finalization method and that is referenced by a static field. This is because these objects may have already been finalized.

Environment.Is64BitOperatingSystem Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current operating system is a 64-bit operating system.

C#

```
public static bool Is64BitOperatingSystem { get; }
```

Property Value

Boolean

`true` if the operating system is 64-bit; otherwise, `false`.

Applies to

Product	Versions

Environment.MachineName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the NetBIOS name of this local computer.

C#

```
public static string MachineName { get; }
```

Property Value

String

The name of this computer.

Exceptions

InvalidOperationException

The name of this computer cannot be obtained.

Examples

The following example displays the name of the computer that runs the code example. (The machine name is omitted from the example output for security reasons.)

C#

```
// Sample for the Environment.MachineName property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
//  <-- Keep this information secure! -->
    Console.WriteLine("MachineName: {0}", Environment.MachineName);
    }
```

```
}
/*
This example produces the following results:
(Any result that is lengthy, specific to the machine on which this sample
was tested, or reveals information that should remain secure, has been
omitted and marked "!---OMITTED---!".)

MachineName: !---OMITTED---!
*/
```

Remarks

The name of this computer is established at system startup when the name is read from the registry. If this computer is a node in a cluster, the name of the node is returned.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Environment.NewLine Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the newline string defined for this environment.

C#

```
public static string NewLine { get; }
```

Property Value

String

`\r\n` for non-Unix platforms, or `\n` for Unix platforms.

Examples

The following example displays two lines separated by a newline.

C#

```
// Sample for the Environment.NewLine property
using System;

class Sample
{
    public static void Main()
    {
        Console.WriteLine();
        Console.WriteLine($"NewLine: {Environment.NewLine}  first
line{Environment.NewLine}  second line");
    }
}

/*
This example produces the following results:

NewLine:
  first line
```

```
  second line
*/
```

Remarks

The property value of NewLine is a constant customized specifically for the current platform and implementation of the .NET Framework. For more information about the escape characters in the property value, see Character Escapes.

The functionality provided by NewLine is often what is meant by the terms newline, line feed, line break, carriage return, CRLF, and end of line.

NewLine can be used in conjunction with language-specific newline support such as the escape characters '\r' and '\n' in Microsoft C# and C/C++, or `vbCrLf` in Microsoft Visual Basic.

NewLine is automatically appended to text processed by the Console.WriteLine and StringBuilder.AppendLine methods.

Applies to

Environment.OSVersion Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current platform identifier and version number.

```
C#
public static OperatingSystem OSVersion { get; }
```

Property Value

OperatingSystem

The platform identifier and version number.

Exceptions

InvalidOperationException

This property was unable to obtain the system version.

-or-

The obtained platform identifier is not a member of PlatformID

Remarks

Environment.OSVersion returns an OS version that may be incorrect when an application runs under Windows compatibility mode. For more information, see GetVersionExA function remarks.

In .NET 5 and later versions, Environment.OSVersion returns the actual OS version in compatibility modes specified by the application manifest. For more information, see Environment.OSVersion returns the correct operating system version.

To identify the operating system platform, for example, Linux or Windows, you can use the RuntimeInformation.IsOSPlatform method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Environment.ProcessorCount Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of processors available to the current process.

C#

```
public static int ProcessorCount { get; }
```

Property Value

Int32

The 32-bit signed integer that specifies the number of processors that are available.

Examples

The following example demonstrates the ProcessorCount property.

C#

```
// This example demonstrates the
//     Environment.ProcessorCount property.
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine("The number of processors " +
        "on this computer is {0}.",
        Environment.ProcessorCount);
    }
}
/*
This example produces the following results:

The number of processors on this computer is 1.
*/
```

Remarks

On Linux and macOS systems for all .NET versions and on Windows systems starting with .NET 6, this API returns the minimum of:

- The number of logical processors on the machine.
- If the process is running with CPU affinity, the number of processors that the process is affinitized to.
- If the process is running with a CPU utilization limit, the CPU utilization limit rounded up to the next whole number.

The value returned by this API is fixed at .NET runtime startup for the process lifetime. It does not reflect changes in the environment settings while the process is running.

For more information about processor groups and logical processors, see Processor Groups.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Environment.ProcessPath Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the path of the executable that started the currently executing process. Returns `null` when the path is not available.

```
C#
public static string? ProcessPath { get; }
```

Property Value

String

The path of the executable that started the currently executing process.

Remarks

If the executable is renamed or deleted before this property is first accessed, the return value is undefined and depends on the operating system.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Environment.StackTrace Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets current stack trace information.

C#

```
public static string StackTrace { get; }
```

Property Value

String

A string containing stack trace information. This value can be Empty.

Examples

The following example demonstrates the StackTrace property.

C#

```
// Sample for the Environment.StackTrace property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
    Console.WriteLine("StackTrace: '{0}'", Environment.StackTrace);
    }
}
/*
This example produces the following results:

StackTrace: '   at System.Environment.GetStackTrace(Exception e)
   at System.Environment.GetStackTrace(Exception e)
   at System.Environment.get_StackTrace()
```

```
    at Sample.Main()'
 */
```

Remarks

The StackTrace property lists method calls in reverse chronological order, that is, the most recent method call is described first, and one line of stack trace information is listed for each method call on the stack. However, the StackTrace property might not report as many method calls as expected due to code transformations that occur during optimization.

> **Note**
>
> For a hierarchical view of the stack trace information by class, use the **StackTrace** class.

The StackTrace property formats the stack trace information for each method call as follows:

"at `FullClassName`.`MethodName`(`MethodParams`) in `FileName` :line `LineNumber` "

The literal "at" is preceded by three spaces, and the entire substring starting with "in" is omitted if debug symbols are not available. The placeholders, `FullClassName`, `MethodName`, `MethodParams`, `FileName`, and `LineNumber`, are replaced by actual values, and are defined as follows:

`FullClassName` The full name of the class, including the namespace.

`MethodName` The name of the method.

`MethodParams` The list of parameter type/name pairs. Each pair is separated by a comma (","). This information is omitted if `MethodName` takes no parameters.

`FileName` The name of the source file where the `MethodName` method is declared. This information is omitted if debug symbols are not available.

`LineNumber` The number of the line in `FileName` that contains the source code from `MethodName` for the instruction that is on the call stack. This information is omitted if debug symbols are not available.

The Environment.NewLine string terminates each line of the stack trace.

Applies to

Product	Versions

Environment.SystemDirectory Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the fully qualified path of the system directory.

C#

```
public static string SystemDirectory { get; }
```

Property Value

String

A string containing a directory path.

Examples

The following example displays the system directory of the computer that runs the code example. (The system directory is omitted from the example output for security reasons.)

C#

```
// Sample for the Environment.SystemDirectory property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
//  <-- Keep this information secure! -->
    Console.WriteLine("SystemDirectory: {0}", Environment.SystemDirectory);
    }
}
/*
This example produces the following results:
```

```
SystemDirectory: C:\WINNT\System32
*/
```

Remarks

An example of the value returned is the string "C:\WINDOWS\System32".

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Environment.SystemPageSize Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of bytes in the operating system's memory page.

C#

```
public static int SystemPageSize { get; }
```

Property Value

Int32

The number of bytes in the system memory page.

Remarks

This information can be useful when determining whether to use the MemoryMappedFileOptions.DelayAllocatePages option when you work with memory-mapped files.

In Windows, this value is the `dwPageSize` member in the `SYSTEM_INFO` structure.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Environment.TickCount Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of milliseconds elapsed since the system started.

C#

```
public static int TickCount { get; }
```

Property Value

Int32

A 32-bit signed integer containing the amount of time in milliseconds that has passed since the last time the computer was started.

Examples

The following example demonstrates how to retrieve the positive range of values returned by the TickCount property. The TickCount property cycles between Int32.MinValue, which is a negative number, and Int32.MaxValue once every 49.8 days. This code sample removes the sign bit to yield a nonnegative number that cycles between zero and MaxValue once every 24.9 days.

C#

```
// Sample for the Environment.TickCount property.

// TickCount cycles between Int32.MinValue, which is a negative
// number, and Int32.MaxValue once every 49.8 days. This sample
// removes the sign bit to yield a nonnegative number that cycles
// between zero and Int32.MaxValue once every 24.9 days.

using System;

class Sample
{
    public static void Main()
```

```
    {
    int result = Environment.TickCount & Int32.MaxValue;
    Console.WriteLine("TickCount: {0}", result);
    }
}
/*
This example produces an output similar to the following:

TickCount: 101931139
*/
```

Remarks

The value of this property is derived from the system timer and is stored as a 32-bit signed integer. Note that, because it is derived from the system timer, the resolution of the TickCount property is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds.

> ⓘ **Important**
>
> Because the value of the **TickCount** property value is a 32-bit signed integer, if the system runs continuously, **TickCount** will increment from zero to **Int32.MaxValue** for approximately 24.9 days, then jump to **Int32.MinValue**, which is a negative number, then increment back to zero during the next 24.9 days. You can work around this issue by calling the Windows **GetTickCount** function, which resets to zero after approximately 49.7 days, or by calling the **GetTickCount64** function.

TickCount is different from the DateTime.Ticks property, which is the number of 100-nanosecond intervals that have elapsed since 1/1/0001, 12:00am.

Use the DateTime.Now property to obtain the current local date and time on this computer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Environment.TickCount64 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of milliseconds elapsed since the system started.

C#

```
public static long TickCount64 { get; }
```

Property Value

Int64

The elapsed milliseconds since the system started.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Environment.UserDomainName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the network domain name associated with the current user.

```
C#
public static string UserDomainName { get; }
```

Property Value

String

The network domain name associated with the current user.

Exceptions

PlatformNotSupportedException

The operating system does not support retrieving the network domain name.

InvalidOperationException

The network domain name cannot be retrieved.

Remarks

The domain account credentials for a user are formatted as the user's domain name, the '\' character, and user name. Use the UserDomainName property to obtain the user's domain name without the user name, and the UserName property to obtain the user name without the domain name. For example, if a user's domain name and user name are CORPORATENETWORK\john, the UserDomainName property returns "CORPORATENETWORK".

The UserDomainName property first attempts to get the domain name component of the Windows account name for the current user. If that attempt fails, this property attempts to get the domain name associated with the user name provided by the UserName property. If that attempt fails because the host computer is not joined to a domain, then the host computer name is returned.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Environment.UserInteractive Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current process is running in user interactive mode.

C#

```
public static bool UserInteractive { get; }
```

Property Value

Boolean

`true` if the current process is running in user interactive mode; otherwise, `false`.

Examples

The following example displays whether the current process is running in user interactive mode.

C#

```
// Sample for the Environment.UserInteractive property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
    Console.WriteLine("UserInteractive: {0}", Environment.UserInteractive);
    }
}
/*
This example produces the following results:

UserInteractive: True
*/
```

Remarks

The UserInteractive property reports `false` for a Windows process or a service like IIS that runs without a user interface. If this property is `false`, do not display modal dialogs or message boxes because there is no graphical user interface for the user to interact with.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Environment.UserName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the user name of the person who is associated with the current thread.

C#

```
public static string UserName { get; }
```

Property Value

String

The user name of the person who is associated with the current thread.

Examples

The following example displays the user name of the person who started the current thread.

C#

```
// Sample for the Environment.UserName property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
//  <-- Keep this information secure! -->
    Console.WriteLine("UserName: {0}", Environment.UserName);
    }
}
```

Remarks

You can use the UserName property to identify the user on the current thread, to the system and application for security or access purposes. It can also be used to customize a particular application for each user.

On Windows the UserName property wraps a call to the Windows GetUserName function. The domain account credentials for a user are formatted as the user's domain name, the '\' character, and user name. Use the UserDomainName property to obtain the user's domain name and the UserName property to obtain the user name.

On Unix platforms the UserName property wraps a call to the `getpwuid_r` function.

If an ASP.NET application runs in a development environment, the UserName property returns the name of the current user. In a published ASP.NET application, this property returns the name of the application pool account (such as Default AppPool).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Environment.Version Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a version consisting of the major, minor, build, and revision numbers of the common language runtime.

```
C#

public static Version Version { get; }
```

Property Value

Version

The version of the common language runtime.

Examples

The following example displays the version of the common language runtime.

```
C#

// Sample for the Environment.Version property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
    Console.WriteLine("Version: {0}", Environment.Version.ToString());
    }
}
```

Remarks

For .NET Core 3.x and .NET 5+, the Environment.Version property returns the .NET runtime version number.

For the .NET Framework Versions 4, 4.5, 4.5.1, and 4.5.2, the Environment.Version property returns a Version object whose string representation has the form `4.0.30319.xxxxx`. For the .NET Framework 4.6 and later versions, and .NET Core versions before 3.0, it has the form `4.0.30319.42000`.

> ⚠ **Warning**
>
> For the .NET Framework 4.5 and later, we do not recommend using the **Version** property to detect the version of the runtime; instead, you can determine the version of the common language runtime by querying the registry. For more information, see **How to: Determine Which .NET Framework Versions Are Installed**.

For more information about the version of the common language runtime that is installed with each version of the .NET Framework, see Versions and Dependencies.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Environment.WorkingSet Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the amount of physical memory mapped to the process context.

C#

```
public static long WorkingSet { get; }
```

Property Value

Int64

A 64-bit signed integer containing the number of bytes of physical memory mapped to the process context.

Examples

The following example displays the size of the working set of the computer that runs the code example.

C#

```
// Sample for the Environment.WorkingSet property
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine("WorkingSet: {0}", Environment.WorkingSet);
    }
}
/*
This example produces the following results:

WorkingSet: 5038080
*/
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Environment.Exit(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Terminates this process and returns an exit code to the operating system.

```
C#
public static void Exit (int exitCode);
```

Parameters

`exitCode` Int32

The exit code to return to the operating system. Use 0 (zero) to indicate that the process completed successfully.

Exceptions

SecurityException

The caller does not have sufficient security permission to perform this function.

Remarks

For the `exitCode` parameter, use a non-zero number to indicate an error. In your application, you can define your own error codes in an enumeration, and return the appropriate error code based on the scenario. For example, return a value of 1 to indicate that the required file is not present, and a value of 2 to indicate that the file is in the wrong format. For a list of exit codes used by the Windows operating system, see System Error Codes in the Windows documentation.

Calling the Exit method differs from using your programming language's `return` statement in the following ways:

- Exit always terminates an application. Using the `return` statement may terminate an application only if it is used in the application entry point, such as in the `Main` method.

- Exit terminates an application immediately, even if other threads are running. If the `return` statement is called in the application entry point, it causes an application to terminate only after all foreground threads have terminated.
- Exit requires the caller to have permission to call unmanaged code. The `return` statement does not.
- If Exit is called from a `try` or `catch` block, the code in any `finally` block does not execute. If the `return` statement is used, the code in the `finally` block does execute.
- If Exit is called when code in a constrained execution region (CER) is running, the CER will not complete execution. If the `return` statement is used, the CER completes execution.

Applies to

Product	Versions

Environment.ExpandEnvironment Variables(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Replaces the name of each environment variable embedded in the specified string with the string equivalent of the value of the variable, then returns the resulting string.

C#

```
public static string ExpandEnvironmentVariables (string name);
```

Parameters

name String

A string containing the names of zero or more environment variables. Each environment variable is quoted with the percent sign character (%).

Returns

String

A string with each environment variable replaced by its value.

Exceptions

ArgumentNullException

`name` is `null`.

Examples

The following example shows how to obtain the system drive and system root variables.

C#

```
// Sample for the Environment.ExpandEnvironmentVariables method
using System;

class Sample
{
    public static void Main()
    {
        // Keep this information secure!
        string query = "My system drive is %SystemDrive% and my system root
is %SystemRoot%";

        string str = Environment.ExpandEnvironmentVariables(query);

        Console.WriteLine(str);
    }
}
/*
This example prints:

My system drive is C: and my system root is C:\WINDOWS
*/
```

Remarks

COM interop is used to retrieve the environment variables from the operating system. If the environment variables cannot be retrieved due to a COM error, the HRESULT that explains the cause of the failure is used to generate one of several possible exceptions; that is, the exception depends on the HRESULT. For more information about how the HRESULT is processed, see the Remarks section of the Marshal.ThrowExceptionForHR method.

Replacement only occurs for environment variables that are set. For example, suppose `name` is "MyENV = %MyENV%". If the environment variable, MyENV, is set to 42, this method returns "MyENV = 42". If MyENV is not set, no change occurs; this method returns "MyENV = %MyENV%".

The size of the return value is limited to 32K.

Applies to

Product	Versions

Environment.FailFast Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message and optional exception information is included in error reporting to Microsoft. For Unix-like systems, the message, alongside the stack trace, is written to the standard error stream.

Overloads

Expand table

FailFast(String)	Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message is included in error reporting to Microsoft. For Unix-like systems, the message, alongside the stack trace, is written to the standard error stream.
FailFast(String, Exception)	Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message and exception information is included in error reporting to Microsoft. For Unix-like systems, the message alongside the stack trace is written to the standard error stream.

FailFast(String)

Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message is included in error reporting to Microsoft. For Unix-like systems, the message, alongside the stack trace, is written to the standard error stream.

C#

```
public static void FailFast (string? message);
```

Parameters

`message` String

A message that explains why the process was terminated, or `null` if no explanation is provided.

Examples

The following example writes a log entry to the Windows Application event log when running under Windows, or writes the error message to the standard error stream when running under a Unix-like system, and terminates the current process.

C#

```
using System;

class Example
{
    public static void Main()
    {
       string causeOfFailure = "A catastrophic failure has occurred.";

       // Assume your application has failed catastrophically and must
       // terminate immediately. The try-finally block is not executed
       // and is included only to demonstrate that instructions within
       // try-catch blocks and finalizers are not performed.
       try
       {
           Environment.FailFast(causeOfFailure);
       }
       finally
       {
           Console.WriteLine("This finally block will not be executed.");
       }
   }
}
/*
The example produces no output because the application is terminated.
However, an entry is made in the Windows Application event log, and
the log entry contains the text from the causeOfFailure variable.
*/
```

Remarks

This method terminates a process without running any active `try`/`finally` blocks or finalizers.

On Windows, the `Environment.FailFast` method writes the `message` string to the Windows Application event log, creates a dump of your application, and then terminates the current process. The `message` string is also included in error reporting to Microsoft via Windows Error Reporting. For more information, see Windows Error Reporting: Getting Started.

On Unix-like systems, the message is written to the standard error stream, alongside the stack trace information.

Use the `Environment.FailFast` method instead of the Exit method to terminate your application if the state of your application is damaged beyond repair, and executing your application's `try`/`finally` blocks and finalizers will corrupt program resources.

Calling the `Environment.FailFast` method to terminate execution of an application running in the Visual Studio debugger throws an ExecutionEngineException and automatically triggers the fatalExecutionEngineError managed debugging assistant (MDA).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FailFast(String, Exception)

Immediately terminates the process before reporting an error message. For Windows, the error message is written to the Windows Application event log, and the message and exception information is included in error reporting to Microsoft. For Unix-like systems, the message alongside the stack trace is written to the standard error stream.

```
C#
```

```
public static void FailFast (string? message, Exception? exception);
```

Parameters

`message` String

A message that explains why the process was terminated, or `null` if no explanation is provided.

`exception` Exception

An exception that represents the error that caused the termination. This is typically the exception in a `catch` block.

Remarks

This method terminates the process without running any active `try`/`finally` blocks or finalizers.

On Windows, the `Environment.FailFast` method writes the `message` string to the Windows Application event log, creates a dump of your application, and then terminates the current process.

Information is reported to Microsoft by using Windows Error Reporting. For more information, see Windows Error Reporting: Getting Started. Error reporting to Microsoft includes `message` and `exception` information, which provides details used to classify the error. Although `exception` is not handled because the process is terminated, the contextual information that raised the exception is still obtained.

On Unix-like systems, the message is written to the standard error stream, alongside the stack trace information.

If `exception` is `null`, or if `exception` is not thrown, this method operates the same as the FailFast(String) method overload.

Use the `Environment.FailFast` method instead of the Exit method to terminate your application if the state of your application is damaged beyond repair, and executing your application's `try`/`finally` blocks and finalizers will corrupt program resources.

Calling the `Environment.FailFast` method to terminate execution of an application running in the Visual Studio debugger throws an ExecutionEngineException and automatically triggers the fatalExecutionEngineError managed debugging assistant (MDA).

Environment.GetCommandLineArgs Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string array containing the command-line arguments for the current process.

C#

```
public static string[] GetCommandLineArgs ();
```

Returns

String[]

An array of strings where each element contains a command-line argument. The first element is the executable file name, and the following zero or more elements contain the remaining command-line arguments.

Exceptions

NotSupportedException

The system does not support command-line arguments.

Examples

The following example displays the application's command line arguments.

C#

```
using System;

class Sample
{
    public static void Main()
    {
        Console.WriteLine();
```

```
        //  Invoke this sample with an arbitrary set of command line
arguments.
        string[] arguments = Environment.GetCommandLineArgs();
        Console.WriteLine("GetCommandLineArgs: {0}", string.Join(", ",
arguments));
    }
}
/*
This example produces output like the following:

    C:\>GetCommandLineArgs ARBITRARY TEXT

      GetCommandLineArgs: GetCommandLineArgs, ARBITRARY, TEXT
*/
```

Remarks

The first element in the array contains the file name of the executing program. If the file name is not available, the first element is equal to String.Empty. The remaining elements contain any additional tokens entered on the command line.

In .NET 5 and later versions, for single-file publishing, the first element is the name of the host executable.

The program file name can, but is not required to, include path information.

Command line arguments are delimited by spaces. You can use double quotation marks (") to include spaces within an argument. The single quotation mark (), however, does not provide this functionality.

If a double quotation mark follows two or an even number of backslashes, each proceeding backslash pair is replaced with one backslash and the double quotation mark is removed. If a double quotation mark follows an odd number of backslashes, including just one, each preceding pair is replaced with one backslash and the remaining backslash is removed; however, in this case the double quotation mark is not removed.

The following table shows how command line arguments can be delimited, and assumes `MyApp` as the current executing application.

Expand table

Input at the command line	Resulting command line arguments
`MyApp alpha beta`	`MyApp, alpha, beta`

Input at the command line	Resulting command line arguments
`MyApp "alpha with spaces" "beta with spaces"`	`MyApp, alpha with spaces, beta with spaces`
`MyApp 'alpha with spaces' beta`	`MyApp, 'alpha, with, spaces', beta`
`MyApp \\\alpha \\\\"beta`	`MyApp, \\\alpha, \\beta`
`MyApp \\\\\"alpha \"beta`	`MyApp, \\"alpha, "beta`

To obtain the command line as a single string, use the CommandLine property.

Environment.GetEnvironmentVariable Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves the value of an environment variable.

Overloads

Expand table

GetEnvironmentVariable(String)	Retrieves the value of an environment variable from the current process.
GetEnvironmentVariable(String, EnvironmentVariableTarget)	Retrieves the value of an environment variable from the current process or from the Windows operating system registry key for the current user or local machine.

GetEnvironmentVariable(String)

Retrieves the value of an environment variable from the current process.

C#

```
public static string? GetEnvironmentVariable (string variable);
```

Parameters

`variable` String

The name of the environment variable.

Returns

String

The value of the environment variable specified by `variable`, or `null` if the environment variable is not found.

Exceptions

ArgumentNullException

`variable` is `null`.

SecurityException

The caller does not have the required permission to perform this operation.

Examples

The following example uses the GetEnvironmentVariable method to retrieve the `windir` environment variable, which contains the path of the Windows directory.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      if (Environment.OSVersion.Platform == PlatformID.Win32NT)
      {
         // Change the directory to %WINDIR%
         Environment.CurrentDirectory =
Environment.GetEnvironmentVariable("windir");
         DirectoryInfo info = new DirectoryInfo(".");

         Console.WriteLine("Directory Info:   " + info.FullName);
      }
      else
      {
         Console.WriteLine("This example runs on Windows only.");
      }
   }
}
// The example displays output like the following on a .NET
implementation running on Windows:
//        Directory Info:   C:\windows
// The example displays the following output on a .NET implementation on
Unix-based systems:
//        This example runs on Windows only.
```

The following example attempts to retrieve the value of an environment variable named `Test1` from the process environment block. If the variable doesn't exist, the example creates it and retrieves its value. The example displays the value of the variable. If the example created the variable, it also calls the GetEnvironmentVariables(EnvironmentVariableTarget) method with each member of the EnvironmentVariableTarget enumeration to establish that the variable can be retrieved only from the current process environment block. Finally, if the example created the variable, it deletes it.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string value;
      bool toDelete = false;

      // Check whether the environment variable exists.
      value = Environment.GetEnvironmentVariable("Test1");
      // If necessary, create it.
      if (value == null)
      {
         Environment.SetEnvironmentVariable("Test1", "Value1");
         toDelete = true;

         // Now retrieve it.
         value = Environment.GetEnvironmentVariable("Test1");
      }
      // Display the value.
      Console.WriteLine($"Test1: {value}\n");

      // Confirm that the value can only be retrieved from the process
      // environment block if running on a Windows system.
      if (Environment.OSVersion.Platform == PlatformID.Win32NT)
      {
         Console.WriteLine("Attempting to retrieve Test1 from:");
         foreach (EnvironmentVariableTarget enumValue in

Enum.GetValues(typeof(EnvironmentVariableTarget))) {
            value = Environment.GetEnvironmentVariable("Test1",
enumValue);
            Console.WriteLine($"   {enumValue}: {(value != null ? "found"
: "not found")}");
         }
         Console.WriteLine();
      }

      // If we've created it, now delete it.
```

```
        if (toDelete) {
           Environment.SetEnvironmentVariable("Test1", null);
           // Confirm the deletion.
           if (Environment.GetEnvironmentVariable("Test1") == null)
              Console.WriteLine("Test1 has been deleted.");
        }
    }
 }
 // The example displays the following output if run on a Windows system:
 //      Test1: Value1
 //
 //      Attempting to retrieve Test1 from:
 //         Process: found
 //         User: not found
 //         Machine: not found
 //
 //      Test1 has been deleted.
 //
 // The example displays the following output if run on a Unix-based
 system:
 //      Test1: Value1
 //
 //      Test1 has been deleted.
```

UWP	10.0

GetEnvironmentVariable(String, EnvironmentVariableTarget)

Retrieves the value of an environment variable from the current process or from the Windows operating system registry key for the current user or local machine.

C#

```
public static string? GetEnvironmentVariable (string variable,
EnvironmentVariableTarget target);
```

Parameters

`variable` String

The name of an environment variable.

`target` EnvironmentVariableTarget

One of the EnvironmentVariableTarget values. Only Process is supported on .NET running on Unix-based systems.

Returns

String

The value of the environment variable specified by the `variable` and `target` parameters, or `null` if the environment variable is not found.

Exceptions

ArgumentNullException

`variable` is `null`.

ArgumentException

`target` is not a valid EnvironmentVariableTarget value.

SecurityException

The caller does not have the required permission to perform this operation.

Examples

The following example creates environment variables for the EnvironmentVariableTarget.Process, EnvironmentVariableTarget.User, and Machine targets, checks whether the operating system registry contains the user and machine environment variables, then deletes the environment variables. Because .NET on Unix-based systems does not support per-user and per-machine environment variables, only SetEnvironmentVariable(String, String) and SetEnvironmentVariable(String, String, EnvironmentVariableTarget) with a value of EnvironmentVariableTarget.Process successfully store an environment variable to the process environment block.

C#

```
using System;
using System.Collections;
using Microsoft.Win32;

class Sample
{
    public static void Main()
    {
        // Environment variable names for default, process, user, and
machine targets.
        string defaultEnvVar = nameof(defaultEnvVar);
        string processEnvVar = nameof(processEnvVar);
        string userEnvVar = nameof(userEnvVar);
        string machineEnvVar = nameof(machineEnvVar);

        string dft = nameof(dft);
        string process = nameof(process);
        string user = nameof(user);
        string machine = nameof(machine);

        // Set the environment variable for each target.
        Console.WriteLine("Setting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, dft);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, process,

EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, user,
```

```
EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, machine,

EnvironmentVariableTarget.Machine);

        // Define an array of environment variables.
        string[] envVars = { defaultEnvVar,processEnvVar, userEnvVar,
machineEnvVar };

        // Try to get the environment variables from each target.
        // The default (no specified target).
        Console.WriteLine("Retrieving environment variables from the
default target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar) ?? "
(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The process block.
        Console.WriteLine("\nRetrieving environment variables from the
Process target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Process) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The user block.
        Console.WriteLine("\nRetrieving environment variables from the
User target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.User) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The machine block.
        Console.WriteLine("\nRetrieving environment variables from the
Machine target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Machine) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }

        // Delete the environment variable for each target.
        Console.WriteLine("\nDeleting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, null);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, null,
```

```
EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, null,

EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, null,

EnvironmentVariableTarget.Machine);
    }
}
// The example displays the following output if run on a Windows system:
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: machine
//
//      Deleting environment variables for each target...
//
// The example displays the following output if run on a Unix-based
system:
//
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
```

```
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Deleting environment variables for each target...
```

Environment.GetEnvironmentVariables Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves all environment variable names and their values.

Overloads

Expand table

GetEnvironmentVariables()	Retrieves all environment variable names and their values from the current process.
GetEnvironmentVariables(EnvironmentVariableTarget)	Retrieves all environment variable names and their values from the current process, or from the Windows operating system registry key for the current user or local machine.

GetEnvironmentVariables()

Retrieves all environment variable names and their values from the current process.

C#

```
public static System.Collections.IDictionary GetEnvironmentVariables ();
```

Returns

IDictionary

A dictionary that contains all environment variable names and their values; otherwise, an empty dictionary if no environment variables are found.

Exceptions

SecurityException

The caller does not have the required permission to perform this operation.

OutOfMemoryException

The buffer is out of memory.

Examples

The following example demonstrates the GetEnvironmentVariables method.

C#

```
// Sample for the Environment.GetEnvironmentVariables method
using System;
using System.Collections;

class Sample
{
    public static void Main()
    {
       Console.WriteLine();
       Console.WriteLine("GetEnvironmentVariables: ");
       foreach (DictionaryEntry de in
Environment.GetEnvironmentVariables())
           Console.WriteLine("  {0} = {1}", de.Key, de.Value);
    }
}
// Output from the example is not shown, since it is:
//    Lengthy.
//    Specific to the machine on which the example is run.
//    May reveal information that should remain secure.
```

Remarks

The names and values for the environment variables are stored as key-value pairs in the returned IDictionary.

On Windows systems

On Windows systems, the `GetEnvironmentVariables` method returns the following environment variables:

- All per-machine environment variables that are defined at the time the process is created, along with their values.

- All per-user environment variables that are defined at the time the process is created, along with their values.
- Any variables inherited from the parent process from which the .NET application was launched or added to the process block while the process is running. Environment variables are added while the process is running by calling either the SetEnvironmentVariable(String, String) method or the SetEnvironmentVariable(String, String, EnvironmentVariableTarget) method with a `target` value of EnvironmentVariableTarget.Process.

On non-Windows systems

On non-Windows systems, the `GetEnvironmentVariables` method retrieves the name and value of all environment variables that are inherited from the parent process that launched the `dotnet` process or that are defined within the scope of the `dotnet` process itself. Once the `dotnet` process ends, these latter environment variables cease to exist.

.NET running on Unix-based systems does not support per-machine or per-user environment variables.

- GetEnvironmentVariable(String)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetEnvironmentVariables(EnvironmentVariableTarget)

Retrieves all environment variable names and their values from the current process, or from the Windows operating system registry key for the current user or local machine.

```
C#

public static System.Collections.IDictionary GetEnvironmentVariables
(EnvironmentVariableTarget target);
```

Parameters

`target` EnvironmentVariableTarget

One of the EnvironmentVariableTarget values. Only Process is supported on .NET running on Unix-based systems.

Returns

IDictionary

A dictionary that contains all environment variable names and their values from the source specified by the `target` parameter; otherwise, an empty dictionary if no environment variables are found.

Exceptions

SecurityException

The caller does not have the required permission to perform this operation for the specified value of `target`.

ArgumentException

`target` contains an illegal value.

Examples

The following example creates environment variables for the EnvironmentVariableTarget.Process, EnvironmentVariableTarget.User, and Machine targets, checks whether the operating system registry contains the user and machine environment variables, then deletes the environment variables. Because .NET on

Unix-based systems does not support per-user and per-machine environment variables, only SetEnvironmentVariable(String, String) and SetEnvironmentVariable(String, String, EnvironmentVariableTarget) with a value of EnvironmentVariableTarget.Process successfully store an environment variable to the process environment block.

C#

```
using System;
using System.Collections;
using Microsoft.Win32;

class Sample
{
    public static void Main()
    {
        // Environment variable names for default, process, user, and
machine targets.
        string defaultEnvVar = nameof(defaultEnvVar);
        string processEnvVar = nameof(processEnvVar);
        string userEnvVar = nameof(userEnvVar);
        string machineEnvVar = nameof(machineEnvVar);

        string dft = nameof(dft);
        string process = nameof(process);
        string user = nameof(user);
        string machine = nameof(machine);

        // Set the environment variable for each target.
        Console.WriteLine("Setting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, dft);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, process,

EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, user,

EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, machine,

EnvironmentVariableTarget.Machine);

        // Define an array of environment variables.
        string[] envVars = { defaultEnvVar,processEnvVar, userEnvVar,
machineEnvVar };

        // Try to get the environment variables from each target.
        // The default (no specified target).
        Console.WriteLine("Retrieving environment variables from the
```

```
default target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar) ?? "
(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The process block.
        Console.WriteLine("\nRetrieving environment variables from the
Process target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Process) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The user block.
        Console.WriteLine("\nRetrieving environment variables from the
User target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.User) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The machine block.
        Console.WriteLine("\nRetrieving environment variables from the
Machine target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Machine) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }

        // Delete the environment variable for each target.
        Console.WriteLine("\nDeleting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, null);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, null,

EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, null,

EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, null,

EnvironmentVariableTarget.Machine);
    }
}
// The example displays the following output if run on a Windows system:
```

```
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: machine
//
//      Deleting environment variables for each target...
//
// The example displays the following output if run on a Unix-based
system:
//
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
```

```
//        machineEnvVar: (none)
//
//      Deleting environment variables for each target...
```

Remarks

The names and values of the environment variables are stored as key/value pairs in the returned IDictionary object.

On Windows systems

On Windows systems, the `target` parameter specifies whether the source is the current process, the registry key for the current user, or the registry key for the local machine.

On non-Windows systems

On non-Windows systems, only a `target` value of EnvironmentVariableTarget.Process is supported. Per-process environment variables are inherited from the parent process (typically the shell) used to launch the `dotnet` process or are defined within the scope of the `dotnet` process itself. Once the dotnet process ends, these latter environment variables cease to exist.

Per-machine and per-user environment variables are not supported. A `target` value of EnvironmentVariableTarget.Machine or EnvironmentVariableTarget.User returns an empty array.

Environment.GetFolderPath Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the path to the system special folder that is identified by the specified enumeration.

Overloads

Expand table

GetFolderPath(Environment+SpecialFolder)	Gets the path to the specified system special folder.
GetFolderPath(Environment+SpecialFolder, Environment+SpecialFolderOption)	Gets the path to the specified system special folder using a specified option for accessing special folders.

GetFolderPath(Environment+SpecialFolder)

Gets the path to the specified system special folder.

C#

```
public static string GetFolderPath (Environment.SpecialFolder folder);
```

Parameters

`folder` Environment.SpecialFolder

One of the enumeration values that identifies a system special folder.

Returns

String

The path to the specified system special folder, if that folder physically exists on your computer; otherwise, an empty string ("").

A folder will not physically exist if the operating system did not create it, the existing folder was deleted, or the folder is a virtual directory, such as My Computer, which does not correspond to a physical path.

Exceptions

ArgumentException

`folder` is not a member of Environment.SpecialFolder.

PlatformNotSupportedException

The current platform is not supported.

Examples

The following example demonstrates how to use the GetFolderPath method to return and display the path associated with the `folder` parameter.

C#

```
// Sample for the Environment.GetFolderPath method
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
    Console.WriteLine("GetFolderPath: {0}",

Environment.GetFolderPath(Environment.SpecialFolder.System));
    }
}
/*
This example produces the following results:

GetFolderPath: C:\WINNT\System32
*/
```

Remarks

This method retrieves the path to a system special folder, such as Program Files, Programs, System, or Startup, which can be used to access common information.

Special folders are set by default by the system, or explicitly by the user, when installing a version of Windows.

The `folder` parameter designates the special folder to retrieve and must be one of the values in the Environment.SpecialFolder enumeration; any other value throws an exception.

For more information about special folders, see Constant special item ID list (CSIDL).

.NET Standard	2.0, 2.1

GetFolderPath(Environment+SpecialFolder, Environment+SpecialFolderOption)

Gets the path to the specified system special folder using a specified option for accessing special folders.

C#

```
public static string GetFolderPath (Environment.SpecialFolder folder,
Environment.SpecialFolderOption option);
```

Parameters

`folder` Environment.SpecialFolder

One of the enumeration values that identifies a system special folder.

`option` Environment.SpecialFolderOption

One of the enumeration values that specifies options to use for accessing a special folder.

Returns

String

The path to the specified system special folder, if that folder physically exists on your computer; otherwise, an empty string ("").

A folder will not physically exist if the operating system did not create it, the existing folder was deleted, or the folder is a virtual directory, such as My Computer, which does not correspond to a physical path.

Exceptions

ArgumentException

`folder` is not a member of Environment.SpecialFolder.

-or-

`options` is not a member of Environment.SpecialFolderOption.

PlatformNotSupportedException

The current platform is not supported.

Remarks

This method retrieves the path to a system special folder, such as Program Files, Programs, System, or Startup, which can be used to access common information. Special folders are set by default by the system, or explicitly by the user, when installing a version of Windows.

The `folder` parameter designates the special folder to retrieve and must be one of the values in the Environment.SpecialFolder enumeration; any other value throws an exception.

For more information about special folders, see Constant special item ID list (CSIDL).

Environment.GetLogicalDrives Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an array of string containing the names of the logical drives on the current computer.

C#

```
public static string[] GetLogicalDrives ();
```

Returns

String[]

An array of strings where each element contains the name of a logical drive. For example, if the computer's hard drive is the first logical drive, the first element returned is "C:\".

Exceptions

IOException

An I/O error occurs.

SecurityException

The caller does not have the required permissions.

Examples

The following example shows how to display the logical drives of the current computer using the GetLogicalDrives method.

C#

```
// Sample for the Environment.GetLogicalDrives method
using System;
```

```
class Sample
{
    public static void Main()
    {
    Console.WriteLine();
    String[] drives = Environment.GetLogicalDrives();
    Console.WriteLine("GetLogicalDrives: {0}", String.Join(", ", drives));
    }
}
/*
This example produces the following results:

GetLogicalDrives: A:\, C:\, D:\
*/
```

Environment.SetEnvironmentVariable Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates, modifies, or deletes an environment variable.

Overloads

Expand table

SetEnvironmentVariable(String, String)	Creates, modifies, or deletes an environment variable stored in the current process.
SetEnvironmentVariable(String, String, EnvironmentVariableTarget)	Creates, modifies, or deletes an environment variable stored in the current process or in the Windows operating system registry key reserved for the current user or local machine.

SetEnvironmentVariable(String, String)

Creates, modifies, or deletes an environment variable stored in the current process.

C#

```
public static void SetEnvironmentVariable (string variable, string?
value);
```

Parameters

`variable` String

The name of an environment variable.

`value` String

A value to assign to `variable`.

Exceptions

ArgumentNullException

`variable` is `null`.

ArgumentException

`variable` contains a zero-length string, an initial hexadecimal zero character (0x00), or an equal sign ("=").

-or-

The length of `variable` or `value` is greater than or equal to 32,767 characters.

-or-

An error occurred during the execution of this operation.

SecurityException

The caller does not have the required permission to perform this operation.

Examples

The following example attempts to retrieve the value of an environment variable named `Test1` from the process environment block. If the variable doesn't exist, the example creates the variable and retrieves its value. The example displays the value of the variable. For .NET implementations running on Windows systems, it also calls the GetEnvironmentVariables(EnvironmentVariableTarget) method with each member of the EnvironmentVariableTarget enumeration to establish that the variable can be retrieved only from the current process environment block. (.NET implementations on Unix-based systems only support variables in the process environment block.) Finally, if the example created the variable, it deletes it.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string value;
      bool toDelete = false;
```

```
      // Check whether the environment variable exists.
      value = Environment.GetEnvironmentVariable("Test1");
      // If necessary, create it.
      if (value == null)
      {
         Environment.SetEnvironmentVariable("Test1", "Value1");
         toDelete = true;

         // Now retrieve it.
         value = Environment.GetEnvironmentVariable("Test1");
      }
      // Display the value.
      Console.WriteLine($"Test1: {value}\n");

      // Confirm that the value can only be retrieved from the process
      // environment block if running on a Windows system.
      if (Environment.OSVersion.Platform == PlatformID.Win32NT)
      {
         Console.WriteLine("Attempting to retrieve Test1 from:");
         foreach (EnvironmentVariableTarget enumValue in

Enum.GetValues(typeof(EnvironmentVariableTarget))) {
            value = Environment.GetEnvironmentVariable("Test1",
enumValue);
            Console.WriteLine($"   {enumValue}: {(value != null ? "found"
: "not found")}");
         }
         Console.WriteLine();
      }

      // If we've created it, now delete it.
      if (toDelete) {
         Environment.SetEnvironmentVariable("Test1", null);
         // Confirm the deletion.
         if (Environment.GetEnvironmentVariable("Test1") == null)
            Console.WriteLine("Test1 has been deleted.");
      }
   }
}
// The example displays the following output if run on a Windows system:
//      Test1: Value1
//
//      Attempting to retrieve Test1 from:
//         Process: found
//         User: not found
//         Machine: not found
//
//      Test1 has been deleted.
//
// The example displays the following output if run on a Unix-based
system:
//      Test1: Value1
//
//      Test1 has been deleted.
```

Remarks

Calling this method is equivalent to calling the SetEnvironmentVariable(String, String, EnvironmentVariableTarget) overload with a value of EnvironmentVariableTarget.Process for the `target` argument.

On non-Windows systems, calls to the SetEnvironmentVariable(String, String) method have no effect on any native libraries that are, or will be, loaded.

If the `value` argument is not empty (see the discussion of deleting an environment variable later in this section for the definition of an empty value) and the environment variable named by the `variable` parameter does not exist, the environment variable is created and assigned the contents of `value`. If it does exist, its value is modified. Because the environment variable is defined in the environment block of the current process only, it does not persist after the process has ended.

If `variable` contains a non-initial hexadecimal zero character, the characters before the zero character are considered the environment variable name and all subsequent characters are ignored.

If `value` contains a non-initial hexadecimal zero character, the characters before the zero character are assigned to the environment variable and all subsequent characters are ignored.

If `value` is empty and the environment variable named by `variable` exists, the environment variable is deleted. If `variable` does not exist, no error occurs even though the operation cannot be performed. `value` is considered empty under any of the following conditions:

- It is `null`.
- It is String.Empty.
- It consists of a single character whose value is U+0000.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

SetEnvironmentVariable(String, String, EnvironmentVariableTarget)

Creates, modifies, or deletes an environment variable stored in the current process or in the Windows operating system registry key reserved for the current user or local machine.

C#

```
public static void SetEnvironmentVariable (string variable, string?
value, EnvironmentVariableTarget target);
```

Parameters

`variable` String

The name of an environment variable.

`value` String

A value to assign to `variable`.

`target` EnvironmentVariableTarget

One of the enumeration values that specifies the location of the environment variable.

Exceptions

ArgumentNullException

`variable` is `null`.

ArgumentException

`variable` contains a zero-length string, an initial hexadecimal zero character (0x00), or an equal sign ("=").

-or-

The length of `variable` is greater than or equal to 32,767 characters.

-or-

`target` is not a member of the EnvironmentVariableTarget enumeration.

-or-

`target` is Machine or User, and the length of `variable` is greater than or equal to 255.

-or-

`target` is Process and the length of `value` is greater than or equal to 32,767 characters.

-or-

An error occurred during the execution of this operation.

SecurityException
The caller does not have the required permission to perform this operation.

Examples

The following example creates environment variables for the EnvironmentVariableTarget.Process, EnvironmentVariableTarget.User, and Machine targets, checks whether the operating system registry contains the user and machine environment variables, then deletes the environment variables. Because .NET on Unix-based systems does not support per-user and per-machine environment variables, only SetEnvironmentVariable(String, String) and SetEnvironmentVariable(String, String, EnvironmentVariableTarget) with a value of EnvironmentVariableTarget.Process successfully store an environment variable to the process environment block.

C#

```
using System;
using System.Collections;
using Microsoft.Win32;
```

```
class Sample
{
    public static void Main()
    {
        // Environment variable names for default, process, user, and
machine targets.
        string defaultEnvVar = nameof(defaultEnvVar);
        string processEnvVar = nameof(processEnvVar);
        string userEnvVar = nameof(userEnvVar);
        string machineEnvVar = nameof(machineEnvVar);

        string dft = nameof(dft);
        string process = nameof(process);
        string user = nameof(user);
        string machine = nameof(machine);

        // Set the environment variable for each target.
        Console.WriteLine("Setting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, dft);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, process,

EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, user,

EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, machine,

EnvironmentVariableTarget.Machine);

        // Define an array of environment variables.
        string[] envVars = { defaultEnvVar,processEnvVar, userEnvVar,
machineEnvVar };

        // Try to get the environment variables from each target.
        // The default (no specified target).
        Console.WriteLine("Retrieving environment variables from the
default target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar) ?? "
(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The process block.
        Console.WriteLine("\nRetrieving environment variables from the
Process target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
```

```
EnvironmentVariableTarget.Process) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The user block.
        Console.WriteLine("\nRetrieving environment variables from the
User target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.User) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The machine block.
        Console.WriteLine("\nRetrieving environment variables from the
Machine target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Machine) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }

        // Delete the environment variable for each target.

//        machineEnvVar: machine
//
//      Deleting environment variables for each target...
//
// The example displays the following output if run on a Unix-based
system:
//
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Deleting environment variables for each target...
```

Remarks

The SetEnvironmentVariable(String, String, EnvironmentVariableTarget) method lets you define an environment variable that is available to the current process (the

Process value). Environment variables that are unique to the current process environment block persist only until the process ends.

In addition, on Windows systems only, the SetEnvironmentVariable(String, String, EnvironmentVariableTarget) method lets you define an environment variable that is available to all processes that run on a machine (the EnvironmentVariableTarget.Machine value) and to all processes run by a user (the EnvironmentVariableTarget.User value). Per-machine and per-user environment variables are copied into the environment block of the current process.

On non-Windows systems, calls to the SetEnvironmentVariable(String, String, EnvironmentVariableTarget) method with a value of EnvironmentVariableTarget.Machine or EnvironmentVariableTarget.User are ignored.

On non-Windows systems, calls to the SetEnvironmentVariable(String, String, EnvironmentVariableTarget) method with a value of EnvironmentVariableTarget.Process have no effect on any native libraries that are, or will be, loaded.

If the `value` argument is not empty (see the discussion of deleting an environment variable later in this section for the definition of an empty value) and the environment variable named by the `variable` argument does not exist, the environment variable is created and assigned the contents of `value`. If it does exist, its value is modified.

If `variable` contains a non-initial hexadecimal zero character, the characters before the zero character are considered the environment variable name and all subsequent characters are ignored.

If `value` contains a non-initial hexadecimal zero character, the characters before the zero character are assigned to the environment variable and all subsequent characters are ignored.

If `value` is empty and the environment variable named by `variable` exists, the environment variable is deleted. `value` is considered empty under any of the following conditions:

- It is `null`.
- It is String.Empty.
- It consists of a single character whose value is U+0000.

If `variable` does not exist, no error occurs although the operation cannot be performed. Be careful when `target` is Machine, because you can accidentally delete an environment variable that affects your entire local machine, not just the current process or user.

EnvironmentVariableTarget.Machine and EnvironmentVariableTarget.User on Windows systems

If `target` is EnvironmentVariableTarget.User, the environment variable is stored in the HKEY_CURRENT_USER\Environment key of the local computer's registry. It is also copied to instances of File Explorer that are running as the current user. The environment variable is then inherited by any new processes that the user launches from File Explorer.

Similarly, if `target` is EnvironmentVariableTarget.Machine, the environment variable is stored in the HKEY_LOCAL_MACHINE\SYSTEM\ControlSet001\Control\Session Manager\Environment key of the local computer's registry. It is also copied to all instances of File Explorer. The environment variable is then inherited by any new processes that are launched from File Explorer.

If `target` is User or Machine, other applications are notified of the set operation by a Windows `WM_SETTINGCHANGE` message.

If `target` is EnvironmentVariableTarget.User or EnvironmentVariableTarget.Machine, we recommend that the length of `value` be less than 2048 characters.

Environment.SpecialFolder Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies enumerated constants used to retrieve directory paths to system special folders.

C#

```
public enum Environment.SpecialFolder
```

Inheritance Object → ValueType → Enum → Environment.SpecialFolder

Fields

Expand table

AdminTools	48	The file system directory that is used to store administrative tools for an individual user. The Microsoft Management Console (MMC) will save customized consoles to this directory, and it will roam with the user.
ApplicationData	26	The directory that serves as a common repository for application-specific data for the current roaming user. A roaming user works on more than one computer on a network. A roaming user's profile is kept on a server on the network and is loaded onto a system when the user logs on.
CDBurning	59	The file system directory that acts as a staging area for files waiting to be written to a CD.
CommonAdminTools	47	The file system directory that contains administrative tools for all users of the computer.
CommonApplicationData	35	The directory that serves as a common repository for application-specific data that is used by all users.
CommonDesktopDirectory	25	The file system directory that contains files and folders that appear on the desktop for all users.

CommonDocuments	46	The file system directory that contains documents that are common to all users.
CommonMusic	53	The file system directory that serves as a repository for music files common to all users.
CommonOemLinks	58	This value is recognized in Windows Vista for backward compatibility, but the special folder itself is no longer used.
CommonPictures	54	The file system directory that serves as a repository for image files common to all users.
CommonProgramFiles	43	The directory for components that are shared across applications. To get the x86 common program files directory in a non-x86 process, use the ProgramFilesX86 member.
CommonProgramFilesX86	44	The **Program Files** folder.
CommonPrograms	23	A folder for components that are shared across applications.
CommonStartMenu	22	The file system directory that contains the programs and folders that appear on the **Start** menu for all users.
CommonStartup	24	The file system directory that contains the programs that appear in the **Startup** folder for all users.
CommonTemplates	45	The file system directory that contains the templates that are available to all users.
CommonVideos	55	The file system directory that serves as a repository for video files common to all users.
Cookies	33	The directory that serves as a common repository for Internet cookies.
Desktop	0	The logical Desktop rather than the physical file system location.
DesktopDirectory	16	The directory used to physically store file objects on the desktop. Do not confuse this directory with the desktop folder itself, which is a virtual folder.
Favorites	6	The directory that serves as a common repository for the user's favorite items.
Fonts	20	A virtual folder that contains fonts.
History	34	The directory that serves as a common repository for Internet history items.

InternetCache	32	The directory that serves as a common repository for temporary Internet files.
LocalApplicationData	28	The directory that serves as a common repository for application-specific data that is used by the current, non-roaming user.
LocalizedResources	57	The file system directory that contains localized resource data.
MyComputer	17	The **My Computer** folder. When passed to the `Environment.GetFolderPath` method, the `MyComputer` enumeration member always yields the empty string ("") because no path is defined for the My Computer folder.
MyDocuments	5	The **My Documents** folder. This member is equivalent to Personal.
MyMusic	13	The **My Music** folder.
MyPictures	39	The **My Pictures** folder.
MyVideos	14	The file system directory that serves as a repository for videos that belong to a user.
NetworkShortcuts	19	A file system directory that contains the link objects that may exist in the **My Network Places** virtual folder.
Personal	5	The directory that serves as a common repository for documents. This member is equivalent to MyDocuments.
PrinterShortcuts	27	The file system directory that contains the link objects that can exist in the **Printers** virtual folder.
ProgramFiles	38	The program files directory. In a non-x86 process, passing ProgramFiles to the GetFolderPath(Environment+SpecialFolder) method returns the path for non-x86 programs. To get the x86 program files directory in a non-x86 process, use the ProgramFilesX86 member.
ProgramFilesX86	42	The x86 **Program Files** folder.
Programs	2	The directory that contains the user's program groups.
Recent	8	The directory that contains the user's most recently used documents.
Resources	56	The file system directory that contains resource data.
SendTo	9	The directory that contains the Send To menu items.

StartMenu	11	The directory that contains the Start menu items.
Startup	7	The directory that corresponds to the user's Startup program group. The system starts these programs whenever a user logs on or starts Windows.
System	37	The System directory.
SystemX86	41	The Windows **System** folder.
Templates	21	The directory that serves as a common repository for document templates.
UserProfile	40	The user's profile folder. Applications should not create files or folders at this level; they should put their data under the locations referred to by ApplicationData.
Windows	36	The Windows directory or SYSROOT. This corresponds to the %windir% or %SYSTEMROOT% environment variables.

Examples

The following example shows how to use Environment.SpecialFolder with the Environment.GetFolderPath method to get the System directory.

C#

```
// Sample for the Environment.GetFolderPath method
using System;

class Sample
{
    public static void Main()
    {
    Console.WriteLine();
    Console.WriteLine("GetFolderPath: {0}",

Environment.GetFolderPath(Environment.SpecialFolder.System));
    }
}
/*
This example produces the following results:

GetFolderPath: C:\WINNT\System32
*/
```

Remarks

The system special folders are folders such as **Program Files**, **Programs**, **System**, or **Startup**, which contain common information. Special folders are set by default by the system, or explicitly by the user, when installing a version of Windows.

The Environment.GetFolderPath method returns the locations associated with this enumeration. The locations of these folders can have different values on different operating systems, the user can change some of the locations, and the locations are localized.

For more information about special folders, see the KNOWNFOLDERID constants in the Windows documentation.

Environment.SpecialFolderOption Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies options to use for getting the path to a special folder.

C#

```
public enum Environment.SpecialFolderOption
```

Inheritance Object → ValueType → Enum → Environment.SpecialFolderOption

Fields

Expand table

Create	32768	The path to the folder is created if it does not already exist.
DoNotVerify	16384	The path to the folder is returned without verifying whether the path exists. If the folder is located on a network, specifying this option can reduce lag time.
None	0	The path to the folder is verified. If the folder exists, the path is returned. If the folder does not exist, an empty string is returned. This is the default behavior.

Remarks

The System.Environment.SpecialFolderOption enumeration is used to define the precise behavior of the Environment.GetFolderPath method.

Applies to

EnvironmentVariableTarget Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the location where an environment variable is stored or retrieved in a set or get operation.

```
C#

public enum EnvironmentVariableTarget
```

Inheritance Object → ValueType → Enum → EnvironmentVariableTarget

Fields

Expand table

Machine	2	The environment variable is stored or retrieved from the `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Session Manager\Environment` key in the Windows operating system registry. This value should be used on .NET implementations running on Windows systems only.
Process	0	The environment variable is stored or retrieved from the environment block associated with the current process.
User	1	The environment variable is stored or retrieved from the `HKEY_CURRENT_USER\Environment` key in the Windows operating system registry. This value should be used on .NET implementations running on Windows systems only.

Examples

The following example uses the EnvironmentVariableTarget enumeration in methods that create, retrieve, and delete environment variables. The output from the example shows that environmnent variables stored and retrieved without specifying a `EnvironmentVariableTarget` value are stored in the environment block associated with the current process (`EnvironmentVariableTarget.Process`). The example output from

Unix-based systems also shows that attempts to define an environment variable with a value other than `EnvironmentVariableTarget.Process` is ignored.

C#

```
using System;
using System.Collections;
using Microsoft.Win32;

class Sample
{
    public static void Main()
    {
        // Environment variable names for default, process, user, and
machine targets.
        string defaultEnvVar = nameof(defaultEnvVar);
        string processEnvVar = nameof(processEnvVar);
        string userEnvVar = nameof(userEnvVar);
        string machineEnvVar = nameof(machineEnvVar);

        string dft = nameof(dft);
        string process = nameof(process);
        string user = nameof(user);
        string machine = nameof(machine);

        // Set the environment variable for each target.
        Console.WriteLine("Setting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, dft);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, process,

EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, user,
                                           EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, machine,

EnvironmentVariableTarget.Machine);

        // Define an array of environment variables.
        string[] envVars = { defaultEnvVar,processEnvVar, userEnvVar,
machineEnvVar };

        // Try to get the environment variables from each target.
        // The default (no specified target).
        Console.WriteLine("Retrieving environment variables from the default
target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar) ?? "
(none)";
```

```
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The process block.
        Console.WriteLine("\nRetrieving environment variables from the
Process target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Process) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The user block.
        Console.WriteLine("\nRetrieving environment variables from the User
target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.User) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }
        // The machine block.
        Console.WriteLine("\nRetrieving environment variables from the
Machine target:");
        foreach (var envVar in envVars)
        {
          var value = Environment.GetEnvironmentVariable(envVar,
EnvironmentVariableTarget.Machine) ?? "(none)";
          Console.WriteLine($"   {envVar}: {value}");
        }

        // Delete the environment variable for each target.
        Console.WriteLine("\nDeleting environment variables for each
target...\n");
        // The default target (the current process).
        Environment.SetEnvironmentVariable(defaultEnvVar, null);
        // The current process.
        Environment.SetEnvironmentVariable(processEnvVar, null,

EnvironmentVariableTarget.Process);
        // The current user.
        Environment.SetEnvironmentVariable(userEnvVar, null,
                                           EnvironmentVariableTarget.User);
        // The local machine.
        Environment.SetEnvironmentVariable(machineEnvVar, null,

EnvironmentVariableTarget.Machine);
    }
}
// The example displays the following output if run on a Windows system:
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: user
```

```
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: user
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: machine
//
//      Deleting environment variables for each target...
//
// The example displays the following output if run on a Unix-based system:
//
//      Setting environment variables for each target...
//
//      Retrieving environment variables from the default target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Process target:
//        defaultEnvVar: dft
//        processEnvVar: process
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the User target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Retrieving environment variables from the Machine target:
//        defaultEnvVar: (none)
//        processEnvVar: (none)
//        userEnvVar: (none)
//        machineEnvVar: (none)
//
//      Deleting environment variables for each target...
```

Remarks

The EnvironmentVariableTarget enumeration is used by certain overloads of the Environment.SetEnvironmentVariable, Environment.GetEnvironmentVariable, and Environment.GetEnvironmentVariables methods to specify the location, or target, where the name and value of an environment variable is stored or retrieved.

The target can be one of three locations:

- The environment block associated with the current process (`EnvironmentVariableTarget.Process`).

  The user creates the environment variable in a set operation. When the process terminates, the operating system destroys the environment variable in that process.

- The Windows operating system registry key reserved for environment variables associated with the current user (`EnvironmentVariableTarget.User`).

  On Windows systems, when the user creates the environment variable in a set operation, the operating system stores the environment variable in the system registry, but not in the current process. If the user starts a new process, the operating system copies the environment variable from the registry to that process. When the process terminates, the operating system destroys the environment variable in that process. However, the environment variable in the registry persists until the user removes it programmatically or by means of an operating system tool.

  On Unix-based systems, an attempt to create an enviroment variable with `EnvironmentVariable.User` has no effect, and an attempt to retrieve an enviroment variable using `EnvironmentVariable.User` returns `null` (in C#) or `Nothing` (in Visual Basic).

- The registry key reserved for environment variables associated with all users on the local machine (`EnvironmentVariableTarget.Machine`).

  When a user creates the environment variable in a set operation, the operating system stores the environment variable in the system registry, but not in the current process. If any user on the local machine starts a new process, the operating system copies the environment variable from the registry to that process. When the process terminates, the operating system destroys the environment variable in that process. However, the environment variable in the

registry persists until a user removes it programmatically or by means of an operating system tool.

On Unix-based systems, an attempt to create an enviroment variable with `EnvironmentVariable.Machine` has no effect, and an attempt to retrieve an enviroment variable using `EnvironmentVariable.Machine` returns `null` (in C#) or `Nothing` (in Visual Basic).

EventArgs Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the base class for classes that contain event data, and provides a value to use for events that do not include event data.

C#

```
public class EventArgs
```

Inheritance Object → EventArgs

Derived Microsoft.VisualBasic.ApplicationServices.ApplyApplicationDefaultsEventArgs
Microsoft.VisualBasic.ApplicationServices.StartupNextInstanceEventArgs
Microsoft.VisualBasic.Devices.NetworkAvailableEventArgs
Microsoft.Win32.PowerModeChangedEventArgs
Microsoft.Win32.SessionEndedEventArgs
More...

Examples

The following example shows a custom event data class named `ThresholdReachedEventArgs` that derives from the EventArgs class. An instance of the event data class is passed to the event handler for the `ThresholdReached` event.

C#

```
using System;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            Counter c = new Counter(new Random().Next(10));
            c.ThresholdReached += c_ThresholdReached;
```

```
            Console.WriteLine("press 'a' key to increase total");
            while (Console.ReadKey(true).KeyChar == 'a')
            {
                Console.WriteLine("adding one");
                c.Add(1);
            }
        }

        static void c_ThresholdReached(object sender,
ThresholdReachedEventArgs e)
        {
            Console.WriteLine("The threshold of {0} was reached at {1}.",
e.Threshold,  e.TimeReached);
            Environment.Exit(0);
        }
    }

    class Counter
    {
        private int threshold;
        private int total;

        public Counter(int passedThreshold)
        {
            threshold = passedThreshold;
        }

        public void Add(int x)
        {
            total += x;
            if (total >= threshold)
            {
                ThresholdReachedEventArgs args = new
ThresholdReachedEventArgs();
                args.Threshold = threshold;
                args.TimeReached = DateTime.Now;
                OnThresholdReached(args);
            }
        }

        protected virtual void OnThresholdReached(ThresholdReachedEventArgs
e)
        {
            EventHandler<ThresholdReachedEventArgs> handler =
ThresholdReached;
            if (handler != null)
            {
                handler(this, e);
            }
        }

        public event EventHandler<ThresholdReachedEventArgs>
ThresholdReached;
    }
```

```
    public class ThresholdReachedEventArgs : EventArgs
    {
        public int Threshold { get; set; }
        public DateTime TimeReached { get; set; }
    }
}
```

Remarks

This class serves as the base class for all classes that represent event data. For example, the System.AssemblyLoadEventArgs class derives from EventArgs and is used to hold the data for assembly load events. To create a custom event data class, create a class that derives from the EventArgs class and provide the properties to store the necessary data. The name of your custom event data class should end with `EventArgs`.

To pass an object that does not contain any data, use the Empty field.

For more information about events, see the Handling and Raising Events article.

Constructors

Expand table

EventArgs()	Initializes a new instance of the EventArgs class.

Fields

Expand table

Empty	Provides a value to use with events that do not have event data.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)

GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

EventArgs.Empty Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a value to use with events that do not have event data.

C#

```
public static readonly EventArgs Empty;
```

Field Value

EventArgs

Examples

The following example shows a simple counting application that raises an event when a threshold is equaled or exceeded. The Empty field is passed to the `OnThresholdReached` method.

C#

```
using System;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            Counter c = new Counter(new Random().Next(10));
            c.ThresholdReached += c_ThresholdReached;

            Console.WriteLine("press 'a' key to increase total");
            while (Console.ReadKey(true).KeyChar == 'a')
            {
                Console.WriteLine("adding one");
                c.Add(1);
            }
        }
```

```
        static void c_ThresholdReached(object sender, EventArgs e)
        {
            Console.WriteLine("The threshold was reached.");
            Environment.Exit(0);
        }
    }

    class Counter
    {
        private int threshold;
        private int total;

        public Counter(int passedThreshold)
        {
            threshold = passedThreshold;
        }

        public void Add(int x)
        {
            total += x;
            if (total >= threshold)
            {
                OnThresholdReached(EventArgs.Empty);
            }
        }

        protected virtual void OnThresholdReached(EventArgs e)
        {
            EventHandler handler = ThresholdReached;
            if (handler != null)
            {
                handler(this, e);
            }
        }

        public event EventHandler ThresholdReached;
    }
}
```

Remarks

Pass this value to event handlers that are associated with events that do not have data.

Applies to

EventHandler Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the method that will handle an event that has no event data.

C#

```
public delegate void EventHandler(object? sender, EventArgs e);
```

Parameters

sender Object

The source of the event.

e EventArgs

An object that contains no event data.

Examples

The following example shows an event named `ThresholdReached` that is associated with an EventHandler delegate. The method assigned to the EventHandler delegate is called in the `OnThresholdReached` method.

C#

```
using System;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            Counter c = new Counter(new Random().Next(10));
            c.ThresholdReached += c_ThresholdReached;

            Console.WriteLine("press 'a' key to increase total");
```

```
            while (Console.ReadKey(true).KeyChar == 'a')
            {
                Console.WriteLine("adding one");
                c.Add(1);
            }
        }

        static void c_ThresholdReached(object sender,
ThresholdReachedEventArgs e)
        {
            Console.WriteLine("The threshold of {0} was reached at {1}.",
e.Threshold,  e.TimeReached);
            Environment.Exit(0);
        }
    }

    class Counter
    {
        private int threshold;
        private int total;

        public Counter(int passedThreshold)
        {
            threshold = passedThreshold;
        }

        public void Add(int x)
        {
            total += x;
            if (total >= threshold)
            {
                ThresholdReachedEventArgs args = new
ThresholdReachedEventArgs();
                args.Threshold = threshold;
                args.TimeReached = DateTime.Now;
                OnThresholdReached(args);
            }
        }

        protected virtual void OnThresholdReached(ThresholdReachedEventArgs
e)
        {
            EventHandler<ThresholdReachedEventArgs> handler =
ThresholdReached;
            if (handler != null)
            {
                handler(this, e);
            }
        }

        public event EventHandler<ThresholdReachedEventArgs>
ThresholdReached;
    }

    public class ThresholdReachedEventArgs : EventArgs
```

```
    {
        public int Threshold { get; set; }
        public DateTime TimeReached { get; set; }
    }
}
```

Remarks

The event model in the .NET Framework is based on having an event delegate that connects an event with its handler. To raise an event, two elements are needed:

- A delegate that identifies the method that provides the response to the event.
- Optionally, a class that holds the event data, if the event provides data.

The delegate is a type that defines a signature, that is, the return value type and parameter list types for a method. You can use the delegate type to declare a variable that can refer to any method with the same signature as the delegate.

The standard signature of an event handler delegate defines a method that does not return a value. This method's first parameter is of type Object and refers to the instance that raises the event. Its second parameter is derived from type EventArgs and holds the event data. If the event does not generate event data, the second parameter is simply the value of the EventArgs.Empty field. Otherwise, the second parameter is a type derived from EventArgs and supplies any fields or properties needed to hold the event data.

The EventHandler delegate is a predefined delegate that specifically represents an event handler method for an event that does not generate data. If your event does generate data, you must use the generic EventHandler<TEventArgs> delegate class.

To associate the event with the method that will handle the event, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate.

For more information about event handler delegates, see Handling and Raising Events.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

EventHandler<TEventArgs> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the method that will handle an event when the event provides data.

C#

```
public delegate void EventHandler<TEventArgs>(object? sender, TEventArgs e);
```

Type Parameters

TEventArgs

The type of the event data generated by the event.

Parameters

sender Object

The source of the event.

e TEventArgs

An object that contains the event data.

Examples

The following example shows an event named `ThresholdReached`. The event is associated with an EventHandler<TEventArgs> delegate.

C#

```
using System;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
```

```
        {
            Counter c = new Counter(new Random().Next(10));
            c.ThresholdReached += c_ThresholdReached;

            Console.WriteLine("press 'a' key to increase total");
            while (Console.ReadKey(true).KeyChar == 'a')
            {
                Console.WriteLine("adding one");
                c.Add(1);
            }
        }

        static void c_ThresholdReached(object sender,
ThresholdReachedEventArgs e)
        {
            Console.WriteLine("The threshold of {0} was reached at {1}.",
e.Threshold,  e.TimeReached);
            Environment.Exit(0);
        }
    }

    class Counter
    {
        private int threshold;
        private int total;

        public Counter(int passedThreshold)
        {
            threshold = passedThreshold;
        }

        public void Add(int x)
        {
            total += x;
            if (total >= threshold)
            {
                ThresholdReachedEventArgs args = new
ThresholdReachedEventArgs();
                args.Threshold = threshold;
                args.TimeReached = DateTime.Now;
                OnThresholdReached(args);
            }
        }

        protected virtual void OnThresholdReached(ThresholdReachedEventArgs
e)
        {
            EventHandler<ThresholdReachedEventArgs> handler =
ThresholdReached;
            if (handler != null)
            {
                handler(this, e);
            }
        }
```

```
        public event EventHandler<ThresholdReachedEventArgs>
ThresholdReached;
    }

    public class ThresholdReachedEventArgs : EventArgs
    {
        public int Threshold { get; set; }
        public DateTime TimeReached { get; set; }
    }
}
```

Remarks

The event model in the .NET Framework is based on having an event delegate that connects an event with its handler. To raise an event, two elements are needed:

- A delegate that refers to a method that provides the response to the event.
- Optionally, a class that holds the event data, if the event provides data.

The delegate is a type that defines a signature, that is, the return value type and parameter list types for a method. You can use the delegate type to declare a variable that can refer to any method with the same signature as the delegate.

The standard signature of an event handler delegate defines a method that does not return a value. This method's first parameter is of type Object and refers to the instance that raises the event. Its second parameter is derived from type EventArgs and holds the event data. If the event does not generate event data, the second parameter is simply the value of the EventArgs.Empty field. Otherwise, the second parameter is a type derived from EventArgs and supplies any fields or properties needed to hold the event data.

The EventHandler<TEventArgs> delegate is a predefined delegate that represents an event handler method for an event that generates data. The advantage of using EventHandler<TEventArgs> is that you do not need to code your own custom delegate if your event generates event data. You simply provide the type of the event data object as the generic parameter.

To associate the event with the method that will handle the event, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate.

For more information about event handler delegates, see Handling and Raising Events.

Exception Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents errors that occur during application execution.

C#

```
public class Exception : System.Runtime.Serialization.ISerializable
```

Inheritance Object → Exception

Derived Microsoft.CSharp.RuntimeBinder.RuntimeBinderException
Microsoft.CSharp.RuntimeBinder.RuntimeBinderInternalCompilerException
Microsoft.Extensions.CommandLineUtils.CommandParsingException
Microsoft.Extensions.Hosting.HostAbortedException
Microsoft.Extensions.Options.OptionsValidationException
More...

Implements ISerializable

Remarks

For more information about this API, see Supplemental API remarks for Exception.

Constructors

Expand table

Exception()	Initializes a new instance of the Exception class.
Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the Exception class with serialized data.

Exception(String)	Initializes a new instance of the Exception class with a specified error message.
Exception(String, Exception)	Initializes a new instance of the Exception class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception.
HelpLink	Gets or sets a link to the help file associated with this exception.
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.
Inner Exception	Gets the Exception instance that caused the current exception.
Message	Gets a message that describes the current exception.
Source	Gets or sets the name of the application or the object that causes the error.
StackTrace	Gets a string representation of the immediate frames on the call stack.
TargetSite	Gets the method that throws the current exception.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.**

	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType()	Gets the runtime type of the current instance.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception.

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Exception Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Exception class.

Overloads

Expand table

Exception()	Initializes a new instance of the Exception class.
Exception(String)	Initializes a new instance of the Exception class with a specified error message.
Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the Exception class with serialized data.
Exception(String, Exception)	Initializes a new instance of the Exception class with a specified error message and a reference to the inner exception that is the cause of this exception.

Exception()

Initializes a new instance of the Exception class.

C#

```
public Exception ();
```

Examples

The following code example derives an `Exception` that uses a predefined message. The code demonstrates the use of the parameterless constructor for the derived

class and the base `Exception` class.

C#

```
// Example for the Exception( ) constructor.
using System;

namespace NDP_UE_CS
{
    // Derive an exception with a predefined message.
    class NotEvenException : Exception
    {
        public NotEvenException( ) :
            base( "The argument to a function requiring " +
                "even input is not divisible by 2." )
        { }
    }

    class NewExceptionDemo
    {
        public static void Main()
        {
            Console.WriteLine(
                "This example of the Exception( ) constructor " +
                "generates the following output." );
            Console.WriteLine(
                "\nHere, an exception is thrown using the \n" +
                "parameterless constructor of the base class.\n" );

            CalcHalf( 12 );
            CalcHalf( 15 );

            Console.WriteLine(
                "\nHere, an exception is thrown using the \n" +
                "parameterless constructor of a derived class.\n" );

            CalcHalf2( 24 );
            CalcHalf2( 27 );
        }

        // Half throws a base exception if the input is not even.
        static int Half( int input )
        {
            if( input % 2 != 0 )
                throw new Exception( );

            else return input / 2;
        }

        // Half2 throws a derived exception if the input is not even.
        static int Half2( int input )
        {
            if( input % 2 != 0 )
                throw new NotEvenException( );
```

```
            else return input / 2;
        }

        // CalcHalf calls Half and catches any thrown exceptions.
        static void CalcHalf(int input )
        {
            try
            {
                int halfInput = Half( input );
                Console.WriteLine(
                    "Half of {0} is {1}.", input, halfInput );
            }
            catch( Exception ex )
            {
                Console.WriteLine( ex.ToString( ) );
            }
        }

        // CalcHalf2 calls Half2 and catches any thrown exceptions.
        static void CalcHalf2(int input )
        {
            try
            {
                int halfInput = Half2( input );
                Console.WriteLine(
                    "Half of {0} is {1}.", input, halfInput );
            }
            catch( Exception ex )
            {
                Console.WriteLine( ex.ToString( ) );
            }
        }
    }
}

/*
This example of the Exception( ) constructor generates the following
output.

Here, an exception is thrown using the
parameterless constructor of the base class.

Half of 12 is 6.
System.Exception: Exception of type System.Exception was thrown.
   at NDP_UE_CS.NewExceptionDemo.Half(Int32 input)
   at NDP_UE_CS.NewExceptionDemo.CalcHalf(Int32 input)

Here, an exception is thrown using the
parameterless constructor of a derived class.

Half of 24 is 12.
NDP_UE_CS.NotEvenException: The argument to a function requiring even
input is
not divisible by 2.
```

```
    at NDP_UE_CS.NewExceptionDemo.Half2(Int32 input)
    at NDP_UE_CS.NewExceptionDemo.CalcHalf2(Int32 input)
*/
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error and takes into account the current system culture.

All the derived classes should provide this parameterless constructor. The following table shows the initial property values for an instance of Exception.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	A system-supplied localized description.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Exception(String)

Initializes a new instance of the Exception class with a specified error message.

C#

```
public Exception (string? message);
```

Parameters

`message` String

The message that describes the error.

Examples

The following code example derives an `Exception` for a specific condition. The code demonstrates the use of the constructor that takes a caller-specified message as a parameter, for both the derived class and the base `Exception` class.

C#

```
// Example for the Exception( string ) constructor.
using System;

namespace NDP_UE_CS2
{
    // Derive an exception with a specifiable message.
    class NotEvenException : Exception
    {
        const string notEvenMessage =
            "The argument to a function requiring " +
            "even input is not divisible by 2.";

        public NotEvenException( ) :
            base( notEvenMessage )
        { }

        public NotEvenException( string auxMessage ) :
            base( String.Format( "{0} - {1}",
                auxMessage, notEvenMessage ) )
        { }
    }

    class NewSExceptionDemo
    {
        public static void Main()
        {
            Console.WriteLine(
                "This example of the Exception( string )\n" +
                "constructor generates the following output." );
            Console.WriteLine(
                "\nHere, an exception is thrown using the \n" +
                "constructor of the base class.\n" );

            CalcHalf( 18 );
```

```
            CalcHalf( 21 );

            Console.WriteLine(
                "\nHere, an exception is thrown using the \n" +
                "constructor of a derived class.\n" );

            CalcHalf2( 30 );
            CalcHalf2( 33 );
        }

        // Half throws a base exception if the input is not even.
        static int Half( int input )
        {
            if( input % 2 != 0 )
                throw new Exception( String.Format(
                    "The argument {0} is not divisible by 2.",
                    input ) );

            else return input / 2;
        }

        // Half2 throws a derived exception if the input is not even.
        static int Half2( int input )
        {
            if( input % 2 != 0 )
                throw new NotEvenException(
                    String.Format( "Invalid argument: {0}", input ) );

            else return input / 2;
        }

        // CalcHalf calls Half and catches any thrown exceptions.
        static void CalcHalf(int input )
        {
            try
            {
                int halfInput = Half( input );
                Console.WriteLine(
                    "Half of {0} is {1}.", input, halfInput );
            }
            catch( Exception ex )
            {
                Console.WriteLine( ex.ToString( ) );
            }
        }

        // CalcHalf2 calls Half2 and catches any thrown exceptions.
        static void CalcHalf2(int input )
        {
            try
            {
                int halfInput = Half2( input );
                Console.WriteLine(
                    "Half of {0} is {1}.", input, halfInput );
            }
```

```
            catch( Exception ex )
            {
                Console.WriteLine( ex.ToString( ) );
            }
        }
    }
}

/*
This example of the Exception( string )
constructor generates the following output.

*/
```

Remarks

This constructor initializes the Message property of the new instance by using the `message` parameter. If the `message` parameter is `null`, this is the same as calling the Exception constructor.

The following table shows the initial property values for an instance of Exception.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Exception(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the Exception class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected Exception (System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

SerializationException

The class name is `null` or HResult is zero (0).

Examples

The following code example defines a derived serializable `Exception` class. The code forces a divide-by-0 error and then creates an instance of the derived exception using the (SerializationInfo, StreamingContext) constructor. The code serializes the instance to a file, deserializes the file into a new exception, which it throws, and then catches and displays the exception's data.

C#

```
using System;
using System.IO;
using System.Runtime.Serialization;
using System.Runtime.Serialization.Formatters.Soap;

// Define a serializable derived exception class.
[Serializable]
class SecondLevelException : Exception, ISerializable
{
    // This public constructor is used by class instantiators.
    public SecondLevelException(string message, Exception inner) :
        base(message, inner)
    {
        HelpLink = "http://MSDN.Microsoft.com";
        Source = "Exception_Class_Samples";
    }

    // This protected constructor is used for deserialization.
    protected SecondLevelException(SerializationInfo info,
        StreamingContext context) :
            base(info, context)
    { }

    // GetObjectData performs a custom serialization.
    public override void GetObjectData(SerializationInfo info,
        StreamingContext context)
    {
        // Change the case of two properties, and then use the
```

```
        // method of the base class.
        HelpLink = HelpLink.ToLower();
        Source = Source.ToUpperInvariant();

        base.GetObjectData(info, context);
    }
}

class SerializationDemo
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of the Exception constructor " +
            "and Exception.GetObjectData\nwith Serialization" +
            "Info and StreamingContext parameters " +
            "generates \nthe following output.\n");

        try
        {
            // This code forces a division by 0 and catches the
            // resulting exception.
            try
            {
                int zero = 0;
                int ecks = 1 / zero;
            }
            catch (Exception ex)
            {
                // Create a new exception to throw again.
                SecondLevelException newExcept =
                    new SecondLevelException(
                        "Forced a division by 0 and threw " +
                        "another exception.", ex);

                Console.WriteLine(
                    "Forced a division by 0, caught the " +
                    "resulting exception, \n" +
                    "and created a derived exception:\n");
                Console.WriteLine("HelpLink: {0}",
                    newExcept.HelpLink);
                Console.WriteLine("Source:   {0}",
                    newExcept.Source);

                // This FileStream is used for the serialization.
                FileStream stream =
                    new FileStream("NewException.dat",
                        FileMode.Create);

                try
                {
                    // Serialize the derived exception.
                    SoapFormatter formatter =
                        new SoapFormatter(null,
                            new StreamingContext(
```

```
                                StreamingContextStates.File));
                    formatter.Serialize(stream, newExcept);

                    // Rewind the stream and deserialize the
                    // exception.
                    stream.Position = 0;
                    SecondLevelException deserExcept =
                        (SecondLevelException)
                            formatter.Deserialize(stream);

                    Console.WriteLine(
                        "\nSerialized the exception, and then " +
                        "deserialized the resulting stream " +
                        "into a \nnew exception. " +
                        "The deserialization changed the case " +
                        "of certain properties:\n");

                    // Throw the deserialized exception again.
                    throw deserExcept;
                }
                catch (SerializationException se)
                {
                    Console.WriteLine("Failed to serialize: {0}",
                        se.ToString());
                }
                finally
                {
                    stream.Close();
                }
            }
        }
        catch (Exception ex)
        {
            Console.WriteLine("HelpLink: {0}", ex.HelpLink);
            Console.WriteLine("Source:   {0}", ex.Source);

            Console.WriteLine();
            Console.WriteLine(ex.ToString());
        }
    }
}
/*
This example displays the following output.

Forced a division by 0, caught the resulting exception,
and created a derived exception:

HelpLink: http://MSDN.Microsoft.com
Source:   Exception_Class_Samples

Serialized the exception, and then deserialized the resulting stream into
a
new exception. The deserialization changed the case of certain
properties:
```

```
HelpLink: http://msdn.microsoft.com
Source:   EXCEPTION_CLASS_SAMPLES

NDP_UE_CS.SecondLevelException: Forced a division by 0 and threw another
except
ion. ---> System.DivideByZeroException: Attempted to divide by zero.
   at NDP_UE_CS.SerializationDemo.Main()
   --- End of inner exception stack trace ---
   at NDP_UE_CS.SerializationDemo.Main()
*/
```

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

.NET Standard	2.0, 2.1

Exception(String, Exception)

Initializes a new instance of the Exception class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public Exception (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception, or a null reference (`Nothing` in Visual Basic) if no inner exception is specified.

Examples

The following code example derives an `Exception` for a specific condition. The code demonstrates the use of the constructor that takes a message and an inner exception as parameters, for both the derived class and the base `Exception` class.

C#

```
// Example for the Exception( string, Exception ) constructor.
using System;

namespace NDP_UE_CS
{
    // Derive an exception with a specifiable message and inner
exception.
    class LogTableOverflowException : Exception
    {
        const string overflowMessage =
            "The log table has overflowed.";

        public LogTableOverflowException( ) :
            base( overflowMessage )
        { }

        public LogTableOverflowException( string auxMessage ) :
            base( String.Format( "{0} - {1}",
                overflowMessage, auxMessage ) )
        { }

        public LogTableOverflowException(
            string auxMessage, Exception inner ) :
                base( String.Format( "{0} - {1}",
                    overflowMessage, auxMessage ), inner )
        { }
    }

    class LogTable
    {
        public LogTable( int numElements )
        {
            logArea = new string[ numElements ];
```

```
            elemInUse = 0;
        }

        protected string[ ] logArea;
        protected int       elemInUse;

        // The AddRecord method throws a derived exception
        // if the array bounds exception is caught.
        public    int       AddRecord( string newRecord )
        {
            try
            {
                logArea[ elemInUse ] = newRecord;
                return elemInUse++;
            }
            catch( Exception ex )
            {
                throw new LogTableOverflowException(
                    String.Format( "Record \"{0}\" was not logged.",
                        newRecord ), ex );
            }
        }
    }

    class OverflowDemo
    {
        // Create a log table and force an overflow.
        public static void Main()
        {
            LogTable log = new LogTable( 4 );

            Console.WriteLine(
                "This example of the Exception( string, Exception )" +
                "\nconstructor generates the following output." );
            Console.WriteLine(
                "\nExample of a derived exception " +
                "that references an inner exception:\n" );
            try
            {
                for( int count = 1; ; count++ )
                {
                    log.AddRecord(
                        String.Format(
                            "Log record number {0}", count ) );
                }
            }
            catch( Exception ex )
            {
                Console.WriteLine( ex.ToString( ) );
            }
        }
    }
}

/*
```

```
This example of the Exception( string, Exception )
constructor generates the following output.

Example of a derived exception that references an inner exception:

NDP_UE_CS.LogTableOverflowException: The log table has overflowed. -
Record "Lo
g record number 5" was not logged. ---> System.IndexOutOfRangeException:
Index
was outside the bounds of the array.
   at NDP_UE_CS.LogTable.AddRecord(String newRecord)
   --- End of inner exception stack trace ---
   at NDP_UE_CS.LogTable.AddRecord(String newRecord)
   at NDP_UE_CS.OverflowDemo.Main()
*/
```

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of Exception.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Exception.Data Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a collection of key/value pairs that provide additional user-defined information about the exception.

C#

```
public virtual System.Collections.IDictionary Data { get; }
```

Property Value

IDictionary

An object that implements the IDictionary interface and contains a collection of user-defined key/value pairs. The default is an empty collection.

Examples

The following example demonstrates how to add and retrieve information using the Data property.

C#

```
// This example demonstrates the Exception.Data property.
using System;
using System.Collections;

class Sample
{
   public static void Main()
   {
      Console.WriteLine("\nException with some extra information...");
      RunTest(false);
      Console.WriteLine("\nException with all extra information...");
      RunTest(true);
   }

   public static void RunTest(bool displayDetails)
```

```
    {
        try {
            NestedRoutine1(displayDetails);
        }
        catch (Exception e) {
            Console.WriteLine("An exception was thrown.");
            Console.WriteLine(e.Message);
            if (e.Data.Count > 0) {
                Console.WriteLine("  Extra details:");
                foreach (DictionaryEntry de in e.Data)
                    Console.WriteLine("    Key: {0,-20}      Value: {1}",
                                      "'" + de.Key.ToString() + "'", de.Value);
            }
        }
    }

    public static void NestedRoutine1(bool displayDetails)
    {
        try {
            NestedRoutine2(displayDetails);
        }
        catch (Exception e) {
            e.Data["ExtraInfo"] = "Information from NestedRoutine1.";
            e.Data.Add("MoreExtraInfo", "More information from
NestedRoutine1.");
            throw;
        }
    }

    public static void NestedRoutine2(bool displayDetails)
    {
        Exception e = new Exception("This statement is the original exception
message.");
        if (displayDetails) {
            string s = "Information from NestedRoutine2.";
            int i = -903;
            DateTime dt = DateTime.Now;
            e.Data.Add("stringInfo", s);
            e.Data["IntInfo"] = i;
            e.Data["DateTimeInfo"] = dt;
        }
        throw e;
    }
}
// The example displays the following output:
//    Exception with some extra information...
//    An exception was thrown.
//    This statement is the original exception message.
//      Extra details:
//        Key: 'ExtraInfo'               Value: Information from
NestedRoutine1.
//        Key: 'MoreExtraInfo'           Value: More information from
NestedRoutine1.
//
//    Exception with all extra information...
```

```
//    An exception was thrown.
//    This statement is the original exception message.
//      Extra details:
//        Key: 'stringInfo'              Value: Information from
NestedRoutine2.
//        Key: 'IntInfo'                 Value: -903
//        Key: 'DateTimeInfo'            Value: 7/29/2013 10:50:13 AM
//        Key: 'ExtraInfo'               Value: Information from
NestedRoutine1.
//        Key: 'MoreExtraInfo'           Value: More information from
NestedRoutine1.
```

Exception.HelpLink Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets a link to the help file associated with this exception.

C#

```
public virtual string? HelpLink { get; set; }
```

Property Value

String

The Uniform Resource Name (URN) or Uniform Resource Locator (URL).

Examples

The following code example throws an `Exception` that sets the `HelpLink` property in its constructor and then catches the exception and displays `HelpLink`.

C#

```
// Example for the Exception.HelpLink, Exception.Source,
// Exception.StackTrace, and Exception.TargetSite properties.
using System;

namespace NDP_UE_CS
{
    // Derive an exception; the constructor sets the HelpLink and
    // Source properties.
    class LogTableOverflowException : Exception
    {
        const string overflowMessage = "The log table has overflowed.";

        public LogTableOverflowException(
            string auxMessage, Exception inner ) :
                base( String.Format( "{0} - {1}",
                    overflowMessage, auxMessage ), inner )
        {
```

```
            this.HelpLink = "https://docs.microsoft.com";
            this.Source = "Exception_Class_Samples";
        }
    }

    class LogTable
    {
        public LogTable( int numElements )
        {
            logArea = new string[ numElements ];
            elemInUse = 0;
        }

        protected string[ ] logArea;
        protected int       elemInUse;

        // The AddRecord method throws a derived exception if
        // the array bounds exception is caught.
        public    int       AddRecord( string newRecord )
        {
            try
            {
                logArea[ elemInUse ] = newRecord;
                return elemInUse++;
            }
            catch( Exception e )
            {
                throw new LogTableOverflowException(
                    String.Format( "Record \"{0}\" was not logged.",
                        newRecord ), e );
            }
        }
    }

    class OverflowDemo
    {
        // Create a log table and force an overflow.
        public static void Main()
        {
            LogTable log = new LogTable( 4 );

            Console.WriteLine(

                "   Exception.HelpLink, \n   Exception.Source, \n" +
                "   Exception.StackTrace, and \n   Exception." +
                "TargetSite \ngenerates the following output." );

            try
            {
                for( int count = 1; ; count++ )
                {
                    log.AddRecord(
                        String.Format(
                            "Log record number {0}", count ) );
                }
```

```
            }
            catch( Exception ex )
            {
                Console.WriteLine( "\nMessage ---\n{0}", ex.Message );
                Console.WriteLine(
                    "\nHelpLink ---\n{0}", ex.HelpLink );
                Console.WriteLine( "\nSource ---\n{0}", ex.Source );
                Console.WriteLine(
                    "\nStackTrace ---\n{0}", ex.StackTrace );
                Console.WriteLine(
                    "\nTargetSite ---\n{0}", ex.TargetSite );
            }
        }
    }
}

/*
This example of
   Exception.Message,
   Exception.HelpLink,
   Exception.Source,
   Exception.StackTrace, and
   Exception.TargetSite
generates the following output.

Message ---
The log table has overflowed. - Record "Log record number 5" was not logged.

HelpLink ---
https://docs.microsoft.com

Source ---
Exception_Class_Samples

StackTrace ---
   at NDP_UE_CS.LogTable.AddRecord(String newRecord)
   at NDP_UE_CS.OverflowDemo.Main()

TargetSite ---
Int32 AddRecord(System.String)
*/
```

Remarks

The return value, which represents a help file, is a URN or URL. For example, the `HelpLink` value could be:

"file:///C:/Applications/Bazzal/help.html#ErrorNum42"

Exception.HResult Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

C#

```
public int HResult { get; set; }
```

Property Value

Int32

The HRESULT value.

Examples

The following code example defines a derived `Exception` class that sets the `HResult` property to a custom value in its constructor.

C#

```
// Example for the Exception.HResult property.
using System;

namespace NDP_UE_CS
{
    // Create the derived exception class.
    class SecondLevelException : Exception
    {
        const int SecondLevelHResult = unchecked( (int)0x81234567 );

        // Set HResult for this exception, and include it in
        // the exception message.
        public SecondLevelException( string message, Exception inner ) :
            base( string.Format( "(HRESULT:0x{1:X8}) {0}",
                message, SecondLevelHResult ), inner )
        {
            HResult = SecondLevelHResult;
```

```
        }
    }

    class HResultDemo
    {
        public static void Main()
        {
            // This function forces a division by 0 and throws
            // a second exception.
            try
            {
                try
                {
                    int  zero = 0;
                    int  ecks = 1 / zero;
                }
                catch( Exception ex )
                {
                    throw new SecondLevelException(
                        "Forced a division by 0 and threw " +
                        "a second exception.", ex );
                }
            }
            catch( Exception ex )
            {
                Console.WriteLine( ex.ToString( ) );
            }
        }
    }
}

/*
This example of Exception.HResult generates the following output.

NDP_UE_CS.SecondLevelException: (HRESULT:0x81234567) Forced a division by 0
and
 threw a second exception. ---> System.DivideByZeroException: Attempted to
divi
de by zero.
   at NDP_UE_CS.HResultDemo.Main()
   --- End of inner exception stack trace ---
   at NDP_UE_CS.HResultDemo.Main()
*/
```

Remarks

HRESULT is a 32-bit value, divided into three different fields: a severity code, a facility code, and an error code. The severity code indicates whether the return value represents information, warning, or error. The facility code identifies the area of the system responsible for the error. The error code is a unique number that is assigned to represent the exception. Each exception is mapped to a distinct HRESULT. When

managed code throws an exception, the runtime passes the HRESULT to the COM client. When unmanaged code returns an error, the HRESULT is converted to an exception, which is then thrown by the runtime. For information about HRESULT values and their corresponding .NET Framework exceptions, see How to: Map HRESULTs and Exceptions. See Common HRESULT Values in the Windows documentation for a list of the values you are most likely to encounter.

Starting with the .NET Framework 4.5, the HResult property's setter is protected, whereas its getter is public. In previous versions of the .NET Framework, both getter and setter are protected.

Exception.InnerException Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the Exception instance that caused the current exception.

```
C#

public Exception? InnerException { get; }
```

Property Value

Exception

An object that describes the error that caused the current exception. The InnerException property returns the same value as was passed into the Exception(String, Exception) constructor, or `null` if the inner exception value was not supplied to the constructor. This property is read-only.

Examples

The following example demonstrates throwing and catching an exception that references an inner exception.

```
C#

using System;

public class AppException : Exception
{
   public AppException(String message) : base (message)
   {}

   public AppException(String message, Exception inner) :
base(message,inner) {}
}

public class Example
{
```

```
    public static void Main()
    {
       Example ex = new Example();

       try {
          ex.CatchInner();
       }
       catch(AppException e) {
          Console.WriteLine ("In catch block of Main method.");
          Console.WriteLine("Caught: {0}", e.Message);
          if (e.InnerException != null)
             Console.WriteLine("Inner exception: {0}", e.InnerException);
       }
    }

    public void ThrowInner ()
    {
       throw new AppException("Exception in ThrowInner method.");
    }

    public void CatchInner()
    {
       try {
          this.ThrowInner();
       }
       catch (AppException e) {
          throw new AppException("Error in CatchInner caused by calling the
ThrowInner method.", e);
       }
    }
}
// The example displays the following output:
//    In catch block of Main method.
//    Caught: Error in CatchInner caused by calling the ThrowInner method.
//    Inner exception: AppException: Exception in ThrowInner method.
//       at Example.ThrowInner()
//       at Example.CatchInner()
```

Remarks

When an exception `X` is thrown as a direct result of a previous exception `Y`, the InnerException property of `X` should contain a reference to `Y`.

Use the InnerException property to obtain the set of exceptions that led to the current exception.

You can create a new exception that catches an earlier exception. The code that handles the second exception can make use of the additional information from the earlier exception to handle the error more appropriately.

Suppose that there is a function that reads a file and formats the data from that file. In this example, as the code tries to read the file, an IOException is thrown. The function catches the IOException and throws a FileNotFoundException. The IOException could be saved in the InnerException property of the FileNotFoundException, enabling the code that catches the FileNotFoundException to examine the cause of the initial error.

The InnerException property, which holds a reference to the inner exception, is set upon initialization of the exception object.

Exception.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a message that describes the current exception.

C#

```
public virtual string Message { get; }
```

Property Value

String

The error message that explains the reason for the exception, or an empty string ("").

Examples

The following code example throws and then catches an Exception exception and displays the exception's text message using the Message property.

C#

```
// Example for the Exception.HelpLink, Exception.Source,
// Exception.StackTrace, and Exception.TargetSite properties.
using System;

namespace NDP_UE_CS
{
    // Derive an exception; the constructor sets the HelpLink and
    // Source properties.
    class LogTableOverflowException : Exception
    {
        const string overflowMessage = "The log table has overflowed.";

        public LogTableOverflowException(
            string auxMessage, Exception inner ) :
                base( String.Format( "{0} - {1}",
                    overflowMessage, auxMessage ), inner )
        {
```

```
            this.HelpLink = "https://docs.microsoft.com";
            this.Source = "Exception_Class_Samples";
        }
    }

    class LogTable
    {
        public LogTable( int numElements )
        {
            logArea = new string[ numElements ];
            elemInUse = 0;
        }

        protected string[ ] logArea;
        protected int       elemInUse;

        // The AddRecord method throws a derived exception if
        // the array bounds exception is caught.
        public    int       AddRecord( string newRecord )
        {
            try
            {
                logArea[ elemInUse ] = newRecord;
                return elemInUse++;
            }
            catch( Exception e )
            {
                throw new LogTableOverflowException(
                    String.Format( "Record \"{0}\" was not logged.",
                        newRecord ), e );
            }
        }
    }

    class OverflowDemo
    {
        // Create a log table and force an overflow.
        public static void Main()
        {
            LogTable log = new LogTable( 4 );

            Console.WriteLine(
                "This example of \n   Exception.Message, \n" +
                "   Exception.HelpLink, \n   Exception.Source, \n" +
                "   Exception.StackTrace, and \n   Exception." +
                "TargetSite \ngenerates the following output." );

            try
            {
                for( int count = 1; ; count++ )
                {
                    log.AddRecord(
                        String.Format(
                            "Log record number {0}", count ) );
                }
```

```
            }
            catch( Exception ex )
            {
                Console.WriteLine( "\nMessage ---\n{0}", ex.Message );
                Console.WriteLine(
                    "\nHelpLink ---\n{0}", ex.HelpLink );
                Console.WriteLine( "\nSource ---\n{0}", ex.Source );
                Console.WriteLine(
                    "\nStackTrace ---\n{0}", ex.StackTrace );
                Console.WriteLine(
                    "\nTargetSite ---\n{0}", ex.TargetSite );
            }
        }
    }
}

/*
This example of
   Exception.Message,
   Exception.HelpLink,
   Exception.Source,
   Exception.StackTrace, and
   Exception.TargetSite
generates the following output.

Message ---
The log table has overflowed. - Record "Log record number 5" was not logged.

HelpLink ---
https://docs.microsoft.com

Source ---
Exception_Class_Samples

StackTrace ---
   at NDP_UE_CS.LogTable.AddRecord(String newRecord)
   at NDP_UE_CS.OverflowDemo.Main()

TargetSite ---
Int32 AddRecord(System.String)
*/
```

Remarks

Error messages target the developer who is handling the exception. The text of the Message property should completely describe the error and, when possible, should also explain how to correct the error. Top-level exception handlers may display the message to end-users, so you should ensure that it is grammatically correct and that each sentence of the message ends with a period. Do not use question marks or exclamation

points. If your application uses localized exception messages, you should ensure that they are accurately translated.

> **Important**
>
> Do not disclose sensitive information in exception messages without checking for the appropriate permissions.

The value of the Message property is included in the information returned by ToString. The Message property is set only when creating an Exception. If no message was supplied to the constructor for the current instance, the system supplies a default message that is formatted using the current system culture.

Notes to Inheritors

The Message property is overridden in classes that require control over message content or format. Application code typically accesses this property when it needs to display information about an exception that has been caught.

The error message should be localized.

Exception.Source Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the name of the application or the object that causes the error.

C#

```
public virtual string? Source { get; set; }
```

Property Value

String

The name of the application or the object that causes the error.

Exceptions

ArgumentException

The object must be a runtime System.Reflection object.

Examples

The following example throws an `Exception` that sets the `Source` property in its constructor and then catches the exception and displays `Source`.

C#

```
// Example for the Exception.HelpLink, Exception.Source,
// Exception.StackTrace, and Exception.TargetSite properties.
using System;

namespace NDP_UE_CS
{
    // Derive an exception; the constructor sets the HelpLink and
    // Source properties.
    class LogTableOverflowException : Exception
    {
        const string overflowMessage = "The log table has overflowed.";
```

```
        public LogTableOverflowException(
            string auxMessage, Exception inner ) :
                base( String.Format( "{0} - {1}",
                    overflowMessage, auxMessage ), inner )
        {
            this.HelpLink = "https://docs.microsoft.com";
            this.Source = "Exception_Class_Samples";
        }
    }

    class LogTable
    {
        public LogTable( int numElements )
        {
            logArea = new string[ numElements ];
            elemInUse = 0;
        }

        protected string[ ] logArea;
        protected int       elemInUse;

        // The AddRecord method throws a derived exception if
        // the array bounds exception is caught.
        public    int       AddRecord( string newRecord )
        {
            try
            {
                logArea[ elemInUse ] = newRecord;
                return elemInUse++;
            }
            catch( Exception e )
            {
                throw new LogTableOverflowException(
                    String.Format( "Record \"{0}\" was not logged.",
                        newRecord ), e );
            }
        }
    }

    class OverflowDemo
    {
        // Create a log table and force an overflow.
        public static void Main()
        {
            LogTable log = new LogTable( 4 );

            Console.WriteLine(
                "This example of \n   Exception.Message, \n" +
                "   Exception.HelpLink, \n   Exception.Source, \n" +
                "   Exception.StackTrace, and \n   Exception." +
                "TargetSite \ngenerates the following output." );

            try
            {
```

```
                for( int count = 1; ; count++ )
                {
                    log.AddRecord(
                        String.Format(
                            "Log record number {0}", count ) );
                }
            }
            catch( Exception ex )
            {
                Console.WriteLine( "\nMessage ---\n{0}", ex.Message );
                Console.WriteLine(
                    "\nHelpLink ---\n{0}", ex.HelpLink );
                Console.WriteLine( "\nSource ---\n{0}", ex.Source );
                Console.WriteLine(
                    "\nStackTrace ---\n{0}", ex.StackTrace );
                Console.WriteLine(
                    "\nTargetSite ---\n{0}", ex.TargetSite );
            }
        }
    }
}

/*
This example of
   Exception.Message,
   Exception.HelpLink,
   Exception.Source,
   Exception.StackTrace, and
   Exception.TargetSite
generates the following output.

Message ---
The log table has overflowed. - Record "Log record number 5" was not logged.

HelpLink ---
https://docs.microsoft.com

Source ---
Exception_Class_Samples

StackTrace ---
   at NDP_UE_CS.LogTable.AddRecord(String newRecord)
   at NDP_UE_CS.OverflowDemo.Main()

TargetSite ---
Int32 AddRecord(System.String)
*/
```

Remarks

If the Source property is not set explicitly, the runtime automatically sets it to the name of the assembly in which the exception originated.

Exception.StackTrace Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a string representation of the immediate frames on the call stack.

C#

```
public virtual string? StackTrace { get; }
```

Property Value

String

A string that describes the immediate frames of the call stack. If no stack trace is available (such as prior to stack unwinding from a `throw` statement), the value is `null`.

Examples

The following code example throws an `Exception` and then catches it and displays a stack trace using the `StackTrace` property.

C#

```
// Example for the Exception.HelpLink, Exception.Source,
// Exception.StackTrace, and Exception.TargetSite properties.
using System;

namespace NDP_UE_CS
{
    // Derive an exception; the constructor sets the HelpLink and
    // Source properties.
    class LogTableOverflowException : Exception
    {
        const string overflowMessage = "The log table has overflowed.";

        public LogTableOverflowException(
            string auxMessage, Exception inner ) :
                base( String.Format( "{0} - {1}",
                    overflowMessage, auxMessage ), inner )
```

```
        {
            this.HelpLink = "https://docs.microsoft.com";
            this.Source = "Exception_Class_Samples";
        }
    }

    class LogTable
    {
        public LogTable( int numElements )
        {
            logArea = new string[ numElements ];
            elemInUse = 0;
        }

        protected string[ ] logArea;
        protected int       elemInUse;

        // The AddRecord method throws a derived exception if
        // the array bounds exception is caught.
        public    int       AddRecord( string newRecord )
        {
            try
            {
                logArea[ elemInUse ] = newRecord;
                return elemInUse++;
            }
            catch( Exception e )
            {
                throw new LogTableOverflowException(
                    String.Format( "Record \"{0}\" was not logged.",
                        newRecord ), e );
            }
        }
    }

    class OverflowDemo
    {
        // Create a log table and force an overflow.
        public static void Main()
        {
            LogTable log = new LogTable( 4 );

            Console.WriteLine(
                "This example of \n   Exception.Message, \n" +
                "   Exception.HelpLink, \n   Exception.Source, \n" +
                "   Exception.StackTrace, and \n   Exception." +
                "TargetSite \ngenerates the following output." );

            try
            {
                for( int count = 1; ; count++ )
                {
                    log.AddRecord(
                        String.Format(
                            "Log record number {0}", count ) );
```

```
                }
            }
            catch( Exception ex )
            {
                Console.WriteLine( "\nMessage ---\n{0}", ex.Message );
                Console.WriteLine(
                    "\nHelpLink ---\n{0}", ex.HelpLink );
                Console.WriteLine( "\nSource ---\n{0}", ex.Source );
                Console.WriteLine(
                    "\nStackTrace ---\n{0}", ex.StackTrace );
                Console.WriteLine(
                    "\nTargetSite ---\n{0}", ex.TargetSite );
            }
        }
    }
}

```

Remarks

The execution stack keeps track of all the methods that are in execution at a given instant. A trace of the method calls is called a stack trace. The stack trace listing provides a way to follow the call stack to the line number in the method where the exception occurs.

The StackTrace property returns the frames of the call stack that originate at the location where the exception was thrown. You can obtain information about additional frames in the call stack by creating a new instance of the System.Diagnostics.StackTrace class and using its StackTrace.ToString method.

The common language runtime (CLR) updates the stack trace whenever an exception is thrown in application code (by using the `throw` keyword). If the exception was rethrown in a method that is different than the method where it was originally thrown, the stack trace contains both the location in the method where the exception was originally thrown, and the location in the method where the exception was rethrown. If the exception is thrown, and later rethrown, in the same method, the stack trace only contains the location where the exception was rethrown and does not include the location where the exception was originally thrown.

The StackTrace property may not report as many method calls as expected because of code transformations, such as inlining, that occur during optimization.

Notes to Inheritors

The `StackTrace` property is overridden in classes that require control over the stack trace content or format.

By default, the stack trace is captured immediately before an exception object is thrown. Use StackTrace to get stack trace information when no exception is being thrown.

Exception.TargetSite Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the method that throws the current exception.

C#

```
public System.Reflection.MethodBase? TargetSite { get; }
```

Property Value

MethodBase

The MethodBase that threw the current exception.

Examples

The following code example throws an `Exception` and then catches it and displays the originating method using the `TargetSite` property.

C#

```
// Example for the Exception.HelpLink, Exception.Source,
// Exception.StackTrace, and Exception.TargetSite properties.
using System;

namespace NDP_UE_CS
{
    // Derive an exception; the constructor sets the HelpLink and
    // Source properties.
    class LogTableOverflowException : Exception
    {
        const string overflowMessage = "The log table has overflowed.";

        public LogTableOverflowException(
            string auxMessage, Exception inner ) :
                base( String.Format( "{0} - {1}",
                    overflowMessage, auxMessage ), inner )
        {
```

```
            this.HelpLink = "https://docs.microsoft.com";
            this.Source = "Exception_Class_Samples";
        }
    }

    class LogTable
    {
        public LogTable( int numElements )
        {
            logArea = new string[ numElements ];
            elemInUse = 0;
        }

        protected string[ ] logArea;
        protected int       elemInUse;

        // The AddRecord method throws a derived exception if
        // the array bounds exception is caught.
        public    int       AddRecord( string newRecord )
        {
            try
            {
                logArea[ elemInUse ] = newRecord;
                return elemInUse++;
            }
            catch( Exception e )
            {
                throw new LogTableOverflowException(
                    String.Format( "Record \"{0}\" was not logged.",
                        newRecord ), e );
            }
        }
    }

    class OverflowDemo
    {
        // Create a log table and force an overflow.
        public static void Main()
        {
            LogTable log = new LogTable( 4 );

            Console.WriteLine(
                "This example of \n   Exception.Message, \n" +
                "   Exception.HelpLink, \n   Exception.Source, \n" +
                "   Exception.StackTrace, and \n   Exception." +
                "TargetSite \ngenerates the following output." );

            try
            {
                for( int count = 1; ; count++ )
                {
                    log.AddRecord(
                        String.Format(
                            "Log record number {0}", count ) );
                }
```

```
            }
            catch( Exception ex )
            {
                Console.WriteLine( "\nMessage ---\n{0}", ex.Message );
                Console.WriteLine(
                    "\nHelpLink ---\n{0}", ex.HelpLink );
                Console.WriteLine( "\nSource ---\n{0}", ex.Source );
                Console.WriteLine(
                    "\nStackTrace ---\n{0}", ex.StackTrace );
                Console.WriteLine(
                    "\nTargetSite ---\n{0}", ex.TargetSite );
            }
        }
    }
}

/*
This example of
   Exception.Message,
   Exception.HelpLink,
   Exception.Source,
   Exception.StackTrace, and
   Exception.TargetSite
generates the following output.

Message ---
The log table has overflowed. - Record "Log record number 5" was not logged.

HelpLink ---
https://docs.microsoft.com

Source ---
Exception_Class_Samples

StackTrace ---
   at NDP_UE_CS.LogTable.AddRecord(String newRecord)
   at NDP_UE_CS.OverflowDemo.Main()

TargetSite ---
Int32 AddRecord(System.String)
*/
```

Remarks

If the method that throws this exception is not available and the stack trace is not a null reference (`Nothing` in Visual Basic), TargetSite obtains the method from the stack trace. If the stack trace is a null reference, TargetSite also returns a null reference.

> ⓘ **Note**

The **TargetSite** property may not accurately report the name of the method in which an exception was thrown if the exception handler handles an exception across application domain boundaries.

Exception.GetBaseException Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.

C#

```
public virtual Exception GetBaseException ();
```

Returns

Exception

The first exception thrown in a chain of exceptions. If the InnerException property of the current exception is a null reference (`Nothing` in Visual Basic), this property returns the current exception.

Examples

The following code example defines two derived `Exception` classes. It forces an exception and then throws it again with each of the derived classes. The code shows the use of the `GetBaseException` method to retrieve the original exception.

C#

```
// Example for the Exception.GetBaseException method.
using System;

namespace NDP_UE_CS
{
    // Define two derived exceptions to demonstrate nested exceptions.
    class SecondLevelException : Exception
    {
        public SecondLevelException( string message, Exception inner )
            : base( message, inner )
        { }
    }
```

```
class ThirdLevelException : Exception
{
    public ThirdLevelException( string message, Exception inner )
        : base( message, inner )
    { }
}

class NestedExceptions
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of Exception.GetBaseException " +
            "generates the following output." );
        Console.WriteLine(
            "\nThe program forces a division by 0, then " +
            "throws the exception \ntwice more, " +
            "using a different derived exception each time.\n" );

        try
        {
            // This function calls another that forces a
            // division by 0.
            Rethrow( );
        }
        catch( Exception ex )
        {
            Exception current;

            Console.WriteLine(
                "Unwind the nested exceptions " +
                "using the InnerException property:\n" );

            // This code unwinds the nested exceptions using the
            // InnerException property.
            current = ex;
            while( current != null )
            {
                Console.WriteLine( current.ToString( ) );
                Console.WriteLine( );
                current = current.InnerException;
            }

            // Display the innermost exception.
            Console.WriteLine(
                "Display the base exception " +
                "using the GetBaseException method:\n" );
            Console.WriteLine(
                ex.GetBaseException( ).ToString( ) );
        }
    }

    // This function catches the exception from the called
    // function DivideBy0( ) and throws another in response.
    static void Rethrow()
```

```
        {
            try
            {
                DivideBy0( );
            }
            catch( Exception ex )
            {
                throw new ThirdLevelException(
                    "Caught the second exception and " +
                    "threw a third in response.", ex );
            }
        }

        // This function forces a division by 0 and throws a second
        // exception.
        static void DivideBy0( )
        {
            try
            {
                int  zero = 0;
                int  ecks = 1 / zero;
            }
            catch( Exception ex )
            {
                throw new SecondLevelException(
                    "Forced a division by 0 and threw " +
                    "a second exception.", ex );
            }
        }
    }
}

/*
This example of Exception.GetBaseException generates the following output.

The program forces a division by 0, then throws the exception
twice more, using a different derived exception each time.

Unwind the nested exceptions using the InnerException property:

NDP_UE_CS.ThirdLevelException: Caught the second exception and threw a third
in
 response. ---> NDP_UE_CS.SecondLevelException: Forced a division by 0 and
thre
w a second exception. ---> System.DivideByZeroException: Attempted to divide
by
 zero.
   at NDP_UE_CS.NestedExceptions.DivideBy0()
   --- End of inner exception stack trace ---
   at NDP_UE_CS.NestedExceptions.DivideBy0()
   at NDP_UE_CS.NestedExceptions.Rethrow()
   --- End of inner exception stack trace ---
   at NDP_UE_CS.NestedExceptions.Rethrow()
   at NDP_UE_CS.NestedExceptions.Main()
```

```
NDP_UE_CS.SecondLevelException: Forced a division by 0 and threw a second
excep
tion. ---> System.DivideByZeroException: Attempted to divide by zero.
   at NDP_UE_CS.NestedExceptions.DivideBy0()
   --- End of inner exception stack trace ---
   at NDP_UE_CS.NestedExceptions.DivideBy0()
   at NDP_UE_CS.NestedExceptions.Rethrow()

System.DivideByZeroException: Attempted to divide by zero.
   at NDP_UE_CS.NestedExceptions.DivideBy0()

Display the base exception using the GetBaseException method:

System.DivideByZeroException: Attempted to divide by zero.
   at NDP_UE_CS.NestedExceptions.DivideBy0()
*/
```

Remarks

A chain of exceptions consists of a set of exceptions such that each exception in the chain was thrown as a direct result of the exception referenced in its `InnerException` property. For a given chain, there can be exactly one exception that is the root cause of all other exceptions in the chain. This exception is called the base exception and its `InnerException` property always contains a null reference.

For all exceptions in a chain of exceptions, the `GetBaseException` method must return the same object (the base exception).

Use the `GetBaseException` method when you want to find the root cause of an exception but do not need information about exceptions that may have occurred between the current exception and the first exception.

Notes to Inheritors

The `GetBaseException` method is overridden in classes that require control over the exception content or format.

Exception.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

When overridden in a derived class, sets the SerializationInfo with information about the exception.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public virtual void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` parameter is a null reference (`Nothing` in Visual Basic).

Examples

The following code example defines a derived serializable `Exception` class that implements `GetObjectData`, which makes minor changes to two properties and then calls the base class to perform the serialization. The example forces a divide-by-0 error and then creates an instance of the derived exception. The code serializes the instance to a file, deserializes the file into a new exception, which it throws, and then catches and displays the exception's data.

C#

```
using System;
using System.IO;
using System.Runtime.Serialization;
using System.Runtime.Serialization.Formatters.Soap;

                    newExcept.Source);

                // This FileStream is used for the serialization.
                FileStream stream =
                    new FileStream("NewException.dat",
                        FileMode.Create);

                try
                {
                    // Serialize the derived exception.
                    SoapFormatter formatter =
```

```
                        new SoapFormatter(null,
                            new StreamingContext(
                                StreamingContextStates.File));
                    formatter.Serialize(stream, newExcept);

                    // Rewind the stream and deserialize the
                    // exception.
                    stream.Position = 0;
                    SecondLevelException deserExcept =
                        (SecondLevelException)
                            formatter.Deserialize(stream);

                    Console.WriteLine(
                        "\nSerialized the exception, and then " +
                        "deserialized the resulting stream " +
                        "into a \nnew exception. " +
                        "The deserialization changed the case " +
                        "of certain properties:\n");

                    // Throw the deserialized exception again.
                    throw deserExcept;
                }
                catch (SerializationException se)
                {
                    Console.WriteLine("Failed to serialize: {0}",
                        se.ToString());
                }
                finally
                {
                    stream.Close();
                }
            }
        }
        catch (Exception ex)
        {
            Console.WriteLine("HelpLink: {0}", ex.HelpLink);
            Console.WriteLine("Source:   {0}", ex.Source);

            Console.WriteLine();
            Console.WriteLine(ex.ToString());
        }
    }
}
/*
This example displays the following output.

Forced a division by 0, caught the resulting exception,
and created a derived exception:

HelpLink: http://MSDN.Microsoft.com
Source:   Exception_Class_Samples

Serialized the exception, and then deserialized the resulting stream into a
new exception. The deserialization changed the case of certain properties:
```

```
HelpLink: http://msdn.microsoft.com
Source:   EXCEPTION_CLASS_SAMPLES

NDP_UE_CS.SecondLevelException: Forced a division by 0 and threw another
except
ion. ---> System.DivideByZeroException: Attempted to divide by zero.
   at NDP_UE_CS.SerializationDemo.Main()
   --- End of inner exception stack trace ---
   at NDP_UE_CS.SerializationDemo.Main()
*/
```

Remarks

`GetObjectData` sets a SerializationInfo with all the exception object data targeted for serialization. During deserialization, the exception is reconstituted from the `SerializationInfo` transmitted over the stream.

Exception.GetType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the runtime type of the current instance.

C#

```
public Type GetType ();
```

Returns

Type

A Type object that represents the exact runtime type of the current instance.

Remarks

The GetType method exists to support the .NET Framework infrastructure, and internally invokes the fundamental method, Object.GetType.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Exception.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates and returns a string representation of the current exception.

C#

```
public override string ToString ();
```

Returns

String

A string representation of the current exception.

Examples

The following example causes an exception and displays the result of calling ToString on that exception. Note that the Exception.ToString method is called implicitly when the Exception class instance appears in the argument list of the Console.WriteLine method.

C#

```
using System;

public class TestClass
{}

public class Example
{
   public static void Main()
   {
      var test = new TestClass();
      Object[] objectsToCompare = { test, test.ToString(), 123,
                                    123.ToString(), "some text",
                                    "Some Text" };
      string s = "some text";
      foreach (var objectToCompare in objectsToCompare) {
         try {
```

```
            int i = s.CompareTo(objectToCompare);
            Console.WriteLine("Comparing '{0}' with '{1}': {2}",
                              s, objectToCompare, i);
         }
         catch (ArgumentException e) {
            Console.WriteLine("Bad argument: {0} (type {1})",
                              objectToCompare,
                              objectToCompare.GetType().Name);
            Console.WriteLine("Exception information: {0}", e);
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//     Bad argument: TestClass (type TestClass)
//     Exception information: System.ArgumentException: Object must be of
type String.
//        at System.String.CompareTo(Object value)
//        at Example.Main()
//
//     Comparing 'some text' with 'TestClass': -1
//
//     Bad argument: 123 (type Int32)
//     Exception information: System.ArgumentException: Object must be of
type String.
//        at System.String.CompareTo(Object value)
//        at Example.Main()
//
//     Comparing 'some text' with '123': 1
//
//     Comparing 'some text' with 'some text': 0
//
//     Comparing 'some text' with 'Some Text': -1
```

Remarks

ToString returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by `ToString` is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

The default implementation of ToString obtains the name of the class that threw the current exception, the message, the result of calling ToString on the inner exception, and the result of calling Environment.StackTrace. If any of these members is `null`, its value is not included in the returned string.

If there is no error message or if it is an empty string (""), then no error message is returned. The name of the inner exception and the stack trace are returned only if they are not `null`.

This method overrides Object.ToString.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Exception.SerializeObjectState Event

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> **Caution**
>
> BinaryFormatter serialization is obsolete and should not be used. See **https://aka.ms/binaryformatter** for more information.

Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception.

C#

```
[System.Obsolete("BinaryFormatter serialization is obsolete and should not be used. See https://aka.ms/binaryformatter for more information.", DiagnosticId="SYSLIB0011", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
protected event EventHandler<System.Runtime.Serialization.SafeSerializationEventArgs>? SerializeObjectState;
```

Event Type

EventHandler<SafeSerializationEventArgs>

Attributes ObsoleteAttribute

Remarks

The exception state object implements the ISafeSerializationData interface.

When the SerializeObjectState event is subscribed to, the exception is deserialized and created as an empty exception. The exception's constructor is not run, and the exception state is also deserialized. The CompleteDeserialization callback method of the exception

state object is then notified so that it can push deserialized data into the empty exception.

The SerializeObjectState event enables transparent exception types to serialize and deserialize exception data. Transparent code can execute commands within the bounds of the permission set it is operating within, but cannot execute, call, derive from, or contain critical code.

If the SerializeObjectState event is not subscribed to, deserialization occurs as usual using the Exception constructor.

Typically, a handler for the SerializeObjectState event is added in the exception's constructor to provide for its serialization. But because the constructor is not executed when the SerializeObjectState event handler executes, serializing a deserialized exception can throw a SerializationException exception when you try to deserialize the exception. To avoid this, you should also add the handler for the SerializeObjectState event in the ISafeSerializationData.CompleteDeserialization method. See the Examples section for an illustration.

Notes to Inheritors

If this event is subscribed to and used, all derived types that follow in the inheritance hierarchy must implement the same serialization mechanism.

ExecutionEngineException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> ExecutionEngineException previously indicated an unspecified fatal error in the runtime. The runtime no longer raises this exception so this type is obsolete.

The exception that is thrown when there is an internal error in the execution engine of the common language runtime. This class cannot be inherited.

C#

```
[System.Obsolete("ExecutionEngineException previously indicated an
unspecified fatal error in the runtime. The runtime no longer raises this
exception so this type is obsolete.")]
public sealed class ExecutionEngineException : SystemException
```

Inheritance Object → Exception → SystemException → ExecutionEngineException

Attributes ObsoleteAttribute

Remarks

There is no non-obsolete alternative to ExecutionEngineException. If further execution of your application cannot be sustained, use the FailFast method.

Constructors

Expand table

ExecutionEngineException()	Initializes a new instance of the ExecutionEngineException class.

ExecutionEngineException(String)	Initializes a new instance of the ExecutionEngineException class with a specified error message.
ExecutionEngineException(String, Exception)	Initializes a new instance of the ExecutionEngineException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
InnerException	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)

GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5 *(4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

ExecutionEngineException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ExecutionEngineException class.

Overloads

Expand table

ExecutionEngineException()	Initializes a new instance of the ExecutionEngineException class.
ExecutionEngineException(String)	Initializes a new instance of the ExecutionEngineException class with a specified error message.
ExecutionEngineException(String, Exception)	Initializes a new instance of the ExecutionEngineException class with a specified error message and a reference to the inner exception that is the cause of this exception.

ExecutionEngineException()

Initializes a new instance of the ExecutionEngineException class.

C#

```
public ExecutionEngineException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Internal error occurred." This message takes into account the current system culture.

The following table shows the initial property values for an instance of ExecutionEngineException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ExecutionEngineException(String)

Initializes a new instance of the ExecutionEngineException class with a specified error message.

C#

```
public ExecutionEngineException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of ExecutionEngineException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ExecutionEngineException(String, Exception)

Initializes a new instance of the ExecutionEngineException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public ExecutionEngineException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is

raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of ExecutionEngineException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

FieldAccessException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an invalid attempt to access a private or protected field inside a class.

C#

```
public class FieldAccessException : MemberAccessException
```

Inheritance Object → Exception → SystemException → MemberAccessException → FieldAccessException

Remarks

This exception is typically thrown when the access level of a field in a class library is changed, and one or more assemblies referencing the library have not been recompiled.

FieldAccessException uses the HRESULT COR_E_FIELDACCESS, which has the value 0x80131507.

For a list of initial property values for an instance of FieldAccessException, see the FieldAccessException constructors.

> **Note**
>
> This exception is not included in the **.NET for Windows Store apps** or the **Portable Class Library**, but it is thrown by some members that are. To catch the exception in that case, write a `catch` statement for **MemberAccessException** instead.

Constructors

Expand table

FieldAccessException()	Initializes a new instance of the FieldAccessException class.
FieldAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the FieldAccessException class with serialized data.
FieldAccessException(String)	Initializes a new instance of the FieldAccessException class with a specified error message.
FieldAccessException(String, Exception)	Initializes a new instance of the FieldAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FieldAccessException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the FieldAccessException class.

Overloads

Expand table

FieldAccessException()	Initializes a new instance of the FieldAccessException class.
FieldAccessException(String)	Initializes a new instance of the FieldAccessException class with a specified error message.
FieldAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the FieldAccessException class with serialized data.
FieldAccessException(String, Exception)	Initializes a new instance of the FieldAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

FieldAccessException()

Initializes a new instance of the FieldAccessException class.

C#

```
public FieldAccessException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to access a field that is not accessible by the caller." This message takes the current system culture into account.

The following table shows the initial property values for an instance of FieldAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FieldAccessException(String)

Initializes a new instance of the FieldAccessException class with a specified error message.

C#

```
public FieldAccessException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Remarks

This constructor initializes the Message property of the new instance by using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor must ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of FieldAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FieldAccessException(SerializationInfo, StreamingContext)

⊗ Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the FieldAccessException class with serialized data.

```C#
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
protected FieldAccessException (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object that was transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

FieldAccessException(String, Exception)

Initializes a new instance of the FieldAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public FieldAccessException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or returns `null` if it does not supply the inner exception value to the constructor. The caller of this constructor must ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of FieldAccessException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The localized error message string.

Applies to

FileStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser based on the File scheme.

C#

```
public class FileStyleUriParser : UriParser
```

Inheritance Object → UriParser → FileStyleUriParser

Constructors

Expand table

FileStyleUriParser()	Creates a customizable parser based on the File scheme.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)

IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

FlagsAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that an enumeration can be treated as a bit field; that is, a set of flags.

C#

```
[System.AttributeUsage(System.AttributeTargets.Enum, Inherited=false)]
public class FlagsAttribute : Attribute
```

Inheritance Object → Attribute → FlagsAttribute

Attributes AttributeUsageAttribute

Remarks

For more information about this API, see Supplemental API remarks for FlagsAttribute.

Constructors

Expand table

FlagsAttribute()	Initializes a new instance of the FlagsAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

FlagsAttribute Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the FlagsAttribute class.

C#

```
public FlagsAttribute ();
```

Examples

The following example defines a `PhoneService` enumeration that represents forms of communication provided by a telephone company. It initializes three variables representing the service provided to three different households, and then indicates which households have no service, which households have only cell phone service, and which households have both cell phone and land line service. Finally, it implicitly calls the Enum.ToString(String) method to display the types of service provided to each household.

C#

```
using System;

[Flags]
public enum PhoneService
{
   None = 0,
   LandLine = 1,
   Cell = 2,
   Fax = 4,
   Internet = 8,
   Other = 16
}

public class Example
{
   public static void Main()
   {
      // Define three variables representing the types of phone service
```

```
      // in three households.
      var household1 = PhoneService.LandLine | PhoneService.Cell |
                       PhoneService.Internet;
      var household2 = PhoneService.None;
      var household3 = PhoneService.Cell | PhoneService.Internet;

      // Store the variables in an array for ease of access.
      PhoneService[] households = { household1, household2, household3 };

      // Which households have no service?
      for (int ctr = 0; ctr < households.Length; ctr++)
         Console.WriteLine("Household {0} has phone service: {1}",
                           ctr + 1,
                           households[ctr] == PhoneService.None ?
                               "No" : "Yes");
      Console.WriteLine();

      // Which households have cell phone service?
      for (int ctr = 0; ctr < households.Length; ctr++)
         Console.WriteLine("Household {0} has cell phone service: {1}",
                           ctr + 1,
                           (households[ctr] & PhoneService.Cell) ==
PhoneService.Cell ?
                              "Yes" : "No");
      Console.WriteLine();

      // Which households have cell phones and land lines?
      var cellAndLand = PhoneService.Cell | PhoneService.LandLine;
      for (int ctr = 0; ctr < households.Length; ctr++)
         Console.WriteLine("Household {0} has cell and land line service:
{1}",
                           ctr + 1,
                           (households[ctr] & cellAndLand) == cellAndLand ?
                              "Yes" : "No");
      Console.WriteLine();

      // List all types of service of each household?//
      for (int ctr = 0; ctr < households.Length; ctr++)
         Console.WriteLine("Household {0} has: {1:G}",
                           ctr + 1, households[ctr]);
      Console.WriteLine();
   }
}
// The example displays the following output:
//    Household 1 has phone service: Yes
//    Household 2 has phone service: No
//    Household 3 has phone service: Yes
//
//    Household 1 has cell phone service: Yes
//    Household 2 has cell phone service: No
//    Household 3 has cell phone service: Yes
//
//    Household 1 has cell and land line service: Yes
//    Household 2 has cell and land line service: No
//    Household 3 has cell and land line service: No
```

```
//
//    Household 1 has: LandLine, Cell, Internet
//    Household 2 has: None
//    Household 3 has: Cell, Internet
```

F#

```fsharp
open System

[<Flags>]
type PhoneService =
    | None = 0
    | LandLine = 1
    | Cell = 2
    | Fax = 4
    | Internet = 8
    | Other = 16

// Define three variables representing the types of phone service
// in three households.
let household1 =
    PhoneService.LandLine ||| PhoneService.Cell ||| PhoneService.Internet

let household2 =
    PhoneService.None

let household3 =
    PhoneService.Cell ||| PhoneService.Internet

// Store the variables in a list for ease of access.
let households =
    [ household1; household2; household3 ]

// Which households have no service?
for i = 0 to households.Length - 1 do
    printfn $"""Household {i + 1} has phone service: {if households[i] =
PhoneService.None then "No" else "Yes"}"""
printfn ""

// Which households have cell phone service?
for i = 0 to households.Length - 1 do
    printfn $"""Household {i + 1} has cell phone service: {if households[i]
&&& PhoneService.Cell = PhoneService.Cell then "Yes" else "No"}"""
printfn ""

// Which households have cell phones and land lines?
let cellAndLand =
    PhoneService.Cell ||| PhoneService.LandLine

for i = 0 to households.Length - 1 do
    printfn $"""Household {i + 1} has cell and land line service: {if
households[i] &&& cellAndLand = cellAndLand then "Yes" else "No"}"""
printfn ""
```

```
// List all types of service of each household?//
for i = 0 to households.Length - 1 do
    printfn $"Household {i + 1} has: {households[i]:G}"

// The example displays the following output:
//    Household 1 has phone service: Yes
//    Household 2 has phone service: No
//    Household 3 has phone service: Yes
//
//    Household 1 has cell phone service: Yes
//    Household 2 has cell phone service: No
//    Household 3 has cell phone service: Yes
//
//    Household 1 has cell and land line service: Yes
//    Household 2 has cell and land line service: No
//    Household 3 has cell and land line service: No
//
//    Household 1 has: LandLine, Cell, Internet
//    Household 2 has: None
//    Household 3 has: Cell, Internet
```

VB

```
<Flags()>
Public Enum PhoneService As Integer
   None = 0
   LandLine = 1
   Cell = 2
   Fax = 4
   Internet = 8
   Other = 16
End Enum

Module Example
   Public Sub Main()
      ' Define three variables representing the types of phone service
      ' in three households.
      Dim household1 As PhoneService = PhoneService.LandLine Or
                                       PhoneService.Cell Or
                                       PhoneService.Internet
      Dim household2 As PhoneService = PhoneService.None
      Dim household3 As PhoneService = PhoneService.Cell Or
                                       PhoneService.Internet

      ' Store the variables in an array for ease of access.
      Dim households() As PhoneService = { household1, household2,
                                           household3 }

      ' Which households have no service?
      For ctr As Integer = 0 To households.Length - 1
         Console.WriteLine("Household {0} has phone service: {1}",
                           ctr + 1,
```

```
                            If(households(ctr) = PhoneService.None,
                               "No", "Yes"))
      Next
      Console.WriteLine()

      ' Which households have cell phone service?
      For ctr As Integer = 0 To households.Length - 1
         Console.WriteLine("Household {0} has cell phone service: {1}",
                            ctr + 1,
                            If((households(ctr) And PhoneService.Cell) =
PhoneService.Cell,
                               "Yes", "No"))
      Next
      Console.WriteLine()

      ' Which households have cell phones and land lines?
      Dim cellAndLand As PhoneService = PhoneService.Cell Or
PhoneService.LandLine
      For ctr As Integer = 0 To households.Length - 1
         Console.WriteLine("Household {0} has cell and land line service:
{1}",
                            ctr + 1,
                            If((households(ctr) And cellAndLand) =
cellAndLand,
                               "Yes", "No"))
      Next
      Console.WriteLine()

      ' List all types of service of each household?'
      For ctr As Integer = 0 To households.Length - 1
         Console.WriteLine("Household {0} has: {1:G}",
                            ctr + 1, households(ctr))
      Next
      Console.WriteLine()
   End Sub
End Module
' The example displays the following output:
'    Household 1 has phone service: Yes
'    Household 2 has phone service: No
'    Household 3 has phone service: Yes
'
'    Household 1 has cell phone service: Yes
'    Household 2 has cell phone service: No
'    Household 3 has cell phone service: Yes
'
'    Household 1 has cell and land line service: Yes
'    Household 2 has cell and land line service: No
'    Household 3 has cell and land line service: No
'
'    Household 1 has: LandLine, Cell, Internet
'    Household 2 has: None
'    Household 3 has: Cell, Internet
```

The following example illustrates the use of the `FlagsAttribute` attribute and shows the effect on the ToString method of using `FlagsAttribute` on an Enum declaration.

C#

```
using System;

class Example
{
   // Define an Enum without FlagsAttribute.
   enum SingleHue : short
   {
      None = 0,
      Black = 1,
      Red = 2,
      Green = 4,
      Blue = 8
   };

   // Define an Enum with FlagsAttribute.
   [Flags]
   enum MultiHue : short
   {
      None = 0,
      Black = 1,
      Red = 2,
      Green = 4,
      Blue = 8
   };

   static void Main( )
   {
      // Display all possible combinations of values.
      Console.WriteLine(
           "All possible combinations of values without FlagsAttribute:");
      for(int val = 0; val <= 16; val++ )
         Console.WriteLine( "{0,3} - {1:G}", val, (SingleHue)val);

      // Display all combinations of values, and invalid values.
      Console.WriteLine(
           "\nAll possible combinations of values with FlagsAttribute:");
      for( int val = 0; val <= 16; val++ )
         Console.WriteLine( "{0,3} - {1:G}", val, (MultiHue)val);
   }
}
// The example displays the following output:
//       All possible combinations of values without FlagsAttribute:
//         0 - None
//         1 - Black
//         2 - Red
//         3 - 3
//         4 - Green
//         5 - 5
```

```
//          6 - 6
//          7 - 7
//          8 - Blue
//          9 - 9
//         10 - 10
//         11 - 11
//         12 - 12
//         13 - 13
//         14 - 14
//         15 - 15
//         16 - 16
//
//       All possible combinations of values with FlagsAttribute:
//          0 - None
//          1 - Black
//          2 - Red
//          3 - Black, Red
//          4 - Green
//          5 - Black, Green
//          6 - Red, Green
//          7 - Black, Red, Green
//          8 - Blue
//          9 - Black, Blue
//         10 - Red, Blue
//         11 - Black, Red, Blue
//         12 - Green, Blue
//         13 - Black, Green, Blue
//         14 - Red, Green, Blue
//         15 - Black, Red, Green, Blue
//         16 - 16
```

F#

```fsharp
open System

// Define an Enum without FlagsAttribute.
type SingleHue =
    | None = 0
    | Black = 1
    | Red = 2
    | Green = 4
    | Blue = 8

// Define an Enum with FlagsAttribute.
[<Flags>]
type MultiHue =
    | None = 0
    | Black = 1
    | Red = 2
    | Green = 4
    | Blue = 8

// Display all possible combinations of values.
```

```
printfn "All possible combinations of values without FlagsAttribute:"
for i = 0 to 16 do
    printfn $"{i,3} - {enum<SingleHue> i:G}"

// Display all combinations of values, and invalid values.
printfn "\nAll possible combinations of values with FlagsAttribute:"
for i = 0 to 16 do
    printfn $"{i,3} - {enum<MultiHue> i:G}"

// The example displays the following output:
//       All possible combinations of values without FlagsAttribute:
//         0 - None
//         1 - Black
//         2 - Red
//         3 - 3
//         4 - Green
//         5 - 5
//         6 - 6
//         7 - 7
//         8 - Blue
//         9 - 9
//        10 - 10
//        11 - 11
//        12 - 12
//        13 - 13
//        14 - 14
//        15 - 15
//        16 - 16
//
//       All possible combinations of values with FlagsAttribute:
//         0 - None
//         1 - Black
//         2 - Red
//         3 - Black, Red
//         4 - Green
//         5 - Black, Green
//         6 - Red, Green
//         7 - Black, Red, Green
//         8 - Blue
//         9 - Black, Blue
//        10 - Red, Blue
//        11 - Black, Red, Blue
//        12 - Green, Blue
//        13 - Black, Green, Blue
//        14 - Red, Green, Blue
//        15 - Black, Red, Green, Blue
//        16 - 16
```

VB

```
Module Example
   ' Define an Enum without FlagsAttribute.
   Enum SingleHue As Short
```

```
        None = 0
        Black = 1
        Red = 2
        Green = 4
        Blue = 8
    End Enum

    ' Define an Enum with FlagsAttribute.
    <Flags()>
    Enum MultiHue As Short
        None = 0
        Black = 1
        Red = 2
        Green = 4
        Blue = 8
    End Enum

    Sub Main()
        ' Display all possible combinations of values.
        Console.WriteLine(
             "All possible combinations of values without FlagsAttribute:")
        For val As Integer = 0 To 16
           Console.WriteLine("{0,3} - {1:G}", val, CType(val, SingleHue))
      Next
      Console.WriteLine()

      ' Display all combinations of values, and invalid values.
      Console.WriteLine(
           "All possible combinations of values with FlagsAttribute:")
      For val As Integer = 0 To 16
         Console.WriteLine( "{0,3} - {1:G}", val, CType(val, MultiHue))
      Next
    End Sub
End Module
' The example displays the following output:
'       All possible combinations of values without FlagsAttribute:
'         0 - None
'         1 - Black
'         2 - Red
'         3 - 3
'         4 - Green
'         5 - 5
'         6 - 6
'         7 - 7
'         8 - Blue
'         9 - 9
'        10 - 10
'        11 - 11
'        12 - 12
'        13 - 13
'        14 - 14
'        15 - 15
'        16 - 16
'
'       All possible combinations of values with FlagsAttribute:
```

```
'          0 - None
'          1 - Black
'          2 - Red
'          3 - Black, Red
'          4 - Green
'          5 - Black, Green
'          6 - Red, Green
'          7 - Black, Red, Green
'          8 - Blue
'          9 - Black, Blue
'         10 - Red, Blue
'         11 - Black, Red, Blue
'         12 - Green, Blue
'         13 - Black, Green, Blue
'         14 - Red, Green, Blue
'         15 - Black, Red, Green, Blue
'         16 - 16
```

FormatException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when the format of an argument is invalid, or when a composite format string is not well formed.

```
C#
public class FormatException : SystemException
```

Inheritance Object → Exception → SystemException → FormatException

Derived System.IO.FileFormatException
System.Net.CookieException
System.Reflection.CustomAttributeFormatException
System.UriFormatException

Remarks

A FormatException exception can be thrown for one of the following reasons:

- In a call to a method that converts a string to some other data type, the string doesn't conform to the required pattern. This typically occurs when calling some methods of the Convert class and the `Parse` and `ParseExact` methods of some types.

  In most cases, particularly if the string that you're converting is input by a user or read from a file, you should use a `try/catch` (`try/with` in F#) block and handle the FormatException exception if the conversion is unsuccessful. You can also replace the call to the conversion method with a call to a `TryParse` or `TryParseExact` method, if one exists. However, a FormatException exception that is thrown when you're trying to parse a predefined or hard-coded string indicates a program error. In this case, you should correct the error rather than handle the exception.

The conversion of a string to the following types in the System namespace can throw a FormatException exception:

- Boolean. The Boolean.Parse(String) and Convert.ToBoolean(String) methods require the string to be converted to be "True", "true", "False", or "false". Any other value throws a FormatException exception.

- DateTime and DateTimeOffset. All date and time data is interpreted based on the formatting conventions of a particular culture: either the current culture (or, in some cases, the current application domain culture), the invariant culture, or a specified culture. When you call the DateTime.ParseExact(String, String, IFormatProvider, DateTimeStyles) and DateTimeOffset.ParseExact(String, String[], IFormatProvider, DateTimeStyles) methods, date and time data must also conform *exactly* to a pattern specified by one or more standard format strings or custom format strings that are provided as arguments in the method call. If it doesn't conform to an expected culture-specific pattern, a FormatException exception is thrown. This means that date and time data saved in a culture-specific format on one system might not parse successfully on another system.

  For more information about parsing dates and times, see Parsing Date and Time Strings and the documentation for the method that threw the exception.

- **GUIDs.** The string representation of a GUID must consist of 32 hexadecimal digits (0-F), and must be in one of the five formats output by the Guid.ToString method. For more information, see the Guid.Parse method.

- **Numeric types, including all signed integers, unsigned integers, and floating-point types.** The string to be parsed must consist of the Latin digits 0-9. A positive or negative sign, decimal separator, group separators, and currency symbol may also be permitted. Trying to parse a string that contains any other character always throws a FormatException exception.

  All numeric strings are interpreted based on the formatting conventions of a particular culture: either the current culture, the invariant culture, or a specified culture. As a result, a numeric string that is parsed by using the conventions of one culture might fail when using the conventions of another.

  For more information about parsing numeric strings, see Parsing Numeric Strings and the documentation for the specific method that threw the exception.

- **Time intervals.** The string to be parsed must be either in fixed culture-insensitive format or in a culture-sensitive format defined by the current culture,

the invariant culture, or a specified culture. If the string isn't in an appropriate format, or if, at the minimum, the days, hours, and minutes components of the time interval aren't present, the parsing method throws a FormatException exception. For more information, see the documentation for the TimeSpan parsing method that threw the exception.

- A type implements the IFormattable interface, which supports format strings that define how an object is converted to its string representation, and an invalid format string is used. This is most common in a formatting operation. In the following example, the "Q" standard format string is used in a composite format string to format a number. However, "Q" is not a valid standard format string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      decimal price = 169.32m;
      Console.WriteLine("The cost is {0:Q2}.", price);
   }
}
// The example displays the following output:
//    Unhandled Exception: System.FormatException: Format specifier was
invalid.
//       at System.Number.FormatDecimal(Decimal value, String format,
NumberFormatInfo info)
//       at System.Decimal.ToString(String format, IFormatProvider
provider)
//       at System.Text.StringBuilder.AppendFormat(IFormatProvider
provider, String format, Object[] args)
//       at System.IO.TextWriter.WriteLine(String format, Object arg0)
//       at System.IO.TextWriter.SyncTextWriter.WriteLine(String
format, Object arg0)
//       at Example.Main()
```

This exception results from a coding error. To correct the error, either remove the format string or substitute a valid one. The following example corrects the error by replacing the invalid format string with the "C" (currency) format string.

C#

```
using System;

public class Example
{
   public static void Main()
```

```
    {
        decimal price = 169.32m;
        Console.WriteLine("The cost is {0:C2}.", price);
    }
}
// The example displays the following output:
//    The cost is $169.32.
```

A FormatException exception can also be thrown by parsing methods, such as DateTime.ParseExact and Guid.ParseExact, that require the string to be parsed to conform exactly to the pattern specified by a format string. In the following example, the string representation of a GUID is expected to conform to the pattern specified by the "G" standard format string. However, the Guid structure's implementation of IFormattable does not support the "G" format string.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        string guidString = "ba748d5c-ae5f-4cca-84e5-1ac5291c38cb";
        Console.WriteLine(Guid.ParseExact(guidString, "G"));
    }
}
// The example displays the following output:
//    Unhandled Exception: System.FormatException:
//       Format String can be only "D", "d", "N", "n", "P", "p", "B",
"b", "X" or "x".
//       at System.Guid.ParseExact(String input, String format)
//       at Example.Main()
```

This exception also results from a coding error. To correct it, call a parsing method that doesn't require a precise format, such as DateTime.Parse or Guid.Parse, or substitute a valid format string. The following example corrects the error by calling the Guid.Parse method.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        string guidString = "ba748d5c-ae5f-4cca-84e5-1ac5291c38cb";
        Console.WriteLine(Guid.Parse(guidString));
```

```
    }
}
// The example displays the following output:
//    ba748d5c-ae5f-4cca-84e5-1ac5291c38cb
```

- One or more of the indexes of the format items in a composite format string is greater than the indexes of the items in the object list or parameter array. In the following example, the largest index of a format item in the format string is 3. Because the indexes of items in the object list are zero-based, this format string would require the object list to have four items. Instead, it has only three, `dat`, `temp`, and `scale`, so the code results in a FormatException exception at run time:.

C#

```
using System;

public class Example
{
   public enum TemperatureScale
   { Celsius, Fahrenheit, Kelvin }

   public static void Main()
   {
      String info = GetCurrentTemperature();
      Console.WriteLine(info);
   }

   private static String GetCurrentTemperature()
   {
      DateTime dat = DateTime.Now;
      Decimal temp = 20.6m;
      TemperatureScale scale = TemperatureScale.Celsius;
      String result;

      result = String.Format("At {0:t} on {1:D}, the temperature is
{2:F1} {3:G}",
                             dat, temp, scale);
      return result;
   }
}
// The example displays output like the following:
//    Unhandled Exception: System.FormatException: Format specifier was
invalid.
//       at System.Number.FormatDecimal(Decimal value, String format,
NumberFormatInfo info)
//       at System.Decimal.ToString(String format, IFormatProvider
provider)
//       at System.Text.StringBuilder.AppendFormat(IFormatProvider
provider, String format, Object[] args)
//       at System.String.Format(IFormatProvider provider, String
```

```
format, Object[] args)
//       at Example.Main()
```

In this case, the FormatException exception is a result of developer error. It should be corrected rather than handled in a `try/catch` block by making sure that each item in the object list corresponds to the index of a format item. To correct this example, change the index of the second format item to refer to the `dat` variable, and decrement the index of each subsequent format item by one.

C#

```
using System;

public class Example
{
   public enum TemperatureScale
   { Celsius, Fahrenheit, Kelvin }

   public static void Main()
   {
      String info = GetCurrentTemperature();
      Console.WriteLine(info);
   }

   private static String GetCurrentTemperature()
   {
      DateTime dat = DateTime.Now;
      Decimal temp = 20.6m;
      TemperatureScale scale = TemperatureScale.Celsius;
      String result;

      result = String.Format("At {0:t} on {0:D}, the temperature is
{1:F1} {2:G}",
                             dat, temp, scale);
      return result;
   }
}
// The example displays output like the following:
//    At 10:40 AM on Wednesday, June 04, 2014, the temperature is 20.6
Celsius
```

- The composite format string isn't well-formed. When this happens, the FormatException exception is always a result of developer error. It should be corrected rather than handled in a `try/catch` block.

  Trying to include literal braces in a string, as the following example does, will throw the exception.

C#

```
result = String.Format("The text has {0} '{' characters and {1} '}'
characters.",
                       nOpen, nClose);
```

The recommended technique for including literal braces in a composite format string is to include them in the object list and use format items to insert them into the result string. For example, you can modify the previous composite format string as shown here.

```C#
string result;
int nOpen = 1;
int nClose = 2;
result = String.Format("The text has {0} '{{' characters and {1} '}}'
characters.",
                       nOpen, nClose);
Console.WriteLine(result);
```

The exception is also thrown if your format string contains a typo. The following call to the String.Format method omits a closing brace and pairs an opening brace with a closing bracket.

```C#
int n1 = 10;
int n2 = 20;
String result = String.Format("{0 + {1] = {2}",
                              n1, n2, n1 + n2);
```

To correct the error, ensure that all opening and closing braces correspond.

```C#
String result = String.Format("{0} + {1} = {2}",
                              n1, n2, n1 + n2);
```

- You've supplied the object list in a composite formatting method as a strongly typed parameter array, and the FormatException exception indicates that the index of one or more format items exceeds the number of arguments in the object list. This occurs because no explicit conversion between array types exists, so instead the compiler treats the array as a single argument rather than as a parameter array. For example, the following call to the Console.WriteLine(String, Object[]) method

throws a FormatException exception, although the highest index of the format items is 3, and the parameter array of type Int32 has four elements.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Random rnd = new Random();
      int[]  numbers = new int[4];
      int total = 0;
      for (int ctr = 0; ctr <= 2; ctr++) {
         int number = rnd.Next(1001);
         numbers[ctr] = number;
         total += number;
      }
      numbers[3] = total;
      Console.WriteLine("{0} + {1} + {2} = {3}", numbers);
   }
}
// The example displays the following output:
//    Unhandled Exception:
//    System.FormatException:
//       Index (zero based) must be greater than or equal to zero and
less than the size of the argument list.
//       at System.Text.StringBuilder.AppendFormat(IFormatProvider
provider, String format, Object[] args)
//       at System.IO.TextWriter.WriteLine(String format, Object arg0)
//       at System.IO.TextWriter.SyncTextWriter.WriteLine(String
format, Object arg0)
//       at Example.Main()
```

Instead of handling this exception, you should eliminate its cause. Because neither Visual Basic nor C# can convert an integer array to an object array, you have to perform the conversion yourself before calling the composite formatting method. The following example provides one implementation.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Random rnd = new Random();
```

```
        int[]  numbers = new int[4];
        int total = 0;
        for (int ctr = 0; ctr <= 2; ctr++) {
           int number = rnd.Next(1001);
           numbers[ctr] = number;
           total += number;
        }
        numbers[3] = total;
        object[] values = new object[numbers.Length];
        numbers.CopyTo(values, 0);
        Console.WriteLine("{0} + {1} + {2} = {3}", values);
    }
}
// The example displays output like the following:
//         477 + 956 + 901 = 2334
```

FormatException uses the HRESULT COR_E_FORMAT, which has the value 0x80131537.

The FormatException class derives from Exception and adds no unique members. For a list of initial property values for an instance of FormatException, see the FormatException constructors.

Constructors

Expand table

FormatException()	Initializes a new instance of the FormatException class.
FormatException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the FormatException class with serialized data.
FormatException(String)	Initializes a new instance of the FormatException class with a specified error message.
FormatException(String, Exception)	Initializes a new instance of the FormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception.

	(Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object.

	(Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

FormatException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the FormatException class with serialized data.
FormatException(String, Exception)	Initializes a new instance of the FormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

FormatException()

Initializes a new instance of the FormatException class.

C#

```
public FormatException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Invalid format." This message

takes into account the current system culture.

The following table shows the initial property values for an instance of FormatException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FormatException(String)

Initializes a new instance of the FormatException class with a specified error message.

C#

```
public FormatException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of FormatException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FormatException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the FormatException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected FormatException (System.Runtime.Serialization.SerializationInfo
info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

FormatException(String, Exception)

Initializes a new instance of the FormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public FormatException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of FormatException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

FormattableString Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a composite format string, along with the arguments to be formatted.

C#

```
public abstract class FormattableString : IFormattable
```

Inheritance Object → FormattableString

Implements IFormattable

Remarks

A composite format string consists of fixed text intermixed with indexed placeholders, called format items, that correspond to the objects in the list. The formatting operation yields a result string that consists of the original fixed text intermixed with the string representation of the objects in the list. Composite formatting is supported by methods such as String.Format, Console.WriteLine, and StringBuilder.AppendFormat. For more information on composite formatting, see Composite Formatting.

A FormattableString instance may result from an interpolated string in C# or Visual Basic.

Constructors

Expand table

FormattableString()	Instantiates a new instance of the FormattableString class.

Properties

Expand table

ArgumentCount	Gets the number of arguments to be formatted.
Format	Returns the composite format string.

Methods

Expand table

CurrentCulture(FormattableString)	Returns a result string in which arguments are formatted by using the conventions of the current culture.
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetArgument(Int32)	Returns the argument at the specified index position.
GetArguments()	Returns an object array that contains one or more objects to format.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
Invariant(FormattableString)	Returns a result string in which arguments are formatted by using the conventions of the invariant culture.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns the string that results from formatting the composite format string along with its arguments by using the formatting conventions of the current culture.
ToString(IFormatProvider)	Returns the string that results from formatting the composite format string along with its arguments by using the formatting conventions of a specified culture.

Explicit Interface Implementations

Expand table

IFormattable.ToString(String, IFormat	Returns the string that results from formatting the format string along with its arguments by using the formatting conventions of a

Provider)	specified culture.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FormattableString.ArgumentCount Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of arguments to be formatted.

C#

```
public abstract int ArgumentCount { get; }
```

Property Value

Int32

The number of arguments to be formatted.

Remarks

The arguments can be retrieved from the object array returned by the GetArguments method, or they can be retrieved individually by index number from the GetArgument method. The indexes of individual arguments range from zero to ArgumentCount - 1.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

FormattableString.Format Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the composite format string.

```
C#
public abstract string Format { get; }
```

Property Value

String

The composite format string.

Remarks

A composite format string consists of zero or more runs of fixed text intermixed with one or more format items, which are indicated by an index number delimited with brackets (for example, `{0}`). The index of each format item corresponds to an argument in an object list that follows the composite format string. For example, in the following statement:

```
C#
String.Format("Name = {0}, hours = {1:hh}", name, DateTime.Now);
```

the composite format string is `"Name = {0}, hours = {1:hh}"`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FormattableString.CurrentCulture(FormattableString) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a result string in which arguments are formatted by using the conventions of the current culture.

```
C#
public static string CurrentCulture (FormattableString formattable);
```

Parameters

`formattable` FormattableString

The string to be formatted.

Returns

String

The string that results from formatting the current instance by using the conventions of the current culture.

Remarks

This static method may be imported in C# or F# by:

```
C#
using static System.FormattableString;
```

``fsharp open type System.FormattableString

```
Within the scope of that import directive, an interpolated string may be
formatted in the current culture by writing, for example:
```csharp
    CurrentCulture($"{{ lat = {latitude}; lon = {longitude} }}");
```

F#

```
    CurrentCulture $"{{ lat = {latitude}; lon = {longitude} }}"
```

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

```

FormattableString.GetArgument(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the argument at the specified index position.

```
C#
public abstract object? GetArgument (int index);
```

Parameters

`index` Int32

The index of the argument. Its value can range from zero to one less than the value of ArgumentCount.

Returns

Object

The argument.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

FormattableString.GetArguments Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an object array that contains one or more objects to format.

C#

```
public abstract object?[] GetArguments ();
```

Returns

Object[]

An object array that contains one or more objects to format.

Remarks

Clients should not modify the contents of the array.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

FormattableString.Invariant(FormattableString) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a result string in which arguments are formatted by using the conventions of the invariant culture.

```
C#
public static string Invariant (FormattableString formattable);
```

Parameters

formattable FormattableString

The object to convert to a result string.

Returns

String

The string that results from formatting the current instance by using the conventions of the invariant culture.

Exceptions

ArgumentNullException

`formattable` is `null`.

Remarks

This static method can be imported in C# by the following statement:

```
C#
```

```
using static System.FormattableString;
```

Within the scope that `using static` directive, an interpolated string may be formatted using the conventions of the invariant culture by code such as the following:

```C#
Invariant($"{{ lat = {latitude}; lon = {longitude} }}")
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

FormattableString.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string that results from formatting the composite format string along with its arguments.

Overloads

Expand table

ToString()	Returns the string that results from formatting the composite format string along with its arguments by using the formatting conventions of the current culture.
ToString(IFormatProvider)	Returns the string that results from formatting the composite format string along with its arguments by using the formatting conventions of a specified culture.

ToString()

Returns the string that results from formatting the composite format string along with its arguments by using the formatting conventions of the current culture.

C#

```
public override string ToString ();
```

Returns

String

A result string formatted by using the conventions of the current culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Returns the string that results from formatting the composite format string along with its arguments by using the formatting conventions of a specified culture.

C#

```
public abstract string ToString (IFormatProvider? formatProvider);
```

Parameters

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

Returns

String

A result string formatted by using the conventions of `formatProvider`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

FormattableString.IFormattable.ToString(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string that results from formatting the format string along with its arguments by using the formatting conventions of a specified culture.

```
C#

string IFormattable.ToString (string ignored, IFormatProvider
formatProvider);
```

Parameters

ignored String

A string. This argument is ignored.

formatProvider IFormatProvider

An object that provides culture-specific formatting information.

Returns

String

A string formatted using the conventions of the `formatProvider` parameter.

Implements

ToString(String, IFormatProvider)

Remarks

This implementation calls the derived class' ToString(IFormatProvider) implementation.

This member is an explicit interface implementation. It can be used only when the FormattableString instance is cast to an IFormattable interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

FtpStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser based on the File Transfer Protocol (FTP) scheme.

C#

```
public class FtpStyleUriParser : UriParser
```

Inheritance Object → UriParser → FtpStyleUriParser

Constructors

Expand table

FtpStyleUriParser()	Creates a customizable parser based on the File Transfer Protocol (FTP) scheme.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)

InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Func<TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has no parameters and returns a value of the type specified by the `TResult` parameter.

```
C#

public delegate TResult Func<out TResult>();
```

Type Parameters

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Examples

The following example demonstrates how to use a delegate that takes no parameters. This code creates a generic class named `LazyValue` that has a field of type Func<TResult>. This delegate field can store a reference to any function that returns a value of the type that corresponds to the type parameter of the `LazyValue` object. The `LazyValue` type also has a `Value` property that executes the function (if it has not already been executed) and returns the resulting value.

The example creates two methods and instantiates two `LazyValue` objects with lambda expressions that call these methods. The lambda expressions do not take parameters

because they just need to call a method. As the output shows, the two methods are executed only when the value of each `LazyValue` object is retrieved.

C#

```
using System;

static class Func1
{
   public static void Main()
   {
      // Note that each lambda expression has no parameters.
      LazyValue<int> lazyOne = new LazyValue<int>(() => ExpensiveOne());
      LazyValue<long> lazyTwo = new LazyValue<long>(() =>
ExpensiveTwo("apple"));

      Console.WriteLine("LazyValue objects have been created.");

      // Get the values of the LazyValue objects.
      Console.WriteLine(lazyOne.Value);
      Console.WriteLine(lazyTwo.Value);
   }

   static int ExpensiveOne()
   {
      Console.WriteLine("\nExpensiveOne() is executing.");
      return 1;
   }

   static long ExpensiveTwo(string input)
   {
      Console.WriteLine("\nExpensiveTwo() is executing.");
      return (long)input.Length;
   }
}

class LazyValue<T> where T : struct
{
   private Nullable<T> val;
   private Func<T> getValue;

   // Constructor.
   public LazyValue(Func<T> func)
   {
      val = null;
      getValue = func;
   }

   public T Value
   {
      get
      {
         if (val == null)
            // Execute the delegate.
```

```
            val = getValue();
        return (T)val;
    }
  }
}
/* The example produces the following output:

    LazyValue objects have been created.

    ExpensiveOne() is executing.
    1

    ExpensiveTwo() is executing.
    5
*/
```

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have no parameters and must return a value.

> **Note**
>
> To reference a method that has no parameters and returns `void` (`unit`, in F#) (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the **Action** delegate instead.

When you use the Func<TResult> delegate, you do not have to explicitly define a delegate that encapsulates a parameterless method. For example, the following code explicitly declares a delegate named `WriteMethod` and assigns a reference to the `OutputTarget.SendToFile` instance method to its delegate instance.

C#

```
using System;
using System.IO;

delegate bool WriteMethod();

public class TestDelegate
{
   public static void Main()
   {
      OutputTarget output = new OutputTarget();
```

```
        WriteMethod methodCall = output.SendToFile;
        if (methodCall())
           Console.WriteLine("Success!");
        else
           Console.WriteLine("File write operation failed.");
    }
}

public class OutputTarget
{
    public bool SendToFile()
    {
        try
        {
           string fn = Path.GetTempFileName();
           StreamWriter sw = new StreamWriter(fn);
           sw.WriteLine("Hello, World!");
           sw.Close();
           return true;
        }
        catch
        {
           return false;
        }
    }
}
```

The following example simplifies this code by instantiating the Func<TResult> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;
using System.IO;

public class TestDelegate
{
    public static void Main()
    {
        OutputTarget output = new OutputTarget();
        Func<bool> methodCall = output.SendToFile;
        if (methodCall())
           Console.WriteLine("Success!");
        else
           Console.WriteLine("File write operation failed.");
    }
}

public class OutputTarget
{
    public bool SendToFile()
    {
        try
```

```
        {
            string fn = Path.GetTempFileName();
            StreamWriter sw = new StreamWriter(fn);
            sw.WriteLine("Hello, World!");
            sw.Close();
            return true;
        }
        catch
        {
            return false;
        }
    }
}
```

You can use the Func<TResult> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;
using System.IO;

public class Anonymous
{
    public static void Main()
    {
        OutputTarget output = new OutputTarget();
        Func<bool> methodCall = delegate() { return output.SendToFile(); };
        if (methodCall())
            Console.WriteLine("Success!");
        else
            Console.WriteLine("File write operation failed.");
    }
}

public class OutputTarget
{
    public bool SendToFile()
    {
        try
        {
            string fn = Path.GetTempFileName();
            StreamWriter sw = new StreamWriter(fn);
            sw.WriteLine("Hello, World!");
            sw.Close();
            return true;
        }
        catch
        {
            return false;
        }
```

```
    }
}
```

You can also assign a lambda expression to a Func<T,TResult> delegate, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (VB), Lambda Expressions (C#), and Lambda Expressions (F#).)

C#

```
using System;
using System.IO;

public class Anonymous
{
   public static void Main()
   {
      OutputTarget output = new OutputTarget();
      Func<bool> methodCall = () => output.SendToFile();
      if (methodCall())
         Console.WriteLine("Success!");
      else
         Console.WriteLine("File write operation failed.");
   }
}

public class OutputTarget
{
   public bool SendToFile()
   {
      try
      {
         string fn = Path.GetTempFileName();
         StreamWriter sw = new StreamWriter(fn);
         sw.WriteLine("Hello, World!");
         sw.Close();
         return true;
      }
      catch
      {
         return false;
      }
   }
}
```

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate. In particular, because many methods of types in the System.Linq namespace have `Func` parameters, you can pass these methods a lambda expression without explicitly instantiating a `Func` delegate.

If you have an expensive computation that you want to execute only if the result is actually needed, you can assign the expensive function to a Func<TResult> delegate. The execution of the function can then be delayed until a property that accesses the value is used in an expression. The example in the next section demonstrates how to do this.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions

Func<T,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has one parameter and returns a value of the type specified by the `TResult` parameter.

```
C#
public delegate TResult Func<in T,out TResult>(T arg);
```

Type Parameters

`T`

The type of the parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg` T

The parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Examples

The following example demonstrates how to declare and use a Func<T,TResult> delegate. This example declares a Func<T,TResult> variable and assigns it a lambda expression that converts the characters in a string to uppercase. The delegate that encapsulates this method is subsequently passed to the Enumerable.Select method to change the strings in an array of strings to uppercase.

C#

```
// Declare a Func variable and assign a lambda expression to the
// variable. The method takes a string and converts it to uppercase.
Func<string, string> selector = str => str.ToUpper();

// Create an array of strings.
string[] words = { "orange", "apple", "Article", "elephant" };
// Query the array and select strings according to the selector method.
IEnumerable<String> aWords = words.Select(selector);

// Output the results to the console.
foreach (String word in aWords)
    Console.WriteLine(word);

/*
This code example produces the following output:

ORANGE
APPLE
ARTICLE
ELEPHANT

*/
```

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have one parameter that is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has one parameter and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T>**

delegate instead.

When you use the Func<T,TResult> delegate, you do not have to explicitly define a delegate that encapsulates a method with a single parameter. For example, the following code explicitly declares a delegate named `ConvertMethod` and assigns a reference to the `UppercaseString` method to its delegate instance.

C#

```
using System;

delegate string ConvertMethod(string inString);

public class DelegateExample
{
   public static void Main()
   {
      // Instantiate delegate to reference UppercaseString method
      ConvertMethod convertMeth = UppercaseString;
      string name = "Dakota";
      // Use delegate instance to call UppercaseString method
      Console.WriteLine(convertMeth(name));
   }

   private static string UppercaseString(string inputString)
   {
      return inputString.ToUpper();
   }
}
```

The following example simplifies this code by instantiating the Func<T,TResult> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
// Instantiate delegate to reference UppercaseString method
Func<string, string> convertMethod = UppercaseString;
string name = "Dakota";
// Use delegate instance to call UppercaseString method
Console.WriteLine(convertMethod(name));

string UppercaseString(string inputString)
{
   return inputString.ToUpper();
}

// This code example produces the following output:
```

```
//
//    DAKOTA
```

You can also use the Func<T,TResult> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
 Func<string, string> convert = delegate(string s)
    { return s.ToUpper();};

 string name = "Dakota";
 Console.WriteLine(convert(name));

// This code example produces the following output:
//
//    DAKOTA
```

You can also assign a lambda expression to a Func<T,TResult> delegate, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (VB), Lambda Expressions (C#) and Lambda Expressions (F#).)

C#

```
Func<string, string> convert = s => s.ToUpper();

string name = "Dakota";
Console.WriteLine(convert(name));

// This code example produces the following output:
//
//    DAKOTA
```

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate. In particular, because many methods of types in the System.Linq namespace have Func<T,TResult> parameters, you can pass these methods a lambda expression without explicitly instantiating a Func<T,TResult> delegate.

Func<T1,T2,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has two parameters and returns a value of the type specified by the `TResult` parameter.

```
C#
public delegate TResult Func<in T1,in T2,out TResult>(T1 arg1, T2 arg2);
```

Type Parameters

`T1`

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T2`

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

arg2 T2

The second parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Examples

The following example demonstrates how to declare and use a Func<T1,T2,TResult> delegate. This example declares a Func<T1,T2,TResult> variable and assigns it a lambda expression that takes a String value and an Int32 value as parameters. The lambda expression returns `true` if the length of the String parameter is equal to the value of the Int32 parameter. The delegate that encapsulates this method is subsequently used in a query to filter strings in an array of strings.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Func3Example
{
   public static void Main()
   {
      Func<String, int, bool> predicate = (str, index) => str.Length == index;

      String[] words = { "orange", "apple", "Article", "elephant", "star", "and" };
      IEnumerable<String> aWords = words.Where(predicate).Select(str => str);

      foreach (String word in aWords)
         Console.WriteLine(word);
   }
}
```

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must

correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have two parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has two parameters and returns `void` (`unit` in F#) (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2>** delegate instead.

When you use the Func<T1,T2,TResult> delegate you do not have to explicitly define a delegate that encapsulates a method with two parameters. For example, the following code explicitly declares a delegate named `ExtractMethod` and assigns a reference to the `ExtractWords` method to its delegate instance.

C#

```
using System;

delegate string[] ExtractMethod(string stringToManipulate, int maximum);

public class DelegateExample
{
   public static void Main()
   {
      // Instantiate delegate to reference ExtractWords method
      ExtractMethod extractMeth = ExtractWords;
      string title = "The Scarlet Letter";
      // Use delegate instance to call ExtractWords method and display
result
      foreach (string word in extractMeth(title, 5))
         Console.WriteLine(word);
   }

   private static string[] ExtractWords(string phrase, int limit)
   {
      char[] delimiters = new char[] {' '};
      if (limit > 0)
         return phrase.Split(delimiters, limit);
      else
         return phrase.Split(delimiters);
   }
}
```

The following example simplifies this code by instantiating a Func<T1,T2,TResult> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;

public class GenericFunc
{
   public static void Main()
   {
      // Instantiate delegate to reference ExtractWords method
      Func<string, int, string[]> extractMethod = ExtractWords;
      string title = "The Scarlet Letter";
      // Use delegate instance to call ExtractWords method and display
result
      foreach (string word in extractMethod(title, 5))
         Console.WriteLine(word);
   }

   private static string[] ExtractWords(string phrase, int limit)
   {
      char[] delimiters = new char[] {' '};
      if (limit > 0)
         return phrase.Split(delimiters, limit);
      else
         return phrase.Split(delimiters);
   }
}
```

You can use the Func<T1,T2,TResult> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;

public class Anonymous
{
   public static void Main()
   {
      Func<string, int, string[]> extractMeth = delegate(string s, int i)
         { char[] delimiters = new char[] {' '};
           return i > 0 ? s.Split(delimiters, i) : s.Split(delimiters);
         };

      string title = "The Scarlet Letter";
      // Use Func instance to call ExtractWords method and display result
      foreach (string word in extractMeth(title, 5))
         Console.WriteLine(word);
   }
}
```

You can also assign a lambda expression to a Func<T1,T2,TResult> delegate, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (VB), Lambda Expressions (C#) and Lambda Expressions (F#).)

C#

```
using System;

public class LambdaExpression
{
   public static void Main()
   {
      char[] separators = new char[] {' '};
      Func<string, int, string[]> extract = (s, i) =>
           i > 0 ? s.Split(separators, i) : s.Split(separators) ;

      string title = "The Scarlet Letter";
      // Use Func instance to call ExtractWords method and display result
      foreach (string word in extract(title, 5))
         Console.WriteLine(word);
   }
}
```

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate. In particular, because many methods of types in the System.Linq namespace have Func<T1,T2,TResult> parameters, you can pass these methods a lambda expression without explicitly instantiating a Func<T1,T2,TResult> delegate.

Func<T1,T2,T3,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has three parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,out TResult>(T1 arg1, T2
arg2, T3 arg3);
```

Type Parameters

`T1`

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T2`

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T3`

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.

This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Examples

The following example demonstrates how to declare and use a Func<T1,T2,TResult> delegate. This example declares a Func<T1,T2,TResult> variable and assigns it a lambda expression that takes a String value and an Int32 value as parameters. The lambda expression returns `true` if the length of the String parameter is equal to the value of the Int32 parameter. The delegate that encapsulates this method is subsequently used in a query to filter strings in an array of strings.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Func3Example
{
   public static void Main()
   {
      Func<String, int, bool> predicate = (str, index) => str.Length ==
index;

      String[] words = { "orange", "apple", "Article", "elephant", "star",
"and" };
```

```
      IEnumerable<String> aWords = words.Where(predicate).Select(str =>
str);

      foreach (String word in aWords)
         Console.WriteLine(word);
   }
}
```

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have three parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has three parameters and returns `void` (`unit` in F#) (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3>** delegate instead.

When you use the Func<T1,T2,T3,TResult> delegate, you do not have to explicitly define a delegate that encapsulates a method with three parameters. For example, the following code explicitly declares a generic delegate named `ParseNumber` and assigns a reference to the Parse method to its delegate instance.

C#

```
using System;
using System.Globalization;

delegate T ParseNumber<T>(string input, NumberStyles styles,
                          IFormatProvider provider);

public class DelegateExample
{
   public static void Main()
   {
      string numericString = "-1,234";
      ParseNumber<int> parser = int.Parse;
      Console.WriteLine(parser(numericString,
                               NumberStyles.Integer | NumberStyles.AllowThousands,
                               CultureInfo.InvariantCulture));
```

```
    }
}
```

The following example simplifies this code by instantiating the Func<T1,T2,T3,TResult> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;
using System.Globalization;

public class GenericFunc
{
   public static void Main()
   {
      string numericString = "-1,234";
      Func<string, NumberStyles, IFormatProvider, int> parser = int.Parse;
      Console.WriteLine(parser(numericString,
                               NumberStyles.Integer | NumberStyles.AllowThousands,
                               CultureInfo.InvariantCulture));
   }
}
```

You can use the Func<T1,T2,T3,TResult> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;
using System.Globalization;

public class Anonymous
{
   public static void Main()
   {
      string numericString = "-1,234";
      Func<string, NumberStyles, IFormatProvider, int> parser =
           delegate(string s, NumberStyles sty, IFormatProvider p)
           { return int.Parse(s, sty, p); };
      Console.WriteLine(parser(numericString,
                               NumberStyles.Integer | NumberStyles.AllowThousands,
                               CultureInfo.InvariantCulture));
   }
}
```

You can also assign a lambda expression to a Func<T1,T2,T3,TResult> delegate, as the following example illustrates. (For an introduction to lambda expressions, see Lambda

Expressions (VB), Lambda Expressions (C#) and Lambda Expressions (F#).)

C#

```
using System;
using System.Globalization;

public class LambdaExpression
{
   public static void Main()
   {
      string numericString = "-1,234";
      Func<string, NumberStyles, IFormatProvider, int> parser = (s, sty, p)
                   => int.Parse(s, sty, p);
      Console.WriteLine(parser(numericString,
                       NumberStyles.Integer | NumberStyles.AllowThousands,
                       CultureInfo.InvariantCulture));
   }
}
```

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate. In particular, because many methods of types in the System.Linq namespace have `Func` parameters, you can pass these methods a lambda expression without explicitly instantiating a `Func` delegate.

Extension Methods

Func<T1,T2,T3,T4,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has four parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,out TResult>(T1 arg1,
T2 arg2, T3 arg3, T4 arg4);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Examples

The following example demonstrates how to declare and use a Func<T1,T2,TResult> delegate. This example declares a Func<T1,T2,TResult> variable and assigns it a lambda expression that takes a String value and an Int32 value as parameters. The lambda expression returns `true` if the length of the String parameter is equal to the value of the Int32 parameter. The delegate that encapsulates this method is subsequently used in a query to filter strings in an array of strings.

```
C#
```

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Func3Example
{
   public static void Main()
   {
      Func<String, int, bool> predicate = (str, index) => str.Length ==
index;

      String[] words = { "orange", "apple", "Article", "elephant", "star",
"and" };
      IEnumerable<String> aWords = words.Where(predicate).Select(str =>
str);

      foreach (String word in aWords)
         Console.WriteLine(word);
   }
}
```

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have four parameters, each of which is passed to it by value, and that it must return a value.

> ⓘ **Note**
>
> To reference a method that has four parameters and returns `void` (`unit` in F#) (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4>** delegate instead.

When you use the Func<T1,T2,T3,T4,TResult> delegate, you do not have to explicitly define a delegate that encapsulates a method with four parameters. For example, the following code explicitly declares a generic delegate named `Searcher` and assigns a reference to the IndexOf method to its delegate instance.

C#

```
using System;

delegate int Searcher(string searchString, int start, int count,
```

```
                          StringComparison type);

public class DelegateExample
{
   public static void Main()
   {
      string title = "The House of the Seven Gables";
      int position = 0;
      Searcher finder = title.IndexOf;
      do
      {
         int characters = title.Length - position;
         position = finder("the", position, characters,
                          StringComparison.InvariantCultureIgnoreCase);
         if (position >= 0)
         {
            position++;
            Console.WriteLine("'The' found at position {0} in {1}.",
                              position, title);
         }
      } while (position > 0);
   }
}
```

The following example simplifies this code by instantiating the Func<T1,T2,T3,T4,TResult> delegate instead of explicitly defining a new delegate and assigning a named method to it.

C#

```
using System;

public class DelegateExample
{
   public static void Main()
   {
      string title = "The House of the Seven Gables";
      int position = 0;
      Func<string, int, int, StringComparison, int> finder = title.IndexOf;
      do
      {
         int characters = title.Length - position;
         position = finder("the", position, characters,
                          StringComparison.InvariantCultureIgnoreCase);
         if (position >= 0)
         {
            position++;
            Console.WriteLine("'The' found at position {0} in {1}.",
                              position, title);
         }
      } while (position > 0);
```

```
    }
}
```

You can use the Func<T1,T2,T3,T4,TResult> delegate with anonymous methods in C#, as the following example illustrates. (For an introduction to anonymous methods, see Anonymous Methods.)

C#

```
using System;

public class DelegateExample
{
   public static void Main()
   {
      string title = "The House of the Seven Gables";
      int position = 0;
      Func<string, int, int, StringComparison, int> finder =
           delegate(string s, int pos, int chars, StringComparison type)
           { return title.IndexOf(s, pos, chars, type); };
      do
      {
         int characters = title.Length - position;
         position = finder("the", position, characters,
                           StringComparison.InvariantCultureIgnoreCase);
         if (position >= 0)
         {
            position++;
            Console.WriteLine("'The' found at position {0} in {1}.",
                              position, title);
         }
      } while (position > 0);
   }
}
```

You can also assign a lambda expression to a Func<T1,T2,TResult> delegate, as the following example illustrates. (For an introduction to lambda expressions, see Lambda Expressions (VB), Lambda Expressions (C#) and Lambda Expressions (F#).)

C#

```
using System;

public class DelegateExample
{
   public static void Main()
   {
      string title = "The House of the Seven Gables";
      int position = 0;
      Func<string, int, int, StringComparison, int> finder =
```

```
            (s, pos, chars, type) => title.IndexOf(s, pos, chars, type);
        do
        {
           int characters = title.Length - position;
           position = finder("the", position, characters,
                             StringComparison.InvariantCultureIgnoreCase);
           if (position >= 0)
           {
              position++;
              Console.WriteLine("'The' found at position {0} in {1}.",
                                position, title);
           }
        } while (position > 0);
    }
}
```

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate. In particular, because many methods of types in the System.Linq namespace have `Func` parameters, you can pass these methods a lambda expression without explicitly instantiating a `Func` delegate.

Func<T1,T2,T3,T4,T5,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has five parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.

This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have five parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has five parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,TResult> delegate with anonymous methods and lambda expressions.

Func<T1,T2,T3,T4,T5,T6,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has six parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,out
TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

arg6 T6

The sixth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have six parameters, each of which is passed to it by value, and that it must return a value.

> **Note**

Func<T1,T2,T3,T4,T5,T6,T7,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has seven parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,out
TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have seven parameters, each of which is passed to it by value, and that it must return a value.

Func<T1,T2,T3,T4,T5,T6,T7,T8,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has eight parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in
T8,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7
arg7, T8 arg8);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have eight parameters, each of which is passed to it by value, and that it must return a value.

Note

To reference a method that has eight parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has nine parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in
T8,in T9,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6,
T7 arg7, T8 arg8, T9 arg9);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that

the encapsulated method must have nine parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has nine parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 10 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in
T8,in T9,in T10,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6
arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 10 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 10 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 11 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T4

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 11 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 11 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 12 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T4`

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 12 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 12 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 13 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T4`

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 13 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 13 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 14 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13,in T14,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13, T14 arg14);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T4`

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T14`

The type of the fourteenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

`arg14` T14

The fourteenth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 14 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 14 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 15 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13,in T14,in T15,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13, T14 arg14, T15 arg15);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T4`

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T14`

The type of the fourteenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T15`

The type of the fifteenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

arg14 T14

The fourteenth parameter of the method that this delegate encapsulates.

arg15 T15

The fifteenth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 15 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 15 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly assigning it to a delegate.

Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,TResult> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Encapsulates a method that has 16 parameters and returns a value of the type specified by the `TResult` parameter.

C#

```
public delegate TResult Func<in T1,in T2,in T3,in T4,in T5,in T6,in T7,in T8,in T9,in T10,in T11,in T12,in T13,in T14,in T15,in T16,out TResult>(T1 arg1, T2 arg2, T3 arg3, T4 arg4, T5 arg5, T6 arg6, T7 arg7, T8 arg8, T9 arg9, T10 arg10, T11 arg11, T12 arg12, T13 arg13, T14 arg14, T15 arg15, T16 arg16);
```

Type Parameters

T1

The type of the first parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T2

The type of the second parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

T3

The type of the third parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T4`

The type of the fourth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T5`

The type of the fifth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T6`

The type of the sixth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T7`

The type of the seventh parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T8`

The type of the eighth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T9`

The type of the ninth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T10`

The type of the tenth parameter of the method that this delegate encapsulates.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance,

see Covariance and Contravariance in Generics.

`T11`

The type of the eleventh parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T12`

The type of the twelfth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T13`

The type of the thirteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T14`

The type of the fourteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T15`

The type of the fifteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`T16`

The type of the sixteenth parameter of the method that this delegate encapsulates. This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

`TResult`

The type of the return value of the method that this delegate encapsulates.

This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

`arg1` T1

The first parameter of the method that this delegate encapsulates.

`arg2` T2

The second parameter of the method that this delegate encapsulates.

`arg3` T3

The third parameter of the method that this delegate encapsulates.

`arg4` T4

The fourth parameter of the method that this delegate encapsulates.

`arg5` T5

The fifth parameter of the method that this delegate encapsulates.

`arg6` T6

The sixth parameter of the method that this delegate encapsulates.

`arg7` T7

The seventh parameter of the method that this delegate encapsulates.

`arg8` T8

The eighth parameter of the method that this delegate encapsulates.

`arg9` T9

The ninth parameter of the method that this delegate encapsulates.

`arg10` T10

The tenth parameter of the method that this delegate encapsulates.

`arg11` T11

The eleventh parameter of the method that this delegate encapsulates.

`arg12` T12

The twelfth parameter of the method that this delegate encapsulates.

`arg13` T13

The thirteenth parameter of the method that this delegate encapsulates.

`arg14` T14

The fourteenth parameter of the method that this delegate encapsulates.

`arg15` T15

The fifteenth parameter of the method that this delegate encapsulates.

`arg16` T16

The sixteenth parameter of the method that this delegate encapsulates.

Return Value

TResult

The return value of the method that this delegate encapsulates.

Remarks

You can use this delegate to represent a method that can be passed as a parameter without explicitly declaring a custom delegate. The encapsulated method must correspond to the method signature that is defined by this delegate. This means that the encapsulated method must have 16 parameters, each of which is passed to it by value, and that it must return a value.

> **Note**
>
> To reference a method that has 16 parameters and returns `void` (or in Visual Basic, that is declared as a `Sub` rather than as a `Function`), use the generic **Action<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>** delegate instead.

You can also use the Func<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,TResult> delegate with anonymous methods and lambda expressions.

The underlying type of a lambda expression is one of the generic `Func` delegates. This makes it possible to pass a lambda expression as a parameter without explicitly

assigning it to a delegate.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GC Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Controls the system garbage collector, a service that automatically reclaims unused memory.

C#

```
public static class GC
```

Inheritance Object → GC

Examples

The following example uses several GC methods to get generation and memory information about a block of unused objects and print it to the console. The unused objects are then collected, and the resulting memory totals are displayed.

C#

```
using System;

namespace GCCollectIntExample
{
    class MyGCCollectClass
    {
        private const long maxGarbage = 1000;

        static void Main()
        {
            MyGCCollectClass myGCCol = new MyGCCollectClass();

            // Determine the maximum number of generations the system
        // garbage collector currently supports.
            Console.WriteLine("The highest generation is {0}",
GC.MaxGeneration);

            myGCCol.MakeSomeGarbage();
```

```
            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));

            // Determine the best available approximation of the number
        // of bytes currently allocated in managed memory.
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of generation 0 only.
            GC.Collect(0);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));

            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of all generations up to and including
2.
            GC.Collect(2);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));
            Console.Read();
        }

        void MakeSomeGarbage()
        {
            Version vt;

            for(int i = 0; i < maxGarbage; i++)
            {
                // Create objects and release them to fill up memory
        // with unused objects.
                vt = new Version();
            }
        }
    }
}
```

Remarks

For more information about this API, see Supplemental API remarks for GC.

Properties

Expand table

MaxGeneration	Gets the maximum number of generations that the system currently supports.

Methods

Expand table

AddMemoryPressure(Int64)	Informs the runtime of a large allocation of unmanaged memory that should be taken into account when scheduling garbage collection.
AllocateArray<T>(Int32, Boolean)	Allocates an array.
AllocateUninitializedArray<T>(Int32, Boolean)	Allocates an array while skipping zero-initialization, if possible.
CancelFullGCNotification()	Cancels the registration of a garbage collection notification.
Collect()	Forces an immediate garbage collection of all generations.
Collect(Int32)	Forces an immediate garbage collection from generation 0 through a specified generation.
Collect(Int32, GCCollectionMode)	Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value.
Collect(Int32, GCCollectionMode, Boolean)	Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value, with a value specifying whether the collection should be blocking.
Collect(Int32, GCCollectionMode, Boolean, Boolean)	Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value, with values that specify whether the collection should be blocking and compacting.
CollectionCount(Int32)	Returns the number of times garbage collection has occurred for the specified generation of objects.
EndNoGCRegion()	Ends the no GC region latency mode.
GetAllocatedBytesForCurrentThread()	Gets the total number of bytes allocated to the current thread since the beginning of its lifetime.
GetConfigurationVariables()	Gets the configurations used by the garbage collector.
GetGCMemoryInfo()	Gets garbage collection memory information.

GetGCMemoryInfo(GCKind)	Gets garbage collection memory information.
GetGeneration(Object)	Returns the current generation number of the specified object.
GetGeneration(WeakReference)	Returns the current generation number of the target of a specified weak reference.
GetTotalAllocatedBytes(Boolean)	Gets a count of the bytes allocated over the lifetime of the process. The returned value does not include any native allocations.
GetTotalMemory(Boolean)	Retrieves the heap size excluding fragmentation. For example if the total GC heap size is 100mb and fragmentation, ie, space taken up by free objects, takes up 40mb, this API would report 60mb. A parameter indicates whether this method can wait a short interval before returning, to allow the system to collect garbage and finalize objects.
GetTotalPauseDuration()	Gets the total amount of time paused in GC since the beginning of the process.
KeepAlive(Object)	References the specified object, which makes it ineligible for garbage collection from the start of the current routine to the point where this method is called.
RefreshMemoryLimit()	Instructs the Garbage Collector to reconfigure itself by detecting the various memory limits on the system.
RegisterForFullGCNotification(Int32, Int32)	Specifies that a garbage collection notification should be raised when conditions favor full garbage collection and when the collection has been completed.
RegisterNoGCRegionCallback(Int64, Action)	Registers a callback to be invoked when a certain amount of memory is allocated in the no GC region.
RemoveMemoryPressure(Int64)	Informs the runtime that unmanaged memory has been released and no longer needs to be taken into account when scheduling garbage collection.
