ReRegisterForFinalize(Object)	Requests that the system call the finalizer for the specified object for which SuppressFinalize(Object) has previously been called.
SuppressFinalize(Object)	Requests that the common language runtime not call the finalizer for the specified object.
TryStartNoGCRegion(Int64)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available.
TryStartNoGCRegion(Int64, Boolean)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available, and

	controls whether the garbage collector does a full blocking garbage collection if not enough memory is initially available.
TryStartNoGCRegion(Int64, Int64)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available for the large object heap and the small object heap.
TryStartNoGCRegion(Int64, Int64, Boolean)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available for the large object heap and the small object heap, and controls whether the garbage collector does a full blocking garbage collection if not enough memory is initially available.
WaitForFullGCApproach()	Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.
WaitForFull GCApproach(Int32)	Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.
WaitForFull GCApproach(TimeSpan)	Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.
WaitForFullGCComplete()	Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime has completed.
WaitForFull GCComplete(Int32)	Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by common language the runtime has completed.
WaitForFull GCComplete(TimeSpan)	Returns the status of a registered notification about whether a blocking garbage collection has completed. May wait indefinitely for a full collection.
WaitForPendingFinalizers()	Suspends the current thread until the thread that is processing the queue of finalizers has emptied that queue.

GC.MaxGeneration Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum number of generations that the system currently supports.

C#

```
public static int MaxGeneration { get; }
```

Property Value

Int32

A value that ranges from zero to the maximum number of supported generations.

Examples

The following example demonstrates how to use the MaxGeneration property to display the largest generation number currently in use.

C#

```
using System;

namespace GCCollectIntExample
{
    class MyGCCollectClass
    {
        private const long maxGarbage = 1000;

        static void Main()
        {
            MyGCCollectClass myGCCol = new MyGCCollectClass();

            // Determine the maximum number of generations the system
        // garbage collector currently supports.
            Console.WriteLine("The highest generation is {0}",
GC.MaxGeneration);
```

```
            myGCCol.MakeSomeGarbage();

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));

            // Determine the best available approximation of the number
        // of bytes currently allocated in managed memory.
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of generation 0 only.
            GC.Collect(0);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));

            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of all generations up to and including
2.
            GC.Collect(2);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));
            Console.Read();
        }

        void MakeSomeGarbage()
        {
            Version vt;

            for(int i = 0; i < maxGarbage; i++)
            {
                // Create objects and release them to fill up memory
        // with unused objects.
                vt = new Version();
            }
        }
    }
}
```

Remarks

The generation number, or age, of an object is an implementation-defined relative measure of an object's lifespan. The most recently created objects are in generation 0 and the oldest objects are in a generation less than or equal to the generation returned by the MaxGeneration property.

The garbage collector assumes that newer memory is more likely to be eligible for garbage collection than older memory. Therefore, the garbage collector improves its performance by adjusting generation numbers each time it reclaims memory, and the MaxGeneration property value can grow over time.

If object aging is implemented, the MaxGeneration property returns the maximum generation number used by the system; otherwise, this property returns zero.

For this implementation, the value returned by the MaxGeneration property is guaranteed to remain constant for the lifetime of an executing application.

Use the MaxGeneration property to determine the maximum value you can specify when calling the Collect(Int32) method that takes a generation parameter.

GC.AddMemoryPressure(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Informs the runtime of a large allocation of unmanaged memory that should be taken into account when scheduling garbage collection.

```
C#
public static void AddMemoryPressure (long bytesAllocated);
```

Parameters

`bytesAllocated` Int64

The incremental amount of unmanaged memory that has been allocated.

Exceptions

ArgumentOutOfRangeException

`bytesAllocated` is less than or equal to 0.

-or-

On a 32-bit computer, `bytesAllocated` is larger than Int32.MaxValue.

Remarks

In determining when to schedule garbage collection, the runtime takes into account how much managed memory is allocated. If a small managed object allocates a large amount of unmanaged memory, the runtime takes into account only the managed memory, and thus underestimates the urgency of scheduling garbage collection. The AddMemoryPressure method informs the runtime of this additional pressure on system memory.

The AddMemoryPressure and RemoveMemoryPressure methods improve performance only for types that exclusively depend on finalizers to release the unmanaged resources.

It's not necessary to use these methods in types that follow the dispose pattern, where finalizers are used to clean up unmanaged resources only in the event that a consumer of the type forgets to call `Dispose`. For more information on object finalization and the dispose pattern, see Cleaning Up Unmanaged Resources.

In the simplest usage pattern, a managed object allocates unmanaged memory in the constructor and releases it in the `Finalize` method. Call the AddMemoryPressure method after allocating the unmanaged memory, and call the RemoveMemoryPressure method after releasing it.

In more complicated scenarios, where the unmanaged memory allocation changes substantially during the lifetime of the managed object, you can call the AddMemoryPressure and RemoveMemoryPressure methods to communicate these incremental changes to the runtime.

> **Caution**
>
> You must ensure that you remove exactly the amount of pressure you add. Failing to do so can adversely affect the performance of the system in applications that run for long periods of time.

Applies to

GC.AllocateArray<T>(Int32, Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Allocates an array.

C#

```
public static T[] AllocateArray<T> (int length, bool pinned = false);
```

Type Parameters

T

Specifies the type of the array element.

Parameters

length Int32

Specifies the length of the array.

pinned Boolean

Specifies whether the allocated array must be pinned.

Returns

T[]

An array object.

Remarks

If pinned is set to `true`, `T` must not be a reference type or a type that contains object references.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GC.AllocateUninitializedArray<T>(Int32, Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Allocates an array while skipping zero-initialization, if possible.

C#

```
public static T[] AllocateUninitializedArray<T> (int length, bool pinned =
false);
```

Type Parameters

`T`

Specifies the type of the array element.

Parameters

`length` Int32

Specifies the length of the array.

`pinned` Boolean

Specifies whether the allocated array must be pinned.

Returns

T[]

An array object with uninitialized memory.

Remarks

If pinned is set to `true`, `T` must not be a reference type or a type that contains object references.

Skipping zero-initialization is a security risk. The unitialized array can contain invalid valuetype instances or sensitive information created by other parts of the application. The code operating on unitialized arrays should be heavily scrutinized to ensure that the unitialized data is never read.

Skipping zero-initialization using this API only has a material performance benefit for large arrays, such as buffers of several kilobytes or more.

GC.CancelFullGCNotification Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Cancels the registration of a garbage collection notification.

C#

```
public static void CancelFullGCNotification ();
```

Exceptions

InvalidOperationException

This member is not available when concurrent garbage collection is enabled. See the <gcConcurrent> runtime setting for information about how to disable concurrent garbage collection.

Examples

The following example cancels a garbage collection registration. This example is part of a larger example provided for the Garbage Collection Notifications topic.

C#

```
finalExit = true;
checkForNotify = false;
GC.CancelFullGCNotification();
```

Remarks

This method cancels a garbage collection notification that was registered by using the RegisterForFullGCNotification method. You do not have to call this method before adjusting threshold parameter values in subsequent calls to the RegisterForFullGCNotification method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GC.Collect Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Forces garbage collection.

Overloads

Expand table

Collect()	Forces an immediate garbage collection of all generations.
Collect(Int32)	Forces an immediate garbage collection from generation 0 through a specified generation.
Collect(Int32, GCCollectionMode)	Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value.
Collect(Int32, GCCollectionMode, Boolean)	Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value, with a value specifying whether the collection should be blocking.
Collect(Int32, GCCollectionMode, Boolean, Boolean)	Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value, with values that specify whether the collection should be blocking and compacting.

Collect()

Forces an immediate garbage collection of all generations.

C#

```
public static void Collect ();
```

Examples

The following example demonstrates how to use the Collect method to perform a collection on all generations of memory. The code generates a number of unused objects, and then calls the Collect method to clean them from memory.

C#

```
using System;

class MyGCCollectClass
{
   private const int maxGarbage = 1000;

   static void Main()
   {
      // Put some objects in memory.
      MyGCCollectClass.MakeSomeGarbage();
      Console.WriteLine("Memory used before collection:       {0:N0}",
                        GC.GetTotalMemory(false));

      // Collect all generations of memory.
      GC.Collect();
      Console.WriteLine("Memory used after full collection:   {0:N0}",
                        GC.GetTotalMemory(true));
   }

   static void MakeSomeGarbage()
   {
      Version vt;

      // Create objects and release them to fill up memory with unused
objects.
      for(int i = 0; i < maxGarbage; i++) {
         vt = new Version();
      }
   }
}
// The output from the example resembles the following:
//       Memory used before collection:       79,392
//       Memory used after full collection:   52,640
```

Remarks

Use this method to try to reclaim all memory that is inaccessible. It performs a blocking garbage collection of all generations.

All objects, regardless of how long they have been in memory, are considered for collection; however, objects that are referenced in managed code are not collected. Use this method to force the system to try to reclaim the maximum amount of available memory.

Starting with the .NET Framework 4.5.1, you can compact the large object heap (LOH) by setting the GCSettings.LargeObjectHeapCompactionMode property to GCLargeObjectHeapCompactionMode.CompactOnce before calling the Collect method, as the following example illustrates.

C#

```
GCSettings.LargeObjectHeapCompactionMode =
GCLargeObjectHeapCompactionMode.CompactOnce;
GC.Collect();
```

See also

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Collect(Int32)

Forces an immediate garbage collection from generation 0 through a specified generation.

C#

```
public static void Collect (int generation);
```

Parameters

generation	Int32

The number of the oldest generation to be garbage collected.

Exceptions

ArgumentOutOfRangeException

`generation` is not valid.

Examples

The following example demonstrates how to use the Collect method to perform a collection on individual layers of memory. The code generates a number of unused objects, and then calls the Collect method to clean them from memory.

C#

```
using System;

namespace GCCollectIntExample
{
    class MyGCCollectClass
    {
        private const long maxGarbage = 1000;

        static void Main()
        {
            MyGCCollectClass myGCCol = new MyGCCollectClass();

            // Determine the maximum number of generations the system
        // garbage collector currently supports.
            Console.WriteLine("The highest generation is {0}",
GC.MaxGeneration);

            myGCCol.MakeSomeGarbage();

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}",
GC.GetGeneration(myGCCol));

            // Determine the best available approximation of the number
        // of bytes currently allocated in managed memory.
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of generation 0 only.
            GC.Collect(0);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}",
GC.GetGeneration(myGCCol));
```

```
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of all generations up to and
including 2.
            GC.Collect(2);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}",
GC.GetGeneration(myGCCol));
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));
            Console.Read();
        }

        void MakeSomeGarbage()
        {
            Version vt;

            for(int i = 0; i < maxGarbage; i++)
            {
                // Create objects and release them to fill up memory
        // with unused objects.
                vt = new Version();
            }
        }
    }
}
```

Remarks

Use this method to try to reclaim memory that is inaccessible. However, using this method does not guarantee that all inaccessible memory in the specified generation is reclaimed.

If object aging is implemented, the garbage collector does not collect objects with a generation number that is higher than the specified generation. If object aging is not implemented, the garbage collector considers all objects during the garbage collection.

Use the MaxGeneration property to determine the maximum valid value of the `generation` parameter.

To have the garbage collector consider all objects regardless of their generation, use the version of this method that takes no parameters. To have the garbage collector reclaim objects based on a GCCollectionMode setting, use the GC.Collect(Int32, GCCollectionMode) method overload.

- Induced Collections

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Collect(Int32, GCCollectionMode)

Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value.

```
C#

public static void Collect (int generation, GCCollectionMode mode);
```

Parameters

`generation` Int32

The number of the oldest generation to be garbage collected.

`mode` GCCollectionMode

An enumeration value that specifies whether the garbage collection is forced (Default or Forced) or optimized (Optimized).

Exceptions

ArgumentOutOfRangeException

`generation` is not valid.

-or-

`mode` is not one of the GCCollectionMode values.

Examples

The following example forces a garbage collection for generation 2 objects with the Optimized setting.

C#

```
using System;

class Program
{
    static void Main(string[] args)
    {
        GC.Collect(2, GCCollectionMode.Optimized);
    }
}
```

Remarks

Use the `mode` parameter to specify whether garbage collection should occur immediately or only if the time is optimal to reclaim objects. Using this method does not guarantee that all inaccessible memory in the specified generation is reclaimed.

To adjust the intrusiveness of garbage collection during critical periods in your application, set the LatencyMode property.

The garbage collector does not collect objects with a generation number higher than specified by the `generation` parameter. Use the MaxGeneration property to determine the maximum valid value of `generation`.

To have the garbage collector consider all objects regardless of their generation, use the version of this method that takes no parameters.

To have the garbage collector reclaim objects up to a specified generation of objects, use the GC.Collect(Int32) method overload. When you specify the maximum generation, all objects are collected.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Collect(Int32, GCCollectionMode, Boolean)

Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value, with a value specifying whether the collection should be blocking.

C#

```
public static void Collect (int generation, GCCollectionMode mode, bool
blocking);
```

Parameters

`generation` Int32

The number of the oldest generation to be garbage collected.

`mode` GCCollectionMode

An enumeration value that specifies whether the garbage collection is forced (Default or Forced) or optimized (Optimized).

`blocking` Boolean

`true` to perform a blocking garbage collection; `false` to perform a background garbage collection where possible.

Exceptions

ArgumentOutOfRangeException

`generation` is not valid.

-or-

`mode` is not one of the GCCollectionMode values.

Remarks

The following table summarizes the interaction of the `mode` and `blocking` parameters:

Expand table

`mode`	`blocking` is `true`	`blocking` is `false`
Forced or Default	A blocking collection is performed as soon as possible. If a background collection is in progress and `generation` is 0 or 1, the Collect(Int32, GCCollectionMode, Boolean) method immediately triggers a blocking collection and returns when the collection is finished. If a background collection is in progress and `generation` is 2, the method waits until the background collection is finished, triggers a blocking generation 2 collection, and then returns.	A collection is performed as soon as possible. The Collect(Int32, GCCollectionMode, Boolean) method requests a background collection, but this is not guaranteed; depending on the circumstances, a blocking collection may still be performed. If a background collection is already in progress, the method returns immediately.
Optimized	A blocking collection may be performed, depending on the state of the garbage collector and the `generation` parameter. The garbage collector tries to provide optimal performance.	A collection may be performed, depending on the state of the garbage collector. The Collect(Int32, GCCollectionMode, Boolean) method requests a background collection, but this is not guaranteed; depending on the circumstances, a blocking collection may still be performed. The garbage collector tries to provide optimal performance. If a background collection is already in progress, the method returns immediately.

If a call to the Collect(Int32, GCCollectionMode, Boolean) method performs a full blocking garbage collection, you can also compact the large object heap by setting the GCSettings.LargeObjectHeapCompactionMode property to

GCLargeObjectHeapCompactionMode.CompactOnce before calling the Collect method.

UWP	10.0

Collect(Int32, GCCollectionMode, Boolean, Boolean)

Forces a garbage collection from generation 0 through a specified generation, at a time specified by a GCCollectionMode value, with values that specify whether the collection should be blocking and compacting.

C#

```
public static void Collect (int generation, GCCollectionMode mode, bool
blocking, bool compacting);
```

Parameters

`generation` Int32

The number of the oldest generation to be garbage collected.

`mode` GCCollectionMode

An enumeration value that specifies whether the garbage collection is forced (Default or Forced) or optimized (Optimized).

`blocking` Boolean

`true` to perform a blocking garbage collection; `false` to perform a background garbage collection where possible.

`compacting` Boolean

`true` to compact the small object heap; `false` to sweep only.

Remarks

If `blocking` is `false`, the GC decides whether to perform a background or a blocking garbage collection. If `compacting` is `true`, it performs a blocking garbage collection.

If `compacting` is `true`, the runtime compacts the small object heap (SOH). The large object heap (LOH) is not compacted unless the GCSettings.LargeObjectHeapCompactionMode property is set to GCLargeObjectHeapCompactionMode.CompactOnce. Note that this includes all blocking garbage collections, not just full blocking garbage collections.

You can call the Collect(Int32, GCCollectionMode, Boolean, Boolean) method to reduce the managed heap to the smallest size possible, as the following code fragment illustrates.

```
C#

GCSettings.LargeObjectHeapCompactionMode =
GCLargeObjectHeapCompactionMode.CompactOnce;
GC.Collect(2, GCCollectionMode.Forced, true, true);
```

Specifying `true` for the `compacting` argument guarantees a compacting, full blocking garbage collection. Setting the GCSettings.LargeObjectHeapCompactionMode property to GCLargeObjectHeapCompactionMode.CompactOnce ensures that both the LOH and SOH are compacted.

Applies to

▼ .NET 9 and other versions

Product	Versions

GC.CollectionCount(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the number of times garbage collection has occurred for the specified generation of objects.

```
C#
public static int CollectionCount (int generation);
```

Parameters

`generation` Int32

The generation of objects for which the garbage collection count is to be determined.

Returns

Int32

The number of times garbage collection has occurred for the specified generation since the process was started.

Exceptions

ArgumentOutOfRangeException

`generation` is less than 0.

Remarks

If you implement your own resource management, you might need to force garbage collection periodically by calling the Collect method. Because this is an expensive operation, you can improve performance by skipping the call when a garbage collection has occurred recently. Save the value returned by CollectionCount immediately after calling Collect. The next time you need to call Collect, compare the current value

returned by CollectionCount to the saved value. If the two values are equal, no collection has occurred in the interim and it is reasonable to call Collect again.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

GC.EndNoGCRegion Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Ends the no GC region latency mode.

C#

```
public static void EndNoGCRegion ();
```

Exceptions

InvalidOperationException

The garbage collector is not in no GC region latency mode.

-or-

The no GC region latency mode was ended previously because a garbage collection was induced.

-or-

A memory allocation exceeded the amount specified in the call to the TryStartNoGCRegion(Int64) method.

Remarks

The EndNoGCRegion method throws an InvalidOperationException if the garbage collector is not in no GC region latency mode. This occurs under any of the following conditions:

- The TryStartNoGCRegion method was not called previously.
- The call to the TryStartNoGCRegion method returned `false`.
- The call to the TryStartNoGCRegion method threw an exception.

You can prevent an exception for any of these reasons by using code such as the following:

```C#
if (GCSettings.LatencyMode == GCLatencyMode.NoGCRegion)
   GC.EndNoGCRegion();
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GC.GetAllocatedBytesForCurrentThread Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total number of bytes allocated to the current thread since the beginning of its lifetime.

C#

```
public static long GetAllocatedBytesForCurrentThread ();
```

Returns

Int64

The total number of bytes allocated to the current thread since the beginning of its lifetime.

Remarks

The `GetAllocatedBytesForCurrentThread` method returns the total number of bytes allocated on the managed heap during the lifetime of a thread, not the total number of bytes that have survived garbage collection. The returned value also does not include any native allocations.

This method is most useful in monitoring scenarios for measuring the difference in memory allocation between time intervals or events.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.8, 4.8.1
.NET Standard	2.1

GC.GetConfigurationVariables Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the configurations used by the garbage collector.

C#

```
public static System.Collections.Generic.IReadOnlyDictionary<string,object>
GetConfigurationVariables ();
```

Returns

IReadOnlyDictionary<String,Object>

A read-only dictionary with the configuration names and values as the keys and values of the dictionary, respectively.

Remarks

The value of these configurations don't necessarily have to be the same as the ones that are passed by the user. For example, for the `GCHeapCount` configuration, if the user supplies a value higher than the number of CPUs, the configuration that's used is that of the number of CPUs.

Applies to

Product	Versions
.NET	7, 8, 9

GC.GetGCMemoryInfo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetGCMemoryInfo()	Gets garbage collection memory information.
GetGCMemoryInfo(GCKind)	Gets garbage collection memory information.

GetGCMemoryInfo()

Gets garbage collection memory information.

C#

```
public static GCMemoryInfo GetGCMemoryInfo ();
```

Returns

GCMemoryInfo

An object that contains information about the garbage collector's memory usage.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

GetGCMemoryInfo(GCKind)

Gets garbage collection memory information.

```
C#
public static GCMemoryInfo GetGCMemoryInfo (GCKind kind);
```

Parameters

`kind` GCKind

The kind of collection for which to retrieve memory information.

Returns

GCMemoryInfo

An object that contains information about the garbage collector's memory usage.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GC.GetGeneration Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the current generation number of an object.

Overloads

Expand table

GetGeneration(Object)	Returns the current generation number of the specified object.
GetGeneration(WeakReference)	Returns the current generation number of the target of a specified weak reference.

GetGeneration(Object)

Returns the current generation number of the specified object.

C#

```
public static int GetGeneration (object obj);
```

Parameters

`obj` Object

The object that generation information is retrieved for.

Returns

Int32

The current generation number of `obj`, or Int32.MaxValue.

Examples

The following example demonstrates how to use the GetGeneration method to determine the age of an object. The example then performs garbage collections to clean up memory and compare the pre and post collection memory totals in the console.

C#

```
using System;

namespace GCCollectIntExample
{
    class MyGCCollectClass
    {
        private const long maxGarbage = 1000;

        static void Main()
        {
            MyGCCollectClass myGCCol = new MyGCCollectClass();

            // Determine the maximum number of generations the system
        // garbage collector currently supports.
            Console.WriteLine("The highest generation is {0}",
GC.MaxGeneration);

            myGCCol.MakeSomeGarbage();

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}",
GC.GetGeneration(myGCCol));

            // Determine the best available approximation of the number
        // of bytes currently allocated in managed memory.
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of generation 0 only.
            GC.Collect(0);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}",
GC.GetGeneration(myGCCol));

            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of all generations up to and
including 2.
            GC.Collect(2);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}",
GC.GetGeneration(myGCCol));
            Console.WriteLine("Total Memory: {0}",
```

```
GC.GetTotalMemory(false));
            Console.Read();
        }

        void MakeSomeGarbage()
        {
            Version vt;

            for(int i = 0; i < maxGarbage; i++)
            {
                // Create objects and release them to fill up memory
        // with unused objects.
                vt = new Version();
            }
        }
    }
}
```

Remarks

Use this method to determine the age of an object, and then use that information with the Collect method to force the garbage collector to collect objects in the same generation. For example, use this method when you have a set of objects that are created as a group and that become inaccessible at the same time.

Starting in .NET 8, this method might return MaxValue for objects allocated on non-GC heaps. For more information, see GC.GetGeneration might return Int32.MaxValue.

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetGeneration(WeakReference)

Returns the current generation number of the target of a specified weak reference.

```
C#

public static int GetGeneration (WeakReference wo);
```

Parameters

wo WeakReference

A WeakReference that refers to the target object whose generation number is to be determined.

Returns

Int32

The current generation number of the target of `wo`, or MaxValue.

Exceptions

ArgumentException

Garbage collection has already been performed on `wo`.

ArgumentNullException

The target of the weak reference has already been garbage collected.

Examples

The following example demonstrates the use of the GetGeneration method to determine the age of a weak reference object.

```
C#

using System;

namespace GCGetGenerationWeakExample
{
    public class MyGCCollectClass
    {
        private const long maxGarbage = 1000;

        static void Main()
```

```
        {
            // Create a strong reference to an object.
            MyGCCollectClass myGCCol = new MyGCCollectClass();

            // Put some objects in memory.
            myGCCol.MakeSomeGarbage();

            // Get the generation of managed memory where myGCCol is
stored.
            Console.WriteLine("The object is in generation: {0}",
GC.GetGeneration(myGCCol));

            // Perform a full garbage collection.
            // Because there is a strong reference to myGCCol, it will
            // not be garbage collected.
            GC.Collect();

            // Get the generation of managed memory where myGCCol is
stored.
            Console.WriteLine("The object is in generation: {0}",
GC.GetGeneration(myGCCol));

            // Create a WeakReference to myGCCol.
            WeakReference wkref = new WeakReference(myGCCol);
            // Remove the strong reference to myGCCol.
            myGCCol = null;

            // Get the generation of managed memory where wkref is
stored.
            Console.WriteLine("The WeakReference to the object is in
generation: {0}", GC.GetGeneration(wkref));

            // Perform another full garbage collection.
            // A WeakReference will not survive a garbage collection.
            GC.Collect();

            // Try to get the generation of managed memory where wkref is
stored.
            // Because it has been collected, an exception will be
thrown.
            try
            {
                Console.WriteLine("The WeakReference to the object is in
generation: {0}", GC.GetGeneration(wkref));
                Console.Read();
            }
            catch(Exception e)
            {
                Console.WriteLine("The WeakReference to the object has
been garbage collected: '{0}'", e);
                Console.Read();
            }
        }

        void MakeSomeGarbage()
```

```
        {
            Version vt;

            for(int i = 0; i < maxGarbage; i++)
            {
                // Create objects and release them to fill up memory
                // with unused objects.
                vt = new Version();
            }
        }
    }
}
```

Remarks

Starting in .NET 8, this method might return MaxValue for objects allocated on non-GC heaps. For more information, see GC.GetGeneration might return Int32.MaxValue.

GC.GetTotalAllocatedBytes(Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a count of the bytes allocated over the lifetime of the process. The returned value does not include any native allocations.

C#

```
public static long GetTotalAllocatedBytes (bool precise = false);
```

Parameters

`precise` Boolean

If `true`, gather a precise number; otherwise, gather an approximate count. Gathering a precise value entails a significant performance penalty.

Returns

Int64

The total number of bytes allocated over the lifetime of the process.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

GC.GetTotalMemory(Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves the heap size excluding fragmentation. For example if the total GC heap size is 100mb and fragmentation, ie, space taken up by free objects, takes up 40mb, this API would report 60mb. A parameter indicates whether this method can wait a short interval before returning, to allow the system to collect garbage and finalize objects.

```
C#

public static long GetTotalMemory (bool forceFullCollection);
```

Parameters

`forceFullCollection` Boolean

`true` to indicate that this method can wait for garbage collection to occur before returning; otherwise, `false`.

Returns

Int64

The heap size, in bytes, excluding fragmentation.

Examples

The following example demonstrates how to use the GetTotalMemory method to get and display the number of bytes currently allocated in managed memory.

```
C#

using System;

namespace GCCollectIntExample
{
    class MyGCCollectClass
```

```
    {
        private const long maxGarbage = 1000;

        static void Main()
        {
            MyGCCollectClass myGCCol = new MyGCCollectClass();

            // Determine the maximum number of generations the system
        // garbage collector currently supports.
            Console.WriteLine("The highest generation is {0}",
GC.MaxGeneration);

            myGCCol.MakeSomeGarbage();

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));

            // Determine the best available approximation of the number
        // of bytes currently allocated in managed memory.
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of generation 0 only.
            GC.Collect(0);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));

            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));

            // Perform a collection of all generations up to and including
2.
            GC.Collect(2);

            // Determine which generation myGCCol object is stored in.
            Console.WriteLine("Generation: {0}", GC.GetGeneration(myGCCol));
            Console.WriteLine("Total Memory: {0}",
GC.GetTotalMemory(false));
            Console.Read();
        }

        void MakeSomeGarbage()
        {
            Version vt;

            for(int i = 0; i < maxGarbage; i++)
            {
                // Create objects and release them to fill up memory
        // with unused objects.
                vt = new Version();
            }
        }
    }
}
```

Remarks

If the `forceFullCollection` parameter is `true`, this method waits a short interval before returning while the system collects garbage and finalizes objects. The duration of the interval is an internally specified limit determined by the number of garbage collection cycles completed and the change in the amount of memory recovered between cycles. The garbage collector does not guarantee that all inaccessible memory is collected.

GC.KeepAlive(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

References the specified object, which makes it ineligible for garbage collection from the start of the current routine to the point where this method is called.

C#

```
public static void KeepAlive (object? obj);
```

Parameters

obj Object

The object to reference.

Examples

The following code example creates an object at the beginning of its `Main` method and does not refer to the object again until the end, when the KeepAlive method is called. The object persists for the 30-second duration of the `Main` method, despite calls to the Collect and WaitForPendingFinalizers methods.

C#

```
using System;
using System.Threading;
using System.Runtime.InteropServices;

// A simple class that exposes two static Win32 functions.
// One is a delegate type and the other is an enumerated type.
public class MyWin32
{
    // Declare the SetConsoleCtrlHandler function
    // as external and receiving a delegate.
    [DllImport("Kernel32")]
    public static extern Boolean SetConsoleCtrlHandler(HandlerRoutine
Handler,
        Boolean Add);
```

```
    // A delegate type to be used as the handler routine
    // for SetConsoleCtrlHandler.
    public delegate Boolean HandlerRoutine(CtrlTypes CtrlType);

    // An enumerated type for the control messages
    // sent to the handler routine.
    public enum CtrlTypes
    {
        CTRL_C_EVENT = 0,
        CTRL_BREAK_EVENT,
        CTRL_CLOSE_EVENT,
        CTRL_LOGOFF_EVENT = 5,
        CTRL_SHUTDOWN_EVENT
    }
}

public class MyApp
{
    // A private static handler function in the MyApp class.
    static Boolean Handler(MyWin32.CtrlTypes CtrlType)
    {
        String message = "This message should never be seen!";

        // A switch to handle the event type.
        switch(CtrlType)
        {
            case MyWin32.CtrlTypes.CTRL_C_EVENT:
                message = "A CTRL_C_EVENT was raised by the user.";
                break;
            case MyWin32.CtrlTypes.CTRL_BREAK_EVENT:
                message = "A CTRL_BREAK_EVENT was raised by the user.";
                break;
            case MyWin32.CtrlTypes.CTRL_CLOSE_EVENT:
                message = "A CTRL_CLOSE_EVENT was raised by the user.";
                break;
            case MyWin32.CtrlTypes.CTRL_LOGOFF_EVENT:
                message = "A CTRL_LOGOFF_EVENT was raised by the user.";
                break;
            case MyWin32.CtrlTypes.CTRL_SHUTDOWN_EVENT:
                message = "A CTRL_SHUTDOWN_EVENT was raised by the user.";
                break;
        }

        // Use interop to display a message for the type of event.
        Console.WriteLine(message);

        return true;
    }

    public static void Main()
    {

        // Use interop to set a console control handler.
        MyWin32.HandlerRoutine hr = new MyWin32.HandlerRoutine(Handler);
```

```
        MyWin32.SetConsoleCtrlHandler(hr, true);

        // Give the user some time to raise a few events.
        Console.WriteLine("Waiting 30 seconds for console ctrl events...");

        // The object hr is not referred to again.
        // The garbage collector can detect that the object has no
        // more managed references and might clean it up here while
        // the unmanaged SetConsoleCtrlHandler method is still using it.

        // Force a garbage collection to demonstrate how the hr
        // object will be handled.
        GC.Collect();
        GC.WaitForPendingFinalizers();
        GC.Collect();

        Thread.Sleep(30000);

        // Display a message to the console when the unmanaged method
        // has finished its work.
        Console.WriteLine("Finished!");

        // Call GC.KeepAlive(hr) at this point to maintain a reference to
hr.
        // This will prevent the garbage collector from collecting the
        // object during the execution of the SetConsoleCtrlHandler method.
        GC.KeepAlive(hr);
        Console.Read();
    }
}
```

Remarks

The purpose of the KeepAlive method is to ensure the existence of a reference to an object that is at risk of being prematurely reclaimed by the garbage collector. A common scenario where this might happen is when there are no references to the object in managed code or data, but the object is still in use in unmanaged code such as Windows APIs, unmanaged DLLs, or methods using COM.

This method references the `obj` parameter, making that object ineligible for garbage collection from the start of the routine to the point, in execution order, where this method is called. Code this method at the end, not the beginning, of the range of instructions where `obj` must be available.

The KeepAlive method performs no operation and produces no side effects other than extending the lifetime of the object passed in as a parameter.

GC.RefreshMemoryLimit Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Instructs the Garbage Collector to reconfigure itself by detecting the various memory limits on the system.

C#

```
public static void RefreshMemoryLimit ();
```

Exceptions

InvalidOperationException

The hard limit is too low. This can happen if the heap hard limit that the refresh will set, either because of new AppData settings or implied by the container memory-limit changes, is lower than what's already committed.

-or-

The hard limit is invalid. This can happen, for example, with negative heap hard-limit percentages.

Remarks

In addition to actual physical memory limit and container-limit settings, these configuration settings can be overwritten:

```
    - GCHeapHardLimit
    - GCHeapHardLimitPercent
    - GCHeapHardLimitSOH
    - GCHeapHardLimitLOH
    - GCHeapHardLimitPOH
    - GCHeapHardLimitSOHPercent
    - GCHeapHardLimitLOHPercent
    - GCHeapHardLimitPOHPercent
```

Instead of updating the environment variable (which won't be read), these override these settings by using a ulong value in the AppContext.

For example, you can use `AppContext.SetData("GCHeapHardLimit", (ulong) 100 * 1024 * 1024)` to override the GCHeapHardLimit to 100M.

This API only handles configs that can be handled when the runtime is loaded. For configs that don't have any effects on 32-bit systems (like the GCHeapHardLimit* ones), this API will not handle it.

GC.RegisterForFullGCNotification(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies that a garbage collection notification should be raised when conditions favor full garbage collection and when the collection has been completed.

C#

```
public static void RegisterForFullGCNotification (int
maxGenerationThreshold, int largeObjectHeapThreshold);
```

Parameters

`maxGenerationThreshold` Int32

A number between 1 and 99 that specifies when the notification should be raised based on the objects allocated in generation 2.

`largeObjectHeapThreshold` Int32

A number between 1 and 99 that specifies when the notification should be raised based on objects allocated in the large object heap.

Exceptions

ArgumentOutOfRangeException

`maxGenerationThreshold` or `largeObjectHeapThreshold` is not between 1 and 99.

InvalidOperationException

This member is not available when concurrent garbage collection is enabled. See the <gcConcurrent> runtime setting for information about how to disable concurrent garbage collection.

Examples

The following example shows how to register a garbage collection notification and start a thread to monitor the status of the garbage collection notification. This code example is part of a larger example provided for Garbage Collection Notifications topic.

C#

```
using System;
using System.Collections.Generic;
using System.Threading;

namespace GCNotify
{
    class Program
    {
        // Variable for continual checking in the
        // While loop in the WaitForFullGCProc method.
        static bool checkForNotify = false;

        // Variable for suspending work
        // (such servicing allocated server requests)
        // after a notification is received and then
        // resuming allocation after inducing a garbage collection.
        static bool bAllocate = false;

        // Variable for ending the example.
        static bool finalExit = false;

        // Collection for objects that
        // simulate the server request workload.
        static List<byte[]> load = new List<byte[]>();

        public static void Main(string[] args)
        {
            try
            {
                // Register for a notification.
                GC.RegisterForFullGCNotification(10, 10);
                Console.WriteLine("Registered for GC notification.");

                checkForNotify = true;
                bAllocate = true;

                // Start a thread using WaitForFullGCProc.
                Thread thWaitForFullGC = new Thread(new
ThreadStart(WaitForFullGCProc));
                thWaitForFullGC.Start();

                // While the thread is checking for notifications in
                // WaitForFullGCProc, create objects to simulate a server
workload.
                try
                {
```

```
                    int lastCollCount = 0;
                    int newCollCount = 0;

                    while (true)
                    {
                        if (bAllocate)
                        {
                            load.Add(new byte[1000]);
                            newCollCount = GC.CollectionCount(2);
                            if (newCollCount != lastCollCount)
                            {
                                // Show collection count when it increases:
                                Console.WriteLine("Gen 2 collection count:
{0}", GC.CollectionCount(2).ToString());
                                lastCollCount = newCollCount;
                            }

                            // For ending the example (arbitrary).
                            if (newCollCount == 500)
                            {
                                finalExit = true;
                                checkForNotify = false;
                                break;
                            }
                        }
                    }
                }
                catch (OutOfMemoryException)
                {
                    Console.WriteLine("Out of memory.");

                    }
                }

                Thread.Sleep(500);
                // FinalExit is set to true right before
                // the main thread cancelled notification.
                if (finalExit)
                {
                    break;
                }
            }
        }

        private static void RedirectRequests()
        {
            // Code that sends requests
            // to other servers.

            // Suspend work.
            bAllocate = false;
        }

        private static void FinishExistingRequests()
        {
            // Code that waits a period of time
            // for pending requests to finish.

            // Clear the simulated workload.
            load.Clear();
        }

        private static void AcceptRequests()
        {
            // Code that resumes processing
            // requests on this server.

            // Resume work.
            bAllocate = true;
        }
```

```
    }
}
```

Remarks

For each generation, the garbage collector sets a threshold for allocations into that generation. When the size of allocations exceeds this threshold, a garbage collection is triggered on that generation. For example, if generation 2's threshold is 20MB (which means that 20MB survives generation 1 collections and is promoted into generation 2), and more than 20MB has survived generation 1 and is prompted into generation 2, the next garbage collection will be attempted as a generation 2 collection. Similarly, if the large object heap's (LOH's) threshold is 20MB and your app has allocated more than 20MB of large objects, the next garbage collection will also be attempted as a generation 2 collection (since the LOH is only collected in gen2 garbage collections).

The `maxGenerationThreshold` and `largeObjectHeapThreshold` thresholds control how much in advance you are notified before a full garbage collection occurs. The greater the threshold, the more allocations that can occur between notification and the next full garbage collection.

If you have situations in which a full garbage collection by the common language runtime would adversely affect your application's performance, you can ask to be notified when the runtime is about to do a full garbage collection and circumvent that collection by inducing a collection yourself (using the Collect method) when conditions are still favorable. In addition to changing the garbage collection schedule yourself, full GC notification is useful in following the scenarios:

- You monitor for the approach of a full garbage collection and, when you are notified that one is approaching, you reduce live data size (for example, by releasing some cache entries). As a result, when the garbage collection occurs, it is able to reclaim more memory.

- You monitor for the completion of a full garbage collection so that you can collect some statistics. For example, you might want to measure the size of the heap at GC completion so that you know the size of live data. (After a full GC, the heap is at its smallest size.)

For more information about what represents a full garbage collection, see Garbage Collection Notifications.

When you register for a garbage collection notification, you can be notified when a full garbage collection is approaching and when it is completed. This pattern resembles how

the operating system monitors for low memory notifications.

Use the following guidelines for specifying the `maxGenerationThreshold` and `largeObjectHeapThreshold` parameters:

- The larger the threshold value, the more allocations will occur between the notification and the full garbage collection.

  A larger threshold value provides more opportunities for the runtime to check for an approaching collection. This increases the likelihood that you will be notified. However, you should not set the threshold too high because that results in a more allocations before the runtime induces the next collection.

  When you induce a collection yourself upon notification using a high threshold value, fewer objects are reclaimed than would be reclaimed by the runtime's next collection.

- The smaller the threshold value, the fewer the allocations between notification and the full garbage collection.

GC.RegisterNoGCRegionCallback(Int64, Action) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Registers a callback to be invoked when a certain amount of memory is allocated in the no GC region.

C#

```
public static void RegisterNoGCRegionCallback (long totalSize, Action
callback);
```

Parameters

`totalSize` Int64

The total size of the no GC region.

`callback` Action

The callback to be executed when a certain amount of memory is allocated in the no GC region.

Exceptions

ArgumentOutOfRangeException

`totalSize` is less than or equal to 0.

ArgumentNullException

The `callback` argument is `null`.

InvalidOperationException

The GC is not currently under a NoGC region.

-or-

Another callback is already registered.

-or-

The `totalSize` exceeds the size of the No GC region.

-or-

The operation to withhold memory for the callback failed.

GC.RemoveMemoryPressure(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Informs the runtime that unmanaged memory has been released and no longer needs to be taken into account when scheduling garbage collection.

```
C#
public static void RemoveMemoryPressure (long bytesAllocated);
```

Parameters

`bytesAllocated` Int64

The amount of unmanaged memory that has been released.

Exceptions

ArgumentOutOfRangeException

`bytesAllocated` is less than or equal to 0.

-or-

On a 32-bit computer, `bytesAllocated` is larger than Int32.MaxValue.

Remarks

In determining when to schedule garbage collection, the runtime takes into account how much managed memory is allocated. If a small managed object allocates a large amount of unmanaged memory, the runtime takes into account only the managed memory, and thus underestimates the urgency of scheduling garbage collection. The AddMemoryPressure method informs the runtime of this additional pressure on system memory, and the RemoveMemoryPressure method informs the runtime that the additional pressure has been released.

The AddMemoryPressure and RemoveMemoryPressure methods improve performance only for types that exclusively depend on finalizers to release the unmanaged resources. It's not necessary to use these methods in types that follow the dispose pattern, where finalizers are used to clean up unmanaged resources only in the event that a consumer of the type forgets to call `Dispose`. For more information on object finalization and the dispose pattern, see Cleaning Up Unmanaged Resources.

In the simplest usage pattern, a managed object allocates unmanaged memory in the constructor and releases it in the `Finalize` method. Call the AddMemoryPressure method after allocating the unmanaged memory, and call the RemoveMemoryPressure method after releasing it.

In more complicated scenarios, where the unmanaged memory allocation changes substantially during the lifetime of the managed object, you can call the AddMemoryPressure and RemoveMemoryPressure methods to communicate these incremental changes to the runtime.

> **Caution**
>
> You must ensure that you remove exactly the amount of pressure you add. Failing to do so can adversely affect the performance of the system in applications that run for long periods of time.

GC.ReRegisterForFinalize(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Requests that the system call the finalizer for the specified object for which SuppressFinalize(Object) has previously been called.

C#

```
public static void ReRegisterForFinalize (object obj);
```

Parameters

obj Object

The object that a finalizer must be called for.

Exceptions

ArgumentNullException

`obj` is `null`.

Examples

The following example demonstrates how to use the ReRegisterForFinalize method to finalize an object a second time after garbage collection.

C#

```
using System;

namespace ReRegisterForFinalizeExample
{
    class MyMainClass
    {
        static void Main()
        {
```

```
            // Create a MyFinalizeObject.
            MyFinalizeObject mfo = new MyFinalizeObject();

            // Release the reference to mfo.
            mfo = null;

            // Force a garbage collection.
            GC.Collect();

            // At this point mfo will have gone through the first Finalize.
            // There should now be a reference to mfo in the static
            // MyFinalizeObject.currentInstance field.  Setting this value
            // to null and forcing another garbage collection will now
            // cause the object to Finalize permanently.
            MyFinalizeObject.currentInstance = null;
            GC.Collect();
        }
    }

    class MyFinalizeObject
    {
        public static MyFinalizeObject currentInstance = null;
        private bool hasFinalized = false;

        ~MyFinalizeObject()
        {
            if(hasFinalized == false)
            {
                Console.WriteLine("First finalization");

                // Put this object back into a root by creating
                // a reference to it.
                MyFinalizeObject.currentInstance = this;

                // Indicate that this instance has finalized once.
                hasFinalized = true;

                // Place a reference to this object back in the
                // finalization queue.
                GC.ReRegisterForFinalize(this);
            }
            else
            {
                Console.WriteLine("Second finalization");
            }
        }
    }
}
```

Remarks

The ReRegisterForFinalize method adds the `obj` parameter to the list of objects that request finalization before the garbage collector frees the object. The `obj` parameter must be the caller of this method.

Calling the ReRegisterForFinalize method does not guarantee that the garbage collector will call an object's finalizer.

By default, all objects that implement finalizers are added to the list of objects that require finalization; however, an object might have already been finalized or might have disabled finalization by calling the SuppressFinalize method.

A finalizer can use this method to resurrect itself or an object that it references.

GC.SuppressFinalize(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Requests that the common language runtime not call the finalizer for the specified object.

```
C#

public static void SuppressFinalize (object obj);
```

Parameters

obj Object

The object whose finalizer must not be executed.

Exceptions

ArgumentNullException

`obj` is `null`.

Examples

The following example demonstrates how to use the SuppressFinalize method in a resource class to prevent a redundant garbage collection from being called. The example uses the dispose pattern to free both managed resources (that is, objects that implement IDisposable) and unmanaged resources.

```
C#

using System;
using System.ComponentModel;
using System.Runtime.InteropServices;

public class ConsoleMonitor : IDisposable
{
   const int STD_INPUT_HANDLE = -10;
   const int STD_OUTPUT_HANDLE = -11;
```

```
   const int STD_ERROR_HANDLE = -12;

   [DllImport("kernel32.dll", SetLastError = true)]
   static extern IntPtr GetStdHandle(int nStdHandle);

   [DllImport("kernel32.dll", SetLastError = true)]
   static extern bool WriteConsole(IntPtr hConsoleOutput, string lpBuffer,
          uint nNumberOfCharsToWrite, out uint lpNumberOfCharsWritten,
          IntPtr lpReserved);

   [DllImport("kernel32.dll", SetLastError = true)]
   static extern bool CloseHandle(IntPtr handle);

   private bool disposed = false;
   private IntPtr handle;
   private Component component;

   public ConsoleMonitor()
   {
      handle = GetStdHandle(STD_OUTPUT_HANDLE);
      if (handle == IntPtr.Zero)
         throw new InvalidOperationException("A console handle is not
available.");

      component = new Component();

      string output = "The ConsoleMonitor class constructor.\n";
      uint written = 0;
      WriteConsole(handle, output, (uint) output.Length, out written,
IntPtr.Zero);
   }

   // The finalizer represents Object.Finalize override.
   ~ConsoleMonitor()
   {
      if (handle != IntPtr.Zero) {
         string output = "The ConsoleMonitor finalizer.\n";
         uint written = 0;
         WriteConsole(handle, output, (uint) output.Length, out written,
IntPtr.Zero);
      }
      else {
         Console.Error.WriteLine("Object finalization.");
      }
      Dispose(disposing: false);
   }

   public void Write()
   {
      string output = "The Write method.\n";
      uint written = 0;
      WriteConsole(handle, output, (uint) output.Length, out written,
IntPtr.Zero);
   }
```

```
   public void Dispose()
   {
      string output = "The Dispose method.\n";
      uint written = 0;
      WriteConsole(handle, output, (uint) output.Length, out written,
IntPtr.Zero);

      Dispose(disposing: true);
      GC.SuppressFinalize(this);
   }

   private void Dispose(bool disposing)
   {
      string output = String.Format("The Dispose({0}) method.\n",
disposing);
      uint written = 0;
      WriteConsole(handle, output, (uint) output.Length, out written,
IntPtr.Zero);

      // Execute if resources have not already been disposed.
      if (! disposed) {
         // If the call is from Dispose, free managed resources.
         if (disposing) {
            Console.Error.WriteLine("Disposing of managed resources.");
            if (component != null)
               component.Dispose();
         }
         // Free unmanaged resources.
         output = "Disposing of unmanaged resources.";
         WriteConsole(handle, output, (uint) output.Length, out written,
IntPtr.Zero);

         if (handle != IntPtr.Zero) {
            if (! CloseHandle(handle))
               Console.Error.WriteLine("Handle cannot be closed.");
         }
      }
      disposed = true;
   }
}

public class Example
{
   public static void Main()
   {
      Console.WriteLine("ConsoleMonitor instance....");
      ConsoleMonitor monitor = new ConsoleMonitor();
      monitor.Write();
      monitor.Dispose();
   }
}
// If the monitor.Dispose method is not called, the example displays the
following output:
//       ConsoleMonitor instance....
//       The ConsoleMonitor class constructor.
```

```
//       The Write method.
//       The ConsoleMonitor finalizer.
//       The Dispose(False) method.
//       Disposing of unmanaged resources.
//
// If the monitor.Dispose method is called, the example displays the
following output:
//       ConsoleMonitor instance....
//       The ConsoleMonitor class constructor.
//       The Write method.
//       The Dispose method.
//       The Dispose(True) method.
//       Disposing of managed resources.
//       Disposing of unmanaged resources.
```

Remarks

This method sets a bit in the object header of `obj`, which the runtime checks when calling finalizers. A finalizer, which is represented by the Object.Finalize method, is used to release unmanaged resources before an object is garbage-collected. If `obj` does not have a finalizer or the GC has already signaled the finalizer thread to run the finalizer, the call to the SuppressFinalize method has no effect.

Objects that implement the IDisposable interface can call this method from the object's IDisposable.Dispose implementation to prevent the garbage collector from calling Object.Finalize on an object that does not require it. Typically, this is done to prevent the finalizer from releasing unmanaged resources that have already been freed by the IDisposable.Dispose implementation.

GC.TryStartNoGCRegion Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Attempts to disallow garbage collection during the execution of a critical path.

Overloads

Expand table

TryStartNoGCRegion(Int64, Int64, Boolean)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available for the large object heap and the small object heap, and controls whether the garbage collector does a full blocking garbage collection if not enough memory is initially available.
TryStartNoGCRegion(Int64, Int64)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available for the large object heap and the small object heap.
TryStartNoGCRegion(Int64, Boolean)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available, and controls whether the garbage collector does a full blocking garbage collection if not enough memory is initially available.
TryStartNoGCRegion(Int64)	Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available.

Remarks

Important

You cannot nest calls to the **TryStartNoGCRegion** method, and you should only call the **EndNoGCRegion** method if the runtime is currently in no GC region latency mode. In other words, you should not call **TryStartNoGCRegion** multiple times (after the first method call, subsequent calls will not succeed), and you should not

expect calls to **EndNoGCRegion** to succeed just because the first call to **TryStartNoGCRegion** succeeded.

TryStartNoGCRegion(Int64, Int64, Boolean)

Attempts to disallow garbage collection during the execution of a critical path if a specified amount of memory is available for the large object heap and the small object heap, and controls whether the garbage collector does a full blocking garbage collection if not enough memory is initially available.

```
C#

public static bool TryStartNoGCRegion (long totalSize, long lohSize, bool
disallowFullBlockingGC);
```

Parameters

`totalSize` Int64

The amount of memory in bytes to allocate without triggering a garbage collection. `totalSize` - `lohSize` must be less than or equal to the size of an ephemeral segment. For information on the size of an ephemeral segment, see the "Ephemeral generations and segments" section in the Fundamentals of Garbage Collection article.

`lohSize` Int64

The number of bytes in `totalSize` to use for large object heap (LOH) allocations.

`disallowFullBlockingGC` Boolean

`true` to omit a full blocking garbage collection if the garbage collector is initially unable to allocate the specified memory on the small object heap (SOH) and LOH; otherwise, `false`.

Returns

Boolean

`true` if the runtime was able to commit the required amount of memory and the garbage collector is able to enter no GC region latency mode; otherwise, `false`.

Exceptions

ArgumentOutOfRangeException

`totalSize` - `lohSize` exceeds the ephemeral segment size.

InvalidOperationException

The process is already in no GC region latency mode.

Remarks

The TryStartNoGCRegion(Int64, Int64, Boolean) method attempts to place the garbage collector in no GC region latency mode, which disallows garbage collection while an app executes a critical region of code. If the runtime is unable to initially allocate the requested amount of memory and the `disallowFullBlockingGC` argument is `false`, the garbage collector performs a full blocking garbage collection in an attempt to free additional memory; otherwise, the allocation fails, and the method returns `false`. The garbage collector enters no GC region latency mode if it is able to allocate `lohSize` for the LOH and `totalSize` - `lohSize` for the small object heap (SOH).

`lohSize` must be large enough to handle all memory allocations that occur in the critical path for the LOH, and `totalSize` - `lohSize` must be large enough to handle all memory allocations that occur in the critical path for the SOH. This includes allocations by the app, as well as allocations that the runtime makes on the app's behalf.

Setting `disallowFullBlockingGC` to `true` to prevent a full blocking garbage collection if not enough memory is initially available is most useful in load balancing scenarios: one system can call this method and report itself as ready to accept requests if it returns `true`, and have the load balancer redirect requests to other systems if it returns `false`. It can then do a full blocking garbage collection when it's not handling requests by calling the Collect(Int32, GCCollectionMode, Boolean, Boolean) method.

> **ⓘ Important**
>
> You cannot nest calls to the **TryStartNoGCRegion** method, and you should only call the **EndNoGCRegion** method if the runtime is currently in no GC region latency mode. In other words, you should not call **TryStartNoGCRegion** multiple times (after the first method call, subsequent calls will not succeed), and you

should not expect calls to **EndNoGCRegion** to succeed just because the first call to **TryStartNoGCRegion** succeeded.

You exit the no GC region latency mode by calling the EndNoGCRegion method.

GC.WaitForFullGCApproach Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.

Overloads

Expand table

WaitForFullGCApproach()	Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.
WaitForFullGCApproach(Int32)	Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.
WaitForFullGCApproach(TimeSpan)	Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.

WaitForFullGCApproach()

Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.

C#

```
public static GCNotificationStatus WaitForFullGCApproach ();
```

Returns

GCNotificationStatus

The status of the registered garbage collection notification.

Examples

The following example shows how to use this method to determine whether a full, blocking garbage collection is approaching. Whenever the status of the notification is Succeeded, the user method `OnFullGCApproachNotify` is called to perform actions in response to the approaching collection. This code example is part of a larger example provided for Garbage Collection Notifications topic.

C#

```
// Check for a notification of an approaching collection.
GCNotificationStatus s = GC.WaitForFullGCApproach();
if (s == GCNotificationStatus.Succeeded)
{
    Console.WriteLine("GC Notification raised.");
    OnFullGCApproachNotify();
}
else if (s == GCNotificationStatus.Canceled)
{
    Console.WriteLine("GC Notification cancelled.");
    break;
}
else
{
    // This can occur if a timeout period
    // is specified for WaitForFullGCApproach(Timeout)
    // or WaitForFullGCComplete(Timeout)
    // and the time out period has elapsed.
    Console.WriteLine("GC Notification not applicable.");
    break;
}
```

Remarks

Use the GCNotificationStatus enumeration returned by this method to determine the status of the current garbage collection notification that was registered by using the RegisterForFullGCNotification method. You can also use the WaitForFullGCComplete method to determine whether the full garbage collection has completed.

When the enumeration returns Succeeded, you can do tasks such as preventing additional objects from being allocated and inducing a collection yourself with the Collect method. Note that the notification does not guarantee that a full garbage

collection will occur, only that conditions have reached the threshold that are favorable for a full garbage collection to occur.

This method waits indefinitely for a garbage collection notification to be obtained. If you want to specify a time-out period for the method to return if the notification cannot be obtained, use the GC.WaitForFullGCApproach(Int32) method overload. If you call this method without specifying a time-out, you can call the CancelFullGCNotification method if you are waiting longer than preferred.

You should follow this method with a call to the WaitForFullGCComplete method to make sure that you have had a full garbage collection. Calling this method alone causes indeterminate results.

See also

- Garbage Collection Notifications

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

WaitForFullGCApproach(Int32)

Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime is imminent.

C#

```
public static GCNotificationStatus WaitForFullGCApproach (int
millisecondsTimeout);
```

Parameters

`millisecondsTimeout` Int32

The length of time to wait before a notification status can be obtained. Specify -1 to wait indefinitely.

Returns

GCNotificationStatus

The status of the registered garbage collection notification.

Exceptions

ArgumentOutOfRangeException

`millisecondsTimeout` must be either non-negative or less than or equal to Int32.MaxValue or -1.

Remarks

Use the GCNotificationStatus enumeration returned by this method to determine the status of the current garbage collection notification that was registered by using the RegisterForFullGCNotification method. You can also use the WaitForFullGCComplete method to determine whether the full garbage collection has completed.

Note that this method returns immediately whenever a garbage collection notification status is obtained, regardless of the value specified by `millisecondsTimeout`. If a garbage collection notification status is not obtained before `millisecondsTimeout` times out, this method returns NotApplicable.

When the enumeration returns Succeeded, you can do tasks such as preventing additional objects from being allocated and inducing a collection yourself with the Collect method. Note that the notification does not guarantee that a full garbage collection will occur, only that conditions have reached the threshold that are favorable for a full garbage collection to occur.

You can call the CancelFullGCNotification method when you cannot wait for the time-out period to elapse.

You should follow this method with a call to the WaitForFullGCComplete method to make sure that you have had a full garbage collection. Calling this method alone causes indeterminate results.

GC.WaitForFullGCComplete Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime has completed.

Overloads

Expand table

WaitForFullGCComplete()	Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime has completed.
WaitForFullGCComplete(Int32)	Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by common language the runtime has completed.
WaitForFullGCComplete(TimeSpan)	Returns the status of a registered notification about whether a blocking garbage collection has completed. May wait indefinitely for a full collection.

WaitForFullGCComplete()

Returns the status of a registered notification for determining whether a full, blocking garbage collection by the common language runtime has completed.

C#

```
public static GCNotificationStatus WaitForFullGCComplete ();
```

Returns

GCNotificationStatus

The status of the registered garbage collection notification.

Examples

The following example shows how to use this method to determine whether a full garbage collection has completed. Whenever the status of the notification is Succeeded, the user method `OnFullGCCompletedNotify` is called to perform actions in response to the completed collection. This code example is part of a larger example provided for Garbage Collection Notifications topic.

C#

```
// Check for a notification of a completed collection.
GCNotificationStatus status = GC.WaitForFullGCComplete();
if (status == GCNotificationStatus.Succeeded)
{
    Console.WriteLine("GC Notification raised.");
    OnFullGCCompleteEndNotify();
}
else if (status == GCNotificationStatus.Canceled)
{
    Console.WriteLine("GC Notification cancelled.");
    break;
}
else
{
    // Could be a time out.
    Console.WriteLine("GC Notification not applicable.");
    break;
}
```

Remarks

Use the GCNotificationStatus enumeration returned by this method to determine the status of the current garbage collection notification that was registered by using the RegisterForFullGCNotification method. You can also use the WaitForFullGCApproach method to determine whether a full garbage collection is imminent.

When the enumeration returns Succeeded, you can do tasks such as resuming work and obtaining a collection count with the CollectionCount property.

This method waits indefinitely for a garbage collection notification to be obtained. If you want to specify a time-out period for the method to return if the notification cannot be obtained, use the GC.WaitForFullGCApproach(Int32) method overload. If

you call this method without specifying a time-out, you can call the CancelFullGCNotification method if you are waiting longer than preferred.

This method call should be preceded with a call to the WaitForFullGCApproach method to make sure that you have had a full garbage collection. Calling this method alone can produce indeterminate results.

.NET Standard	2.0, 2.1

WaitForFullGCComplete(Int32)

Returns, in a specified time-out period, the status of a registered notification for determining whether a full, blocking garbage collection by common language the runtime has completed.

C#

```
public static GCNotificationStatus WaitForFullGCComplete (int
millisecondsTimeout);
```

Parameters

`millisecondsTimeout` Int32

The length of time to wait before a notification status can be obtained. Specify -1 to wait indefinitely.

Returns

GCNotificationStatus

The status of the registered garbage collection notification.

Exceptions

InvalidOperationException

`millisecondsTimeout` must be either non-negative or less than or equal to Int32.MaxValue or -1.

Remarks

Use the GCNotificationStatus enumeration returned by this method to determine the status of the current garbage collection notification that was registered by using the RegisterForFullGCNotification method. You can also use the WaitForFullGCApproach method to determine whether a full garbage collection is imminent.

Note that this method returns immediately whenever a garbage collection notification status is obtained, regardless of the value specified by `millisecondsTimeout`. If a garbage collection notification status is not obtained before `millisecondsTimeout` times out, this method returns NotApplicable.

When the enumeration returns Succeeded, you can do tasks such as resuming work and obtaining a collection count with the CollectionCount property.

You can call the CancelFullGCNotification method when you cannot wait for the time-out period to elapse.

This method call should be preceded with a call to the WaitForFullGCApproach method to make sure that you have had a full garbage collection. Calling this method alone can produce indeterminate results.

GC.WaitForPendingFinalizers Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Suspends the current thread until the thread that is processing the queue of finalizers has emptied that queue.

C#

```
public static void WaitForPendingFinalizers ();
```

Examples

The following example demonstrates how to use the WaitForPendingFinalizers method to suspend the current thread until finalization of all the collected objects is complete.

C#

```
using System;

namespace WaitForPendingFinalizersExample
{
   class MyWaitForPendingFinalizersClass
   {
    // You can increase this number to fill up more memory.
    const int numMfos = 1000;
    // You can increase this number to cause more
    // post-finalization work to be done.
    const int maxIterations = 100;

    static void Main(string[] args)
    {
       MyFinalizeObject mfo = null;

       // Create and release a large number of objects
       // that require finalization.
       for(int j = 0; j < numMfos; j++)
       {
          mfo = new MyFinalizeObject();
       }
```

```
        //Release the last object created in the loop.
        mfo = null;

        //Force garbage collection.
        GC.Collect();

        // Wait for all finalizers to complete before continuing.
        // Without this call to GC.WaitForPendingFinalizers,
        // the worker loop below might execute at the same time
        // as the finalizers.
        // With this call, the worker loop executes only after
        // all finalizers have been called.
        GC.WaitForPendingFinalizers();

        // Worker loop to perform post-finalization code.
        for(int i = 0; i < maxIterations; i++)
        {
           Console.WriteLine("Doing some post-finalize work");
        }
     }
    }

    class MyFinalizeObject
    {
     // Make this number very large to cause the finalizer to
     // do more work.
     private const int maxIterations = 10000;

     ~MyFinalizeObject()
     {
        Console.WriteLine("Finalizing a MyFinalizeObject");

        // Do some work.
        for(int i = 0; i < maxIterations; i++)
        {
           // This method performs no operation on i, but prevents
           // the JIT compiler from optimizing away the code inside
           // the loop.
           GC.KeepAlive(i);
        }
         }
     }
 }
```

Remarks

When the garbage collector finds objects that can be reclaimed, it checks each object to determine the object's finalization requirements. If an object implements a finalizer and has not disabled finalization by calling SuppressFinalize, the object is placed in a list of objects that are marked as ready for finalization. The garbage collector calls the Finalize

methods for the objects in this list and removes the entries from the list. This method blocks until all finalizers have run to completion.

The thread on which finalizers are run is unspecified, so there is no guarantee that this method will terminate. However, this thread can be interrupted by another thread while the WaitForPendingFinalizers method is in progress. For example, you can start another thread that waits for a period of time and then interrupts this thread if this thread is still suspended.

Applies to

GCCollectionMode Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the behavior for a forced garbage collection.

C#

```
public enum GCCollectionMode
```

Inheritance Object → ValueType → Enum → GCCollectionMode

Fields

Expand table

Aggressive	3	Requests that the garbage collector decommit as much memory as possible.
Default	0	The default setting for this enumeration, which is currently Forced.
Forced	1	Forces the garbage collection to occur immediately.
Optimized	2	Allows the garbage collector to determine whether the current time is optimal to reclaim objects.

Examples

The following example forces a garbage collection for generation 2 objects with the Optimized setting.

C#

```
using System;

class Program
{
    static void Main(string[] args)
    {
```

```
        GC.Collect(2, GCCollectionMode.Optimized);
    }
}
```

Remarks

Use the GC.Collect method overload to specify the GCCollectionMode value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GCGenerationInfo Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the size and the fragmenation of a generation on entry and on exit of the GC reported in GCMemoryInfo.

C#

```
public readonly struct GCGenerationInfo
```

Inheritance Object → ValueType → GCGenerationInfo

Properties

Expand table

FragmentationAfterBytes	Gets the fragmentation in bytes on exit from the reported collection.
FragmentationBeforeBytes	Gets the fragmentation in bytes on entry to the reported collection.
SizeAfterBytes	Gets the size in bytes on exit from the reported collection.
SizeBeforeBytes	Gets the size in bytes on entry to the reported collection.

GCKind Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the kind of a garbage collection.

C#

```
public enum GCKind
```

Inheritance Object → ValueType → Enum → GCKind

Fields

Expand table

Any	0	Any kind of collection.
Background	3	A background collection. This is always a generation 2 collection.
Ephemeral	1	A gen0 or gen1 collection.
FullBlocking	2	A blocking gen2 collection.

Remarks

A GC can be one of the 3 kinds - ephemeral, full blocking, or background. Their frequencies are very different. Ephemeral GCs happen much more often than the other two kinds. Background GCs usually happen infrequently, and full blocking GCs usually happen very infrequently. In order to sample the very infrequent GCs, collections are separated into kinds so callers can ask for all three kinds while maintaining a reasonable sampling rate. For example, if you're sampling once every second, without this distinction, you may never observe a background GC. With this distinction, you can always get info of the last GC of the kind you specify.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GCMemoryInfo Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a set of APIs that can be used to retrieve garbage collection information.

C#

```
public readonly struct GCMemoryInfo
```

Inheritance Object → ValueType → GCMemoryInfo

Remarks

A garbage collection (GC) is identified by its Index, which starts from 1 and increases with each GC. If you ask for a GC that doesn't exist, you'll get all 0's in the info, including the Index. For example, you'll get 0's if you call the GetGCMemoryInfo method before a GC has happened, or you ask for a GC of GCKind.FullBlocking and no full blocking GCs have happened. You can use index 0 to detect that no GCs, or no GCs of the kind you specified, have occurred.

Properties

Expand table

Compacted	Gets a value that indicates if this is a compacting GC or not.
Concurrent	Gets a value that indicates if this is a concurrent GC (background GC) or not.
FinalizationPendingCount	Gets the number of objects that are ready for finalization that this GC observed.
FragmentedBytes	Gets the total fragmentation when the last garbage collection occurred.
Generation	Gets the generation this GC collected. Collecting a generation also collects younger generations.

GenerationInfo	Gets the generation information for all generations.
HeapSizeBytes	Gets the total heap size when the last garbage collection occurred.
HighMemoryLoadThresholdBytes	Gets the high memory load threshold when the last garbage collection occurred.
Index	Gets the index of this GC.
MemoryLoadBytes	Gets the physical memory load when the last garbage collection occurred.
PauseDurations	Gets the durations of the pauses when all managed threads are suspended.
PauseTimePercentage	Gets the pause time percentage in the GC so far. If the pause time is 1.2%, this property's value is 1.2. The value is calculated by taking the sum of all GC pauses so far and dividing that by the total elapsed time of the process since the runtime was loaded. This running counter is updated at the end of each GC. It does not distinguish between GCKind. That is, at every GC, the calculated value is updated, and when you access this property, it gets the latest calculated value.
PinnedObjectsCount	Gets the number of pinned objects this GC observed.
PromotedBytes	Gets the promoted bytes for this GC.
TotalAvailableMemoryBytes	Gets the total available memory for the garbage collector to use when the last garbage collection occurred.
TotalCommittedBytes	Gets the total committed bytes of the managed heap.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

GCMemoryInfo.Compacted Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates if this is a compacting GC or not.

C#

```
public bool Compacted { get; }
```

Property Value

Boolean

`true` if this is a compacting GC; `false` otherwise.

Remarks

A compacting GC is when space occupied by dead objects is reclaimed and surviving objects are compacted.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GCMemoryInfo.Concurrent Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates if this is a concurrent GC (background GC) or not.

C#

```
public bool Concurrent { get; }
```

Property Value

Boolean

`true` if this is a concurrent GC (background GC); `false` otherwise.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

GCMemoryInfo.FinalizationPendingCount Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of objects that are ready for finalization that this GC observed.

C#

```
public long FinalizationPendingCount { get; }
```

Property Value

Int64

The total number of objects observed by this GC that are ready for finalization.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.FragmentedBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total fragmentation when the last garbage collection occurred.

```
C#
public long FragmentedBytes { get; }
```

Property Value

Int64

The total fragmentation when the last garbage collection occurred.

Remarks

For example, the application has the following five objects:

`| OBJ_A | OBJ_B | OBJ_C | OBJ_D | OBJ_E |`

If `OBJ_B`, `OBJ_C`, and `OBJ_E` are garbage collected but the heap is not compacted, the resulting heap will look like the following:

`| OBJ_A | F | OBJ_D |`

The memory between `OBJ_A` and `OBJ_D`, which is marked `F`, is considered part of the `FragmentedBytes` and is used to allocate new objects.

The memory after `OBJ_D` is not considered part of the `FragmentedBytes` but is also used to allocate new objects.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.Generation Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the generation this GC collected. Collecting a generation also collects younger generations.

C#

```
public int Generation { get; }
```

Property Value

Int32

The generation this GC collected.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

GCMemoryInfo.GenerationInfo Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the generation information for all generations.

C#

```
public ReadOnlySpan<GCGenerationInfo> GenerationInfo { get; }
```

Property Value

ReadOnlySpan<GCGenerationInfo>

The generation information for all generations.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GCMemoryInfo.HeapSizeBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total heap size when the last garbage collection occurred.

C#

```
public long HeapSizeBytes { get; }
```

Property Value

Int64

The total heap size, in bytes, when the last garbage collection occurred.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.HighMemoryLoadThresholdBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the high memory load threshold when the last garbage collection occurred.

C#

```
public long HighMemoryLoadThresholdBytes { get; }
```

Property Value

Int64

The high memory load threshold, in bytes, when the last garbage collection occurred.

Remarks

Most of the GC performance heuristics are based on per-process measurements. However, to avoid paging, GC is aware of the global physical memory load on the machine or VM or in the container. GC recognizes a certain memory load percentage as a "high memory load situation". When the memory load percentage is over that threshold, GC becomes more aggressive and will do more full blocking GCs if necessary to reduce the heap size.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.Index Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the index of this GC.

```
C#
public long Index { get; }
```

Property Value

Int64

The index of this GC.

Remarks

GC indices start with 1 and are increased at the beginning of a GC. Since the information is updated at the end of a GC, this means you can get the information for a background GC with a smaller index than a foreground GC that finished earlier.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GCMemoryInfo.MemoryLoadBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the physical memory load when the last garbage collection occurred.

```
C#
public long MemoryLoadBytes { get; }
```

Property Value

Int64

The physical memory load, in bytes, when the last garbage collection occurred.

Remarks

On Windows, memory load is a field in the [MEMORYSTATUS structure](/windows/win32/api/winbase/ns-winbase-memorystatus). It's a number between 0 and 100 that specifies the approximate percentage of physical memory that's in use (0 indicates no memory use and 100 indicates full memory use). Corresponding information is given on other operating systems.

Data is only brought into physical memory on first touch. If you allocated a big object but haven't actually used it, most of its memory isn't in physical memory. In this case, the allocation won't affect the memory load significantly.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.PauseDurations Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the durations of the pauses when all managed threads are suspended.

C#

```
public ReadOnlySpan<TimeSpan> PauseDurations { get; }
```

Property Value

ReadOnlySpan<TimeSpan>

A timespan representing the pause durations.

Remarks

For blocking GCs, there is one pause. Pauses for background GC are illustrated at Background workstation vs. server GC.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Provide product feedback

GCMemoryInfo.PauseTimePercentage Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the pause time percentage in the GC so far. If the pause time is 1.2%, this property's value is 1.2. The value is calculated by taking the sum of all GC pauses so far and dividing that by the total elapsed time of the process since the runtime was loaded. This running counter is updated at the end of each GC. It does not distinguish between GCKind. That is, at every GC, the calculated value is updated, and when you access this property, it gets the latest calculated value.

C#

```
public double PauseTimePercentage { get; }
```

Property Value

Double

The pause time percentage.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GCMemoryInfo.PinnedObjectsCount Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of pinned objects this GC observed.

C#

```
public long PinnedObjectsCount { get; }
```

Property Value

Int64

The total number of pinned objects observed by this GC.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.PromotedBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the promoted bytes for this GC.

```
C#
public long PromotedBytes { get; }
```

Property Value

Int64

The number of promoted bytes for this GC.

Remarks

The promoted bytes represent the objects from the generations that the garbage collection is collecting that survived.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

GCMemoryInfo.TotalAvailableMemoryBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total available memory for the garbage collector to use when the last garbage collection occurred.

```
C#
public long TotalAvailableMemoryBytes { get; }
```

Property Value

Int64

The total available memory, in bytes, for the garbage collector to use when the last garbage collection occurred.

Remarks

This property value will be the value of the `COMPlus_GCHeapHardLimit` environment variable, or the `Server.GC.HeapHardLimit` value in `runtimeconfig.json`, if either is set.

If the program is run in a container, this value is an implementation-defined fraction of the container's size.

Otherwise, the value of the property is the physical memory on the machine that was available for the garbage collector to use when the last garbage collection occurred.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

GCMemoryInfo.TotalCommittedBytes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the total committed bytes of the managed heap.

```
C#
public long TotalCommittedBytes { get; }
```

Property Value

Int64

The total committed bytes of the managed heap.

Remarks

The total committed bytes is the amount of backing store for the memory. On Windows, bytes are committed when `VirtualAlloc` is called with `MEM_COMMIT`. On Linux, bytes are committed when the page mapping is changed to `PROT_WRITE | PROT_READ`.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

GCNotificationStatus Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides information about the current registration for notification of the next full garbage collection.

```
C#
public enum GCNotificationStatus
```

Inheritance Object → ValueType → Enum → GCNotificationStatus

Fields

Expand table

Canceled	2	The current registration was canceled by the user.
Failed	1	The notification failed for any reason.
NotApplicable	4	This value can result when there's no current registration for a garbage collection notification, or a full GC has happened but was done as a background GC (that is, a GC that runs mostly concurrently with user threads) instead of a full blocking GC. Background GC is enabled by default; disabling it improves the prediction accuracy but incurs larger GC pauses.
Succeeded	0	The notification was successful and the registration was not canceled.
Timeout	3	The time specified by the `millisecondsTimeout` parameter for either WaitForFullGCApproach(Int32) or WaitForFullGCComplete(Int32) has elapsed.

Examples

The following example obtains a GCNotificationStatus enumeration from the WaitForFullGCApproach method. If the enumeration returns Succeeded, it calls the custom method `OnFullGCApproachNotify` to perform actions in response to the

approaching full garbage collection. This code example is part of a larger example provided for Garbage Collection Notifications topic.

C#

```
public static void WaitForFullGCProc()
{
    while (true)
    {
        // CheckForNotify is set to true and false in Main.
        while (checkForNotify)
        {
            // Check for a notification of an approaching collection.
            GCNotificationStatus s = GC.WaitForFullGCApproach();
            if (s == GCNotificationStatus.Succeeded)
            {
                Console.WriteLine("GC Notification raised.");
                OnFullGCApproachNotify();
            }
            else if (s == GCNotificationStatus.Canceled)
            {
                Console.WriteLine("GC Notification cancelled.");
                break;
            }
            else
            {
                // This can occur if a timeout period
                // is specified for WaitForFullGCApproach(Timeout)
                // or WaitForFullGCComplete(Timeout)
                // and the time out period has elapsed.
                Console.WriteLine("GC Notification not applicable.");
                break;
            }

            // Check for a notification of a completed collection.
            GCNotificationStatus status = GC.WaitForFullGCComplete();
            if (status == GCNotificationStatus.Succeeded)
            {
                Console.WriteLine("GC Notification raised.");
                OnFullGCCompleteEndNotify();
            }
            else if (status == GCNotificationStatus.Canceled)
            {
                Console.WriteLine("GC Notification cancelled.");
                break;
            }
            else
            {
                // Could be a time out.
                Console.WriteLine("GC Notification not applicable.");
                break;
            }
        }
```

```
        Thread.Sleep(500);
        // FinalExit is set to true right before
        // the main thread cancelled notification.
        if (finalExit)
        {
            break;
        }
    }
}
```

Remarks

Use the RegisterForFullGCNotification method to register for a full garbage collection notification. Then use the WaitForFullGCApproach method or the WaitForFullGCComplete method to return a GCNotificationStatus enumeration that contains the status of the notification.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

GenericUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser for a hierarchical URI.

```
C#
public class GenericUriParser : UriParser
```

Inheritance Object → UriParser → GenericUriParser

Remarks

If you want to create a parser based on a well-known scheme, use HttpStyleUriParser, FtpStyleUriParser, GopherStyleUriParser, LdapStyleUriParser, or NewsStyleUriParser.

When creating a customizable parser, the behavior of the parser is specified by passing a bitwise combination of the values available in the System.GenericUriParserOptions enumeration to the GenericUriParser constructor.

The existing System.Uri class has been extended to provide support for International Resource Identifiers (IRI) and Internationalized Domain Names (IDN). Current users will not see any change from the .NET Framework 2.0 behavior unless they specifically enable IRI. This ensures application compatibility with prior versions of the .NET Framework.

All parsers derived from GenericUriParser will not gain IRI and IDN support by default. The Default option does not include IRI and IDN support. Two new values are added to the System.GenericUriParserOptions enumeration to indicate if a custom parser supports IRI and IDN.

For more information on IRI and IDN support, see the Remarks section for the System.Uri class.

Constructors

Expand table

GenericUriParser(GenericUriParserOptions)	Create a customizable parser for a hierarchical URI.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

GenericUriParser(GenericUriParserOptions) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Create a customizable parser for a hierarchical URI.

```
C#
public GenericUriParser (GenericUriParserOptions options);
```

Parameters

`options` GenericUriParserOptions

Specify the options for this GenericUriParser.

Remarks

Use this constructor as an argument to UriParser.Register(UriParser, String, Int32)

If you want to create a parser based on a well-known scheme, use HttpStyleUriParser, FtpStyleUriParser, GopherStyleUriParser, LdapStyleUriParser, or NewsStyleUriParser.

When creating a customizable parser, the behavior of the parser is specified by passing a bitwise combination of the values available in the System.GenericUriParserOptions enumeration to the GenericUriParser constructor.

The existing System.Uri class has been extended to provide support for International Resource Identifiers (IRI) and Internationalized Domain Names (IDN). Current users will not see any change from the .NET Framework 2.0 behavior unless they specifically enable IRI. This ensures application compatibility with prior versions of the .NET Framework.

All parsers derived from GenericUriParser will not gain IRI and IDN support by default. The Default option does not include IRI and IDN support. Two new values are added to the System.GenericUriParserOptions enumeration to indicate if a custom parser supports IRI and IDN.

The IriParsing type indicates the parser supports the parsing rules specified in RFC 3987 for International Resource Identifiers (IRI). Whether IRI is used is dictated by configuration values.

The Idn type indicates the parser supports Internationalized Domain Name (IDN) parsing (IDN) of host names. Whether IDN is used is dictated by configuration values.

The configuration setting for the System.Configuration.IdnElement is indirectly controlled by the System.Configuration.IriParsingElement configuration setting that controls IRI processing in the System.Uri class. IRI processing must be enabled for IDN processing to be possible. If IRI processing is disabled, then IDN processing will be set to the default setting where the .NET Framework 2.0 behavior is used for compatibility and IDN names are not used.

The Internationalized Domain Name (IDN) attribute only controls IDN processing. All other IRI processing (character normalization, for example) is performed by default.

For more information on IRI and IDN support, see the Remarks section for the System.Uri class.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GenericUriParserOptions Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies options for a UriParser.

This enumeration supports a bitwise combination of its member values.

C#

```
[System.Flags]
public enum GenericUriParserOptions
```

Inheritance Object → ValueType → Enum → GenericUriParserOptions

Attributes FlagsAttribute

Fields

Expand table

AllowEmptyAuthority	2	The parser allows a URI with no authority.
Default	0	The parser: requires an authority; converts backslashes into forward slashes; unescapes path dots, forward slashes, and back slashes; and removes trailing dots, empty segments, and dots-only segments.
DontCompressPath	128	The parser does not canonicalize the URI.
DontConvertPathBackslashes	64	The parser does not convert back slashes into forward slashes.
DontUnescapePathDotsAndSlashes	256	The parser does not unescape path dots, forward slashes, or back slashes.
GenericAuthority	1	The parser allows a registry-based authority.

Idn	512	The parser supports Internationalized Domain Name (IDN) parsing (IDN) of host names. Whether IDN is used is dictated by configuration values.
IriParsing	1024	The parser supports the parsing rules specified in RFC 3987 for International Resource Identifiers (IRI). Whether IRI is used is dictated by configuration values.
NoFragment	32	The scheme does not define a fragment part.
NoPort	8	The scheme does not define a port.
NoQuery	16	The scheme does not define a query part.
NoUserInfo	4	The scheme does not define a user information part.

Remarks

You can combine any of these options to configure a generic URI parser by passing the options as a parameter to the GenericUriParser.GenericUriParser(GenericUriParserOptions) constructor.

The existing System.Uri class has been extended to provide support for International Resource Identifiers (IRI) based on RFC 3987. Current users will not see any change from the .NET Framework 2.0 behavior unless they specifically enable IRI. This ensures application compatibility with prior versions of the .NET Framework.

The configuration setting for the System.Configuration.IdnElement is indirectly controlled by the System.Configuration.IriParsingElement configuration setting that controls IRI processing in the System.Uri class. IRI processing must be enabled for IDN processing to be possible. If IRI processing is disabled, then IDN processing will be set to the default setting where the .NET Framework 2.0 behavior is used for compatibility and IDN names are not used.

The Internationalized Domain Name (IDN) attribute only controls IDN processing. All other IRI processing (character normalization, for example) is performed by default.

For more information on IRI support, see the Remarks section for the System.Uri class.

Applies to

Product	Versions

GopherStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser based on the Gopher scheme.

C#

```
public class GopherStyleUriParser : UriParser
```

Inheritance Object → UriParser → GopherStyleUriParser

Constructors

Expand table

GopherStyleUriParser()	Creates a customizable parser based on the Gopher scheme.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)

IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Guid Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a globally unique identifier (GUID).

C#

```
public readonly struct Guid : IComparable, IComparable<Guid>,
IEquatable<Guid>, IParsable<Guid>, ISpanFormattable, ISpanParsable<Guid>,
IUtf8SpanFormattable
```

Inheritance Object → ValueType → Guid

Implements IComparable , IComparable<Guid> , IEquatable<Guid> , IFormattable , ISpanFormattable , IParsable<Guid> , IParsable<TSelf> , ISpanParsable<Guid> , IUtf8SpanFormattable

Examples

The following example uses the System.Runtime.InteropServices.GuidAttribute class to assign a GUID to an interface and to a user-defined class. It retrieves the value of the GUID by calling the GetCustomAttribute method, and compares it with two other GUIDs to determine whether they are equal.

C#

```
using System;
using System.Runtime.InteropServices;

// Guid for the interface IMyInterface.
[Guid("F9168C5E-CEB2-4faa-B6BF-329BF39FA1E4")]
interface IMyInterface
{
    void MyMethod();
}

// Guid for the coclass MyTestClass.
```

```
[Guid("936DA01F-9ABD-4d9d-80C7-02AF85C822A8")]
public class MyTestClass : IMyInterface
{
    public void MyMethod() {}

    public static void Main( string []args )
    {
        GuidAttribute IMyInterfaceAttribute = (GuidAttribute)
Attribute.GetCustomAttribute(typeof(IMyInterface), typeof(GuidAttribute));

        System.Console.WriteLine("IMyInterface Attribute: " +
IMyInterfaceAttribute.Value );

        // Use the string to create a guid.
        Guid myGuid1 = new Guid(IMyInterfaceAttribute.Value );
        // Use a byte array to create a guid.
        Guid myGuid2 = new Guid(myGuid1.ToByteArray());

        if (myGuid1.Equals(myGuid2))
            System.Console.WriteLine("myGuid1 equals myGuid2");
        else
            System.Console.WriteLine("myGuid1 does not equal myGuid2" );

        // Equality operator can also be used to determine if two guids have
same value.
        if ( myGuid1 == myGuid2 )
            System.Console.WriteLine( "myGuid1 == myGuid2" );
        else
            System.Console.WriteLine( "myGuid1 != myGuid2" );
    }
}
// The example displays the following output:
//       IMyInterface Attribute: F9168C5E-CEB2-4faa-B6BF-329BF39FA1E4
//       myGuid1 equals myGuid2
//       myGuid1 == myGuid2
```

Note that the GuidAttribute attribute is typically used in an application to expose a type to COM. If you compile this example, you can run the Assembly Registration tool (Regasm.exe) on the generated assembly to create registry (.reg) and type library (.tlb) files. The .reg file can be used to register the coclass in the registry, and the .tlb file can provide metadata for COM interop.

Remarks

A GUID is a 128-bit integer (16 bytes) that can be used across all computers and networks wherever a unique identifier is required. Such an identifier has a very low probability of being duplicated.

Constructors

Expand table

Guid(Byte[])	Initializes a new instance of the Guid structure by using the specified array of bytes.
Guid(Int32, Int16, Int16, Byte, Byte, Byte, Byte, Byte, Byte, Byte, Byte)	Initializes a new instance of the Guid structure by using the specified integers and bytes.
Guid(Int32, Int16, Int16, Byte[])	Initializes a new instance of the Guid structure by using the specified integers and byte array.
Guid(ReadOnlySpan<Byte>)	Initializes a new instance of the Guid structure by using the value represented by the specified read-only span of bytes.
Guid(ReadOnlySpan<Byte>, Boolean)	
Guid(String)	Initializes a new instance of the Guid structure by using the value represented by the specified string.
Guid(UInt32, UInt16, UInt16, Byte, Byte, Byte, Byte, Byte, Byte, Byte, Byte)	Initializes a new instance of the Guid structure by using the specified unsigned integers and bytes.

Fields

Expand table

Empty	A read-only instance of the Guid structure whose value is all zeros.

Methods

Expand table

CompareTo(Guid)	Compares this instance to a specified Guid object and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
Equals(Guid)	Returns a value indicating whether this instance and a specified Guid object represent the same value.
Equals(Object)	Returns a value that indicates whether this instance is

	equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
NewGuid()	Initializes a new instance of the Guid structure.
Parse(ReadOnlySpan<Char>)	Converts a read-only character span that represents a GUID to the equivalent Guid structure.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String)	Converts the string representation of a GUID to the equivalent Guid structure.
Parse(String, IFormatProvider)	Parses a string into a value.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Converts the character span representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.
ParseExact(String, String)	Converts the string representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.
ToByteArray()	Returns a 16-element byte array that contains the value of this instance.
ToByteArray(Boolean)	
ToString()	Returns a string representation of the value of this instance in registry format.
ToString(String)	Returns a string representation of the value of this Guid instance, according to the provided format specifier.
ToString(String, IFormatProvider)	Returns a string representation of the value of this instance of the Guid class, according to the provided format specifier and culture-specific format information.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>)	
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>)	Tries to format the current GUID instance into the provided character span.
TryParse(ReadOnlySpan<Char>, Guid)	Converts the specified read-only span of characters containing the representation of a GUID to the equivalent Guid structure.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Guid)	Tries to parse a span of characters into a value.

TryParse(String, Guid)	Converts the string representation of a GUID to the equivalent Guid structure.
TryParse(String, IFormatProvider, Guid)	Tries to parse a string into a value.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, Guid)	Converts span of characters representing the GUID to the equivalent Guid structure, provided that the string is in the specified format.
TryParseExact(String, String, Guid)	Converts the string representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.
TryWriteBytes(Span<Byte>)	Tries to write the current GUID instance into a span of bytes.
TryWriteBytes(Span<Byte>, Boolean, Int32)	

Operators

Expand table

Equality(Guid, Guid)	Indicates whether the values of two specified Guid objects are equal.
GreaterThan(Guid, Guid)	Compares two values to determine which is greater.
GreaterThanOrEqual(Guid, Guid)	Compares two values to determine which is greater or equal.
Inequality(Guid, Guid)	Indicates whether the values of two specified Guid objects are not equal.
LessThan(Guid, Guid)	Compares two values to determine which is less.
LessThanOrEqual(Guid, Guid)	Compares two values to determine which is less or equal.

Explicit Interface Implementations

Expand table

ISpanFormattable.TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

Applies to

Product	Versions

Guid Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Guid structure.

Overloads

Expand table

Guid(Byte[])	Initializes a new instance of the Guid structure by using the specified array of bytes.
Guid(ReadOnlySpan<Byte>)	Initializes a new instance of the Guid structure by using the value represented by the specified read-only span of bytes.
Guid(String)	Initializes a new instance of the Guid structure by using the value represented by the specified string.
Guid(ReadOnlySpan<Byte>, Boolean)	
Guid(Int32, Int16, Int16, Byte[])	Initializes a new instance of the Guid structure by using the specified integers and byte array.
Guid(Int32, Int16, Int16, Byte, Byte, Byte, Byte, Byte, Byte, Byte, Byte)	Initializes a new instance of the Guid structure by using the specified integers and bytes.
Guid(UInt32, UInt16, UInt16, Byte, Byte, Byte, Byte, Byte, Byte, Byte, Byte)	Initializes a new instance of the Guid structure by using the specified unsigned integers and bytes.

Guid(Byte[])

Initializes a new instance of the Guid structure by using the specified array of bytes.

C#

```
public Guid (byte[] b);
```

Parameters

b Byte[]

A 16-element byte array containing values with which to initialize the GUID.

Exceptions

ArgumentNullException

`b` is `null`.

ArgumentException

`b` is not 16 bytes long.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Guid(ReadOnlySpan<Byte>)

Initializes a new instance of the Guid structure by using the value represented by the specified read-only span of bytes.

C#

```
public Guid (ReadOnlySpan<byte> b);
```

Parameters

b ReadOnlySpan<Byte>

A read-only span containing the bytes representing the GUID. The span must be exactly 16 bytes long.

Exceptions

ArgumentException

The span must be exactly 16 bytes long.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Guid(String)

Initializes a new instance of the Guid structure by using the value represented by the specified string.

C#

```
public Guid (string g);
```

Parameters

g String

A string that contains a GUID in one of the following formats ("d" represents a hexadecimal digit whose case is ignored):

32 contiguous hexadecimal digits:

dddddddddddddddddddddddddddddddd

-or-

Groups of 8, 4, 4, 4, and 12 hexadecimal digits with hyphens between the groups. The entire GUID can optionally be enclosed in matching braces or parentheses:

dddddddd-dddd-dddd-dddd-dddddddddddd

-or-

{dddddddd-dddd-dddd-dddd-dddddddddddd}

-or-

(dddddddd-dddd-dddd-dddd-dddddddddddd)

-or-

Groups of 8, 4, and 4 hexadecimal digits, and a subset of eight groups of 2 hexadecimal digits, with each group prefixed by "0x" or "0X", and separated by commas. The entire GUID, as well as the subset, is enclosed in matching braces:

{0xdddddddd, 0xdddd, 0xdddd,{0xdd,0xdd,0xdd,0xdd,0xdd,0xdd,0xdd,0xdd}}

All braces, commas, and "0x" prefixes are required. All embedded spaces are ignored. All leading zeros in a group are ignored.

The hexadecimal digits shown in a group are the maximum number of meaningful hexadecimal digits that can appear in that group. You can specify from 1 to the number of hexadecimal digits shown for a group. The specified digits are assumed to be the low-order digits of the group.

Exceptions

ArgumentNullException

`g` is `null`.

FormatException

The format of `g` is invalid.

OverflowException

The format of `g` is invalid.

Examples

The following example passes each string listed in the Remarks section to the Guid(String) constructor.

C#

```
string[] guidStrings = { "ca761232ed4211cebacd00aa0057b223",
                         "CA761232-ED42-11CE-BACD-00AA0057B223",
                         "{CA761232-ED42-11CE-BACD-00AA0057B223}",
                         "(CA761232-ED42-11CE-BACD-00AA0057B223)",
                         "{0xCA761232, 0xED42, 0x11CE, {0xBA, 0xCD, 0x00,
0xAA, 0x00, 0x57, 0xB2, 0x23}}" };
foreach (var guidString in guidStrings)
```

```
{
    var guid = new Guid(guidString);
    Console.WriteLine($"Original string: {guidString}");
    Console.WriteLine($"Guid:            {guid}");
    Console.WriteLine();
}

// The example displays the following output:
//    Original string: ca761232ed4211cebacd00aa0057b223
//    Guid:            ca761232-ed42-11ce-bacd-00aa0057b223
//
//    Original string: CA761232-ED42-11CE-BACD-00AA0057B223
//    Guid:            ca761232-ed42-11ce-bacd-00aa0057b223
//
//    Original string: {CA761232-ED42-11CE-BACD-00AA0057B223}
//    Guid:            ca761232-ed42-11ce-bacd-00aa0057b223
//
//    Original string: (CA761232-ED42-11CE-BACD-00AA0057B223)
//    Guid:            ca761232-ed42-11ce-bacd-00aa0057b223
//
//    Original string: {0xCA761232, 0xED42, 0x11CE, {0xBA, 0xCD, 0x00,
0xAA, 0x00, 0x57, 0xB2, 0x23}}
//    Guid:            ca761232-ed42-11ce-bacd-00aa0057b223
```

Remarks

The alphabetic hexadecimal digits in the `g` parameter can be uppercase or lowercase. For example, the following strings represent the same GUID:

"ca761232ed4211cebacd00aa0057b223"

"CA761232-ED42-11CE-BACD-00AA0057B223"

"{CA761232-ED42-11CE-BACD-00AA0057B223}"

"(CA761232-ED42-11CE-BACD-00AA0057B223)"

"{0xCA761232, 0xED42, 0x11CE, {0xBA, 0xCD, 0x00, 0xAA, 0x00, 0x57, 0xB2, 0x23}}"

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Guid(ReadOnlySpan<Byte>, Boolean)

C#

```
public Guid (ReadOnlySpan<byte> b, bool bigEndian);
```

Parameters

b ReadOnlySpan<Byte>

bigEndian Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Guid(Int32, Int16, Int16, Byte[])

Initializes a new instance of the Guid structure by using the specified integers and byte array.

C#

```
public Guid (int a, short b, short c, byte[] d);
```

Parameters

a Int32

The first 4 bytes of the GUID.

b Int16

The next 2 bytes of the GUID.

c Int16

The next 2 bytes of the GUID.

d Byte[]

The remaining 8 bytes of the GUID.

Exceptions

ArgumentNullException

`d` is `null`.

ArgumentException

`d` is not 8 bytes long.

Examples

`Guid(1,2,3,new byte[]{0,1,2,3,4,5,6,7})` creates a Guid that corresponds to "00000001-0002-0003-0001-020304050607".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Guid(Int32, Int16, Int16, Byte, Byte, Byte, Byte, Byte, Byte, Byte, Byte)

Initializes a new instance of the Guid structure by using the specified integers and bytes.

C#

```
public Guid (int a, short b, short c, byte d, byte e, byte f, byte g,
byte h, byte i, byte j, byte k);
```

Parameters

a Int32

The first 4 bytes of the GUID.

b Int16

The next 2 bytes of the GUID.

c Int16

The next 2 bytes of the GUID.

d Byte

The next byte of the GUID.

e Byte

The next byte of the GUID.

f Byte

The next byte of the GUID.

g Byte

The next byte of the GUID.

h Byte

The next byte of the GUID.

i Byte

The next byte of the GUID.

`j` Byte

The next byte of the GUID.

`k` Byte

The next byte of the GUID.

Examples

The following example creates a GUID whose string representation is "0000000a-000b-000c-0001-020304050607".

```C#
var g = new Guid(0xA, 0xB, 0xC,
                 new Byte[] { 0, 1, 2, 3, 4, 5, 6, 7 } );
Console.WriteLine($"{g:B}");

// The example displays the following output:
//        {0000000a-000b-000c-0001-020304050607}
```

Remarks

Specifying individual bytes in this manner can be used to circumvent byte order restrictions (big-endian or little-endian byte order) on particular types of computers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UWP	10.0

Guid(UInt32, UInt16, UInt16, Byte, Byte, Byte, Byte, Byte, Byte, Byte, Byte)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the Guid structure by using the specified unsigned integers and bytes.

C#

```
[System.CLSCompliant(false)]
public Guid (uint a, ushort b, ushort c, byte d, byte e, byte f, byte g,
byte h, byte i, byte j, byte k);
```

Parameters

a UInt32

The first 4 bytes of the GUID.

b UInt16

The next 2 bytes of the GUID.

c UInt16

The next 2 bytes of the GUID.

d Byte

The next byte of the GUID.

e Byte

The next byte of the GUID.

f Byte

The next byte of the GUID.

g Byte

The next byte of the GUID.

`h` Byte

The next byte of the GUID.

`i` Byte

The next byte of the GUID.

`j` Byte

The next byte of the GUID.

`k` Byte

The next byte of the GUID.

Attributes CLSCompliantAttribute

Remarks

Specifying the bytes in this manner avoids endianness issues.

Applies to

Guid.Empty Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A read-only instance of the Guid structure whose value is all zeros.

C#

```
public static readonly Guid Empty;
```

Field Value

Guid

Remarks

You can compare a GUID with the value of the Guid.Empty field to determine whether a GUID is non-zero. The following example uses the Equality operator to compare two GUID values with Guid.Empty to determine whether they consist exclusively of zeros.

C#

```
// Create a GUID and determine whether it consists of all zeros.
Guid guid1 = Guid.NewGuid();
Console.WriteLine(guid1);
Console.WriteLine($"Empty: {guid1 == Guid.Empty}\n");

// Create a GUID with all zeros and compare it to Empty.
var bytes = new Byte[16];
var guid2 = new Guid(bytes);
Console.WriteLine(guid2);
Console.WriteLine($"Empty: {guid2 == Guid.Empty}");

// The example displays output like the following:
//       11c43ee8-b9d3-4e51-b73f-bd9dda66e29c
//       Empty: False
//
//       00000000-0000-0000-0000-000000000000
//       Empty: True
```

Guid.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or Guid and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Guid)	Compares this instance to a specified Guid object and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.

CompareTo(Guid)

Compares this instance to a specified Guid object and returns an indication of their relative values.

C#

```
public int CompareTo (Guid value);
```

Parameters

`value` Guid

An object to compare to this instance.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return value	Description
A negative integer	This instance is less than `value`.
Zero	This instance is equal to `value`.
A positive integer	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following example calls the CompareTo(Guid) method to compare a GUID value with two similar GUID values.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Guid mainGuid = Guid.Parse("01e75c83-c6f5-4192-b57e-7427cec5560d");
      unchecked {
         Guid guid2 = new Guid(0x01e75c83, (short) 0xc6f5,
                               0x4192,
                               new Byte[] { 0xb5, 0x7e, 0x74, 0x27, 0xce,
0xc5, 0x56, 0x0c} );
         Guid guid3 = Guid.Parse("01e75c84-c6f5-4192-b57e-7427cec5560d");

         Console.WriteLine("{0} {1:F} {2}", mainGuid,
                           (Comparison) mainGuid.CompareTo(guid2),
guid2);
         Console.WriteLine("{0} {1:F} {2}", mainGuid,
                           (Comparison) mainGuid.CompareTo(guid3),
guid3);
      }
   }

   private enum Comparison
   { LessThan = -1, Equals = 0, GreaterThan = 1 }
}
```

```
// The example displays the following output:
//    01e75c83-c6f5-4192-b57e-7427cec5560d GreaterThan 01e75c83-c6f5-
4192-b57e-7427cec5560c
//    01e75c83-c6f5-4192-b57e-7427cec5560d LessThan 01e75c84-c6f5-4192-
b57e-7427cec5560d
```

Remarks

The CompareTo method compares the GUIDs as if they were values provided to the Guid(Int32, Int16, Int16, Byte[]) constructor, as follows:

- It compares the UInt32 values, and returns a result if they are unequal. If they are equal, it performs the next comparison.
- It compares the first UInt16 values, and returns a result if they are unequal. If they are equal, it performs the next comparison.
- It compares the second UInt16 values, and returns a result if they are unequal. If they are equal, it performs the next comparison.
- If performs a byte-by-byte comparison of the next eight Byte values. When it encounters the first unequal pair, it returns the result. Otherwise, it returns 0 to indicate that the two Guid values are equal.

Note that the final eight bytes appear in the string representation of a Guid in reverse order, from low byte to high byte. For example, in the string representation of the Guid value "01e75c83-c6f5-4192-b57e-7427cec5560d", the final eight bytes are "b57e-7427cec5560d." In other words, the final eight bytes are compared on a byte-by-byte basis from left to right starting with 0xb5.

If two GUIDs have equal values for a component, the method compares the next component. When it finds a component whose values are unequal, it returns the result.

This method implements the System.IComparable<T> interface and performs slightly better than the Guid.CompareTo method because it does not have to convert the `value` parameter to a Guid value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return value	Description
A negative integer	This instance is less than `value`.
Zero	This instance is equal to `value`.
A positive integer	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a Guid.

Examples

The following example uses the GuidAttribute attribute to assign a GUID to a class. It retrieves the value of this GUID by calling the Attribute.GetCustomAttribute method and passing the Value property of the returned GuidAttribute object to the Parse method. Then it compares that GUID with an array of values.

C#

```
using System;
using System.Runtime.InteropServices;

[Guid("936DA01F-9ABD-4d9d-80C7-02AF85C822A8")]
public class Example
{
   public static void Main()
   {
      GuidAttribute guidAttr = (GuidAttribute)
Attribute.GetCustomAttribute(typeof(Example),

typeof(GuidAttribute));
      Guid guidValue = Guid.Parse(guidAttr.Value);
      Object[] values = { null , 16,
                          Guid.Parse("01e75c83-c6f5-4192-b57e-
7427cec5560d"),
                          guidValue };
      foreach (var value in values) {
         try {
            Console.WriteLine("{0} and {1}: {2}", guidValue,
                              value == null ? "null" : value,
                              guidValue.CompareTo(value));
         }
         catch (ArgumentException) {
            Console.WriteLine("Cannot compare {0} and {1}", guidValue,
                              value == null ? "null" : value);
         }
      }
   }
}
// The example displays the following output:
//    936da01f-9abd-4d9d-80c7-02af85c822a8 and null: 1
//    Cannot compare 936da01f-9abd-4d9d-80c7-02af85c822a8 and 16
//    936da01f-9abd-4d9d-80c7-02af85c822a8 and 01e75c83-c6f5-4192-b57e-
```

```
7427cec5560d: 1
//    936da01f-9abd-4d9d-80c7-02af85c822a8 and 936da01f-9abd-4d9d-80c7-
02af85c822a8: 0
```

Remarks

The `value` parameter must be `null` or an instance of Guid; otherwise, an exception is thrown. Any instance of Guid, regardless of its value, is considered greater than `null`.

The CompareTo method compares the GUIDs as if they were values provided to the Guid constructor, as follows:

- It compares the Int32 values, and returns a result if they are unequal. If they are equal, it performs the next comparison.
- It compares the first Int16 values, and returns a result if they are unequal. If they are equal, it performs the next comparison.
- It compares the second Int16 values, and returns a result if they are unequal. If they are equal, it performs the next comparison.
- If performs a byte-by-byte comparison of the next eight Byte values. When it encounters the first unequal pair, it returns the result. Otherwise, it returns 0 to indicate that the two Guid values are equal.

If two GUIDs have equal values for a component, the method compares the next component. When it finds a component whose values are unequal, it returns the result.

Note that the final eight bytes appear in the string representation of a Guid in reverse order, from low byte to high byte. For example, in the string representation of the Guid value "01e75c83-c6f5-4192-b57e-7427cec5560d", the final eight bytes are "b57e-7427cec5560d."

Guid.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two instances of Guid represent the same value.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object.
Equals(Guid)	Returns a value indicating whether this instance and a specified Guid object represent the same value.

Equals(Object)

Returns a value that indicates whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? o);
```

Parameters

o Object

The object to compare with this instance.

Returns

Boolean

`true` if `o` is a Guid that has the same value as this instance; otherwise, `false`.

Remarks

Two Guid objects are equal if they have identical byte values.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Guid)

Returns a value indicating whether this instance and a specified Guid object represent the same value.

```
C#

public bool Equals (Guid g);
```

Parameters

`g` Guid

An object to compare to this instance.

Returns

Boolean

`true` if `g` is equal to this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

Two Guid objects are equal if they have identical byte values.

This method performs slightly better than the Equals method because it does not have to box the `g` parameter.

Guid.NewGuid Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Guid structure.

C#

```
public static Guid NewGuid ();
```

Returns

Guid

A new GUID object.

Examples

The following code example creates and displays the values of two Guid objects.

C#

```
// Create and display the value of two GUIDs.
Guid g = Guid.NewGuid();
Console.WriteLine(g);
Console.WriteLine(Guid.NewGuid());

// This code example produces a result similar to the following:

// 0f8fad5b-d9cb-469f-a165-70867728950e
// 7c9e6679-7425-40de-944b-e07fc1f90ae7
```

Remarks

This is a convenient `static` method that you can call to get a new Guid. The method creates a Version 4 Universally Unique Identifier (UUID) as described in RFC 4122, Sec. 4.4. The returned Guid is guaranteed to not equal Guid.Empty.

On Windows, this function wraps a call to the CoCreateGuid function. The generated GUID contains 122 bits of strong entropy.

On non-Windows platforms, starting with .NET 6, this function calls the OS's underlying cryptographically secure pseudo-random number generator (CSPRNG) to generate 122 bits of strong entropy. In previous versions of .NET, the entropy is not guaranteed to be generated by a CSPRNG.

It is recommended that applications **not** use the *NewGuid* method for cryptographic purposes. First, since a Version 4 UUID has a partially predictable bit pattern, the *NewGuid* function cannot serve as a proper cryptographic pseudo-random function (PRF). If the output of *NewGuid* is given to a cryptographic component which requires its input to be generated by a proper PRF, the cryptographic component may not be able to maintain its security properties. Second, *NewGuid* utilizes at most 122 bits of entropy, regardless of platform. Some cryptographic components set a minimum entropy level on their inputs as a matter of policy. Such policies often set the minimum entropy level at 128 bits or higher. Passing the output of *NewGuid* to such a routine may violate its policy.

If an application requires random data for cryptographic purposes, consider using a static method on the RandomNumberGenerator class. That class provides a random number generator suitable for cryptographic use.

Guid.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String, IFormatProvider)	Parses a string into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>)	Converts a read-only character span that represents a GUID to the equivalent Guid structure.
Parse(String)	Converts the string representation of a GUID to the equivalent Guid structure.

Parse(String, IFormatProvider)

Parses a string into a value.

C#

```
public static Guid Parse (string s, IFormatProvider? provider);
```

Parameters

s String

The string to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Guid

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#

public static Guid Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Guid

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Char>)

Converts a read-only character span that represents a GUID to the equivalent Guid structure.

C#

```
public static Guid Parse (ReadOnlySpan<char> input);
```

Parameters

`input` ReadOnlySpan<Char>

A read-only span containing the bytes representing a GUID.

Returns

Guid

A structure that contains the value that was parsed.

Exceptions

FormatException

`input` is not in a recognized format.

-or-

After trimming, the length of the read-only character span is 0.

Remarks

The Parse method trims any leading or trailing white space characters from `input` and converts the remaining characters in `input` to a Guid value. This method can convert a character span that represents any of the five formats produced by the ToString methods, as shown in the following table.

Expand table

Specifier	Description	Format
`N`	32 hexadecimal digits	00000000000000000000000000000000
`D`	32 hexadecimal digits separated by hyphens	00000000-0000-0000-0000-000000000000
`B`	32 hexadecimal digits separated by hyphens, enclosed in braces	{00000000-0000-0000-0000-000000000000}
`P`	32 hexadecimal digits separated by hyphens, enclosed in parentheses	(00000000-0000-0000-0000-000000000000)
`X`	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces	{0x00000000,0x0000,0x0000, {0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

The method throws a FormatException if it is unable to successfully parse the string. Some of the reasons why this might occur include:

- `input` contains characters that are not part of the hexadecimal character set.
- `input` has too many or too few characters.
- `input` is not in one of the formats recognized by the ToString method and listed in the previous table.

Use the TryParse method to catch any unsuccessful parse operations without having to handle an exception.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Parse(String)

Converts the string representation of a GUID to the equivalent Guid structure.

```
C#

public static Guid Parse (string input);
```

Parameters

`input` String

The string to convert.

Returns

Guid

A structure that contains the value that was parsed.

Exceptions

ArgumentNullException

`input` is `null`.

FormatException

`input` is not in a recognized format.

Examples

The following example creates a new GUID, converts it to three separate string representations by calling the ToString(String) method with the "B", "D", and "X" format specifiers, and then calls the Parse method to convert the strings back to Guid values.

```
C#

var originalGuid = Guid.NewGuid();
// Create an array of string representations of the GUID.
string[] stringGuids = { originalGuid.ToString("B"),
```

```
                            originalGuid.ToString("D"),
                            originalGuid.ToString("X") };

// Parse each string representation.
foreach (var stringGuid in stringGuids)
{
    try
    {
        Guid newGuid = Guid.Parse(stringGuid);
        Console.WriteLine($"Converted {stringGuid} to a Guid");
    }
    catch (ArgumentNullException)
    {
        Console.WriteLine("The string to be parsed is null.");
    }
    catch (FormatException)
    {
        Console.WriteLine($"Bad format: {stringGuid}");
    }
}

// The example displays output similar to the following:
//
//    Converted {81a130d2-502f-4cf1-a376-63edeb000e9f} to a Guid
//    Converted 81a130d2-502f-4cf1-a376-63edeb000e9f to a Guid
//    Converted {0x81a130d2,0x502f,0x4cf1,
{0xa3,0x76,0x63,0xed,0xeb,0x00,0x0e,0x9f}} to a Guid
```

Remarks

The Parse method trims any leading or trailing white space from `input` and converts the string representation of a GUID to a Guid value. This method can convert strings in any of the five formats produced by the ToString(String) and ToString(String, IFormatProvider) methods, as shown in the following table.

Expand table

Specifier	Description	Format
N	32 hexadecimal digits	00000000000000000000000000000000
D	32 hexadecimal digits separated by hyphens	00000000-0000-0000-0000-000000000000
B	32 hexadecimal digits separated by hyphens, enclosed in braces	{00000000-0000-0000-0000-000000000000}
P	32 hexadecimal digits separated by hyphens, enclosed in	(00000000-0000-0000-0000-000000000000)

Specifier	Description	Format
	parentheses	
`X`	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces	{0x00000000,0x0000,0x0000, {0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

The method throws a FormatException if it is unable to successfully parse the string. Some of the reasons why this might occur include:

- `input` contains characters that are not part of the hexadecimal character set.
- `input` has too many or too few characters.
- `input` is not in one of the formats recognized by the ToString method and listed in the previous table.

Use the TryParse method to catch any unsuccessful parse operations without having to handle an exception.

Guid.ParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Converts the character span representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.
ParseExact(String, String)	Converts the string representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Converts the character span representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.

C#

```
public static Guid ParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format);
```

Parameters

input ReadOnlySpan<Char>

A read-only span containing the characters representing the GUID to convert.

format ReadOnlySpan<Char>

A read-only span of characters representing one of the following specifiers that indicates the exact format to use when interpreting `input`: "N", "D", "B", "P", or "X".

Returns

Guid

A structure that contains the value that was parsed.

Remarks

The ParseExact method requires the read-only character span to convert to be exactly in the format specified by the `format` parameter, after leading and trailing white-space characters are removed. The following table shows the accepted format specifiers for the `format` parameter. "0" represents a digit; hyphens ("-"), braces ("{", "}"), and parentheses ("(", ")") appear as shown.

Expand table

Specifier	Format of the `input` parameter
N	32 hexadecimal digits: 00000000000000000000000000000000
D	32 hexadecimal digits separated by hyphens: 00000000-0000-0000-0000-000000000000
B	32 hexadecimal digits separated by hyphens, enclosed in braces: {00000000-0000-0000-0000-000000000000}
P	32 hexadecimal digits separated by hyphens, enclosed in parentheses: (00000000-0000-0000-0000-000000000000)
X	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces: {0x00000000,0x0000,0x0000,{0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

ParseExact(String, String)

Converts the string representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.

```
C#
public static Guid ParseExact (string input, string format);
```

Parameters

`input` String

The GUID to convert.

`format` String

One of the following specifiers that indicates the exact format to use when interpreting `input`: "N", "D", "B", "P", or "X".

Returns

Guid

A structure that contains the value that was parsed.

Exceptions

ArgumentNullException

`input` or `format` is `null`.

FormatException

`input` is not in the format specified by `format`.

Examples

The following example calls the ToString(String) method with each of the supported format specifiers to generate an array of strings that represent a single GUID. These

are then passed to the ParseExact method, which successfully parses only the string that conforms to the "B" format specifier.

C#

```
// Define an array of all format specifiers.
string[] formats = { "N", "D", "B", "P", "X" };
Guid guid = Guid.NewGuid();
// Create an array of valid Guid string representations.
var stringGuids = new string[formats.Length];
for (int ctr = 0; ctr < formats.Length; ctr++)
    stringGuids[ctr] = guid.ToString(formats[ctr]);

// Parse the strings in the array using the "B" format specifier.
foreach (var stringGuid in stringGuids)
{
    try
    {
        Guid newGuid = Guid.ParseExact(stringGuid, "B");
        Console.WriteLine($"Successfully parsed {stringGuid}");
    }
    catch (ArgumentNullException)
    {
        Console.WriteLine("The string to be parsed is null.");
    }
    catch (FormatException)
    {
        Console.WriteLine($"Bad Format: {stringGuid}");
    }
}

// The example displays output similar to the following:
//
//    Bad Format: eb5c8c7d187a44e68afb81e854c39457
//    Bad Format: eb5c8c7d-187a-44e6-8afb-81e854c39457
//    Successfully parsed {eb5c8c7d-187a-44e6-8afb-81e854c39457}
//    Bad Format: (eb5c8c7d-187a-44e6-8afb-81e854c39457)
//    Bad Format: {0xeb5c8c7d,0x187a,0x44e6,
{0x8a,0xfb,0x81,0xe8,0x54,0xc3,0x94,0x57}}
```

Remarks

The ParseExact method requires the string to convert to be exactly in the format specified by the `format` parameter, after leading and trailing white-space characters are removed. The following table shows the accepted format specifiers for the `format` parameter. "0" represents a digit; hyphens ("-"), braces ("{", "}"), and parentheses ("(", ")") appear as shown.

Expand table

Specifier	Format of the `input` parameter
N	32 hexadecimal digits: 00000000000000000000000000000000
D	32 hexadecimal digits separated by hyphens: 00000000-0000-0000-0000-000000000000
B	32 hexadecimal digits separated by hyphens, enclosed in braces: {00000000-0000-0000-0000-000000000000}
P	32 hexadecimal digits separated by hyphens, enclosed in parentheses: (00000000-0000-0000-0000-000000000000)
X	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces: {0x00000000,0x0000,0x0000,{0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

Guid.ToByteArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToByteArray()	Returns a 16-element byte array that contains the value of this instance.
ToByteArray(Boolean)	

ToByteArray()

Returns a 16-element byte array that contains the value of this instance.

C#

```
public byte[] ToByteArray ();
```

Returns

Byte[]

A 16-element byte array.

Examples

The following example calls the NewGuid method to create a Guid value, and then calls the ToByteArray method to represent the Guid value as a byte array. It then displays both values to the console. Finally, it instantiates a new Guid value from the byte array and calls its Equals(Guid) method to show that the two Guid values are identical.

C#

```
Guid guid = Guid.NewGuid();
Console.WriteLine($"Guid: {guid}");
var bytes = guid.ToByteArray();
foreach (var byt in bytes)
    Console.Write($"{byt:X2} ");

Console.WriteLine();
var guid2 = new Guid(bytes);
Console.WriteLine($"Guid: {guid2} (Same as First Guid:
{guid2.Equals(guid)})");

// The example displays output similar to the following:
//
//    Guid: 35918bc9-196d-40ea-9779-889d79b753f0
//    C9 8B 91 35 6D 19 EA 40 97 79 88 9D 79 B7 53 F0
//    Guid: 35918bc9-196d-40ea-9779-889d79b753f0 (Same as First Guid:
True)
```

Remarks

You can use the byte array returned by this method to round-trip a Guid value by calling the Guid(Byte[]) constructor.

Note that the order of bytes in the returned byte array is different from the string representation of a Guid value. The order of the beginning four-byte group and the next two two-byte groups is reversed, whereas the order of the last two-byte group and the closing six-byte group is the same. The example provides an illustration.

Guid.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string representation of the value of this instance of the Guid structure.

Overloads

Expand table

ToString(String, IFormatProvider)	Returns a string representation of the value of this instance of the Guid class, according to the provided format specifier and culture-specific format information.
ToString()	Returns a string representation of the value of this instance in registry format.
ToString(String)	Returns a string representation of the value of this Guid instance, according to the provided format specifier.

ToString(String, IFormatProvider)

Returns a string representation of the value of this instance of the Guid class, according to the provided format specifier and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

format String

A single format specifier that indicates how to format the value of this Guid. The `format` parameter can be "N", "D", "B", "P", or "X". If `format` is `null` or an empty string (""), "D" is used.

`provider` IFormatProvider

(Reserved) An object that supplies culture-specific formatting information.

Returns

String

The value of this Guid, represented as a series of lowercase hexadecimal digits in the specified format.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

The value of `format` is not `null`, an empty string (""), "N", "D", "B", "P", or "X".

Remarks

The `provider` parameter is reserved for future use and does not contribute to the execution of this method. You can pass `null` in the method call.

The following table shows the accepted format specifiers for the `format` parameter. "0" represents a digit; hyphens ("-"), braces ("{", "}"), and parentheses ("(", ")") appear as shown.

Expand table

Specifier	Format of return value
`N`	32 digits: 00000000000000000000000000000000
`D`	32 digits separated by hyphens: 00000000-0000-0000-0000-000000000000
`B`	32 digits separated by hyphens, enclosed in braces: {00000000-0000-0000-0000-000000000000}

Specifier	Format of return value
`P`	32 digits separated by hyphens, enclosed in parentheses: (00000000-0000-0000-0000-000000000000)
`X`	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces: {0x00000000,0x0000,0x0000,{0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

The hexadecimal digits a through f are lowercase in the returned string. To convert them to uppercase, call the String.ToUpper method on the returned string.

Because the `provider` parameter is ignored, you cannot use it to provide a custom formatting solution. To represent a Guid value as a string in a format that isn't supported by the standard GUID format strings, call the String.Format(IFormatProvider, String, Object[]) method with a `provider` object that implements both the ICustomFormatter and IFormatProvider interfaces. For more information, see the "Custom Formatting with ICustomFormatter" section in the Formatting Types article.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToString()

Returns a string representation of the value of this instance in registry format.

C#

```
public override string ToString ();
```

Returns

String

The value of this Guid, formatted by using the "D" format specifier as follows:

`xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx`

where the value of the GUID is represented as a series of lowercase hexadecimal digits in groups of 8, 4, 4, 4, and 12 digits and separated by hyphens. An example of a return value is "382c74c3-721d-4f34-80e5-57657b6cbc27". To convert the hexadecimal digits from a through f to uppercase, call the ToUpper() method on the returned string.

Remarks

This method provides a default GUID format that is sufficient for typical use; however, other versions of this method that take a `format` parameter provide a few common format variations.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Returns a string representation of the value of this Guid instance, according to the provided format specifier.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A single format specifier that indicates how to format the value of this Guid. The `format` parameter can be "N", "D", "B", "P", or "X". If `format` is `null` or an empty string (""), "D" is used.

Returns

String

The value of this Guid, represented as a series of lowercase hexadecimal digits in the specified format.

Exceptions

FormatException

The value of `format` is not `null`, an empty string (""), "N", "D", "B", "P", or "X".

Remarks

The following table shows the accepted format specifiers for the `format` parameter. "0" represents a digit; hyphens ("-"), braces ("{", "}"), and parentheses ("(", ")") appear as shown.

Expand table

Specifier	Format of return value
`N`	32 digits: 00000000000000000000000000000000
`D`	32 digits separated by hyphens: 00000000-0000-0000-0000-000000000000
`B`	32 digits separated by hyphens, enclosed in braces: {00000000-0000-0000-0000-000000000000}
`P`	32 digits separated by hyphens, enclosed in parentheses: (00000000-0000-0000-0000-000000000000)

Specifier	Format of return value
`X`	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces: {0x00000000,0x0000,0x0000,{0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

The hexadecimal digits a through f are lowercase in the returned string. To convert them to uppercase, call the String.ToUpper method on the returned string.

Guid.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>)	
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>)	Tries to format the current GUID instance into the provided character span.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>)

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default);
```

Parameters

`utf8Destination` Span<Byte>

`bytesWritten` Int32

`format` ReadOnlySpan<Char>

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>)

Tries to format the current GUID instance into the provided character span.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default);
```

Parameters

`destination` Span<Char>

The span in which to write the GUID as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters written into the span.

`format` ReadOnlySpan<Char>

A read-only span containing the character representing one of the following specifiers that indicates the exact format to use when interpreting `input`: "N", "D", "B", "P", or "X".

Returns

Boolean

`true` if the formatting operation was successful; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Guid.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, IFormatProvider, Guid)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Guid)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, Guid)	Converts the specified read-only span of characters containing the representation of a GUID to the equivalent Guid structure.
TryParse(String, Guid)	Converts the string representation of a GUID to the equivalent Guid structure.

TryParse(ReadOnlySpan<Char>, IFormatProvider, Guid)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out Guid result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Guid

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Guid)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
Guid result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Guid

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, Guid)

Converts the specified read-only span of characters containing the representation of a GUID to the equivalent Guid structure.

C#

```
public static bool TryParse (ReadOnlySpan<char> input, out Guid result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters representing the GUID to convert.

`result` Guid

When this method returns, contains the parsed value. If the method returns `true`, `result` contains a valid Guid. If the method returns `false`, `result` equals Empty.

Returns

Boolean

`true` if the parse operation was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Guid)

Converts the string representation of a GUID to the equivalent Guid structure.

```
C#

public static bool TryParse (string? input, out Guid result);
```

Parameters

`input` String

A string containing the GUID to convert.

`result` Guid

When this method returns, contains the parsed value. If the method returns `true`, `result` contains a valid Guid. If the method returns `false`, `result` equals Empty.

Returns

Boolean

`true` if the parse operation was successful; otherwise, `false`.

Examples

The following example creates a new GUID, converts it to three separate string representations by calling the ToString(String) method with the "B", "D", and "X" format specifiers, and then calls the TryParse method to convert the strings back to Guid values.

```
C#

Guid originalGuid = Guid.NewGuid();
// Create an array of string representations of the GUID.
string[] stringGuids = { originalGuid.ToString("B"),
                         originalGuid.ToString("D"),
                         originalGuid.ToString("X") };
```

```
// Parse each string representation.
foreach (var stringGuid in stringGuids)
{
    if (Guid.TryParse(stringGuid, out var newGuid))
        Console.WriteLine($"Converted {stringGuid} to a Guid");
    else
        Console.WriteLine($"Unable to convert {stringGuid} to a Guid");
}

// The example displays output similar to the following:
//
//    Converted {81a130d2-502f-4cf1-a376-63edeb000e9f} to a Guid
//    Converted 81a130d2-502f-4cf1-a376-63edeb000e9f to a Guid
//    Converted {0x81a130d2,0x502f,0x4cf1,
{0xa3,0x76,0x63,0xed,0xeb,0x00,0x0e,0x9f}} to a Guid
```

Remarks

This method is like the Parse method, except that instead of returning the parsed GUID, it returns `false` if `input` is `null` or not in a recognized format, and doesn't throw an exception. It trims any leading or trailing white space from `input` and converts strings in any of the five formats recognized by the ToString(String) and ToString(String, IFormatProvider) methods, as shown in the following table.

Expand table

Specifier	Description	Format
`N`	32 digits	00000000000000000000000000000000
`D`	32 digits separated by hyphens	00000000-0000-0000-0000-000000000000
`B`	32 digits separated by hyphens, enclosed in braces	{00000000-0000-0000-0000-000000000000}
`P`	32 digits separated by hyphens, enclosed in parentheses	(00000000-0000-0000-0000-000000000000)
`X`	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces	{0x00000000,0x0000,0x0000, {0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

Guid.TryParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, Guid)	Converts span of characters representing the GUID to the equivalent Guid structure, provided that the string is in the specified format.
TryParseExact(String, String, Guid)	Converts the string representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, Guid)

Converts span of characters representing the GUID to the equivalent Guid structure, provided that the string is in the specified format.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format, out Guid result);
```

Parameters

`input` ReadOnlySpan<Char>

A read-only span containing the characters representing the GUID to convert.

`format` ReadOnlySpan<Char>

A read-only span containing a character representing one of the following specifiers that indicates the exact format to use when interpreting `input`: "N", "D", "B", "P", or

"X".

`result` Guid

When this method returns, contains the parsed value. If the method returns `true`, `result` contains a valid Guid. If the method returns `false`, `result` equals Empty.

Returns

Boolean

`true` if the parse operation was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParseExact(String, String, Guid)

Converts the string representation of a GUID to the equivalent Guid structure, provided that the string is in the specified format.

```
C#

public static bool TryParseExact (string? input, string? format, out Guid
result);
```

Parameters

`input` String

The GUID to convert.

`format` String

One of the following specifiers that indicates the exact format to use when interpreting `input`: "N", "D", "B", "P", or "X".

`result` Guid

When this method returns, contains the parsed value. If the method returns `true`, `result` contains a valid Guid. If the method returns `false`, `result` equals Empty.

Returns

Boolean

`true` if the parse operation was successful; otherwise, `false`.

Examples

The following example calls the ToString(String) method with each of the supported format specifiers to generate an array of strings that represent a single GUID. These are then passed to the TryParseExact method, which successfully parses the string that conforms to the "B" format specifier.

C#

```
// Define an array of all format specifiers.
string[] formats = { "N", "D", "B", "P", "X" };
Guid guid = Guid.NewGuid();
// Create an array of valid Guid string representations.
var stringGuids = new string[formats.Length];
for (int ctr = 0; ctr < formats.Length; ctr++)
    stringGuids[ctr] = guid.ToString(formats[ctr]);

// Parse the strings in the array using the "B" format specifier.
foreach (var stringGuid in stringGuids)
{
    if (Guid.TryParseExact(stringGuid, "B", out var newGuid))
        Console.WriteLine($"Successfully parsed {stringGuid}");
    else
        Console.WriteLine($"Unable to parse '{stringGuid}'");
}

// The example displays output similar to the following:
//
//    Unable to parse 'c0fb150f6bf344df984a3a0611ae5e4a'
//    Unable to parse 'c0fb150f-6bf3-44df-984a-3a0611ae5e4a'
//    Successfully parsed {c0fb150f-6bf3-44df-984a-3a0611ae5e4a}
//    Unable to parse '(c0fb150f-6bf3-44df-984a-3a0611ae5e4a)'
//    Unable to parse '{0xc0fb150f,0x6bf3,0x44df,
{0x98,0x4a,0x3a,0x06,0x11,0xae,0x5e,0x4a}}'
```

Remarks

This method requires the string to convert to be exactly in the format specified by the `format` parameter, after leading and trailing white-space characters are removed. It returns `false` if `input` is `null` or is not in the format specified by `format`, and doesn't throw an exception.

The following table shows the accepted format specifiers for the `format` parameter. "0" represents a digit; hyphens ("-"), braces ("{", "}"), and parentheses ("(", ")") appear as shown.

Expand table

Specifier	Format of the `input` parameter
N	32 digits: 00000000000000000000000000000000
D	32 digits separated by hyphens: 00000000-0000-0000-0000-000000000000
B	32 digits separated by hyphens, enclosed in braces: {00000000-0000-0000-0000-000000000000}
P	32 digits separated by hyphens, enclosed in parentheses: (00000000-0000-0000-0000-000000000000)
X	Four hexadecimal values enclosed in braces, where the fourth value is a subset of eight hexadecimal values that is also enclosed in braces: {0x00000000,0x0000,0x0000,{0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00}}

Guid.TryWriteBytes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryWriteBytes(Span<Byte>)	Tries to write the current GUID instance into a span of bytes.
TryWriteBytes(Span<Byte>, Boolean, Int32)	

TryWriteBytes(Span<Byte>)

Tries to write the current GUID instance into a span of bytes.

C#

```
public bool TryWriteBytes (Span<byte> destination);
```

Parameters

`destination` Span<Byte>

When this method returns, the GUID as a span of bytes.

Returns

Boolean

`true` if the GUID is successfully written to the specified span; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryWriteBytes(Span<Byte>, Boolean, Int32)

C#

```
public bool TryWriteBytes (Span<byte> destination, bool bigEndian, out
int bytesWritten);
```

Parameters

`destination` Span<Byte>

`bigEndian` Boolean

`bytesWritten` Int32

Returns

Boolean

Applies to

Guid.Equality(Guid, Guid) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the values of two specified Guid objects are equal.

C#

```
public static bool operator == (Guid a, Guid b);
```

Parameters

a Guid

The first object to compare.

b Guid

The second object to compare.

Returns

Boolean

`true` if `a` and `b` are equal; otherwise, `false`.

Examples

The following example uses the Equality operator to compare two GUID values with Guid.Empty to determine whether they consist exclusively of zeros.

C#

```
// Create a GUID and determine whether it consists of all zeros.
Guid guid1 = Guid.NewGuid();
Console.WriteLine(guid1);
Console.WriteLine($"Empty: {guid1 == Guid.Empty}\n");

// Create a GUID with all zeros and compare it to Empty.
var bytes = new Byte[16];
```

```
var guid2 = new Guid(bytes);
Console.WriteLine(guid2);
Console.WriteLine($"Empty: {guid2 == Guid.Empty}");

// The example displays output like the following:
//       11c43ee8-b9d3-4e51-b73f-bd9dda66e29c
//       Empty: False
//
//       00000000-0000-0000-0000-000000000000
//       Empty: True
```

Remarks

The equivalent method for this operator is Guid.Equals(Object)

Applies to

Product	Versions

Guid.GreaterThan(Guid, Guid) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#
public static bool operator > (Guid left, Guid right);
```

Parameters

`left` Guid

The value to compare with `right`.

`right` Guid

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Applies to

Guid.Inequality(Guid, Guid) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the values of two specified Guid objects are not equal.

```
C#
public static bool operator != (Guid a, Guid b);
```

Parameters

a Guid

The first object to compare.

b Guid

The second object to compare.

Returns

Boolean

`true` if `a` and `b` are not equal; otherwise, `false`.

Remarks

The equivalent method for this operator is Guid.Equals(Object)

Applies to

Product	Versions

Guid.ISpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance into the provided span of characters.

C#

```
bool ISpanFormattable.TryFormat (Span<char> destination, out int
charsWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	6, 7, 8, 9

Guid.IUtf8SpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
bool IUtf8SpanFormattable.TryFormat (Span<byte> utf8Destination, out int
bytesWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Remarks

The Half value type represents a half-precision 16-bit number with values ranging from negative 65,504 to positive 65,504, as well as positive or negative zero, PositiveInfinity, NegativeInfinity, and not a number (NaN).

This is an IEEE 754-compliant `float16` type.

Properties

Expand table

E	Gets the mathematical constant `e`.
Epsilon	Represents the smallest positive Half value that is greater than zero.
MaxValue	Represents the largest possible value of Half.
MinValue	Represents the smallest possible value of Half.
MultiplicativeIdentity	Gets the multiplicative identity of the current type.
NaN	Represents not a number.
NegativeInfinity	Represents negative infinity.
NegativeOne	Gets the value `-1` for the type.
NegativeZero	Gets a value that represents negative `zero`.
One	Gets the value `1` for the type.
Pi	Gets the mathematical constant `pi`.
PositiveInfinity	Represents positive infinity.
Tau	Gets the mathematical constant `tau`.
Zero	Gets the value `0` for the type.

Methods

Expand table

Abs(Half)	Computes the absolute of a value.
Acos(Half)	Computes the arc-cosine of a value.
Acosh(Half)	Computes the hyperbolic arc-cosine of a value.
AcosPi(Half)	Computes the arc-cosine of a value and divides the result by `pi`.
Asin(Half)	Computes the arc-sine of a value.
Asinh(Half)	Computes the hyperbolic arc-sine of a value.
AsinPi(Half)	Computes the arc-sine of a value and divides the result by `pi`.
Atan(Half)	Computes the arc-tangent of a value.
Atan2(Half, Half)	Computes the arc-tangent of the quotient of two values.
Atan2Pi(Half, Half)	Computes the arc-tangent for the quotient of two values and divides the result by `pi`.
Atanh(Half)	Computes the hyperbolic arc-tangent of a value.
AtanPi(Half)	Computes the arc-tangent of a value and divides the result by pi.
BitDecrement(Half)	Decrements a value to the smallest value that compares less than a given value.
BitIncrement(Half)	Increments a value to the smallest value that compares greater than a given value.
Cbrt(Half)	Computes the cube-root of a value.
Ceiling(Half)	Computes the ceiling of a value.
Clamp(Half, Half, Half)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Half)	Compares this instance to a specified half-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified half-precision floating-point number.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is

	less than, equal to, or greater than the value of the specified object.
CopySign(Half, Half)	Copies the sign of a value to the sign of another value.
Cos(Half)	Computes the cosine of a value.
Cosh(Half)	Computes the hyperbolic cosine of a value.
CosPi(Half)	Computes the cosine of a value that has been multipled by `pi`.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DegreesToRadians(Half)	Converts a given value from degrees to radians.
Equals(Half)	Compares this instance for equality with `other`.
Equals(Object)	Returns a value that indicates whether this instance is equal to the specified `obj`.
Exp(Half)	Computes `E` raised to a given power.
Exp10(Half)	Computes `10` raised to a given power.
Exp10M1(Half)	Computes `10` raised to a given power and subtracts one.
Exp2(Half)	Computes `2` raised to a given power.
Exp2M1(Half)	Computes `2` raised to a given power and subtracts one.
ExpM1(Half)	Computes `E` raised to a given power and subtracts one.
Floor(Half)	Computes the floor of a value.
FusedMultiplyAdd(Half, Half, Half)	Computes the fused multiply-add of three values.
GetHashCode()	Returns the hash code for this instance.
Hypot(Half, Half)	Computes the hypotenuse given two values representing the lengths of the shorter sides in a right-angled triangle.

Ieee754Remainder(Half, Half)	Computes the remainder of two values as specified by IEEE 754.
ILogB(Half)	Computes the integer logarithm of a value.
IsEvenInteger(Half)	Determines if a value represents an even integral number.
IsFinite(Half)	Determines whether the specified value is finite (zero, subnormal, or normal).
IsInfinity(Half)	Returns a value indicating whether the specified number evaluates to positive infinity.
IsInteger(Half)	Determines if a value represents an integral value.
IsNaN(Half)	Determines whether the specified value is not a number.
IsNegative(Half)	Determines whether the specified value is negative.
IsNegativeInfinity(Half)	Determines whether the specified value is negative infinity.
IsNormal(Half)	Determines whether the specified value is normal.
IsOddInteger(Half)	Determines if a value represents an odd integral number.
IsPositive(Half)	Determines if a value is positive.
IsPositiveInfinity(Half)	Determines whether the specified value is positive infinity.
IsPow2(Half)	Determines if a value is a power of two.
IsRealNumber(Half)	Determines if a value represents a real number.
IsSubnormal(Half)	Determines whether the specified value is subnormal.
Lerp(Half, Half, Half)	Performs a linear interpolation between two values based on the given weight.
Log(Half)	Computes the natural (`base-E` logarithm of a value.
Log(Half, Half)	Computes the logarithm of a value in the specified base.
Log10(Half)	Computes the base-10 logarithm of a value.
Log10P1(Half)	Computes the base-10 logarithm of a value plus one.
Log2(Half)	Computes the log2 of a value.
Log2P1(Half)	Computes the base-2 logarithm of a value plus one.
LogP1(Half)	Computes the natural (`base-E`) logarithm of a value plus one.

Max(Half, Half)	Compares two values to compute which is greater.
MaxMagnitude(Half, Half)	Compares two values to compute which is greater.
MaxMagnitudeNumber(Half, Half)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
MaxNumber(Half, Half)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
Min(Half, Half)	Compares two values to compute which is lesser.
MinMagnitude(Half, Half)	Compares two values to compute which is lesser.
MinMagnitudeNumber(Half, Half)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
MinNumber(Half, Half)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.
Parse(String)	Converts the string representation of a number to its half-precision floating-point number equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its single-precision floating-point number equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its single-precision floating-point number equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.
Pow(Half, Half)	Computes a value raised to a given power.
RadiansToDegrees(Half)	Converts a given value from radians to degrees.

ReciprocalEstimate(Half)	Computes an estimate of the reciprocal of a value.
ReciprocalSqrtEstimate(Half)	Computes an estimate of the reciprocal square root of a value.
RootN(Half, Int32)	Computes the n-th root of a value.
Round(Half)	Rounds a value to the nearest integer using the default rounding mode (ToEven).
Round(Half, Int32)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Half, Int32, MidpointRounding)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Half, MidpointRounding)	Rounds a value to the nearest integer using the specified rounding mode.
ScaleB(Half, Int32)	Computes the product of a value and its base-radix raised to the specified power.
Sign(Half)	Computes the sign of a value.
Sin(Half)	Computes the sine of a value.
SinCos(Half)	Computes the sine and cosine of a value.
SinCosPi(Half)	Computes the sine and cosine of a value that has been multiplied by `pi`.
Sinh(Half)	Computes the hyperbolic sine of a value.
SinPi(Half)	Computes the sine of a value that has been multiplied by `pi`.
Sqrt(Half)	Computes the square-root of a value.
Tan(Half)	Computes the tangent of a value.
Tanh(Half)	Computes the hyperbolic tangent of a value.
TanPi(Half)	Computes the tangent of a value that has been multipled by `pi`.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
Truncate(Half)	Truncates a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current Half instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, Half)	Tries to convert a UTF-8 character span containing the string representation of a number to its half-precision floating-point number equivalent.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Half)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Half)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Half)	Converts the span representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Half)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Half)	Converts the span representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Half)	Converts the string representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, Half)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, Half)	Converts the string representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Operators

Expand table

Addition(Half, Half)	Adds two values together to compute their sum.
CheckedExplicit(Half)	
Decrement(Half)	Decrements a value.
Division(Half, Half)	Divides two values together to compute their quotient.
Equality(Half, Half)	Returns a value that indicates whether two specified Half values are equal.
Explicit(Char to Half)	Explicitly converts a Char value to its nearest representable half-precision floating-point value.
Explicit(Decimal to Half)	Explicitly converts a Decimal value to its nearest representable half-precision floating-point value.
Explicit(Double to Half)	An explicit operator to convert a Double value to a Half.
Explicit(Half to Byte)	Explicitly converts a half-precision floating-point value to its nearest representable Byte value.
Explicit(Half to Char)	Explicitly converts a half-precision floating-point value to its nearest representable Char value.
Explicit(Half to Decimal)	Explicitly converts a half-precision floating-point value to its nearest representable Decimal value.
Explicit(Half to Double)	An explicit operator to convert a Half value to a Double.
Explicit(Half to Int128)	Explicitly converts a half-precision floating-point value to its nearest representable Int128.
Explicit(Half to Int16)	Explicitly converts a half-precision floating-point value to its nearest representable Int16 value.
Explicit(Half to Int32)	Explicitly converts a half-precision floating-point value to its nearest representable Int32 value.
Explicit(Half to Int64)	Explicitly converts a half-precision floating-point value to its nearest representable Int64 value.
Explicit(Half to IntPtr)	Explicitly converts a half-precision floating-point value to its nearest representable IntPtr value.
Explicit(Half to SByte)	Explicitly converts a half-precision floating-point value to its nearest representable SByte value.

Explicit(Half to Single)	An explicit operator to convert a Half value to a Single.
Explicit(Half to UInt128)	Explicitly converts a half-precision floating-point value to its nearest representable UInt128.
Explicit(Half to UInt16)	Explicitly converts a half-precision floating-point value to its nearest representable UInt16 value.
Explicit(Half to UInt32)	Explicitly converts a half-precision floating-point value to its nearest representable UInt32 value.
Explicit(Half to UInt64)	Explicitly converts a half-precision floating-point value to its nearest representable UInt64 value.
Explicit(Half to UIntPtr)	Explicitly converts a half-precision floating-point value to its nearest representable UIntPtr value.
Explicit(Int16 to Half)	Explicitly converts a Int16 value to its nearest representable half-precision floating-point value.
Explicit(Int32 to Half)	Explicitly converts a Int32 value to its nearest representable half-precision floating-point value.
Explicit(Int64 to Half)	Explicitly converts a Int64 value to its nearest representable half-precision floating-point value.
Explicit(IntPtr to Half)	Explicitly converts a IntPtr value to its nearest representable half-precision floating-point value.
Explicit(Single to Half)	An explicit operator to convert a Single value to a Half.
Explicit(UInt16 to Half)	Explicitly converts a UInt16 value to its nearest representable half-precision floating-point value.
Explicit(UInt32 to Half)	Explicitly converts a UInt32 value to its nearest representable half-precision floating-point value.
Explicit(UInt64 to Half)	Explicitly converts a UInt64 value to its nearest representable half-precision floating-point value.
Explicit(UIntPtr to Half)	Explicitly converts a UIntPtr value to its nearest representable half-precision floating-point value.
GreaterThan(Half, Half)	Returns a value that indicates whether a specified Half value is greater than another specified Half value.
GreaterThan OrEqual(Half, Half)	Returns a value that indicates whether `left` is greater than or equal to `right`.
Implicit(Byte to Half)	Implicitly converts a Byte value to its nearest representable half-precision floating-point value.

Implicit(SByte to Half)	Implicitly converts a SByte value to its nearest representable half-precision floating-point value.
Increment(Half)	Increments a value.
Inequality(Half, Half)	Returns a value that indicates whether two specified Half values are not equal.
LessThan(Half, Half)	Returns a value that indicates whether a specified Half value is less than another specified Half value.
LessThanOrEqual(Half, Half)	Returns a value that indicates whether a specified Half value is less than or equal to another specified Half value.
Modulus(Half, Half)	Divides two values together to compute their modulus or remainder.
Multiply(Half, Half)	Multiplies two values together to compute their product.
Subtraction(Half, Half)	Subtracts two values to compute their difference.
UnaryNegation(Half)	Computes the unary negation of a value.
UnaryPlus(Half)	Computes the unary plus of a value.

Explicit Interface Implementations

Expand table

IAdditiveIdentity<Half,Half>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryNumber<Half>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<Half,Half,Half>.BitwiseAnd(Half, Half)	Computes the bitwise-and of two values.
IBitwiseOperators<Half,Half,Half>.BitwiseOr(Half, Half)	Computes the bitwise-or of two values.
IBitwiseOperators<Half,Half,Half>.ExclusiveOr(Half, Half)	Computes the exclusive-or of two values.
IBitwiseOperators<Half,Half,Half>.OnesComplement(Half)	Computes the ones-complement representation of a given value.
IFloatingPoint<Half>.GetExponentByteCount()	Gets the number of bytes that will be written as part of TryWriteExponentLittleEndian(Span<Byte>, Int32).

IFloatingPoint<Half>.GetExponentShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current exponent.
IFloatingPoint<Half>.GetSignificandBitLength()	Gets the length, in bits, of the current significand.
IFloatingPoint<Half>.GetSignificandByteCount()	Gets the number of bytes that will be written as part of TryWriteSignificandLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Half>.TryWriteExponentBigEndian(Span<Byte>, Int32)	Tries to write the current exponent, in big-endian format, to a given span.
IFloatingPoint<Half>.TryWriteExponentLittleEndian(Span<Byte>, Int32)	Tries to write the current exponent, in little-endian format, to a given span.
IFloatingPoint<Half>.TryWriteSignificandBigEndian(Span<Byte>, Int32)	Tries to write the current significand, in big-endian format, to a given span.
IFloatingPoint<Half>.TryWriteSignificandLittleEndian(Span<Byte>, Int32)	Tries to write the current significand, in little-endian format, to a given span.
INumberBase<Half>.IsCanonical(Half)	Determines if a value is in its canonical representation.
INumberBase<Half>.IsComplexNumber(Half)	Determines if a value represents a complex number.
INumberBase<Half>.IsImaginaryNumber(Half)	Determines if a value represents a pure imaginary number.
INumberBase<Half>.IsZero(Half)	Determines if a value is zero.
INumberBase<Half>.Radix	Gets the radix, or base, for the type.
INumberBase<Half>.TryConvertFromChecked<TOther>(TOther, Half)	
INumberBase<Half>.TryConvertFromSaturating<TOther>(TOther, Half)	
INumberBase<Half>.TryConvertFromTruncating<TOther>(TOther, Half)	
INumberBase<Half>.TryConvertToChecked<TOther>(Half, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Half>.TryConvertToSaturating<TOther>(Half, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

INumberBase<Half>.TryConvertToTruncating<TOther>(Half, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Half.E Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the mathematical constant `e`.

```
C#
public static Half E { get; }
```

Property Value

Half

Implements

E

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Epsilon Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest positive Half value that is greater than zero.

C#

```
public static Half Epsilon { get; }
```

Property Value

Half

5.9604645E-08

Implements

Epsilon

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of Half.

C#

```
public static Half MaxValue { get; }
```

Property Value

Half

65504

Implements

MaxValue

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Half.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of Half.

C#

```
public static Half MinValue { get; }
```

Property Value

Half

-65504

Implements

MinValue

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Half.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
public static Half MultiplicativeIdentity { get; }
```

Property Value

Half

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Half.NaN Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents not a number.

```
C#
public static Half NaN { get; }
```

Property Value

Half

NaN.

Implements

NaN

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Half.NegativeInfinity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents negative infinity.

C#

```
public static Half NegativeInfinity { get; }
```

Property Value

Half

-Infinity.

Implements

NegativeInfinity

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.NegativeOne Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `-1` for the type.

C#

```
public static Half NegativeOne { get; }
```

Property Value

Half

Implements

NegativeOne

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.NegativeZero Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that represents negative `zero`.

C#

```
public static Half NegativeZero { get; }
```

Property Value

Half

Implements

NegativeZero

Applies to

Product	Versions
.NET	7, 8, 9

Half.Abs(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static Half Abs (Half value);
```

Parameters

`value` Half

The value for which to get its absolute.

Returns

Half

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Acos(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-cosine of a value.

```
C#
public static Half Acos (Half x);
```

Parameters

x Half

The value, in radians, whose arc-cosine is to be computed.

Returns

Half

The arc-cosine of `x`.

Implements

Acos(TSelf)

Remarks

This computes `arccos(x)` in the interval `[+0, +π]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.Acosh(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic arc-cosine of a value.

C#

```
public static Half Acosh (Half x);
```

Parameters

x Half

The value, in radians, whose hyperbolic arc-cosine is to be computed.

Returns

Half

The hyperbolic arc-cosine of `x`.

Implements

Acosh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.AcosPi(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-cosine of a value and divides the result by `pi`.

```
C#
public static Half AcosPi (Half x);
```

Parameters

x Half

The value whose arc-cosine is to be computed.

Returns

Half

The arc-cosine of `x`, divided by `pi`.

Implements

AcosPi(TSelf)

Remarks

This computes `arccos(x) / π` in the interval `[-0.5, +0.5]`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Asin(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-sine of a value.

```
C#
public static Half Asin (Half x);
```

Parameters

x Half

The value, in radians, whose arc-sine is to be computed.

Returns

Half

The arc-sine of `x`.

Implements

Asin(TSelf)

Remarks

This computes `arcsin(x)` in the interval `[-π / 2, +π / 2]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.Asinh(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic arc-sine of a value.

C#

```
public static Half Asinh (Half x);
```

Parameters

x Half

The value, in radians, whose hyperbolic arc-sine is to be computed.

Returns

Half

The hyperbolic arc-sine of `x`.

Implements

Asinh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Atan(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of a value.

```
C#
public static Half Atan (Half x);
```

Parameters

x Half

The value, in radians, whose arc-tangent is to be computed.

Returns

Half

The arc-tangent of `x`.

Implements

Atan(TSelf)

Remarks

This computes `arctan(x)` in the interval `[-π / 2, +π / 2]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Atan2(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of the quotient of two values.

C#

```
public static Half Atan2 (Half y, Half x);
```

Parameters

y Half

The y-coordinate of a point.

x Half

The x-coordinate of a point.

Returns

Half

The arc-tangent of `y` divided-by `x`.

Implements

Atan2(TSelf, TSelf)

Remarks

This computes `arctan(y / x)` in the interval `[-π, +π]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.Atan2Pi(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent for the quotient of two values and divides the result by `pi`.

```
C#
public static Half Atan2Pi (Half y, Half x);
```

Parameters

y Half

The y-coordinate of a point.

x Half

The x-coordinate of a point.

Returns

Half

The arc-tangent of `y` divided-by `x`, divided by `pi`.

Implements

Atan2Pi(TSelf, TSelf)

Remarks

This computes `arctan(y / x) / π` in the interval `[-1, +1]`.

Applies to

Product	Versions
.NET	7, 8, 9

Half.Atanh(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic arc-tangent of a value.

C#

```
public static Half Atanh (Half x);
```

Parameters

x Half

The value, in radians, whose hyperbolic arc-tangent is to be computed.

Returns

Half

The hyperbolic arc-tangent of `x`.

Implements

Atanh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.AtanPi(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of a value and divides the result by pi.

```
C#
public static Half AtanPi (Half x);
```

Parameters

x Half

The value whose arc-tangent is to be computed.

Returns

Half

The arc-tangent of `x`, divided by `pi`.

Implements

AtanPi(TSelf)

Remarks

This computes `arctan(x) / π` in the interval `[-0.5, +0.5]`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.BitDecrement(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value to the smallest value that compares less than a given value.

C#

```
public static Half BitDecrement (Half x);
```

Parameters

x Half

The value to be bitwise decremented.

Returns

Half

The smallest value that compares less than `x`.

Implements

BitDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.BitIncrement(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value to the smallest value that compares greater than a given value.

C#

```
public static Half BitIncrement (Half x);
```

Parameters

x Half

The value to be bitwise incremented.

Returns

Half

The smallest value that compares greater than `x`.

Implements

BitIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Cbrt(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cube-root of a value.

C#

```
public static Half Cbrt (Half x);
```

Parameters

x Half

The value whose cube-root is to be computed.

Returns

Half

The cube-root of `x`.

Implements

Cbrt(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Ceiling(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ceiling of a value.

C#

```
public static Half Ceiling (Half x);
```

Parameters

x Half

The value whose ceiling is to be computed.

Returns

Half

The ceiling of `x`.

Implements

Ceiling(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Clamp(Half, Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static Half Clamp (Half value, Half min, Half max);
```

Parameters

`value` Half

The value to clamp.

`min` Half

The inclusive minimum to which `value` should clamp.

`max` Half

The inclusive maximum to which `value` should clamp.

Returns

Half

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(Half)	Compares this instance to a specified half-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified half-precision floating-point number.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.

CompareTo(Half)

Compares this instance to a specified half-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified half-precision floating-point number.

C#

```
public int CompareTo (Half other);
```

Parameters

`other` Half

A half-precision floating-point number to compare.

Returns

Int32

A value less than zero if this is less than `other`, zero if this is equal to `other`, or a value greater than zero if this is greater than `other`.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

CompareTo(Object)

Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.

C#

```
public int CompareTo (object? obj);
```

Parameters

`obj` Object

An object to compare, or `null`.

Returns

Int32

A value less than zero if this instance is less than `obj`, or this instance is not a number (NaN) and `obj` is a number.

-or-

Zero if this instance is equal to `obj`, or this instance and `obj` are both not a number (NaN), PositiveInfinity, or NegativeInfinity.

-or-

A value greater than zero if this instance is greater than `obj`, or this instance is a number and `obj` is not a number (NaN), or `obj` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not of type Half.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.CopySign(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
public static Half CopySign (Half value, Half sign);
```

Parameters

`value` Half

The value whose magnitude is used in the result.

`sign` Half

The value whose sign is used in the result.

Returns

Half

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Cos(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cosine of a value.

```
C#
public static Half Cos (Half x);
```

Parameters

x Half

The value, in radians, whose cosine is to be computed.

Returns

Half

The cosine of `x`.

Implements

Cos(TSelf)

Remarks

This computes `cos(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Cosh(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic cosine of a value.

C#

```
public static Half Cosh (Half x);
```

Parameters

x Half

The value, in radians, whose hyperbolic cosine is to be computed.

Returns

Half

The hyperbolic cosine of `x`.

Implements

Cosh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.CosPi(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cosine of a value that has been multipled by `pi`.

```
C#
public static Half CosPi (Half x);
```

Parameters

x Half

The value, in half-revolutions, whose cosine is to be computed.

Returns

Half

The cosine of `x` multiplied-by `pi`.

Implements

CosPi(TSelf)

Remarks

This computes `cos(x * π)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

public static Half CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Half

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static Half CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

Half

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static Half CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

Half

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.DegreesToRadians(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a given value from degrees to radians.

C#

```
public static Half DegreesToRadians (Half degrees);
```

Parameters

`degrees` Half

The value to convert to radians.

Returns

Half

The value of `degrees` converted to radians.

Implements

DegreesToRadians(TSelf)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Half.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Half)	Compares this instance for equality with `other`.
Equals(Object)	Returns a value that indicates whether this instance is equal to the specified `obj`.

Equals(Half)

Compares this instance for equality with `other`.

C#

```
public bool Equals (Half other);
```

Parameters

`other` Half

A half-precision floating point number to compare to this instance.

Returns

Boolean

`true` if the current object is equal to `other`; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Equals(Object)

Returns a value that indicates whether this instance is equal to the specified `obj`.

```
C#
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare to this instance.

Returns

Boolean

`true` if `obj` is an instance of Half and equals the value of this instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Half.Exp(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `E` raised to a given power.

```
C#
public static Half Exp (Half x);
```

Parameters

x Half

The power to which `E` is raised.

Returns

Half

`E` raised to the power of `x`.

Implements

Exp(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Half.Exp10(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `10` raised to a given power.

```
C#
public static Half Exp10 (Half x);
```

Parameters

x Half

The power to which `10` is raised.

Returns

Half

10^x

Implements

Exp10(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Exp10M1(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `10` raised to a given power and subtracts one.

```
C#
public static Half Exp10M1 (Half x);
```

Parameters

x Half

The power to which `10` is raised.

Returns

Half

`10ˣ - 1`

Implements

Exp10M1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Exp2(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `2` raised to a given power.

```
C#
public static Half Exp2 (Half x);
```

Parameters

x Half

The power to which `2` is raised.

Returns

Half

2^x

Implements

Exp2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Half.FusedMultiplyAdd(Half, Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the fused multiply-add of three values.

```
C#
public static Half FusedMultiplyAdd (Half left, Half right, Half addend);
```

Parameters

`left` Half

The value which `right` multiplies.

`right` Half

The value which multiplies `left`.

`addend` Half

The value that is added to the product of `left` and `right`.

Returns

Half

The result of `left` times `right` plus `addend` computed as one ternary operation.

Implements

FusedMultiplyAdd(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Hypot(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hypotenuse given two values representing the lengths of the shorter sides in a right-angled triangle.

```
C#
public static Half Hypot (Half x, Half y);
```

Parameters

x Half

The value to square and add to `y`.

y Half

The value to square and add to `x`.

Returns

Half

The square root of `x`-squared plus `y`-squared.

Implements

Hypot(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.Ieee754Remainder(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the remainder of two values as specified by IEEE 754.

```
C#
public static Half Ieee754Remainder (Half left, Half right);
```

Parameters

`left` Half

The value which `right` divides.

`right` Half

The value which divides `left`.

Returns

Half

The remainder of `left` divided-by `right` as specified by IEEE 754.

Implements

Ieee754Remainder(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.ILogB(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the integer logarithm of a value.

C#

```
public static int ILogB (Half x);
```

Parameters

x Half

The value whose integer logarithm is to be computed.

Returns

Int32

The integer logarithm of `x`.

Implements

ILogB(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Half.IsEvenInteger(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (Half value);
```

Parameters

`value` Half

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is finite (zero, subnormal, or normal).

C#

```
public static bool IsFinite (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if the specified value is finite (zero, subnormal or normal); otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.IsInfinity(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to positive infinity.

C#

```
public static bool IsInfinity (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if `value` evaluates to PositiveInfinity; otherwise `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

.NET feedback

Half.IsInteger(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral value.

```
C#
public static bool IsInteger (Half value);
```

Parameters

`value` Half

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` and `3.0` will return `true` while `2.2` and `3.3` will return `false`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.IsNaN(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is not a number.

C#

```
public static bool IsNaN (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if `value` evaluates to not a number NaN; otherwise `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

.NET feedback

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

.NET is an open source project. Select a link to provide feedback:

- Open a documentation issue

Half.IsNegative(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is negative.

C#

```
public static bool IsNegative (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if negative; `false` otherwise.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

.NET feedback

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.IsNegativeInfinity(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is negative infinity.

C#

```
public static bool IsNegativeInfinity (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if `value` evaluates to NegativeInfinity; otherwise `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

.NET feedback

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

.NET is an open source project. Select a link to provide feedback:

Half.IsNormal(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is normal.

C#

```
public static bool IsNormal (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if `value` is normal; `false` otherwise.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

.NET feedback

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

.NET is an open source project. Select a link to provide feedback:

- Provide product feedback

Half.IsOddInteger(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (Half value);
```

Parameters

value Half

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.IsPositive(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (Half value);
```

Parameters

`value` Half

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.IsPositiveInfinity(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is positive infinity.

C#

```
public static bool IsPositiveInfinity (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if `value` evaluates to PositiveInfinity; otherwise `false`.

Implements

IsPositiveInfinity(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.IsPow2(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (Half value);
```

Parameters

`value` Half

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.IsRealNumber(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
public static bool IsRealNumber (Half value);
```

Parameters

`value` Half

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Remarks

This function returns `true` for a complex number `a + bi` where `b` is zero.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.IsSubnormal(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is subnormal.

C#

```
public static bool IsSubnormal (Half value);
```

Parameters

`value` Half

A Half floating-point number.

Returns

Boolean

`true` if `value` is subnormal; `false` `false`.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.Lerp(Half, Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Performs a linear interpolation between two values based on the given weight.

C#

```
public static Half Lerp (Half value1, Half value2, Half amount);
```

Parameters

`value1` Half

The first value, which is intended to be the lower bound.

`value2` Half

The second value, which is intended to be the upper bound.

`amount` Half

A value, intended to be between 0 and 1, that indicates the weight of the interpolation.

Returns

Half

The interpolated value.

Implements

Lerp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.Log Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Log(Half)	Computes the natural (`base-E` logarithm of a value.
Log(Half, Half)	Computes the logarithm of a value in the specified base.

Log(Half)

Computes the natural (`base-E` logarithm of a value.

```
C#
public static Half Log (Half x);
```

Parameters

x Half

The value whose natural logarithm is to be computed.

Returns

Half

The natural logarithm of `x`.

Implements

Log(TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Log(Half, Half)

Computes the logarithm of a value in the specified base.

C#

```
public static Half Log (Half x, Half newBase);
```

Parameters

`x` Half

The value whose logarithm is to be computed.

`newBase` Half

The base in which the logarithm is to be computed.

Returns

Half

The base-`newBase` logarithm of `x`.

Implements

Log(TSelf, TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Log10(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the base-10 logarithm of a value.

C#

```
public static Half Log10 (Half x);
```

Parameters

x Half

The value whose base-10 logarithm is to be computed.

Returns

Half

The base-10 logarithm of `x`.

Implements

Log10(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Log10P1(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the base-10 logarithm of a value plus one.

C#

```
public static Half Log10P1 (Half x);
```

Parameters

x Half

The value to which one is added before computing the base-10 logarithm.

Returns

Half

$\log_{10}(x + 1)$

Implements

Log10P1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Log2(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static Half Log2 (Half value);
```

Parameters

`value` Half

The value whose log2 is to be computed.

Returns

Half

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Log2P1(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the base-2 logarithm of a value plus one.

C#

```
public static Half Log2P1 (Half x);
```

Parameters

x Half

The value to which one is added before computing the base-2 logarithm.

Returns

Half

$\log_2(x + 1)$

Implements

Log2P1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Half.LogP1(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the natural (`base-E`) logarithm of a value plus one.

```
C#
public static Half LogP1 (Half x);
```

Parameters

x Half

The value to which one is added before computing the natural logarithm.

Returns

Half

$\log_e(x + 1)$

Implements

LogP1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Half.Max(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static Half Max (Half x, Half y);
```

Parameters

x Half

The value to compare with `y`.

y Half

The value to compare with `x`.

Returns

Half

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.MaxMagnitude(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static Half MaxMagnitude (Half x, Half y);
```

Parameters

x Half

The value to compare with `y`.

y Half

The value to compare with `x`.

Returns

Half

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.MaxMagnitudeNumber(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#
public static Half MaxMagnitudeNumber (Half x, Half y);
```

Parameters

x Half

The value to compare with `y`.

y Half

The value to compare with `x`.

Returns

Half

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitudeNumber` function. This requires NaN inputs to not be propagated back

to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Min(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static Half Min (Half x, Half y);
```

Parameters

x Half

The value to compare with `y`.

y Half

The value to compare with `x`.

Returns

Half

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String)	Converts the string representation of a number to its half-precision floating-point number equivalent.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its single-precision floating-point number equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its single-precision floating-point number equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.

Parse(String)

Converts the string representation of a number to its half-precision floating-point number equivalent.

```
C#

public static Half Parse (string s);
```

Parameters

s String

A string that contains a number to convert.

Returns

Half

A half-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```C#
public static Half Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Half

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```C#
public static Half Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Half

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its single-precision floating-point number equivalent.

```
C#

public static Half Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

Returns

Half

A half-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

ArgumentException

`style` is not a NumberStyles value.

-or-

NumberStyles includes the AllowHexSpecifier value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its single-precision floating-point number equivalent.

```
C#
```

```
public static Half Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Half

A half-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static Half Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Half

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.

C#

```
public static Half Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

Converts the string representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Half

A half-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Exceptions

FormatException

`s` does not represent a number in a valid format.

ArgumentException
`style` is not a NumberStyles value.

-or-

NumberStyles includes the AllowHexSpecifier value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.

C#

```
public static Half Parse (string s, System.Globalization.NumberStyles
style = System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`s` String
A string that contains a number to convert.

`style` NumberStyles
A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider
An object that supplies culture-specific formatting information about `s`.

Returns

Half

A half-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

ArgumentException

`style` is not a NumberStyles value.

-or-

NumberStyles includes the AllowHexSpecifier value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Half.Pow(Half, Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes a value raised to a given power.

```
C#
public static Half Pow (Half x, Half y);
```

Parameters

x Half

The value which is raised to the power of `x`.

y Half

The power to which `x` is raised.

Returns

Half

`x` raised to the power of `y`.

Implements

Pow(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Half.RadiansToDegrees(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a given value from radians to degrees.

C#

```
public static Half RadiansToDegrees (Half radians);
```

Parameters

`radians` Half

The value to convert to degrees.

Returns

Half

The value of `radians` converted to degrees.

Implements

RadiansToDegrees(TSelf)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Half.ReciprocalEstimate(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes an estimate of the reciprocal of a value.

C#

```
public static Half ReciprocalEstimate (Half x);
```

Parameters

x Half

The value whose estimate of the reciprocal is to be computed.

Returns

Half

An estimate of the reciprocal of `x`.

Implements

ReciprocalEstimate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.ReciprocalSqrtEstimate(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes an estimate of the reciprocal square root of a value.

```
C#
public static Half ReciprocalSqrtEstimate (Half x);
```

Parameters

x Half

The value whose estimate of the reciprocal square root is to be computed.

Returns

Half

An estimate of the reciprocal square root of `x`.

Implements

ReciprocalSqrtEstimate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.RootN(Half, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the n-th root of a value.

```
C#
public static Half RootN (Half x, int n);
```

Parameters

x Half

The value whose `n`-th root is to be computed.

n Int32

The degree of the root to be computed.

Returns

Half

The `n`-th root of `x`.

Implements

RootN(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Round Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Round(Half)	Rounds a value to the nearest integer using the default rounding mode (ToEven).
Round(Half, Int32)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Half, MidpointRounding)	Rounds a value to the nearest integer using the specified rounding mode.
Round(Half, Int32, MidpointRounding)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

Round(Half)

Rounds a value to the nearest integer using the default rounding mode (ToEven).

C#

```
public static Half Round (Half x);
```

Parameters

x Half

The value to round.

Returns

Half

The result of rounding `x` to the nearest integer using the default rounding mode.

Implements

Round(TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Half, Int32)

Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

C#

```
public static Half Round (Half x, int digits);
```

Parameters

`x` Half

The value to round.

`digits` Int32

The number of fractional digits to which `x` should be rounded.

Returns

Half

The result of rounding `x` to `digits` fractional-digits using the default rounding mode.

Implements

Round(TSelf, Int32)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Half, MidpointRounding)

Rounds a value to the nearest integer using the specified rounding mode.

C#

```
public static Half Round (Half x, MidpointRounding mode);
```

Parameters

`x` Half

The value to round.

`mode` MidpointRounding

The mode under which `x` should be rounded.

Returns

Half

The result of rounding `x` to the nearest integer using `mode`.

Implements

Round(TSelf, MidpointRounding)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Half, Int32, MidpointRounding)

Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

```
C#

public static Half Round (Half x, int digits, MidpointRounding mode);
```

Parameters

x Half

The value to round.

digits Int32

The number of fractional digits to which `x` should be rounded.

mode MidpointRounding

The mode under which `x` should be rounded.

Returns

Half

The result of rounding `x` to `digits` fractional-digits using `mode`.

Implements

Round(TSelf, Int32, MidpointRounding)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Half.ScaleB(Half, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the product of a value and its base-radix raised to the specified power.

```
C#
public static Half ScaleB (Half x, int n);
```

Parameters

x Half

The value which base-radix raised to the power of `n` multiplies.

n Int32

The value to which base-radix is raised before multipliying `x`.

Returns

Half

The product of `x` and base-radix raised to the power of `n`.

Implements

ScaleB(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Sign(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (Half value);
```

Parameters

`value` Half

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Sin(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine of a value.

```
C#
public static Half Sin (Half x);
```

Parameters

x Half

The value, in radians, whose sine is to be computed.

Returns

Half

The sine of `x`.

Implements

Sin(TSelf)

Remarks

This computes `sin(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.SinCos(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine and cosine of a value.

```
C#
public static (Half Sin, Half Cos) SinCos (Half x);
```

Parameters

x Half

The value, in radians, whose sine and cosine are to be computed.

Returns

ValueTuple<Half,Half>

The sine and cosine of `x`.

Implements

SinCos(TSelf)

Remarks

This computes `(sin(x), cos(x))`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.SinCosPi(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine and cosine of a value that has been multiplied by `pi`.

```
C#
public static (Half SinPi, Half CosPi) SinCosPi (Half x);
```

Parameters

x Half

The value, in half-revolutions, that is multipled by `pi` before computing its sine and cosine.

Returns

ValueTuple<Half,Half>

The sine and cosine of `x` multiplied-by `pi`.

Implements

SinCosPi(TSelf)

Remarks

This computes `(sin(x * π), cos(x * π))`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Sinh(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic sine of a value.

C#

```
public static Half Sinh (Half x);
```

Parameters

x Half

The value, in radians, whose hyperbolic sine is to be computed.

Returns

Half

The hyperbolic sine of `x`.

Implements

Sinh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.SinPi(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine of a value that has been multiplied by `pi`.

```
C#
public static Half SinPi (Half x);
```

Parameters

x Half

The value, in half-revolutions, that is multipled by `pi` before computing its sine.

Returns

Half

The sine of `x` multiplied-by `pi`.

Implements

SinPi(TSelf)

Remarks

This computes `sin(x * π)`.

Applies to

Product	Versions
.NET	7, 8, 9

Half.Sqrt(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the square-root of a value.

C#

```
public static Half Sqrt (Half x);
```

Parameters

x Half

The value whose square-root is to be computed.

Returns

Half

The square-root of `x`.

Implements

Sqrt(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Tan(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the tangent of a value.

```
C#
public static Half Tan (Half x);
```

Parameters

x Half

The value, in radians, whose tangent is to be computed.

Returns

Half

The tangent of `x`.

Implements

Tan(TSelf)

Remarks

This computes `tan(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Tanh(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic tangent of a value.

C#

```
public static Half Tanh (Half x);
```

Parameters

x Half

The value, in radians, whose hyperbolic tangent is to be computed.

Returns

Half

The hyperbolic tangent of `x`.

Implements

Tanh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid.

See also

- Standard numeric format strings
- Custom numeric format strings

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(String, IFormatProvider)

See also

- Standard numeric format strings
- Custom numeric format strings

Applies to

Half.Truncate(Half) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Truncates a value.

C#

```
public static Half Truncate (Half x);
```

Parameters

x Half

The value to truncate.

Returns

Half

The truncation of `x`.

Implements

Truncate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current Half instance into the provided span of characters.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current Half instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful, otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

See also

- Standard numeric format strings
- Custom numeric format strings

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
```

```
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Half.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, Half)	Tries to convert a UTF-8 character span containing the string representation of a number to its half-precision floating-point number equivalent.
TryParse(ReadOnlySpan<Char>, Half)	Converts the span representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Half)	Converts the string representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Half)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Half)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Half)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Half)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Half)	Converts the span representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Half)	Converts the string representation of a number to its half-precision floating-point number equivalent. A

	return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, Half)

Tries to convert a UTF-8 character span containing the string representation of a number to its half-precision floating-point number equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out Half
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A read-only UTF-8 character span that contains the number to convert.

`result` Half

When this method returns, contains a half-precision floating-point number equivalent of the numeric value or symbol contained in `utf8Text` if the conversion succeeded or zero if the conversion failed. The conversion fails if the `utf8Text` is Empty or is not in a valid format. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, Half)

Converts the span representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out Half result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span that contains a number to convert.

`result` Half

When this method returns, contains the half-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or a default Half value if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty or is not a number in a valid format. If `s` is a valid number less than MinValue, `result` contains NegativeInfinity. If `s` is a valid number greater than MaxValue, `result` contains PositiveInfinity. This parameter is treated as uninitialized.

Returns

Boolean

`true` if `s` was converted successfully, `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryParse(String, Half)

Converts the string representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (string? s, out Half result);
```

Parameters

`s` String

A string that contains a number to convert.

`result` Half

When this method returns, contains the half-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or a default Half value if the conversion failed. The conversion fails if `s` is `null` or Empty or is not a number in a valid format. If `s` is a valid number less than MinValue, `result` contains NegativeInfinity. If `s` is a valid number greater than MaxValue, `result` contains PositiveInfinity. This parameter is treated as uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Half)

Tries to parse a span of UTF-8 characters into a value.

```
C#
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out Half result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Half

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, Half)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out Half result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Half

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Half)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
Half result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Half

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Half)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
Half result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Half

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Half)

Converts the span representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
Half result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Half

When this method returns, contains the half-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or a default Half value if the conversion failed. The conversion fails if `s` is not a number in a valid format. If `s` is a valid number less than MinValue, `result` contains NegativeInfinity. If `s` is a valid number greater than MaxValue, `result` contains PositiveInfinity. This parameter is treated as uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

NumberStyles is the AllowHexSpecifier value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryParse(String, NumberStyles, IFormatProvider, Half)

Converts the string representation of a number to its half-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
```

```
  style, IFormatProvider? provider, out Half result);
```

Parameters

`s` String

A string that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Half

When this method returns, contains the half-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or a default Half value if the conversion failed. The conversion fails if `s` is `null` or Empty or is not a number in a valid format. If `s` is a valid number less than MinValue, `result` contains NegativeInfinity. If `s` is a valid number greater than MaxValue, `result` contains PositiveInfinity. This parameter is treated as uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

NumberStyles is the AllowHexSpecifier value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Half.Addition(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

C#

```
public static Half operator + (Half left, Half right);
```

Parameters

`left` Half

The value to which `right` is added.

`right` Half

The value which is added to `left`.

Returns

Half

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.CheckedExplicit(Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
public static byte op_CheckedExplicit (Half value);
```

Parameters

`value` Half

Returns

Byte

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Decrement(Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

C#

```
public static Half operator -- (Half value);
```

Parameters

`value` Half

The value to decrement.

Returns

Half

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Division(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their quotient.

C#

```
public static Half operator / (Half left, Half right);
```

Parameters

`left` Half

The value which `right` divides.

`right` Half

The value which divides `left`.

Returns

Half

The quotient of `left` divided-by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Equality(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two specified Half values are equal.

```
C#
public static bool operator == (Half left, Half right);
```

Parameters

`left` Half

The first value to compare.

`right` Half

The second value to compare.

Returns

Boolean

`true` if `left` and `right` are equal; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.Explicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Explicit(Half to UInt32)	Explicitly converts a half-precision floating-point value to its nearest representable UInt32 value.
Explicit(Half to UInt64)	Explicitly converts a half-precision floating-point value to its nearest representable UInt64 value.
Explicit(Half to UIntPtr)	Explicitly converts a half-precision floating-point value to its nearest representable UIntPtr value.
Explicit(Int16 to Half)	Explicitly converts a Int16 value to its nearest representable half-precision floating-point value.
Explicit(Int32 to Half)	Explicitly converts a Int32 value to its nearest representable half-precision floating-point value.
Explicit(Int64 to Half)	Explicitly converts a Int64 value to its nearest representable half-precision floating-point value.
Explicit(UInt64 to Half)	Explicitly converts a UInt64 value to its nearest representable half-precision floating-point value.
Explicit(Single to Half)	An explicit operator to convert a Single value to a Half.
Explicit(UInt16 to Half)	Explicitly converts a UInt16 value to its nearest representable half-precision floating-point value.
Explicit(UInt32 to Half)	Explicitly converts a UInt32 value to its nearest representable half-precision floating-point value.
Explicit(Half to UInt16)	Explicitly converts a half-precision floating-point value to its nearest representable UInt16 value.

Explicit(UIntPtr to Half)	Explicitly converts a UIntPtr value to its nearest representable half-precision floating-point value.
Explicit(IntPtr to Half)	Explicitly converts a IntPtr value to its nearest representable half-precision floating-point value.
Explicit(Half to UInt128)	Explicitly converts a half-precision floating-point value to its nearest representable UInt128.
Explicit(Half to Single)	An explicit operator to convert a Half value to a Single.
Explicit(Half to SByte)	Explicitly converts a half-precision floating-point value to its nearest representable SByte value.
Explicit(Char to Half)	Explicitly converts a Char value to its nearest representable half-precision floating-point value.
Explicit(Double to Half)	An explicit operator to convert a Double value to a Half.
Explicit(Half to Byte)	Explicitly converts a half-precision floating-point value to its nearest representable Byte value.
Explicit(Half to Char)	Explicitly converts a half-precision floating-point value to its nearest representable Char value.
Explicit(Half to Decimal)	Explicitly converts a half-precision floating-point value to its nearest representable Decimal value.
Explicit(Decimal to Half)	Explicitly converts a Decimal value to its nearest representable half-precision floating-point value.
Explicit(Half to Int128)	Explicitly converts a half-precision floating-point value to its nearest representable Int128.
Explicit(Half to Int16)	Explicitly converts a half-precision floating-point value to its nearest representable Int16 value.
Explicit(Half to Int32)	Explicitly converts a half-precision floating-point value to its nearest representable Int32 value.
Explicit(Half to Int64)	Explicitly converts a half-precision floating-point value to its nearest representable Int64 value.
Explicit(Half to IntPtr)	Explicitly converts a half-precision floating-point value to its nearest representable IntPtr value.
Explicit(Half to Double)	An explicit operator to convert a Half value to a Double.

Explicit(Half to UInt32)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a half-precision floating-point value to its nearest representable UInt32 value.

```C#
[System.CLSCompliant(false)]
public static explicit operator uint (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

UInt32

`value` converted to its nearest representable UInt32 value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to UInt64)

> Important

This API is not CLS-compliant.

Explicitly converts a half-precision floating-point value to its nearest representable UInt64 value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator ulong (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

UInt64

`value` converted to its nearest representable UInt64 value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to UIntPtr)

Important

This API is not CLS-compliant.

Explicitly converts a half-precision floating-point value to its nearest representable UIntPtr value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator UIntPtr (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

UIntPtr

`value` converted to its nearest representable UIntPtr value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int16 to Half)

Explicitly converts a Int16 value to its nearest representable half-precision floating-point value.

```
C#

public static explicit operator Half (short value);
```

Parameters

`value` Int16

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int32 to Half)

Explicitly converts a Int32 value to its nearest representable half-precision floating-point value.

C#

```
public static explicit operator Half (int value);
```

Parameters

`value` Int32

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int64 to Half)

Explicitly converts a Int64 value to its nearest representable half-precision floating-point value.

```
C#

public static explicit operator Half (long value);
```

Parameters

`value` Int64

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt64 to Half)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a UInt64 value to its nearest representable half-precision floating-point value.

```
C#

[System.CLSCompliant(false)]
```

```
public static explicit operator Half (ulong value);
```

Parameters

`value` UInt64

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Single to Half)

An explicit operator to convert a Single value to a Half.

C#

```
public static explicit operator Half (float value);
```

Parameters

`value` Single

The single-precision floating point value to convert to Half.

Returns

Half

The Half representation of the specified single-precision floating point `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Explicit(UInt16 to Half)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a UInt16 value to its nearest representable half-precision floating-point value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator Half (ushort value);
```

Parameters

`value` UInt16

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt32 to Half)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a UInt32 value to its nearest representable half-precision floating-point value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator Half (uint value);
```

Parameters

`value` UInt32

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to UInt16)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a half-precision floating-point value to its nearest representable UInt16 value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator ushort (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

UInt16

`value` converted to its nearest representable UInt16 value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UIntPtr to Half)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a UIntPtr value to its nearest representable half-precision floating-point value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator Half (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(IntPtr to Half)

Explicitly converts a IntPtr value to its nearest representable half-precision floating-point value.

```
C#

public static explicit operator Half (IntPtr value);
```

Parameters

`value` IntPtr

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to UInt128)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a half-precision floating-point value to its nearest representable UInt128.

C#

```
[System.CLSCompliant(false)]
public static explicit operator UInt128 (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Single)

An explicit operator to convert a Half value to a Single.

```
C#
public static explicit operator float (Half value);
```

Parameters

`value` Half

The half-precision floating point value to convert to Single.

Returns

Single

The Single representation of the specified half-precision floating point `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Explicit(Half to SByte)

Important

This API is not CLS-compliant.

Explicitly converts a half-precision floating-point value to its nearest representable SByte value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator sbyte (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

SByte

`value` converted to its nearest representable SByte value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Char to Half)

Explicitly converts a Char value to its nearest representable half-precision floating-point value.

```
C#

public static explicit operator Half (char value);
```

Parameters

`value` Char

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Double to Half)

An explicit operator to convert a Double value to a Half.

```
C#
public static explicit operator Half (double value);
```

Parameters

`value` Double

The double-precision floating point value to convert to Half.

Returns

Half

The Half representation of the specified double-precision floating point `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Explicit(Half to Byte)

Explicitly converts a half-precision floating-point value to its nearest representable Byte value.

```
C#
public static explicit operator byte (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Byte

`value` converted to its nearest representable Byte value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Char)

Explicitly converts a half-precision floating-point value to its nearest representable Char value.

```
C#
public static explicit operator char (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Char

`value` converted to its nearest representable Char value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Decimal)

Explicitly converts a half-precision floating-point value to its nearest representable Decimal value.

```
C#
public static explicit operator decimal (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Decimal

`value` converted to its nearest representable Decimal value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Decimal to Half)

Explicitly converts a Decimal value to its nearest representable half-precision floating-point value.

```
C#
public static explicit operator Half (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Int128)

Explicitly converts a half-precision floating-point value to its nearest representable Int128.

```
C#
public static explicit operator Int128 (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Int16)

Explicitly converts a half-precision floating-point value to its nearest representable Int16 value.

```
C#
public static explicit operator short (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Int16

`value` converted to its nearest representable Int16 value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Int32)

Explicitly converts a half-precision floating-point value to its nearest representable Int32 value.

```
C#
public static explicit operator int (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Int32

`value` converted to its nearest representable Int32 value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Int64)

Explicitly converts a half-precision floating-point value to its nearest representable Int64 value.

```
C#
public static explicit operator long (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

Int64

`value` converted to its nearest representable Int64 value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to IntPtr)

Explicitly converts a half-precision floating-point value to its nearest representable IntPtr value.

```
C#
public static explicit operator IntPtr (Half value);
```

Parameters

`value` Half

The value to convert.

Returns

IntPtr

`value` converted to its nearest representable IntPtr value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Half to Double)

An explicit operator to convert a Half value to a Double.

```
C#
public static explicit operator double (Half value);
```

Parameters

`value` Half

The half-precision floating point value to convert to Double.

Returns

Double

The Double representation of the specified half-precision floating point `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Half.GreaterThan(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Half value is greater than another specified Half value.

```
C#
public static bool operator > (Half left, Half right);
```

Parameters

`left` Half

The first value to compare.

`right` Half

The second value to compare.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.GreaterThanOrEqual(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether `left` is greater than or equal to `right`.

```
C#
public static bool operator >= (Half left, Half right);
```

Parameters

`left` Half

The first value to compare.

`right` Half

The second value to compare.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(SByte to Half)	Implicitly converts a SByte value to its nearest representable half-precision floating-point value.
Implicit(Byte to Half)	Implicitly converts a Byte value to its nearest representable half-precision floating-point value.

Implicit(SByte to Half)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a SByte value to its nearest representable half-precision floating-point value.

C#

```
[System.CLSCompliant(false)]
public static implicit operator Half (sbyte value);
```

Parameters

`value` SByte

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Byte to Half)

Implicitly converts a Byte value to its nearest representable half-precision floating-point value.

```
C#
public static implicit operator Half (byte value);
```

Parameters

`value` Byte

The value to convert.

Returns

Half

`value` converted to its nearest representable half-precision floating-point value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Half.Increment(Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

C#

```
public static Half operator ++ (Half value);
```

Parameters

`value` Half

The value to increment.

Returns

Half

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Inequality(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two specified Half values are not equal.

```
C#
public static bool operator != (Half left, Half right);
```

Parameters

`left` Half

The first value to compare.

`right` Half

The second value to compare.

Returns

Boolean

`true` if `left` and `right` are not equal; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.LessThan(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Half value is less than another specified Half value.

```
C#
public static bool operator < (Half left, Half right);
```

Parameters

left Half

The first value to compare.

right Half

The second value to compare.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.LessThanOrEqual(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Half value is less than or equal to another specified Half value.

C#

```
public static bool operator <= (Half left, Half right);
```

Parameters

`left` Half

The first value to compare.

`right` Half

The second value to compare.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

Half.Modulus(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#
public static Half operator % (Half left, Half right);
```

Parameters

`left` Half

The value which `right` divides.

`right` Half

The value which divides `left`.

Returns

Half

The modulus or remainder of `left` divided-by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Multiply(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#
public static Half operator * (Half left, Half right);
```

Parameters

`left` Half

The value which `right` multiplies.

`right` Half

The value which multiplies `left`.

Returns

Half

The product of `left` multiplied-by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.Subtraction(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#
public static Half operator - (Half left, Half right);
```

Parameters

`left` Half

The value from which `right` is subtracted.

`right` Half

The value which is subtracted from `left`.

Returns

Half

The difference of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.UnaryNegation(Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
public static Half operator - (Half value);
```

Parameters

`value` Half

The value for which to compute the unary negation.

Returns

Half

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.UnaryPlus(Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
public static Half operator + (Half value);
```

Parameters

`value` Half

The value for which to compute the unary plus.

Returns

Half

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.IAdditiveIdentity<Half,Half>.AdditiveIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the additive identity of the current type.

```
C#

static Half
System.Numerics.IAdditiveIdentity<System.Half,System.Half>.AdditiveIdentity
{ get; }
```

Property Value

Half

Implements

AdditiveIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.IBitwiseOperators<Half,Half,Half>.BitwiseAnd(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static Half IBitwiseOperators<Half,Half,Half>.operator & (Half left, Half
right);
```

Parameters

`left` Half

The value to `and` with `right`.

`right` Half

The value to `and` with `left`.

Returns

Half

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.IBitwise Operators<Half,Half,Half>.Bitwise Or(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static Half IBitwiseOperators<Half,Half,Half>.operator | (Half left, Half
right);
```

Parameters

left Half

The value to `or` with `right`.

right Half

The value to `or` with `left`.

Returns

Half

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Half.IBitwiseOperators<Half,Half,Half>.ExclusiveOr(Half, Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static Half IBitwiseOperators<Half,Half,Half>.operator ^ (Half left, Half
right);
```

Parameters

`left` Half

The value to xor with `right`.

`right` Half

The value to xor with `left`.

Returns

Half

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.IBitwiseOperators<Half,Half,Half>.OnesComplement(Half) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
static Half IBitwiseOperators<Half,Half,Half>.operator ~ (Half value);
```

Parameters

`value` Half

The value for which to compute the ones-complement.

Returns

Half

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.IFloatingPoint<Half>.TryWriteExponentBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current exponent, in big-endian format, to a given span.

C#

```
bool IFloatingPoint<Half>.TryWriteExponentBigEndian (Span<byte> destination,
out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current exponent should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the exponent was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteExponentBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Half.INumberBase<Half>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<Half>.TryConvertToChecked<TOther> (Half value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Half

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Half.INumberBase<Half>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<Half>.TryConvertToSaturating<TOther> (Half value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Half

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Half.INumberBase<Half>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<Half>.TryConvertToTruncating<TOther> (Half value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Half

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

HashCode Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Combines the hash code for multiple values into a single hash code.

C#

```
public struct HashCode
```

Inheritance Object → ValueType → HashCode

Examples

The static methods in this class combine the default hash codes of *up to eight* values.

C#

```
using System;
using System.Collections.Generic;

public struct OrderOrderLine : IEquatable<OrderOrderLine>
{
    public int OrderId { get; }
    public int OrderLineId { get; }

    public OrderOrderLine(int orderId, int orderLineId) => (OrderId,
OrderLineId) = (orderId, orderLineId);

    public override bool Equals(object obj) => obj is OrderOrderLine o &&
Equals(o);

    public bool Equals(OrderOrderLine other) => OrderId == other.OrderId &&
OrderLineId == other.OrderLineId;

    public override int GetHashCode() => HashCode.Combine(OrderId,
OrderLineId);
}

class Program
{
```

```
    static void Main(string[] args)
    {
        var set = new HashSet<OrderOrderLine>
        {
            new OrderOrderLine(1, 1),
            new OrderOrderLine(1, 1),
            new OrderOrderLine(1, 2)
        };

        Console.WriteLine($"Item count: {set.Count}.");
    }
}
// The example displays the following output:
// Item count: 2.
```

> ⓘ **Important**
>
> **ToHashCode()** must be called at most once per instance of **HashCode**.

The instance methods in this class combine the hash codes of *more than eight* values.

C#

```
using System;
using System.Collections.Generic;

public struct Path : IEquatable<Path>
{
    public IReadOnlyList<string> Segments { get; }

    public Path(params string[] segments) => Segments = segments;

    public override bool Equals(object obj) => obj is Path o && Equals(o);

    public bool Equals(Path other)
    {
        if (ReferenceEquals(Segments, other.Segments)) return true;
        if (Segments is null || other.Segments is null) return false;
        if (Segments.Count != other.Segments.Count) return false;

        for (var i = 0; i < Segments.Count; i++)
        {
            if (!string.Equals(Segments[i], other.Segments[i]))
                return false;
        }

        return true;
    }

    public override int GetHashCode()
    {
```

```
        var hash = new HashCode();

        for (var i = 0; i < Segments?.Count; i++)
            hash.Add(Segments[i]);

        return hash.ToHashCode();
    }
}

class Program
{
    static void Main(string[] args)
    {
        var set = new HashSet<Path>
        {
            new Path("C:", "tmp", "file.txt"),
            new Path("C:", "tmp", "file.txt"),
            new Path("C:", "tmp", "file.tmp")
        };

        Console.WriteLine($"Item count: {set.Count}.");
    }
}
// The example displays the following output:
// Item count: 2.
```

The instance methods also combine the hash codes produced by a specific IEqualityComparer<T> implementation.

C#

```
using System;
using System.Collections.Generic;

public struct Path : IEquatable<Path>
{
    public IReadOnlyList<string> Segments { get; }

    public Path(params string[] segments) => Segments = segments;

    public override bool Equals(object obj) => obj is Path o && Equals(o);

    public bool Equals(Path other)
    {
        if (ReferenceEquals(Segments, other.Segments)) return true;
        if (Segments is null || other.Segments is null) return false;
        if (Segments.Count != other.Segments.Count) return false;

        for (var i = 0; i < Segments.Count; i++)
        {
            if (!string.Equals(Segments[i], other.Segments[i],
StringComparison.OrdinalIgnoreCase))
                return false;
```

```
        }

        return true;
    }

    public override int GetHashCode()
    {
        var hash = new HashCode();

        for (var i = 0; i < Segments?.Count; i++)
            hash.Add(Segments[i], StringComparer.OrdinalIgnoreCase);

        return hash.ToHashCode();
    }
}

class Program
{
    static void Main(string[] args)
    {
        var set = new HashSet<Path>
        {
            new Path("C:", "tmp", "file.txt"),
            new Path("C:", "TMP", "file.txt"),
            new Path("C:", "tmp", "FILE.TXT")
        };

        Console.WriteLine($"Item count: {set.Count}.");
    }
}
// The example displays the following output:
// Item count: 1.
```

The HashCode structure must be passed by-reference to other methods, as it is a value type.

C#

```
using System;
using System.Collections.Generic;

public struct Path : IEquatable<Path>
{
    public IReadOnlyList<string> Segments { get; }

    public Path(params string[] segments) => Segments = segments;

    public override bool Equals(object obj) => obj is Path o && Equals(o);

    public bool Equals(Path other)
    {
        if (ReferenceEquals(Segments, other.Segments)) return true;
        if (Segments is null || other.Segments is null) return false;
```

```
        if (Segments.Count != other.Segments.Count) return false;

        for (var i = 0; i < Segments.Count; i++)
        {
            if (!PlatformUtils.PathEquals(Segments[i], other.Segments[i]))
                return false;
        }

        return true;
    }

    public override int GetHashCode()
    {
        var hash = new HashCode();

        for (var i = 0; i < Segments?.Count; i++)
            PlatformUtils.AddPath(ref hash, Segments[i]);

        return hash.ToHashCode();
    }
}

internal static class PlatformUtils
{
    public static bool PathEquals(string a, string b) => string.Equals(a, b,
StringComparison.OrdinalIgnoreCase);
    public static void AddPath(ref HashCode hash, string path) =>
hash.Add(path, StringComparer.OrdinalIgnoreCase);
}

class Program
{
    static void Main(string[] args)
    {
        var set = new HashSet<Path>
        {
            new Path("C:", "tmp", "file.txt"),
            new Path("C:", "TMP", "file.txt"),
            new Path("C:", "tmp", "FILE.TXT")
        };

        Console.WriteLine($"Item count: {set.Count}.");
    }
}
// The example displays the following output:
// Item count: 1.
```

Remarks

You can use HashCode to combine multiple values (for example, fields on a structure or class) into a single hash code. This structure has static and instance methods that

operate differently:

- The static methods accept a set of up to eight values to combine.
- Two instance methods operate in a streaming fashion, accepting values one at a time.

> ⚠ **Warning**
>
> It's best-practice to consider hash codes as an implementation detail, as the implementation may change across assembly versions. Do not store hash codes produced by **HashCode** in serialized structures, for example, on-disk. **HashCode** uses a statically initialized random seed to enforce this best practice, meaning that the hash codes are only deterministic within the scope of an operating system process.

Methods

Expand table

Add<T>(T)	Adds a single value to the hash code.
Add<T>(T, IEqualityComparer<T>)	Adds a single value to the hash code, specifying the type that provides the hash code function.
AddBytes(ReadOnlySpan<Byte>)	Adds a span of bytes to the hash code.
Combine<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)	Combines eight values into a hash code.
Combine<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Combines seven values into a hash code.
Combine<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Combines six values into a hash code.
Combine<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Combines five values into a hash code.
Combine<T1,T2,T3,T4>(T1, T2, T3, T4)	Combines four values into a hash code.
Combine<T1,T2,T3>(T1, T2, T3)	Combines three values into a hash code.
Combine<T1,T2>(T1, T2)	Combines two values into a hash code.
Combine<T1>(T1)	Diffuses the hash code returned by the specified value.

Equals(Object)	**Obsolete.** This method is not supported and should not be called.
GetHashCode()	**Obsolete.** This method is not supported and should not be called.
ToHashCode()	Calculates the final hash code after consecutive Add invocations.

HashCode.Add Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Add<T>(T)	Adds a single value to the hash code.
Add<T>(T, IEqualityComparer<T>)	Adds a single value to the hash code, specifying the type that provides the hash code function.

Add<T>(T)

Adds a single value to the hash code.

C#

```
public void Add<T> (T value);
```

Type Parameters

`T`

The type of the value to add to the hash code.

Parameters

`value` T

The value to add to the hash code.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Add<T>(T, IEqualityComparer<T>)

Adds a single value to the hash code, specifying the type that provides the hash code function.

C#

```
public void Add<T> (T value,
System.Collections.Generic.IEqualityComparer<T>? comparer);
```

Type Parameters

`T`

The type of the value to add to the hash code.

Parameters

`value` T

The value to add to the hash code.

`comparer` IEqualityComparer<T>

The IEqualityComparer<T> to use to calculate the hash code. This value can be a null reference (Nothing in Visual Basic), which will use the default equality comparer for `T`.

Applies to

▼ .NET 9 and other versions

HashCode.AddBytes(ReadOnlySpan<Byte>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds a span of bytes to the hash code.

C#

```
public void AddBytes (ReadOnlySpan<byte> value);
```

Parameters

`value` ReadOnlySpan<Byte>

The span to add.

Remarks

This method does not guarantee that the result of adding a span of bytes will match the result of adding the same bytes individually.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Overloads

Expand table

Combine<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)	Combines eight values into a hash code.
Combine<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Combines seven values into a hash code.
Combine<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Combines six values into a hash code.
Combine<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Combines five values into a hash code.
Combine<T1,T2,T3,T4>(T1, T2, T3, T4)	Combines four values into a hash code.
Combine<T1,T2,T3>(T1, T2, T3)	Combines three values into a hash code.
Combine<T1,T2>(T1, T2)	Combines two values into a hash code.
Combine<T1>(T1)	Diffuses the hash code returned by the specified value.

Combine<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)

Combines eight values into a hash code.

C#

```
public static int Combine<T1,T2,T3,T4,T5,T6,T7,T8> (T1 value1, T2 value2,
T3 value3, T4 value4, T5 value5, T6 value6, T7 value7, T8 value8);
```

Type Parameters

`T1`

The type of the first value to combine into the hash code.

`T2`

The type of the second value to combine into the hash code.

`T3`

The type of the third value to combine into the hash code.

`T4`

The type of the fourth value to combine into the hash code.

`T5`

The type of the fifth value to combine into the hash code.

`T6`

The type of the sixth value to combine into the hash code.

`T7`

The type of the seventh value to combine into the hash code.

`T8`

The type of the eighth value to combine into the hash code.

Parameters

`value1` T1

The first value to combine into the hash code.

`value2` T2

The second value to combine into the hash code.

`value3` T3

The third value to combine into the hash code.

`value4` T4

The fourth value to combine into the hash code.

`value5` T5

The fifth value to combine into the hash code.

`value6` T6

The sixth value to combine into the hash code.

`value7` T7

The seventh value to combine into the hash code.

`value8` T8

The eighth value to combine into the hash code.

Returns

Int32

The hash code that represents the eight values.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Combine<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)

Combines seven values into a hash code.

C#

```
public static int Combine<T1,T2,T3,T4,T5,T6,T7> (T1 value1, T2 value2, T3 value3, T4 value4, T5 value5, T6 value6, T7 value7);
```

Type Parameters

`T1`

The type of the first value to combine into the hash code.

`T2`

The type of the second value to combine into the hash code.

`T3`

The type of the third value to combine into the hash code.

`T4`

The type of the fourth value to combine into the hash code.

`T5`

The type of the fifth value to combine into the hash code.

`T6`

The type of the sixth value to combine into the hash code.

`T7`

The type of the seventh value to combine into the hash code.

Parameters

`value1` T1

The first value to combine into the hash code.

`value2` T2

The second value to combine into the hash code.

`value3` T3

The third value to combine into the hash code.

`value4` T4

The fourth value to combine into the hash code.

`value5` T5

The fifth value to combine into the hash code.

`value6` T6

The sixth value to combine into the hash code.

`value7` T7

The seventh value to combine into the hash code.

Returns

Int32

The hash code that represents the seven values.

Applies to

▼ .NET 9 and other versions

Product	Versions

Combine<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)

Combines six values into a hash code.

C#

```
public static int Combine<T1,T2,T3,T4,T5,T6> (T1 value1, T2 value2, T3
value3, T4 value4, T5 value5, T6 value6);
```

Type Parameters

T1

The type of the first value to combine into the hash code.

T2

The type of the second value to combine into the hash code.

T3

The type of the third value to combine into the hash code.

T4

The type of the fourth value to combine into the hash code.

`T5`

The type of the fifth value to combine into the hash code.

`T6`

The type of the sixth value to combine into the hash code.

Parameters

`value1` T1

The first value to combine into the hash code.

`value2` T2

The second value to combine into the hash code.

`value3` T3

The third value to combine into the hash code.

`value4` T4

The fourth value to combine into the hash code.

`value5` T5

The fifth value to combine into the hash code.

`value6` T6

The sixth value to combine into the hash code.

Returns

Int32

The hash code that represents the six values.

Applies to

Combine<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)

Combines five values into a hash code.

```
C#

public static int Combine<T1,T2,T3,T4,T5> (T1 value1, T2 value2, T3
value3, T4 value4, T5 value5);
```

Type Parameters

T1

The type of the first value to combine into the hash code.

T2

The type of the second value to combine into the hash code.

T3

The type of the third value to combine into the hash code.

T4

The type of the fourth value to combine into the hash code.

T5

The type of the fifth value to combine into the hash code.

Parameters

value1 T1

The first value to combine into the hash code.

value2 T2

The second value to combine into the hash code.

value3 T3

The third value to combine into the hash code.

`value4` T4

The fourth value to combine into the hash code.

`value5` T5

The fifth value to combine into the hash code.

Returns

Int32

The hash code that represents the five values.

Applies to

Combine<T1,T2,T3,T4>(T1, T2, T3, T4)

Combines four values into a hash code.

C#

```
public static int Combine<T1,T2,T3,T4> (T1 value1, T2 value2, T3 value3,
T4 value4);
```

Type Parameters

`T1`

The type of the first value to combine into the hash code.

`T2`

The type of the second value to combine into the hash code.

`T3`

The type of the third value to combine into the hash code.

`T4`

The type of the fourth value to combine into the hash code.

Parameters

`value1` T1

The first value to combine into the hash code.

`value2` T2

The second value to combine into the hash code.

`value3` T3

The third value to combine into the hash code.

`value4` T4

The fourth value to combine into the hash code.

Returns

Type Parameters

`T1`

The type of the first value to combine into the hash code.

`T2`

The type of the second value to combine into the hash code.

Parameters

`value1` T1

The first value to combine into the hash code.

`value2` T2

The second value to combine into the hash code.

Returns

Int32

The hash code that represents the two values.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Combine<T1>(T1)

Diffuses the hash code returned by the specified value.

```
C#
```

```
public static int Combine<T1> (T1 value1);
```

Type Parameters

`T1`

The type of the value to add the hash code.

Parameters

`value1` T1

The value to add to the hash code.

Returns

Int32

The hash code that represents the single value.

Remarks

Some data structures assume that hash codes are diffused across a large range. This method improves the quality of the hash code returned by the value and is useful when the underlying data type is simple, for example, an integer value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

HashCode.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> HashCode is a mutable struct and should not be compared with other HashCodes.

This method is not supported and should not be called.

C#

```
[System.Obsolete("HashCode is a mutable struct and should not be compared
with other HashCodes.", true)]
public override bool Equals (object? obj);
```

Parameters

obj Object

Ignored.

Returns

Boolean

This method will always throw a NotSupportedException.

Attributes ObsoleteAttribute

Exceptions

NotSupportedException

Always thrown when this method is called.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Standard	*(2.1)*

HashCode.ToHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the final hash code after consecutive Add invocations.

C#

```
public int ToHashCode ();
```

Returns

Int32

The calculated hash code.

Remarks

This method must be called at most once per instance of HashCode.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

HttpStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser based on the HTTP scheme.

C#

```
public class HttpStyleUriParser : UriParser
```

Inheritance Object → UriParser → HttpStyleUriParser

Constructors

Expand table

HttpStyleUriParser()	Create a customizable parser based on the HTTP scheme.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)

IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

IAsyncDisposable Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a mechanism for releasing unmanaged resources asynchronously.

C#

```
public interface IAsyncDisposable
```

Derived Microsoft.Extensions.DependencyInjection.AsyncServiceScope
System.Collections.Generic.IAsyncEnumerator<T>
System.Data.Common.DbBatch
System.Data.Common.DbCommand
More...

Remarks

For more information about this API, see Supplemental API remarks for IAsyncDisposable.

Methods

Expand table

Dispose Async()	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources asynchronously.

Extension Methods

Expand table

ConfigureAwait(IAsyncDisposable, Boolean)	Configures how awaits on the tasks returned from an async disposable are performed.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IAsyncDisposable.DisposeAsync Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources asynchronously.

```
C#
public System.Threading.Tasks.ValueTask DisposeAsync ();
```

Returns

ValueTask

A task that represents the asynchronous dispose operation.

Remarks

Use this method to asynchronously close or release unmanaged resources such as files, streams, and handles held by an instance of the class that implements this interface. Using this method instead of IDisposable.Dispose enables you to perform a resource-intensive dispose operation without blocking the main thread of a GUI application for a long time.

> ⚠ **Warning**
>
> If you are using a class that implements the **IAsyncDisposable** interface, you should call its `DisposeAsync` implementation when you are finished using the class. For more information, see the "Using an object that implements IAsyncDisposable" section in the **IAsyncDisposable** topic.

When implementing this method, ensure that all held resources are freed by propagating the call through the containment hierarchy. For example, if an object A allocates an object B, and object B allocates an object C, then A's `DisposeAsync`

implementation must call `DisposeAsync` on B, which must in turn call `DisposeAsync` on C. An object must also call the `DisposeAsync` method of its base class if the base class implements IAsyncDisposable.

If an object's `DisposeAsync` method is called more than once, the object must ignore all calls after the first one and synchronously return a successfully completed ValueTask. The object must not throw an exception if its `DisposeAsync` method is called multiple times. Instance methods other than `DisposeAsync` can throw an ObjectDisposedException when resources are already disposed.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IAsyncResult Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the status of an asynchronous operation.

C#

```
public interface IAsyncResult
```

Derived System.IdentityModel.AsyncResult
System.IdentityModel.Selectors.SecurityTokenProvider.SecurityTokenAsyncResult
System.Runtime.Remoting.Messaging.AsyncResult
System.Threading.Tasks.Task
System.Transactions.CommittableTransaction
More...

Examples

The following example demonstrates how to use the AsyncWaitHandle property to get a WaitHandle, and how to wait for an asynchronous call on a delegate. The WaitHandle is signaled when the asynchronous call completes, and you can wait for it by calling the WaitOne method.

The example consists of two classes: the class that contains the method that is called asynchronously, and the class that contains the `Main` method that makes the call.

For more information and more examples of calling methods asynchronously by using delegates, see Calling Synchronous Methods Asynchronously.

C#

```
using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
```

```
{
    public class AsyncDemo
    {
        // The method to be executed asynchronously.
        public string TestMethod(int callDuration, out int threadId)
        {
            Console.WriteLine("Test method begins.");
            Thread.Sleep(callDuration);
            threadId = Thread.CurrentThread.ManagedThreadId;
            return String.Format("My call time was {0}.",
callDuration.ToString());
        }
    }
    // The delegate must have the same signature as the method
    // it will call asynchronously.
    public delegate string AsyncMethodCaller(int callDuration, out int
threadId);
}
```

C#

```
using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
    public class AsyncMain
    {
        static void Main()
        {
            // The asynchronous method puts the thread id here.
            int threadId;

            // Create an instance of the test class.
            AsyncDemo ad = new AsyncDemo();

            // Create the delegate.
            AsyncMethodCaller caller = new AsyncMethodCaller(ad.TestMethod);

            // Initiate the asychronous call.
            IAsyncResult result = caller.BeginInvoke(3000,
                out threadId, null, null);

            Thread.Sleep(0);
            Console.WriteLine("Main thread {0} does some work.",
                Thread.CurrentThread.ManagedThreadId);

            // Wait for the WaitHandle to become signaled.
            result.AsyncWaitHandle.WaitOne();

            // Perform additional processing here.
            // Call EndInvoke to retrieve the results.
            string returnValue = caller.EndInvoke(out threadId, result);
```

```
            // Close the wait handle.
            result.AsyncWaitHandle.Close();

            Console.WriteLine("The call executed on thread {0}, with return
value \"{1}\".",
                threadId, returnValue);
        }
    }
}

/* This example produces output similar to the following:

Main thread 1 does some work.
Test method begins.
The call executed on thread 3, with return value "My call time was 3000.".
 */
```

Remarks

The IAsyncResult interface is implemented by classes containing methods that can operate asynchronously. It is the return type of methods that initiate an asynchronous operation, such as FileStream.BeginRead, and it is passed to methods that conclude an asynchronous operation, such as FileStream.EndRead. IAsyncResult objects are also passed to methods invoked by AsyncCallback delegates when an asynchronous operation completes.

An object that supports the IAsyncResult interface stores state information for an asynchronous operation and provides a synchronization object to allow threads to be signaled when the operation completes.

> **Note**
>
> The **AsyncResult** class is the implementation of **IAsyncResult** that is returned by the `BeginInvoke` method when you use a delegate to call a method asynchronously.

For a detailed description of how the IAsyncResult interface is used, see the Calling Synchronous Methods Asynchronously topic.

Properties

Expand table

AsyncState	Gets a user-defined object that qualifies or contains information about an asynchronous operation.
AsyncWaitHandle	Gets a WaitHandle that is used to wait for an asynchronous operation to complete.
CompletedSynchronously	Gets a value that indicates whether the asynchronous operation completed synchronously.
IsCompleted	Gets a value that indicates whether the asynchronous operation has completed.

IAsyncResult.AsyncState Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a user-defined object that qualifies or contains information about an asynchronous operation.

```
C#

public object? AsyncState { get; }
```

Property Value

Object

A user-defined object that qualifies or contains information about an asynchronous operation.

Examples

The following code example demonstrates how the AsyncState property is used to pass information to a callback method. The last parameter of the `BeginInvoke` method call is a format string, which the callback method uses to format an output message.

The example consists of two classes: the class that contains the method that is called asynchronously, and the class that contains the `Main` method that makes the call.

For more information about how this callback example works, and more examples of calling methods asynchronously by using delegates, see Calling Synchronous Methods Asynchronously.

```
C#

using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
```

```
    public class AsyncDemo
    {
        // The method to be executed asynchronously.
        public string TestMethod(int callDuration, out int threadId)
        {
            Console.WriteLine("Test method begins.");
            Thread.Sleep(callDuration);
            threadId = Thread.CurrentThread.ManagedThreadId;
            return String.Format("My call time was {0}.",
callDuration.ToString());
        }
    }
    // The delegate must have the same signature as the method
    // it will call asynchronously.
    public delegate string AsyncMethodCaller(int callDuration, out int
threadId);
}
```

C#

```
using System;
using System.Threading;
using System.Runtime.Remoting.Messaging;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
    public class AsyncMain
    {
        static void Main()
        {
            // Create an instance of the test class.
            AsyncDemo ad = new AsyncDemo();

            // Create the delegate.
            AsyncMethodCaller caller = new AsyncMethodCaller(ad.TestMethod);

            // The threadId parameter of TestMethod is an out parameter, so
            // its input value is never used by TestMethod. Therefore, a
dummy
            // variable can be passed to the BeginInvoke call. If the
threadId
            // parameter were a ref parameter, it would have to be a class-
            // level field so that it could be passed to both BeginInvoke
and
            // EndInvoke.
            int dummy = 0;

            // Initiate the asynchronous call, passing three seconds (3000
ms)
            // for the callDuration parameter of TestMethod; a dummy
variable
            // for the out parameter (threadId); the callback delegate; and
            // state information that can be retrieved by the callback
```

```
method.
            // In this case, the state information is a string that can be
used
            // to format a console message.
            IAsyncResult result = caller.BeginInvoke(3000,
                out dummy,
                new AsyncCallback(CallbackMethod),
                "The call executed on thread {0}, with return value \"
{1}\".");

            Console.WriteLine("The main thread {0} continues to execute...",
                Thread.CurrentThread.ManagedThreadId);

            // The callback is made on a ThreadPool thread. ThreadPool
threads
            // are background threads, which do not keep the application
running
            // if the main thread ends. Comment out the next line to
demonstrate
            // this.
            Thread.Sleep(4000);

            Console.WriteLine("The main thread ends.");
        }

        // The callback method must have the same signature as the
        // AsyncCallback delegate.
        static void CallbackMethod(IAsyncResult ar)
        {
            // Retrieve the delegate.
            AsyncResult result = (AsyncResult) ar;
            AsyncMethodCaller caller = (AsyncMethodCaller)
result.AsyncDelegate;

            // Retrieve the format string that was passed as state
            // information.
            string formatString = (string) ar.AsyncState;

            // Define a variable to receive the value of the out parameter.
            // If the parameter were ref rather than out then it would have
to
            // be a class-level field so it could also be passed to
BeginInvoke.
            int threadId = 0;

            // Call EndInvoke to retrieve the results.
            string returnValue = caller.EndInvoke(out threadId, ar);

            // Use the format string to format the output message.
            Console.WriteLine(formatString, threadId, returnValue);
        }
    }
}

/* This example produces output similar to the following:
```

```
The main thread 1 continues to execute...
Test method begins.
The call executed on thread 3, with return value "My call time was 3000.".
The main thread ends.
 */
```

Remarks

This property returns the object that is the last parameter of the method that initiates an asynchronous operation.

Notes to Implementers

Implement this property to allow the caller of an asynchronous operation to obtain an application-defined object specified at the start of the operation.

Notes to Callers

This object can be used to pass state information for the asynchronous operation to an AsyncCallback that you provide.

IAsyncResult.AsyncWaitHandle Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a WaitHandle that is used to wait for an asynchronous operation to complete.

C#

```
public System.Threading.WaitHandle AsyncWaitHandle { get; }
```

Property Value

WaitHandle

A WaitHandle that is used to wait for an asynchronous operation to complete.

Examples

The following example demonstrates how to use the AsyncWaitHandle property to get a WaitHandle, and how to wait for an asynchronous call on a delegate. The WaitHandle is signaled when the asynchronous call completes, and you can wait for it by calling the WaitOne method.

The example consists of two classes: the class that contains the method that is called asynchronously, and the class that contains the `Main` method that makes the call.

For more information and more examples of calling methods asynchronously by using delegates, see Calling Synchronous Methods Asynchronously.

C#

```
using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
    public class AsyncDemo
    {
        // The method to be executed asynchronously.
```

```
        public string TestMethod(int callDuration, out int threadId)
        {
            Console.WriteLine("Test method begins.");
            Thread.Sleep(callDuration);
            threadId = Thread.CurrentThread.ManagedThreadId;
            return String.Format("My call time was {0}.",
callDuration.ToString());
        }
    }
    // The delegate must have the same signature as the method
    // it will call asynchronously.
    public delegate string AsyncMethodCaller(int callDuration, out int
threadId);
}
```

C#

```
using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
    public class AsyncMain
    {
        static void Main()
        {
            // The asynchronous method puts the thread id here.
            int threadId;

            // Create an instance of the test class.
            AsyncDemo ad = new AsyncDemo();

            // Create the delegate.
            AsyncMethodCaller caller = new AsyncMethodCaller(ad.TestMethod);

            // Initiate the asychronous call.
            IAsyncResult result = caller.BeginInvoke(3000,
                out threadId, null, null);

            Thread.Sleep(0);
            Console.WriteLine("Main thread {0} does some work.",
                Thread.CurrentThread.ManagedThreadId);

            // Wait for the WaitHandle to become signaled.
            result.AsyncWaitHandle.WaitOne();

            // Perform additional processing here.
            // Call EndInvoke to retrieve the results.
            string returnValue = caller.EndInvoke(out threadId, result);

            // Close the wait handle.
            result.AsyncWaitHandle.Close();
```

```
            Console.WriteLine("The call executed on thread {0}, with return
value \"{1}\".",
                threadId, returnValue);
        }
    }
}

/* This example produces output similar to the following:

Main thread 1 does some work.
Test method begins.
The call executed on thread 3, with return value "My call time was 3000.".
 */
```

Remarks

The return value allows the client to wait for an asynchronous operation to complete instead of polling IsCompleted until the operation concludes. The return value can be used to perform a WaitOne, WaitAny, or WaitAll operation.

The common language runtime supplies a number of waitable objects, such as ManualResetEvent, AutoResetEvent, and Mutex, all of which mirror Win32 synchronization primitives.

Notes to Implementers

The object that implements IAsyncResult does not need to create the WaitHandle until the AsyncWaitHandle property is read. It is the choice of the IAsyncResult implementer. However, if the implementer creates AsyncWaitHandle, it is the responsibility of the implementer to signal the WaitHandle that will terminate the wait at the appropriate time. For example, AsyncResult terminates the wait on behalf of the caller when an asynchronously invoked method returns. Once created, AsyncWaitHandle should be kept alive until the user calls the method that concludes the asynchronous operation. At that time the object behind AsyncWaitHandle can be discarded.

Notes to Callers

Clients that wait for the operation to complete (as opposed to polling) use this property to obtain a synchronization object to wait on.

Note: When you use the `BeginInvoke` method of a delegate to call a method asynchronously and obtain a wait handle from the resulting IAsyncResult, we recommend that you close the wait handle as soon as you are finished using it, by

calling the Close() method. If you simply release all references to the wait handle, system resources are freed when garbage collection reclaims the wait handle, but garbage collection works more efficiently when disposable objects are explicitly closed or disposed. For more information, see the AsyncWaitHandle property.

IAsyncResult.CompletedSynchronously Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the asynchronous operation completed synchronously.

```
C#
public bool CompletedSynchronously { get; }
```

Property Value

Boolean

`true` if the asynchronous operation completed synchronously; otherwise, `false`.

Remarks

If the synchronous completion of the call is detected in the AsyncCallback delegate, it is probable that the thread that initiated the asynchronous operation is the current thread.

Notes to Implementers

Most implementers of the IAsyncResult interface will not use this property and should return `false`. Beginning with the .NET Framework 4.5, a task that is created with the FromAsync(IAsyncResult, Action<IAsyncResult>, TaskCreationOptions) method will not complete if this property is not implemented correctly. See Application Compatibility in 4.5.

Notes to Callers

Use this property to determine if the asynchronous operation completed synchronously. For example, this property can return `true` for an asynchronous I/O operation if the I/O request was small.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IAsyncResult.IsCompleted Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the asynchronous operation has completed.

```
C#

public bool IsCompleted { get; }
```

Property Value

Boolean

`true` if the operation is complete; otherwise, `false`.

Examples

The following example shows how to use the IsCompleted property of the IAsyncResult to discover when an asynchronous call completes. In this case, the asynchronous call is made by using the `BeginInvoke` method of a delegate. You might use the IsCompleted property to poll for completion when making the asynchronous call from a thread that services the user interface. Polling for completion allows the calling thread to continue executing while the asynchronous call executes on a ThreadPool thread.

The example consists of two classes: the class that contains the method that is called asynchronously, and the class that contains the `Main` method that makes the call.

For more information and more examples of calling methods asynchronously by using delegates, see Calling Synchronous Methods Asynchronously.

```
C#

using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
```

```
    public class AsyncDemo
    {
        // The method to be executed asynchronously.
        public string TestMethod(int callDuration, out int threadId)
        {
            Console.WriteLine("Test method begins.");
            Thread.Sleep(callDuration);
            threadId = Thread.CurrentThread.ManagedThreadId;
            return String.Format("My call time was {0}.",
callDuration.ToString());
        }
    }
    // The delegate must have the same signature as the method
    // it will call asynchronously.
    public delegate string AsyncMethodCaller(int callDuration, out int
threadId);
}
```

C#

```
using System;
using System.Threading;

namespace Examples.AdvancedProgramming.AsynchronousOperations
{
    public class AsyncMain
    {
        static void Main() {
            // The asynchronous method puts the thread id here.
            int threadId;

            // Create an instance of the test class.
            AsyncDemo ad = new AsyncDemo();

            // Create the delegate.
            AsyncMethodCaller caller = new AsyncMethodCaller(ad.TestMethod);

            // Initiate the asychronous call.
            IAsyncResult result = caller.BeginInvoke(3000,
                out threadId, null, null);

            // Poll while simulating work.
            while(result.IsCompleted == false) {
                Thread.Sleep(250);
                Console.Write(".");
            }

            // Call EndInvoke to retrieve the results.
            string returnValue = caller.EndInvoke(out threadId, result);

            Console.WriteLine("\nThe call executed on thread {0}, with
return value \"{1}\".",
                threadId, returnValue);
```

```
        }
    }
}

/* This example produces output similar to the following:

Test method begins.
.............
The call executed on thread 3, with return value "My call time was 3000.".
 */
```

Remarks

When this property is `true`, you can assume it is safe to discard any resources you allocate for use by the asynchronous operation.

Notes to Implementers

Implementers will typically return the value of a private field or internal test as the value of this property.

Notes to Callers

Clients that poll for operation status (as opposed to waiting on a synchronization object) use this property to determine the status of the operation.

Applies to

ICloneable Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Supports cloning, which creates a new instance of a class with the same value as an existing instance.

```
C#
public interface ICloneable
```

Derived Microsoft.VisualC.StlClr.Generic.ConstContainerBidirectionalIterator<TValue>
Microsoft.VisualC.StlClr.Generic.ConstContainerRandomAccessIterator<TValue>
Microsoft.VisualC.StlClr.Generic.ConstReverseBidirectionalIterator<TValue>
Microsoft.VisualC.StlClr.Generic.ConstReverseRandomAccessIterator<TValue>
Microsoft.VisualC.StlClr.Generic.ContainerBidirectionalIterator<TValue>
More...

Remarks

The ICloneable interface enables you to provide a customized implementation that creates a copy of an existing object. The ICloneable interface contains one member, the Clone method, which is intended to provide cloning support beyond that supplied by Object.MemberwiseClone. For more information about cloning, deep versus shallow copies, and examples, see the Object.MemberwiseClone method.

Notes to Implementers

The ICloneable interface simply requires that your implementation of the Clone() method return a copy of the current object instance. It does not specify whether the cloning operation performs a deep copy, a shallow copy, or something in between. Nor does it require all property values of the original instance to be copied to the new instance. For example, the Clone() method performs a shallow copy of all properties except the IsReadOnly property; it always sets this property value to `false` in the cloned

object. Because callers of Clone() cannot depend on the method performing a predictable cloning operation, we recommend that ICloneable not be implemented in public APIs.

Methods

Expand table

Clone()	Creates a new object that is a copy of the current instance.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ICloneable.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new object that is a copy of the current instance.

C#

```
public object Clone ();
```

Returns

Object

A new object that is a copy of this instance.

Remarks

The resulting clone must be of the same type as, or compatible with, the original instance.

An implementation of Clone can perform either a deep copy or a shallow copy. In a deep copy, all objects are duplicated; in a shallow copy, only the top-level objects are duplicated and the lower levels contain references. Because callers of Clone cannot depend on the method performing a predictable cloning operation, we recommend that ICloneable not be implemented in public APIs.

See Object.MemberwiseClone for more information on cloning, deep versus shallow copies, and examples.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

IComparable Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a generalized type-specific comparison method that a value type or class implements to order or sort its instances.

C#

```
public interface IComparable
```

Derived System.Boolean
System.Byte
System.Char
System.Data.OracleClient.OracleBinary
System.Data.OracleClient.OracleBoolean
More...

Examples

The following example illustrates the implementation of IComparable and the requisite CompareTo method.

C#

```
using System;
using System.Collections;

public class Temperature : IComparable
{
    // The temperature value
    protected double temperatureF;

    public int CompareTo(object obj) {
        if (obj == null) return 1;

        Temperature otherTemperature = obj as Temperature;
        if (otherTemperature != null)
            return
```

```
this.temperatureF.CompareTo(otherTemperature.temperatureF);
        else
           throw new ArgumentException("Object is not a Temperature");
    }

    public double Fahrenheit
    {
        get
        {
            return this.temperatureF;
        }
        set
        {
            this.temperatureF = value;
        }
    }

    public double Celsius
    {
        get
        {
            return (this.temperatureF - 32) * (5.0/9);
        }
        set
        {
            this.temperatureF = (value * 9.0/5) + 32;
        }
    }
}

public class CompareTemperatures
{
   public static void Main()
   {
      ArrayList temperatures = new ArrayList();
      // Initialize random number generator.
      Random rnd = new Random();

      // Generate 10 temperatures between 0 and 100 randomly.
      for (int ctr = 1; ctr <= 10; ctr++)
      {
         int degrees = rnd.Next(0, 100);
         Temperature temp = new Temperature();
         temp.Fahrenheit = degrees;
         temperatures.Add(temp);
      }

      // Sort ArrayList.
      temperatures.Sort();

      foreach (Temperature temp in temperatures)
         Console.WriteLine(temp.Fahrenheit);
   }
}
// The example displays the following output to the console (individual
```

```
// values may vary because they are randomly generated):
//       2
//       7
//       16
//       17
//       31
//       37
//       58
//       66
//       72
//       95
```

Remarks

This interface is implemented by types whose values can be ordered or sorted. It requires that implementing types define a single method, CompareTo(Object), that indicates whether the position of the current instance in the sort order is before, after, or the same as a second object of the same type. The instance's IComparable implementation is called automatically by methods such as Array.Sort and ArrayList.Sort.

The implementation of the CompareTo(Object) method must return an Int32 that has one of three values, as shown in the following table.

Expand table

Value	Meaning
Less than zero	The current instance precedes the object specified by the CompareTo method in the sort order.
Zero	This current instance occurs in the same position in the sort order as the object specified by the CompareTo method.
Greater than zero	This current instance follows the object specified by the CompareTo method in the sort order.

All numeric types (such as Int32 and Double) implement IComparable, as do String, Char, and DateTime. Custom types should also provide their own implementation of IComparable to enable object instances to be ordered or sorted.

Methods

Expand table

Compare To(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (object? obj);
```

Parameters

obj Object

An object to compare with this instance.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `obj` in the sort order.
Zero	This instance occurs in the same position in the sort order as `obj`.
Greater than zero	This instance follows `obj` in the sort order.

Exceptions

ArgumentException

`obj` is not the same type as this instance.

Examples

The following example illustrates the use of CompareTo to compare a `Temperature` object implementing IComparable with another object. The `Temperature` object implements CompareTo by simply wrapping a call to the Int32.CompareTo method.

C#

```
using System;
using System.Collections;

public class Temperature : IComparable
{
    // The temperature value
    protected double temperatureF;

    public int CompareTo(object obj) {
        if (obj == null) return 1;

        Temperature otherTemperature = obj as Temperature;
        if (otherTemperature != null)
            return
this.temperatureF.CompareTo(otherTemperature.temperatureF);
        else
           throw new ArgumentException("Object is not a Temperature");
    }

    public double Fahrenheit
    {
        get
        {
            return this.temperatureF;
        }
        set
        {
            this.temperatureF = value;
        }
    }

    public double Celsius
    {
        get
        {
            return (this.temperatureF - 32) * (5.0/9);
        }
        set
        {
            this.temperatureF = (value * 9.0/5) + 32;
```

```
        }
    }
}

public class CompareTemperatures
{
   public static void Main()
   {
      ArrayList temperatures = new ArrayList();
      // Initialize random number generator.
      Random rnd = new Random();

      // Generate 10 temperatures between 0 and 100 randomly.
      for (int ctr = 1; ctr <= 10; ctr++)
      {
         int degrees = rnd.Next(0, 100);
         Temperature temp = new Temperature();
         temp.Fahrenheit = degrees;
         temperatures.Add(temp);
      }

      // Sort ArrayList.
      temperatures.Sort();

      foreach (Temperature temp in temperatures)
         Console.WriteLine(temp.Fahrenheit);
   }
}
// The example displays the following output to the console (individual
// values may vary because they are randomly generated):
//       2
//       7
//       16
//       17
//       31
//       37
//       58
//       66
//       72
//       95
```

Remarks

The CompareTo method is implemented by types whose values can be ordered or sorted. It is called automatically by methods of non-generic collection objects, such as Array.Sort, to order each member of the array. If a custom class or structure does not implement IComparable, its members cannot be ordered and the sort operation can throw an InvalidOperationException.

This method is only a definition and must be implemented by a specific class or value type to have effect. The meaning of the comparisons specified in the Return Value section ("precedes", "occurs in the same position as", and "follows") depends on the particular implementation.

By definition, any object compares greater than (or follows) `null`, and two null references compare equal to each other.

The parameter, `obj`, must be the same type as the class or value type that implements this interface; otherwise, an ArgumentException is thrown.

Notes to Implementers

For objects A, B and C, the following must be true:

`A.CompareTo(A)` must return zero.

If `A.CompareTo(B)` returns zero, then `B.CompareTo(A)` must return zero.

If `A.CompareTo(B)` returns zero and `B.CompareTo(C)` returns zero, then `A.CompareTo(C)` must return zero.

If `A.CompareTo(B)` returns a value other than zero, then `B.CompareTo(A)` must return a value of the opposite sign.

If `A.CompareTo(B)` returns a value `x` not equal to zero, and `B.CompareTo(C)` returns a value `y` of the same sign as `x`, then `A.CompareTo(C)` must return a value of the same sign as `x` and `y`.

Notes to Callers

Use the CompareTo(Object) method to determine the ordering of instances of a class.

IComparable<T> Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a generalized comparison method that a value type or class implements to create a type-specific comparison method for ordering or sorting its instances.

C#

```
public interface IComparable<in T>
```

Type Parameters

T

The type of object to compare.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Derived System.Boolean
System.Byte
System.Char
System.DateOnly
System.DateTime
More...

Examples

The following example illustrates the implementation of IComparable<T> for a simple `Temperature` object. The example creates a SortedList<TKey,TValue> collection of strings with `Temperature` object keys, and adds several pairs of temperatures and strings to the list out of sequence. In the call to the Add method, the SortedList<TKey,TValue> collection uses the IComparable<T> implementation to sort the list entries, which are then displayed in order of increasing temperature.

C#

```
using System;
using System.Collections.Generic;

public class Temperature : IComparable<Temperature>
{
    // Implement the generic CompareTo method with the Temperature
    // class as the Type parameter.
    //
    public int CompareTo(Temperature other)
    {
        // If other is not a valid object reference, this instance is
greater.
        if (other == null) return 1;

        // The temperature comparison depends on the comparison of
        // the underlying Double values.
        return m_value.CompareTo(other.m_value);
    }

    // Define the is greater than operator.
    public static bool operator >  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) > 0;
    }

    // Define the is less than operator.
    public static bool operator <  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) < 0;
    }

    // Define the is greater than or equal to operator.
    public static bool operator >=  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) >= 0;
    }

    // Define the is less than or equal to operator.
    public static bool operator <=  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) <= 0;
    }

    // The underlying temperature value.
    protected double m_value = 0.0;

    public double Celsius
    {
```

```
        get
        {
            return m_value - 273.15;
        }
    }

    public double Kelvin
    {
        get
        {
            return m_value;
        }
        set
        {
            if (value < 0.0)
            {
                throw new ArgumentException("Temperature cannot be less than
absolute zero.");
            }
            else
            {
                m_value = value;
            }
        }
    }

    public Temperature(double kelvins)
    {
        this.Kelvin = kelvins;
    }
}

public class Example
{
    public static void Main()
    {
        SortedList<Temperature, string> temps =
            new SortedList<Temperature, string>();

        // Add entries to the sorted list, out of order.
        temps.Add(new Temperature(2017.15), "Boiling point of Lead");
        temps.Add(new Temperature(0), "Absolute zero");
        temps.Add(new Temperature(273.15), "Freezing point of water");
        temps.Add(new Temperature(5100.15), "Boiling point of Carbon");
        temps.Add(new Temperature(373.15), "Boiling point of water");
        temps.Add(new Temperature(600.65), "Melting point of Lead");

        foreach( KeyValuePair<Temperature, string> kvp in temps )
        {
            Console.WriteLine("{0} is {1} degrees Celsius.", kvp.Value,
kvp.Key.Celsius);
        }
    }
}
/* This example displays the following output:
```

```
        Absolute zero is -273.15 degrees Celsius.
        Freezing point of water is 0 degrees Celsius.
        Boiling point of water is 100 degrees Celsius.
        Melting point of Lead is 327.5 degrees Celsius.
        Boiling point of Lead is 1744 degrees Celsius.
        Boiling point of Carbon is 4827 degrees Celsius.
*/
```

Remarks

This interface is implemented by types whose values can be ordered or sorted and provides a strongly typed comparison method for ordering members of a generic collection object. For example, one number can be larger than a second number, and one string can appear in alphabetical order before another. It requires that implementing types define a single method, CompareTo(T), that indicates whether the position of the current instance in the sort order is before, after, or the same as a second object of the same type. Typically, the method is not called directly from developer code. Instead, it is called automatically by methods such as List<T>.Sort() and Add.

Typically, types that provide an IComparable<T> implementation also implement the IEquatable<T> interface. The IEquatable<T> interface defines the Equals method, which determines the equality of instances of the implementing type.

The implementation of the CompareTo(T) method must return an Int32 that has one of three values, as shown in the following table.

Expand table

Value	Meaning
Less than zero	This object precedes the object specified by the CompareTo method in the sort order.
Zero	This current instance occurs in the same position in the sort order as the object specified by the CompareTo method argument.
Greater than zero	This current instance follows the object specified by the CompareTo method argument in the sort order.

All numeric types (such as Int32 and Double) implement IComparable<T>, as do String, Char, and DateTime. Custom types should also provide their own implementation of IComparable<T> to enable object instances to be ordered or sorted.

Notes to Implementers

Replace the type parameter of the IComparable<T> interface with the type that is implementing this interface.

If you implement IComparable<T>, you should overload the `op_GreaterThan`, `op_GreaterThanOrEqual`, `op_LessThan`, and `op_LessThanOrEqual` operators to return values that are consistent with CompareTo(T). In addition, you should also implement IEquatable<T>. See the IEquatable<T> article for complete information.

Methods

Expand table

CompareTo(T)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

Applies to

Product	Versions

IComparable<T>.CompareTo(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (T? other);
```

Parameters

other T

An object to compare with this instance.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `other` in the sort order.
Zero	This instance occurs in the same position in the sort order as `other`.
Greater than zero	This instance follows `other` in the sort order.

Examples

The following code example illustrates the implementation of IComparable<T> for a simple `Temperature` object. The example creates a SortedList<TKey,TValue> collection of strings with `Temperature` object keys, and adds several pairs of temperatures and strings to the list out of sequence. In the call to the Add method, the SortedList<TKey,TValue> collection uses the IComparable<T> implementation to sort the list entries, which are then displayed in order of increasing temperature.

C#

```
using System;
using System.Collections.Generic;

public class Temperature : IComparable<Temperature>
{
    // Implement the generic CompareTo method with the Temperature
    // class as the Type parameter.
    //
    public int CompareTo(Temperature other)
    {
        // If other is not a valid object reference, this instance is
greater.
        if (other == null) return 1;

        // The temperature comparison depends on the comparison of
        // the underlying Double values.
        return m_value.CompareTo(other.m_value);
    }

    // Define the is greater than operator.
    public static bool operator >  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) > 0;
    }

    // Define the is less than operator.
    public static bool operator <  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) < 0;
    }

    // Define the is greater than or equal to operator.
    public static bool operator >=  (Temperature operand1, Temperature
operand2)
    {
       return operand1.CompareTo(operand2) >= 0;
    }

    // Define the is less than or equal to operator.
    public static bool operator <=  (Temperature operand1, Temperature
operand2)
```

```
    {
       return operand1.CompareTo(operand2) <= 0;
    }

    // The underlying temperature value.
    protected double m_value = 0.0;

    public double Celsius
    {
        get
        {
            return m_value - 273.15;
        }
    }

    public double Kelvin
    {
        get
        {
            return m_value;
        }
        set
        {
            if (value < 0.0)
            {
                throw new ArgumentException("Temperature cannot be less than
absolute zero.");
            }
            else
            {
                m_value = value;
            }
        }
    }

    public Temperature(double kelvins)
    {
        this.Kelvin = kelvins;
    }
}

public class Example
{
    public static void Main()
    {
        SortedList<Temperature, string> temps =
            new SortedList<Temperature, string>();

        // Add entries to the sorted list, out of order.
        temps.Add(new Temperature(2017.15), "Boiling point of Lead");
        temps.Add(new Temperature(0), "Absolute zero");
        temps.Add(new Temperature(273.15), "Freezing point of water");
        temps.Add(new Temperature(5100.15), "Boiling point of Carbon");
        temps.Add(new Temperature(373.15), "Boiling point of water");
        temps.Add(new Temperature(600.65), "Melting point of Lead");
```

```
        foreach( KeyValuePair<Temperature, string> kvp in temps )
        {
            Console.WriteLine("{0} is {1} degrees Celsius.", kvp.Value,
kvp.Key.Celsius);
        }
    }
}
/* This example displays the following output:
      Absolute zero is -273.15 degrees Celsius.
      Freezing point of water is 0 degrees Celsius.
      Boiling point of water is 100 degrees Celsius.
      Melting point of Lead is 327.5 degrees Celsius.
      Boiling point of Lead is 1744 degrees Celsius.
      Boiling point of Carbon is 4827 degrees Celsius.
*/
```

Remarks

CompareTo provides a strongly typed comparison method for ordering members of a generic collection object. Because of this, it is usually not called directly from developer code. Instead, it is called automatically by methods such as List<T>.Sort() and Add.

This method is only a definition and must be implemented by a specific class or value type to have effect. The meaning of the comparisons specified in the Return Values section ("precedes", "occurs in the same position as", and "follows) depends on the particular implementation.

By definition, any object compares greater than `null`, and two null references compare equal to each other.

Notes to Implementers

For objects A, B, and C, the following must be true:

`A.CompareTo(A)` is required to return zero.

If `A.CompareTo(B)` returns zero, then `B.CompareTo(A)` is required to return zero.

If `A.CompareTo(B)` returns zero and `B.CompareTo(C)` returns zero, then `A.CompareTo(C)` is required to return zero.

If `A.CompareTo(B)` returns a value other than zero, then `B.CompareTo(A)` is required to return a value of the opposite sign.

If `A.CompareTo(B)` returns a value `x` that is not equal to zero, and `B.CompareTo(C)` returns a value `y` of the same sign as `x`, then `A.CompareTo(C)` is required to return a value of the same sign as `x` and `y`.

Notes to Callers

Use the CompareTo(T) method to determine the ordering of instances of a class.

IConvertible Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Defines methods that convert the value of the implementing reference or value type to a common language runtime type that has an equivalent value.

C#

```
[System.CLSCompliant(false)]
public interface IConvertible
```

Derived System.Boolean
System.Byte
System.Char
System.DateTime
System.DBNull
More...

Attributes CLSCompliantAttribute

Examples

The following code sample demonstrates an implementation of IConvertible for a Complex number class, allowing it to be cast first as a Double and then calling the static Convert members on that Double.

C#

```
using System;
```

```
namespace ConsoleApplication2
{

    /// Class that implements IConvertible
    class Complex : IConvertible
    {
        double  x;
        double  y;

        public Complex(double x, double y)
        {
            this.x = x;
            this.y = y;
        }

        public TypeCode GetTypeCode()
        {
            return TypeCode.Object;
        }

        bool IConvertible.ToBoolean(IFormatProvider provider)
        {
            if( (x != 0.0) || (y != 0.0) )
                return true;
            else
                return false;
        }

        double GetDoubleValue()
        {
            return Math.Sqrt(x*x + y*y);
        }

        byte IConvertible.ToByte(IFormatProvider provider)
        {
            return Convert.ToByte(GetDoubleValue());
        }

        char IConvertible.ToChar(IFormatProvider provider)
        {
            return Convert.ToChar(GetDoubleValue());
        }

        DateTime IConvertible.ToDateTime(IFormatProvider provider)
        {
            return Convert.ToDateTime(GetDoubleValue());
        }

        decimal IConvertible.ToDecimal(IFormatProvider provider)
        {
            return Convert.ToDecimal(GetDoubleValue());
        }

        double IConvertible.ToDouble(IFormatProvider provider)
        {
```

```
            return GetDoubleValue();
        }

        short IConvertible.ToInt16(IFormatProvider provider)
        {
            return Convert.ToInt16(GetDoubleValue());
        }

        int IConvertible.ToInt32(IFormatProvider provider)
        {
            return Convert.ToInt32(GetDoubleValue());
        }

        long IConvertible.ToInt64(IFormatProvider provider)
        {
            return Convert.ToInt64(GetDoubleValue());
        }

        sbyte IConvertible.ToSByte(IFormatProvider provider)
        {
            return Convert.ToSByte(GetDoubleValue());
        }

        float IConvertible.ToSingle(IFormatProvider provider)
        {
            return Convert.ToSingle(GetDoubleValue());
        }

        string IConvertible.ToString(IFormatProvider provider)
        {
            return String.Format("({0}, {1})", x, y);
        }

        object IConvertible.ToType(Type conversionType, IFormatProvider
provider)
        {
            return Convert.ChangeType(GetDoubleValue(),conversionType);
        }

        ushort IConvertible.ToUInt16(IFormatProvider provider)
        {
            return Convert.ToUInt16(GetDoubleValue());
        }

        uint IConvertible.ToUInt32(IFormatProvider provider)
        {
            return Convert.ToUInt32(GetDoubleValue());
        }

        ulong IConvertible.ToUInt64(IFormatProvider provider)
        {
            return Convert.ToUInt64(GetDoubleValue());
        }
    }
```

```
    /// <summary>
    /// Summary description for Class1.
    /// </summary>
    class Class1
    {
        static void Main(string[] args)
        {

            Complex     testComplex = new Complex(4,7);

            WriteObjectInfo(testComplex);
            WriteObjectInfo(Convert.ToBoolean(testComplex));
            WriteObjectInfo(Convert.ToDecimal(testComplex));
            WriteObjectInfo(Convert.ToString(testComplex));
        }

        static void WriteObjectInfo(object testObject)
        {
            TypeCode    typeCode = Type.GetTypeCode( testObject.GetType() );

            switch( typeCode )
            {
                case TypeCode.Boolean:
                    Console.WriteLine("Boolean: {0}", testObject);
                    break;

                case TypeCode.Double:
                    Console.WriteLine("Double: {0}", testObject);
                    break;

                default:
                    Console.WriteLine("{0}: {1}", typeCode.ToString(),
testObject);
                    break;
            }
        }
    }
}
```

Remarks

This interface provides methods to convert the value of an instance of an implementing type to a common language runtime type that has an equivalent value. The common language runtime types are Boolean, SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, UInt64, Single, Double, Decimal, DateTime, Char, and String.

If there is no meaningful conversion to a common language runtime type, then a particular interface method implementation throws InvalidCastException. For example, if this interface is implemented on a Boolean type, the implementation of the ToDateTime

method throws an exception because there is no meaningful DateTime equivalent to a Boolean type.

The common language runtime typically exposes the IConvertible interface through the Convert class. The common language runtime also uses the IConvertible interface internally, in explicit interface implementations, to simplify the code used to support conversions in the Convert class and basic common language runtime types.

In addition to the IConvertible interface, the .NET Framework provides classes called type converters for converting user-defined data types to other data types. For more information, see the Generalized Type Conversion topic.

Notes to Implementers

If you implement the IConvertible interface, your implementation will be called automatically by the ChangeType(Object, Type) method if the Object parameter is an instance of your implementing type and the Type parameter is a common language runtime type.

Most conversion methods have a parameter of type IFormatProvider that represents either the current culture (CurrentCulture) or a specific culture. For the most part, the IConvertible implementations of the base types ignore this parameter. However, you can choose whether to use it in your code.

Methods

Expand table

GetTypeCode()	Returns the TypeCode for this instance.
ToBoolean(IFormatProvider)	Converts the value of this instance to an equivalent Boolean value using the specified culture-specific formatting information.
ToByte(IFormatProvider)	Converts the value of this instance to an equivalent 8-bit unsigned integer using the specified culture-specific formatting information.
ToChar(IFormatProvider)	Converts the value of this instance to an equivalent Unicode character using the specified culture-specific formatting information.
ToDateTime(IFormatProvider)	Converts the value of this instance to an equivalent DateTime using the specified culture-specific formatting information.
ToDecimal(IFormatProvider)	Converts the value of this instance to an equivalent Decimal number using the specified culture-specific formatting information.

ToDouble(IFormatProvider)	Converts the value of this instance to an equivalent double-precision floating-point number using the specified culture-specific formatting information.
ToInt16(IFormatProvider)	Converts the value of this instance to an equivalent 16-bit signed integer using the specified culture-specific formatting information.
ToInt32(IFormatProvider)	Converts the value of this instance to an equivalent 32-bit signed integer using the specified culture-specific formatting information.
ToInt64(IFormatProvider)	Converts the value of this instance to an equivalent 64-bit signed integer using the specified culture-specific formatting information.
ToSByte(IFormatProvider)	Converts the value of this instance to an equivalent 8-bit signed integer using the specified culture-specific formatting information.
ToSingle(IFormatProvider)	Converts the value of this instance to an equivalent single-precision floating-point number using the specified culture-specific formatting information.
ToString(IFormatProvider)	Converts the value of this instance to an equivalent String using the specified culture-specific formatting information.
ToType(Type, IFormatProvider)	Converts the value of this instance to an Object of the specified Type that has an equivalent value, using the specified culture-specific formatting information.
ToUInt16(IFormatProvider)	Converts the value of this instance to an equivalent 16-bit unsigned integer using the specified culture-specific formatting information.
ToUInt32(IFormatProvider)	Converts the value of this instance to an equivalent 32-bit unsigned integer using the specified culture-specific formatting information.
ToUInt64(IFormatProvider)	Converts the value of this instance to an equivalent 64-bit unsigned integer using the specified culture-specific formatting information.

IConvertible.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for this instance.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant that is the TypeCode of the class or value type that implements this interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent Boolean value using the specified culture-specific formatting information.

C#

```
public bool ToBoolean (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Boolean

A Boolean value equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 8-bit unsigned integer using the specified culture-specific formatting information.

C#

```
public byte ToByte (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Byte

An 8-bit unsigned integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent Unicode character using the specified culture-specific formatting information.

C#

```
public char ToChar (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Char

A Unicode character equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent DateTime using the specified culture-specific formatting information.

C#

```
public DateTime ToDateTime (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

DateTime

A DateTime instance equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IConvertible.To Decimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent Decimal number using the specified culture-specific formatting information.

C#

```
public decimal ToDecimal (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Decimal

A Decimal number equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1

IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent double-precision floating-point number using the specified culture-specific formatting information.

C#

```
public double ToDouble (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Double

A double-precision floating-point number equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 16-bit signed integer using the specified culture-specific formatting information.

C#

```
public short ToInt16 (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Int16

An 16-bit signed integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 32-bit signed integer using the specified culture-specific formatting information.

C#

```
public int ToInt32 (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Int32

An 32-bit signed integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 64-bit signed integer using the specified culture-specific formatting information.

C#

```
public long ToInt64 (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Int64

An 64-bit signed integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 8-bit signed integer using the specified culture-specific formatting information.

C#

```
public sbyte ToSByte (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

SByte

An 8-bit signed integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent single-precision floating-point number using the specified culture-specific formatting information.

C#

```
public float ToSingle (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Single

A single-precision floating-point number equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToString(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent String using the specified culture-specific formatting information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

String

A String instance equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an Object of the specified Type that has an equivalent value, using the specified culture-specific formatting information.

C#

```
public object ToType (Type conversionType, IFormatProvider? provider);
```

Parameters

`conversionType` Type

The Type to which the value of this instance is converted.

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

Object

An Object instance of type `conversionType` whose value is equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 16-bit unsigned integer using the specified culture-specific formatting information.

C#

```
public ushort ToUInt16 (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

UInt16

An 16-bit unsigned integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 32-bit unsigned integer using the specified culture-specific formatting information.

C#

```
public uint ToUInt32 (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

UInt32

An 32-bit unsigned integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to an equivalent 64-bit unsigned integer using the specified culture-specific formatting information.

C#

```
public ulong ToUInt64 (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider interface implementation that supplies culture-specific formatting information.

Returns

UInt64

An 64-bit unsigned integer equivalent to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ICustomFormatter Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a method that supports custom formatting of the value of an object.

C#

```
public interface ICustomFormatter
```

Examples

The following example implements ICustomFormatter to allow binary, octal, and hexadecimal formatting of integral values. In this example, a single class, `MyFormatter`, implements both ICustomFormatter and IFormatProvider. Its IFormatProvider.GetFormat method determines whether the `formatType` parameter represents an ICustomFormatter type. If it does, `MyFormatter` returns an instance of itself; otherwise, it returns `null`. Its ICustomFormatter.Format implementation determines whether the format parameter is one of the three supported format strings ("B" for binary, "O" for octal, and "H" for hexadecimal) and formats the `arg` parameter appropriately. Otherwise, if `arg` is not `null`, it calls the `arg` parameter's IFormattable.ToString implementation, if one exists, or its parameterless `ToString` method, if one does not. If `arg` is `null`, the method returns String.Empty.

C#

```
using System;
using System.Globalization;
using System.Numerics;

public class MyFormatter : IFormatProvider, ICustomFormatter
{
    // IFormatProvider.GetFormat implementation.
    public object GetFormat(Type formatType)
    {
        // Determine whether custom formatting object is requested.
        if (formatType == typeof(ICustomFormatter))
            return this;
```

```
        else
            return null;
    }

    // Format number in binary (B), octal (O), or hexadecimal (H).
    public string Format(string format, object arg, IFormatProvider
formatProvider)
    {
        // Handle format string.
        int baseNumber;
        // Handle null or empty format string, string with precision
specifier.
        string thisFmt = String.Empty;
        // Extract first character of format string (precision specifiers
        // are not supported).
        if (!String.IsNullOrEmpty(format))
            thisFmt = format.Length > 1 ? format.Substring(0, 1) : format;

        // Get a byte array representing the numeric value.
        byte[] bytes;
        if (arg is sbyte)
        {
            string byteString = ((sbyte)arg).ToString("X2");
            bytes = new byte[1] { Byte.Parse(byteString,
System.Globalization.NumberStyles.HexNumber) };
        }
        else if (arg is byte)
        {
            bytes = new byte[1] { (byte)arg };
        }
        else if (arg is short)
        {
            bytes = BitConverter.GetBytes((short)arg);
        }
        else if (arg is int)
        {
            bytes = BitConverter.GetBytes((int)arg);
        }
        else if (arg is long)
        {
            bytes = BitConverter.GetBytes((long)arg);
        }
        else if (arg is ushort)
        {
            bytes = BitConverter.GetBytes((ushort)arg);
        }
        else if (arg is uint)
        {
            bytes = BitConverter.GetBytes((uint)arg);
        }
        else if (arg is ulong)
        {
            bytes = BitConverter.GetBytes((ulong)arg);
        }
        else if (arg is BigInteger)
```

```
        {
            bytes = ((BigInteger)arg).ToByteArray();
        }
        else
        {
            try
            {
                return HandleOtherFormats(format, arg);
            }
            catch (FormatException e)
            {
                throw new FormatException(String.Format("The format of '{0}'
is invalid.", format), e);
            }
        }

        switch (thisFmt.ToUpper())
        {
            // Binary formatting.
            case "B":
                baseNumber = 2;
                break;
            case "O":
                baseNumber = 8;
                break;
            case "H":
                baseNumber = 16;
                break;
            // Handle unsupported format strings.
            default:
                try
                {
                    return HandleOtherFormats(format, arg);
                }
                catch (FormatException e)
                {
                    throw new FormatException(String.Format("The format of
'{0}' is invalid.", format), e);
                }
        }

        // Return a formatted string.
        string numericString = String.Empty;
        for (int ctr = bytes.GetUpperBound(0); ctr >=
bytes.GetLowerBound(0); ctr--)
        {
            string byteString = Convert.ToString(bytes[ctr], baseNumber);
            if (baseNumber == 2)
                byteString = new String('0', 8 - byteString.Length) +
byteString;
            else if (baseNumber == 8)
                byteString = new String('0', 4 - byteString.Length) +
byteString;
            // Base is 16.
            else
```

```
                byteString = new String('0', 2 - byteString.Length) +
byteString;

            numericString += byteString + " ";
        }
        return numericString.Trim();
    }

    private string HandleOtherFormats(string format, object arg)
    {
        if (arg is IFormattable)
            return ((IFormattable)arg).ToString(format,
CultureInfo.CurrentCulture);
        else if (arg != null)
            return arg.ToString();
        else
            return String.Empty;
    }
}
```

`MyFormatter` can then be used to provide custom formatting by passing a `MyFormatter` object as the `provider` parameter of the Format method, as the following example shows.

C#

```
public class Example
{
    public static void Main()
    {
        Console.WindowWidth = 100;

        byte byteValue = 124;
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0} (binary: {0:B}) (hex: {0:H})",
byteValue));

        int intValue = 23045;
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0} (binary: {0:B}) (hex: {0:H})",
intValue));

        ulong ulngValue = 31906574882;
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0}\n   (binary: {0:B})\n   (hex:
{0:H})",
                                        ulngValue));

        BigInteger bigIntValue = BigInteger.Multiply(Int64.MaxValue, 2);
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0}\n   (binary: {0:B})\n   (hex:
{0:H})",
```

```
                                        bigIntValue));
    }
}
// The example displays the following output:
//    124 (binary: 01111100) (hex: 7c)
//    23045 (binary: 00000000 00000000 01011010 00000101) (hex: 00 00 5a 05)
//    31906574882
//       (binary: 00000000 00000000 00000000 00000111 01101101 11000111
10110010 00100010)
//       (hex: 00 00 00 07 6d c7 b2 22)
//    18446744073709551614
//       (binary: 00000000 11111111 11111111 11111111 11111111 11111111
11111111 11111111 11111110)
//       (hex: 00 ff ff ff ff ff ff ff fe)
```

Remarks

The ICustomFormatter interface includes a single method, ICustomFormatter.Format. When this interface is implemented by a reference or value type, the Format method returns a custom-formatted string representation of an object's value.

Typically, the ICustomFormatter interface is implemented with the IFormatProvider interface to customize the behavior of two .NET Framework composite string formatting methods that include an IFormatProvider parameter. Specifically, the ICustomFormatter interface can provide custom formatting of the value of an object passed to the String.Format(IFormatProvider, String, Object[]) and StringBuilder.AppendFormat(IFormatProvider, String, Object[]) methods.

Providing a custom representation of an object's value requires that you do the following:

1. Define a class that implements the ICustomFormatter interface and its single member, the Format method.

2. Define a class that implements the IFormatProvider interface and its single member, the GetFormat method. The GetFormat method returns an instance of your ICustomFormatter implementation. Often, a single class implements both ICustomFormatter and IFormatProvider. In that case, the class's `GetFormat` implementation just returns an instance of itself.

3. Pass the IFormatProvider implementation as the `provider` argument of the String.Format(IFormatProvider, String, Object[]) method or a comparable method.

The .NET library method will then use your custom formatting instead of its own.

Notes to Implementers

The common language runtime attempts to use your ICustomFormatter implementation for every format item in a composite format string. As a result, you should expect that your ICustomFormatter implementation will be called to provide formatting services to objects or values that it is not designed to handle. In these cases, your Format(String, Object, IFormatProvider) method must call the appropriate formatting method for that object or value.

There are two kinds of ICustomFormatter implementations: intrinsic and extension.

Intrinsic implementations are implementations that provide custom formatting for an application-defined object. In this case, your implementation should include the following:

- A definition of format strings that define the formatting of the object. Format strings are optional. Typically, a "G" or "g" format string defines the general (or most commonly used) format. However, you are free to define any format strings that you choose. You are also free to decide whether they are case-sensitive or case-insensitive.

- A test to ensure that the type of the object passed to your Format(String, Object, IFormatProvider) method is your application-defined type. If it is not, you should call the object's IFormattable implementation, if one exists, or its ToString() method, if it does not. You should be prepared to handle any exceptions these method calls might throw.

- Code to handle a null format string, if your implementation supports format strings. The most common approach is to replace a null format string with the general format specifier.

- Code to handle any format strings that your implementation supports.

- Code to handle format strings that you do not support. The most common approach is to throw a FormatException, although you can provide default formatting.

Extension implementations are implementations that provide custom formatting for a type that already has formatting support. For example, you could define a `CustomerNumberFormatter` that formats an integral type with hyphens between specific digits. In this case, your implementation should include the following:

- A definition of format strings that extend the formatting of the object. These format strings are required, but they must not conflict with the type's existing

format strings. For example, if you are extending formatting for the Int32 type, you should not implement the "C", "D", "E", "F", and "G" format specifiers, among others.

- A test that the type of the object passed to your Format(String, Object, IFormatProvider) method is a type whose formatting your extension supports. If it is not, call the object's IFormattable implementation, if one exists, or the object's parameterless ToString() method, if it does not. You should be prepared to handle any exceptions these method calls might throw.
- Code to handle any format strings that your extension supports.
- Code to handle any format strings that your extension does not support. These should be passed on to the type's IFormattable implementation. You should be prepared to handle any exceptions these method calls might throw.

Methods

Expand table

Format(String, Object, IFormatProvider)	Converts the value of a specified object to an equivalent string representation using specified format and culture-specific formatting information.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ICustomFormatter.Format(String, Object, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of a specified object to an equivalent string representation using specified format and culture-specific formatting information.

C#

```
public string Format (string? format, object? arg, IFormatProvider?
formatProvider);
```

Parameters

`format` String

A format string containing formatting specifications.

`arg` Object

An object to format.

`formatProvider` IFormatProvider

An object that supplies format information about the current instance.

Returns

String

The string representation of the value of `arg`, formatted as specified by `format` and `formatProvider`.

Examples

The following example implements ICustomFormatter to allow binary, octal, and hexadecimal formatting of integral values. Its ICustomFormatter.Format implementation

determines whether the format parameter is one of the three supported format strings ("B" for binary, "O" for octal, and "H" for hexadecimal) and formats the `arg` parameter appropriately. Otherwise, if `arg` is not `null`, it calls the `arg` parameter's IFormattable.ToString implementation, if one exists, or its parameterless `ToString` method, if one does not. If `arg` is `null`, the method returns String.Empty.

C#

```
using System;
using System.Globalization;
using System.Numerics;

public class MyFormatter : IFormatProvider, ICustomFormatter
{
    // IFormatProvider.GetFormat implementation.
    public object GetFormat(Type formatType)
    {
        // Determine whether custom formatting object is requested.
        if (formatType == typeof(ICustomFormatter))
            return this;
        else
            return null;
    }

    // Format number in binary (B), octal (O), or hexadecimal (H).
    public string Format(string format, object arg, IFormatProvider
formatProvider)
    {
        // Handle format string.
        int baseNumber;
        // Handle null or empty format string, string with precision
specifier.
        string thisFmt = String.Empty;
        // Extract first character of format string (precision specifiers
        // are not supported).
        if (!String.IsNullOrEmpty(format))
            thisFmt = format.Length > 1 ? format.Substring(0, 1) : format;

        // Get a byte array representing the numeric value.
        byte[] bytes;
        if (arg is sbyte)
        {
            string byteString = ((sbyte)arg).ToString("X2");
            bytes = new byte[1] { Byte.Parse(byteString,
System.Globalization.NumberStyles.HexNumber) };
        }
        else if (arg is byte)
        {
            bytes = new byte[1] { (byte)arg };
        }
        else if (arg is short)
        {
```

```
            bytes = BitConverter.GetBytes((short)arg);
        }
        else if (arg is int)
        {
            bytes = BitConverter.GetBytes((int)arg);
        }
        else if (arg is long)
        {
            bytes = BitConverter.GetBytes((long)arg);
        }
        else if (arg is ushort)
        {
            bytes = BitConverter.GetBytes((ushort)arg);
        }
        else if (arg is uint)
        {
            bytes = BitConverter.GetBytes((uint)arg);
        }
        else if (arg is ulong)
        {
            bytes = BitConverter.GetBytes((ulong)arg);
        }
        else if (arg is BigInteger)
        {
            bytes = ((BigInteger)arg).ToByteArray();
        }
        else
        {
            try
            {
                return HandleOtherFormats(format, arg);
            }
            catch (FormatException e)
            {
                throw new FormatException(String.Format("The format of '{0}'
is invalid.", format), e);
            }
        }

        switch (thisFmt.ToUpper())
        {
            // Binary formatting.
            case "B":
                baseNumber = 2;
                break;
            case "O":
                baseNumber = 8;
                break;
            case "H":
                baseNumber = 16;
                break;
            // Handle unsupported format strings.
            default:
                try
                {
```

```
                    return HandleOtherFormats(format, arg);
                }
                catch (FormatException e)
                {
                    throw new FormatException(String.Format("The format of
'{0}' is invalid.", format), e);
                }
        }

        // Return a formatted string.
        string numericString = String.Empty;
        for (int ctr = bytes.GetUpperBound(0); ctr >=
bytes.GetLowerBound(0); ctr--)
        {
            string byteString = Convert.ToString(bytes[ctr], baseNumber);
            if (baseNumber == 2)
                byteString = new String('0', 8 - byteString.Length) +
byteString;
            else if (baseNumber == 8)
                byteString = new String('0', 4 - byteString.Length) +
byteString;
            // Base is 16.
            else
                byteString = new String('0', 2 - byteString.Length) +
byteString;

            numericString += byteString + " ";
        }
        return numericString.Trim();
    }

    private string HandleOtherFormats(string format, object arg)
    {
        if (arg is IFormattable)
            return ((IFormattable)arg).ToString(format,
CultureInfo.CurrentCulture);
        else if (arg != null)
            return arg.ToString();
        else
            return String.Empty;
    }
}
```

`MyFormatter` can then be used to provide custom formatting by passing a `MyFormatter` object as the `provider` parameter of the Format method, as the following example shows.

C#

```
public class Example
{
    public static void Main()
```

```
    {
        Console.WindowWidth = 100;

        byte byteValue = 124;
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0} (binary: {0:B}) (hex: {0:H})",
byteValue));

        int intValue = 23045;
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0} (binary: {0:B}) (hex: {0:H})",
intValue));

        ulong ulngValue = 31906574882;
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0}\n   (binary: {0:B})\n   (hex:
{0:H})",
                                        ulngValue));

        BigInteger bigIntValue = BigInteger.Multiply(Int64.MaxValue, 2);
        Console.WriteLine(String.Format(new MyFormatter(),
                                        "{0}\n   (binary: {0:B})\n   (hex:
{0:H})",
                                        bigIntValue));
    }
}
// The example displays the following output:
//    124 (binary: 01111100) (hex: 7c)
//    23045 (binary: 00000000 00000000 01011010 00000101) (hex: 00 00 5a 05)
//    31906574882
//       (binary: 00000000 00000000 00000000 00000111 01101101 11000111
10110010 00100010)
//       (hex: 00 00 00 07 6d c7 b2 22)
//    18446744073709551614
//       (binary: 00000000 11111111 11111111 11111111 11111111 11111111
11111111 11111111 11111110)
//       (hex: 00 ff ff ff ff ff ff ff fe)
```

Remarks

ICustomFormatter.Format is a callback method. It is called by a method that supports custom formatting, such as String.Format(IFormatProvider, String, Object[]) or StringBuilder.AppendFormat(IFormatProvider, String, Object[]). The implementation is called once for each format item in a composite format string. For example, in the following statement, the ICustomFormatter.Format method is called three times.

C#

```
Console.WriteLine(String.Format(new MyFormatter(),
                                "{0} (binary: {0:B}) (hex: {0:H})",
```

```
byteValue));
```

The `arg` parameter is the object in the object list whose zero-based position corresponds to the index of a particular format item.

The `format` parameter contains a format string, which is the `formatString` component of a format item. If the format item has no `formatString` component, the value of `format` is `null`. If `format` is `null`, depending on the type of `arg`, you may be able to use the default format specification of your choice.

The `formatProvider` parameter is the IFormatProvider implementation that provides formatting for `arg`. Typically, it is an instance of your ICustomFormatter implementation. If `formatProvider` is `null`, ignore that parameter.

Your implementation of the Format method must include the following functionality so the .NET Framework can provide formatting you do not support. If your format method does not support a format, determine whether the object being formatted implements the IFormattable interface. If it does, invoke the IFormattable.ToString method of that interface. Otherwise, invoke the default Object.ToString method of the underlying object. The following code illustrates this pattern.

C#

```
if (arg is IFormattable)
    return ((IFormattable)arg).ToString(format, CultureInfo.CurrentCulture);
else if (arg != null)
    return arg.ToString();
```

Examples

The following example demonstrates how to create a resource class that implements the IDisposable interface.

C#

```
using System;
using System.ComponentModel;

// The following example demonstrates how to create
// a resource class that implements the IDisposable interface
// and the IDisposable.Dispose method.

public class DisposeExample
{
    // A base class that implements IDisposable.
    // By implementing IDisposable, you are announcing that
    // instances of this type allocate scarce resources.
    public class MyResource: IDisposable
    {
        // Pointer to an external unmanaged resource.
```

```
        private IntPtr handle;
        // Other managed resource this class uses.
        private Component component = new Component();
        // Track whether Dispose has been called.
        private bool disposed = false;

        // The class constructor.
        public MyResource(IntPtr handle)
        {
            this.handle = handle;
        }

        // Implement IDisposable.
        // Do not make this method virtual.
        // A derived class should not be able to override this method.
        public void Dispose()
        {
            Dispose(disposing: true);
            // This object will be cleaned up by the Dispose method.
            // Therefore, you should call GC.SuppressFinalize to
            // take this object off the finalization queue
            // and prevent finalization code for this object
            // from executing a second time.
            GC.SuppressFinalize(this);
        }

        // Dispose(bool disposing) executes in two distinct scenarios.
        // If disposing equals true, the method has been called directly
        // or indirectly by a user's code. Managed and unmanaged resources
        // can be disposed.
        // If disposing equals false, the method has been called by the
        // runtime from inside the finalizer and you should not reference
        // other objects. Only unmanaged resources can be disposed.
        protected virtual void Dispose(bool disposing)
        {
            // Check to see if Dispose has already been called.
            if(!this.disposed)
            {
                // If disposing equals true, dispose all managed
                // and unmanaged resources.
                if(disposing)
                {
                    // Dispose managed resources.
                    component.Dispose();
                }

                // Call the appropriate methods to clean up
                // unmanaged resources here.
                // If disposing is false,
                // only the following code is executed.
                CloseHandle(handle);
                handle = IntPtr.Zero;

                // Note disposing has been done.
                disposed = true;
```

```
            }
        }

        // Use interop to call the method necessary
        // to clean up the unmanaged resource.
        [System.Runtime.InteropServices.DllImport("Kernel32")]
        private extern static Boolean CloseHandle(IntPtr handle);

        // Use C# finalizer syntax for finalization code.
        // This finalizer will run only if the Dispose method
        // does not get called.
        // It gives your base class the opportunity to finalize.
        // Do not provide finalizer in types derived from this class.
        ~MyResource()
        {
            // Do not re-create Dispose clean-up code here.
            // Calling Dispose(disposing: false) is optimal in terms of
            // readability and maintainability.
            Dispose(disposing: false);
        }
    }
    public static void Main()
    {
        // Insert code here to create
        // and use the MyResource object.
    }
}
```

Remarks

For more information about this API, see Supplemental API remarks for IDisposable.

IDisposable.Dispose Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources.

C#

```
public void Dispose ();
```

Examples

The following example shows how you can implement the Dispose method.

C#

```
using System;
using System.ComponentModel;

// The following example demonstrates how to create
// a resource class that implements the IDisposable interface
// and the IDisposable.Dispose method.

public class DisposeExample
{
    // A base class that implements IDisposable.
    // By implementing IDisposable, you are announcing that
    // instances of this type allocate scarce resources.
    public class MyResource: IDisposable
    {
        // Pointer to an external unmanaged resource.
        private IntPtr handle;
        // Other managed resource this class uses.
        private Component component = new Component();
        // Track whether Dispose has been called.
        private bool disposed = false;

        // The class constructor.
        public MyResource(IntPtr handle)
        {
            this.handle = handle;
```

```
        }

        // Implement IDisposable.
        // Do not make this method virtual.
        // A derived class should not be able to override this method.
        public void Dispose()
        {
            Dispose(disposing: true);
            // This object will be cleaned up by the Dispose method.
            // Therefore, you should call GC.SuppressFinalize to
            // take this object off the finalization queue
            // and prevent finalization code for this object
            // from executing a second time.
            GC.SuppressFinalize(this);
        }

        // Dispose(bool disposing) executes in two distinct scenarios.
        // If disposing equals true, the method has been called directly
        // or indirectly by a user's code. Managed and unmanaged resources
        // can be disposed.
        // If disposing equals false, the method has been called by the
        // runtime from inside the finalizer and you should not reference
        // other objects. Only unmanaged resources can be disposed.
        protected virtual void Dispose(bool disposing)
        {
            // Check to see if Dispose has already been called.
            if(!this.disposed)
            {
                // If disposing equals true, dispose all managed
                // and unmanaged resources.
                if(disposing)
                {
                    // Dispose managed resources.
                    component.Dispose();
                }

                // Call the appropriate methods to clean up
                // unmanaged resources here.
                // If disposing is false,
                // only the following code is executed.
                CloseHandle(handle);
                handle = IntPtr.Zero;

                // Note disposing has been done.
                disposed = true;
            }
        }

        // Use interop to call the method necessary
        // to clean up the unmanaged resource.
        [System.Runtime.InteropServices.DllImport("Kernel32")]
        private extern static Boolean CloseHandle(IntPtr handle);

        // Use C# finalizer syntax for finalization code.
        // This finalizer will run only if the Dispose method
```

```
        // does not get called.
        // It gives your base class the opportunity to finalize.
        // Do not provide finalizer in types derived from this class.
        ~MyResource()
        {
            // Do not re-create Dispose clean-up code here.
            // Calling Dispose(disposing: false) is optimal in terms of
            // readability and maintainability.
            Dispose(disposing: false);
        }
    }
    public static void Main()
    {
        // Insert code here to create
        // and use the MyResource object.
    }
}
```

Remarks

Use this method to close or release unmanaged resources such as files, streams, and handles held by an instance of the class that implements this interface. By convention, this method is used for all tasks associated with freeing resources held by an object, or preparing an object for reuse.

> ⚠ **Warning**
>
> If you are using a class that implements the **IDisposable** interface, you should call its **Dispose** implementation when you are finished using the class. For more information, see the "Using an object that implements IDisposable" section in the **IDisposable** topic.

When implementing this method, ensure that all held resources are freed by propagating the call through the containment hierarchy. For example, if an object A allocates an object B, and object B allocates an object C, then A's Dispose implementation must call Dispose on B, which must in turn call Dispose on C.

> ⓘ **Important**
>
> The C++ compiler supports deterministic disposal of resources and does not allow direct implementation of the **Dispose** method.

An object must also call the Dispose method of its base class if the base class implements IDisposable. For more information about implementing IDisposable on a base class and its subclasses, see the "IDisposable and the inheritance hierarchy" section in the IDisposable topic.

If an object's Dispose method is called more than once, the object must ignore all calls after the first one. The object must not throw an exception if its Dispose method is called multiple times. Instance methods other than Dispose can throw an ObjectDisposedException when resources are already disposed.

Users might expect a resource type to use a particular convention to denote an allocated state versus a freed state. An example of this is stream classes, which are traditionally thought of as open or closed. The implementer of a class that has such a convention might choose to implement a public method with a customized name, such as `Close`, that calls the Dispose method.

Because the Dispose method must be called explicitly, there is always a danger that the unmanaged resources will not be released, because the consumer of an object fails to call its Dispose method. There are two ways to avoid this:

- Wrap the managed resource in an object derived from System.Runtime.InteropServices.SafeHandle. Your Dispose implementation then calls the Dispose method of the System.Runtime.InteropServices.SafeHandle instances. For more information, see "The SafeHandle alternative" section in the Object.Finalize topic.

- Implement a finalizer to free resources when Dispose is not called. By default, the garbage collector automatically calls an object's finalizer before reclaiming its memory. However, if the Dispose method has been called, it is typically unnecessary for the garbage collector to call the disposed object's finalizer. To prevent automatic finalization, Dispose implementations can call the GC.SuppressFinalize method.

When you use an object that accesses unmanaged resources, such as a StreamWriter, a good practice is to create the instance with a `using` statement. The `using` statement automatically closes the stream and calls Dispose on the object when the code that is using it has completed. For an example, see the StreamWriter class.

IEquatable<T> Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a generalized method that a value type or class implements to create a type-specific method for determining equality of instances.

```
C#
public interface IEquatable<T>
```

Type Parameters

T

The type of objects to compare.

Derived Microsoft.Extensions.AsyncState.AsyncStateToken
Microsoft.Extensions.Compliance.Classification.DataClassification
Microsoft.Extensions.Compliance.Classification.DataClassificationSet
Microsoft.Extensions.Compliance.Testing.RedactedData
Microsoft.Extensions.Compliance.Testing.RedactorRequested
More...

Examples

See the example for the IEquatable<T>.Equals method.

Remarks

This interface is implemented by types whose values can be equated (for example, the numeric and string classes). A value type or class implements the Equals method to create a type-specific method suitable for determining equality of instances.

Note

The **IComparable<T>** interface defines the **CompareTo** method, which determines the sort order of instances of the implementing type. The **IEquatable<T>** interface defines the **Equals** method, which determines the equality of instances of the implementing type.

The IEquatable<T> interface is used by generic collection objects such as Dictionary<TKey,TValue>, List<T>, and LinkedList<T> when testing for equality in such methods as `Contains`, `IndexOf`, `LastIndexOf`, and `Remove`. It should be implemented for any object that might be stored in a generic collection.

Notes to Implementers

Replace the type parameter of the IEquatable<T> interface with the type that is implementing this interface.

If you implement IEquatable<T>, you should also override the base class implementations of Equals(Object) and GetHashCode() so that their behavior is consistent with that of the Equals(T) method. If you do override Equals(Object), your overridden implementation is also called in calls to the static `Equals(System.Object, System.Object)` method on your class. In addition, you should overload the `op_Equality` and `op_Inequality` operators. This ensures that all tests for equality return consistent results.

For information on overriding Equals(Object), see Equals(Object).

For a value type, you should always implement IEquatable<T> and override Equals(Object) for better performance. Equals(Object) boxes value types and relies on reflection to compare two values for equality. Both your implementation of Equals(T) and your override of Equals(Object) should return consistent results.

If you implement IEquatable<T>, you should also implement IComparable<T> if instances of your type can be ordered or sorted. If your type implements IComparable<T>, you almost always also implement IEquatable<T>.

Note that there are some designs where a type supports an order relation, but equality may be distinct from an ordering relation. Consider a `Person` class where you sort alphabetically. Two people with the same name sort the same, but are not the same person.

Methods

IEquatable<T>.Equals(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the current object is equal to another object of the same type.

C#

```
public bool Equals (T? other);
```

Parameters

other T

An object to compare with this object.

Returns

Boolean

`true` if the current object is equal to the `other` parameter; otherwise, `false`.

Examples

The following example shows the partial implementation of a `Person` class that implements IEquatable<T> and has two properties, `LastName` and `SSN`. The Equals method returns `True` if the `SSN` property of two `Person` objects is identical; otherwise, it returns `False`.

C#

```
using System;
using System.Collections.Generic;
using System.Text.RegularExpressions;

public class Person : IEquatable<Person>
{
   private string uniqueSsn;
   private string lName;
```

```
   public Person(string lastName, string ssn)
   {
      if (Regex.IsMatch(ssn, @"\d{9}"))
        uniqueSsn = $"{ssn.Substring(0, 3)}-{ssn.Substring(3, 2)}-
{ssn.Substring(5, 4)}";
      else if (Regex.IsMatch(ssn, @"\d{3}-\d{2}-\d{4}"))
         uniqueSsn = ssn;
      else
         throw new FormatException("The social security number has an
invalid format.");

      this.LastName = lastName;
   }

   public string SSN
   {
      get { return this.uniqueSsn; }
   }

   public string LastName
   {
      get { return this.lName; }
      set {
         if (String.IsNullOrEmpty(value))
            throw new ArgumentException("The last name cannot be null or
empty.");
         else
            this.lName = value;
      }
   }

   public bool Equals(Person other)
   {
      if (other == null)
         return false;

      if (this.uniqueSsn == other.uniqueSsn)
         return true;
      else
         return false;
   }

   public override bool Equals(Object obj)
   {
      if (obj == null)
         return false;

      Person personObj = obj as Person;
      if (personObj == null)
         return false;
      else
         return Equals(personObj);
   }
```

```
    public override int GetHashCode()
    {
       return this.SSN.GetHashCode();
    }

    public static bool operator == (Person person1, Person person2)
    {
       if (((object)person1) == null || ((object)person2) == null)
          return Object.Equals(person1, person2);

       return person1.Equals(person2);
    }

    public static bool operator != (Person person1, Person person2)
    {
       if (((object)person1) == null || ((object)person2) == null)
          return ! Object.Equals(person1, person2);

       return ! (person1.Equals(person2));
    }
 }
```

`Person` objects can then be stored in a List<T> object and can be identified by the `Contains` method, as the following example shows.

C#

```
public class TestIEquatable
{
   public static void Main()
   {
      // Create a Person object for each job applicant.
      Person applicant1 = new Person("Jones", "099-29-4999");
      Person applicant2 = new Person("Jones", "199-29-3999");
      Person applicant3 = new Person("Jones", "299-49-6999");

      // Add applicants to a List object.
      List<Person> applicants = new List<Person>();
      applicants.Add(applicant1);
      applicants.Add(applicant2);
      applicants.Add(applicant3);

       // Create a Person object for the final candidate.
       Person candidate = new Person("Jones", "199-29-3999");
       if (applicants.Contains(candidate))
          Console.WriteLine("Found {0} (SSN {1}).",
                            candidate.LastName, candidate.SSN);
      else
         Console.WriteLine("Applicant {0} not found.", candidate.SSN);

      // Call the shared inherited Equals(Object, Object) method.
      // It will in turn call the IEquatable(Of T).Equals implementation.
      Console.WriteLine("{0}({1}) already on file: {2}.",
```

```
                        applicant2.LastName,
                        applicant2.SSN,
                        Person.Equals(applicant2, candidate));
    }
}
// The example displays the following output:
//       Found Jones (SSN 199-29-3999).
//       Jones(199-29-3999) already on file: True.
```

Remarks

The implementation of the Equals method is intended to perform a test for equality with another object of type `T`, the same type as the current object. The Equals(T) method is called in the following circumstances:

- When the `Equals` method is called and the `other` argument is a strongly-typed object of type `T`. (If `other` is not of type `T`, the base Object.Equals(Object) method is called. Of the two methods, IEquatable<T>.Equals offers slightly better performance.)
- When the search methods of a number of generic collection objects are called. Some of these types and their methods include the following:
  - Some of the generic overloads of the BinarySearch method.
  - The search methods of the List<T> class, including List<T>.Contains(T), List<T>.IndexOf, List<T>.LastIndexOf, and List<T>.Remove.
  - The search methods of the Dictionary<TKey,TValue> class, including ContainsKey and Remove.
  - The search methods of the generic LinkedList<T> class, including LinkedList<T>.Contains and Remove.

In other words, to handle the possibility that objects of a class will be stored in an array or a generic collection object, it is a good idea to implement IEquatable<T> so that the object can be easily identified and manipulated.

When implementing the Equals method, define equality appropriately for the type specified by the generic type argument. For example, if the type argument is Int32, define equality appropriately for the comparison of two 32-bit signed integers.

Notes to Implementers

If you implement Equals(T), you should also override the base class implementations of Equals(Object) and GetHashCode() so that their behavior is consistent with that of the Equals(T) method. If you do override Equals(Object), your overridden implementation is also called in calls to the static `Equals(System.Object, System.Object)` method on your class. In addition, you should overload the `op_Equality` and `op_Inequality` operators. This ensures that all tests for equality return consistent results, which the example illustrates.

IFormatProvider Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a mechanism for retrieving an object to control formatting.

C#

```
public interface IFormatProvider
```

Derived System.Globalization.CultureInfo
System.Globalization.DateTimeFormatInfo
System.Globalization.NumberFormatInfo

Examples

The following example illustrates how an IFormatProvider implementation can change the representation of a date and time value. In this case, a single date is displayed by using CultureInfo objects that represent four different cultures.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      DateTime dateValue = new DateTime(2009, 6, 1, 16, 37, 0);
      CultureInfo[] cultures = { new CultureInfo("en-US"),
                                 new CultureInfo("fr-FR"),
                                 new CultureInfo("it-IT"),
                                 new CultureInfo("de-DE") };
      foreach (CultureInfo culture in cultures)
         Console.WriteLine("{0}: {1}", culture.Name,
dateValue.ToString(culture));
   }
}
// The example displays the following output:
```

```
//       en-US: 6/1/2009 4:37:00 PM
//       fr-FR: 01/06/2009 16:37:00
//       it-IT: 01/06/2009 16.37.00
//       de-DE: 01.06.2009 16:37:00
```

The following example illustrates the use of a class that implements the IFormatProvider interface and the GetFormat method. The `AcctNumberFormat` class converts an Int64 value that represents an account number to a formatted 12-digit account number. Its `GetFormat` method returns a reference to the current `AcctNumberFormat` instance if the `formatType` parameter refers to a class that implements ICustomFormatter; otherwise, `GetFormat` returns `null`.

C#

```
public class AcctNumberFormat : IFormatProvider, ICustomFormatter
{
   private const int ACCT_LENGTH = 12;

   public object GetFormat(Type formatType)
   {
      if (formatType == typeof(ICustomFormatter))
         return this;
      else
         return null;
   }

   public string Format(string fmt, object arg, IFormatProvider
formatProvider)
   {
      // Provide default formatting if arg is not an Int64.
      if (arg.GetType() != typeof(Int64))
         try {
            return HandleOtherFormats(fmt, arg);
         }
         catch (FormatException e) {
            throw new FormatException(String.Format("The format of '{0}' is
invalid.", fmt), e);
         }

      // Provide default formatting for unsupported format strings.
      string ufmt = fmt.ToUpper(CultureInfo.InvariantCulture);
      if (! (ufmt == "H" || ufmt == "I"))
         try {
            return HandleOtherFormats(fmt, arg);
         }
         catch (FormatException e) {
            throw new FormatException(String.Format("The format of '{0}' is
invalid.", fmt), e);
         }

      // Convert argument to a string.
```

```
      string result = arg.ToString();

      // If account number is less than 12 characters, pad with leading
zeroes.
      if (result.Length < ACCT_LENGTH)
         result = result.PadLeft(ACCT_LENGTH, '0');
      // If account number is more than 12 characters, truncate to 12
characters.
      if (result.Length > ACCT_LENGTH)
         result = result.Substring(0, ACCT_LENGTH);

      if (ufmt == "I")                    // Integer-only format.
         return result;
      // Add hyphens for H format specifier.
      else                                          // Hyphenated format.
         return result.Substring(0, 5) + "-" + result.Substring(5, 3) + "-"
+ result.Substring(8);
   }

   private string HandleOtherFormats(string format, object arg)
   {
      if (arg is IFormattable)
         return ((IFormattable)arg).ToString(format,
CultureInfo.CurrentCulture);
      else if (arg != null)
         return arg.ToString();
      else
         return String.Empty;
   }
}
```

The class that implements IFormatProvider can then be used in a call to a formatting and parsing operation. For example, the following code calls the String.Format(IFormatProvider, String, Object[]) method to generate a string that contains a formatted 12-digit account number.

C#

```
using System;
using System.Globalization;

public enum DaysOfWeek { Monday=1, Tuesday=2 };

public class TestFormatting
{
   public static void Main()
   {
      long acctNumber;
      double balance;
      DaysOfWeek wday;
      string output;
```

```
        acctNumber = 104254567890;
        balance = 16.34;
        wday = DaysOfWeek.Monday;

        output = String.Format(new AcctNumberFormat(),
                               "On {2}, the balance of account {0:H} was
{1:C2}.",
                               acctNumber, balance, wday);
        Console.WriteLine(output);

        wday = DaysOfWeek.Tuesday;
        output = String.Format(new AcctNumberFormat(),
                               "On {2}, the balance of account {0:I} was
{1:C2}.",
                               acctNumber, balance, wday);
        Console.WriteLine(output);
    }
}
// The example displays the following output:
//       On Monday, the balance of account 10425-456-7890 was $16.34.
//       On Tuesday, the balance of account 104254567890 was $16.34.
```

Remarks

The IFormatProvider interface supplies an object that provides formatting information for formatting and parsing operations. Formatting operations convert the value of a type to the string representation of that value. Typical formatting methods are the `ToString` methods of a type, as well as Format. Parsing operations convert the string representation of a value to a type with that value. Typical parsing methods are `Parse` and `TryParse`.

The IFormatProvider interface consists of a single method, IFormatProvider.GetFormat. GetFormat is a callback method: The parsing or formatting method calls it and passes it a Type object that represents the type of object that the formatting or parsing method expects will provide formatting information. The GetFormat method is responsible for returning an object of that type.

IFormatProvider implementations are often used implicitly by formatting and parsing methods. For example, the DateTime.ToString(String) method implicitly uses an IFormatProvider implementation that represents the system's current culture. IFormatProvider implementations can also be specified explicitly by methods that have a parameter of type IFormatProvider, such as Int32.Parse(String, IFormatProvider) and String.Format(IFormatProvider, String, Object[]).

The .NET Framework includes the following three predefined IFormatProvider implementations to provide culture-specific information that is used in formatting or

parsing numeric and date and time values:

- The NumberFormatInfo class, which provides information that is used to format numbers, such as the currency, thousands separator, and decimal separator symbols for a particular culture. For information about the predefined format strings recognized by a NumberFormatInfo object and used in numeric formatting operations, see Standard Numeric Format Strings and Custom Numeric Format Strings.

- The DateTimeFormatInfo class, which provides information that is used to format dates and times, such as the date and time separator symbols for a particular culture or the order and format of a date's year, month, and day components. For information about the predefined format strings recognized by a DateTimeFormatInfo object and used in numeric formatting operations, see Standard Date and Time Format Strings and Custom Date and Time Format Strings.

- The CultureInfo class, which represents a particular culture. Its GetFormat method returns a culture-specific NumberFormatInfo or DateTimeFormatInfo object, depending on whether the CultureInfo object is used in a formatting or parsing operation that involves numbers or dates and times.

The .NET Framework also supports custom formatting. This typically involves the creation of a formatting class that implements both IFormatProvider and ICustomFormatter. An instance of this class is then passed as a parameter to a method that performs a custom formatting operation, such as String.Format(IFormatProvider, String, Object[]) The example provides an illustration of such a custom implementation that formats a number as a 12-digit account number.

Methods

Expand table

GetFormat(Type)	Returns an object that provides formatting services for the specified type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IFormatProvider.GetFormat(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an object that provides formatting services for the specified type.

```
C#

public object? GetFormat (Type? formatType);
```

Parameters

`formatType` Type

An object that specifies the type of format object to return.

Returns

Object

An instance of the object specified by `formatType`, if the IFormatProvider implementation can supply that type of object; otherwise, `null`.

Examples

The following example illustrates the use of a class that implements the IFormatProvider interface and the GetFormat method. The `AcctNumberFormat` class converts an Int64 value that represents an account number to a formatted 12-digit account number. Its `GetFormat` method returns a reference to itself if the `formatType` parameter refers to a class that implements ICustomFormatter; otherwise, `GetFormat` returns `null`.

```
C#

public class AcctNumberFormat : IFormatProvider, ICustomFormatter
{
   private const int ACCT_LENGTH = 12;
```

```
   public object GetFormat(Type formatType)
   {
      if (formatType == typeof(ICustomFormatter))
         return this;
      else
         return null;
   }

   public string Format(string fmt, object arg, IFormatProvider
formatProvider)
   {
      // Provide default formatting if arg is not an Int64.
      if (arg.GetType() != typeof(Int64))
         try {
            return HandleOtherFormats(fmt, arg);
         }
         catch (FormatException e) {
            throw new FormatException(String.Format("The format of '{0}' is
invalid.", fmt), e);
         }

      // Provide default formatting for unsupported format strings.
      string ufmt = fmt.ToUpper(CultureInfo.InvariantCulture);
      if (! (ufmt == "H" || ufmt == "I"))
         try {
            return HandleOtherFormats(fmt, arg);
         }
         catch (FormatException e) {
            throw new FormatException(String.Format("The format of '{0}' is
invalid.", fmt), e);
         }

      // Convert argument to a string.
      string result = arg.ToString();

      // If account number is less than 12 characters, pad with leading
zeroes.
      if (result.Length < ACCT_LENGTH)
         result = result.PadLeft(ACCT_LENGTH, '0');
      // If account number is more than 12 characters, truncate to 12
characters.
      if (result.Length > ACCT_LENGTH)
         result = result.Substring(0, ACCT_LENGTH);

      if (ufmt == "I")                    // Integer-only format.
         return result;
      // Add hyphens for H format specifier.
      else                                          // Hyphenated format.
         return result.Substring(0, 5) + "-" + result.Substring(5, 3) + "-"
+ result.Substring(8);
   }

   private string HandleOtherFormats(string format, object arg)
   {
```

```
      if (arg is IFormattable)
         return ((IFormattable)arg).ToString(format,
CultureInfo.CurrentCulture);
      else if (arg != null)
         return arg.ToString();
      else
         return String.Empty;
   }
}
```

An instance of the `AcctNumberFormat` class can then be passed as an argument to a method that provides formatting or parsing services. For example, the following code passes an `AcctNumberFormat` class to the String.Format(IFormatProvider, String, Object[]) method to generate a formatted 12-digit account number.

C#

```
using System;
using System.Globalization;

public enum DaysOfWeek { Monday=1, Tuesday=2 };

public class TestFormatting
{
   public static void Main()
   {
      long acctNumber;
      double balance;
      DaysOfWeek wday;
      string output;

      acctNumber = 104254567890;
      balance = 16.34;
      wday = DaysOfWeek.Monday;

      output = String.Format(new AcctNumberFormat(),
                             "On {2}, the balance of account {0:H} was
{1:C2}.",
                             acctNumber, balance, wday);
      Console.WriteLine(output);

      wday = DaysOfWeek.Tuesday;
      output = String.Format(new AcctNumberFormat(),
                             "On {2}, the balance of account {0:I} was
{1:C2}.",
                             acctNumber, balance, wday);
      Console.WriteLine(output);
   }
}
// The example displays the following output:
```

```
//       On Monday, the balance of account 10425-456-7890 was $16.34.
//       On Tuesday, the balance of account 104254567890 was $16.34.
```

Remarks

GetFormat is a callback method that formatting and parsing methods invoke to retrieve information about the format of the input string in parsing operations or the format of the output string in formatting operations. In the `formatType` parameter, the formatting or parsing method passes the type of object it requires to perform its operation. If the IFormatProvider implementation can supply this formatting or parsing object, it returns that object. If not, it returns `null`.

For example, in the call to the Int32.ToString(IFormatProvider) method, the method argument is an IFormatProvider object that provides information about how the string representation of the current integer instance might be formatted. When the runtime executes the method, it calls the IFormatProvider object's GetFormat method and passes it a Type object that represents the NumberFormatInfo type. If the IFormatProvider object can supply a NumberFormatInfo object, it returns that object. If it cannot supply an object of that type, it returns `null`.

You can implement the IFormatProvider interface and the GetFormat method in classes that provide custom formatting or parsing services. The IFormatProvider implementation is then passed as an argument to any overload of a parsing or formatting method that has a parameter of type IFormatProvider, such as String.Format(IFormatProvider, String, Object[]), Int32.ToString(String, IFormatProvider), or DateTime.Parse(String, IFormatProvider).

IFormattable Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides functionality to format the value of an object into a string representation.

C#

```
public interface IFormattable
```

Derived System.Byte
System.Char
System.DateOnly
System.DateTime
System.DateTimeOffset
More...

Examples

The following example defines a `Temperature` class that implements the IFormattable interface. The class supports four format specifiers: "G" and "C", which indicate that the temperature is to be displayed in Celsius; "F", which indicates that the temperature is to be displayed in Fahrenheit; and "K", which indicates that the temperature is to be displayed in Kelvin. In addition, the IFormattable.ToString implementation also can handle a format string that is `null` or empty. The other two `ToString` methods defined by the `Temperature` class simply wrap a call to the IFormattable.ToString implementation.

C#

```
using System;
using System.Globalization;

public class Temperature : IFormattable
{
   private decimal temp;

   public Temperature(decimal temperature)
```

```
    {
       if (temperature < -273.15m)
         throw new ArgumentOutOfRangeException(String.Format("{0} is less
than absolute zero.",
                                                 temperature));
       this.temp = temperature;
    }

    public decimal Celsius
    {
       get { return temp; }
    }

    public decimal Fahrenheit
    {
       get { return temp * 9 / 5 + 32; }
    }

    public decimal Kelvin
    {
       get { return temp + 273.15m; }
    }

    public override string ToString()
    {
       return this.ToString("G", CultureInfo.CurrentCulture);
    }

    public string ToString(string format)
    {
       return this.ToString(format, CultureInfo.CurrentCulture);
    }

    public string ToString(string format, IFormatProvider provider)
    {
       if (String.IsNullOrEmpty(format)) format = "G";
       if (provider == null) provider = CultureInfo.CurrentCulture;

       switch (format.ToUpperInvariant())
       {
          case "G":
          case "C":
             return temp.ToString("F2", provider) + " °C";
          case "F":
             return Fahrenheit.ToString("F2", provider) + " °F";
          case "K":
             return Kelvin.ToString("F2", provider) + " K";
          default:
             throw new FormatException(String.Format("The {0} format string
is not supported.", format));
       }
    }
}
```

The following example then calls the IFormattable.ToString implementation either directly or by using a composite format string.

C#

```
public class Example
{
   public static void Main()
   {
      // Use composite formatting with format string in the format item.
      Temperature temp1 = new Temperature(0);
      Console.WriteLine("{0:C} (Celsius) = {0:K} (Kelvin) = {0:F}
(Fahrenheit)\n", temp1);

      // Use composite formatting with a format provider.
      temp1 = new Temperature(-40);
      Console.WriteLine(String.Format(CultureInfo.CurrentCulture, "{0:C}
(Celsius) = {0:K} (Kelvin) = {0:F} (Fahrenheit)", temp1));
      Console.WriteLine(String.Format(new CultureInfo("fr-FR"), "{0:C}
(Celsius) = {0:K} (Kelvin) = {0:F} (Fahrenheit)\n", temp1));

      // Call ToString method with format string.
      temp1 = new Temperature(32);
      Console.WriteLine("{0} (Celsius) = {1} (Kelvin) = {2} (Fahrenheit)\n",
                        temp1.ToString("C"), temp1.ToString("K"),
temp1.ToString("F"));

      // Call ToString with format string and format provider
      temp1 = new Temperature(100)      ;
      NumberFormatInfo current = NumberFormatInfo.CurrentInfo;
      CultureInfo nl = new CultureInfo("nl-NL");
      Console.WriteLine("{0} (Celsius) = {1} (Kelvin) = {2} (Fahrenheit)",
                        temp1.ToString("C", current), temp1.ToString("K",
current), temp1.ToString("F", current));
      Console.WriteLine("{0} (Celsius) = {1} (Kelvin) = {2} (Fahrenheit)",
                        temp1.ToString("C", nl), temp1.ToString("K", nl),
temp1.ToString("F", nl));
   }
}
// The example displays the following output:
//    0.00 °C (Celsius) = 273.15 K (Kelvin) = 32.00 °F (Fahrenheit)
//
//    -40.00 °C (Celsius) = 233.15 K (Kelvin) = -40.00 °F (Fahrenheit)
//    -40,00 °C (Celsius) = 233,15 K (Kelvin) = -40,00 °F (Fahrenheit)
//
//    32.00 °C (Celsius) = 305.15 K (Kelvin) = 89.60 °F (Fahrenheit)
//
//    100.00 °C (Celsius) = 373.15 K (Kelvin) = 212.00 °F (Fahrenheit)
//    100,00 °C (Celsius) = 373,15 K (Kelvin) = 212,00 °F (Fahrenheit)
```

Remarks

The IFormattable interface converts an object to its string representation based on a format string and a format provider.

A format string typically defines the general appearance of an object. For example, the .NET Framework supports the following:

- Standard format strings for formatting enumeration values (see Enumeration Format Strings).
- Standard and custom format strings for formatting numeric values (see Standard Numeric Format Strings and Custom Numeric Format Strings).
- Standard and custom format strings for formatting date and time values (see Standard Date and Time Format Strings and Custom Date and Time Format Strings).
- Standard and custom format strings for formatting time intervals (see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings).

You can also define your own format strings to support formatting of your application-defined types.

A format provider returns a formatting object that typically defines the symbols used in converting an object to its string representation. For example, when you convert a number to a currency value, a format provider defines the currency symbol that appears in the result string. The .NET Framework defines three format providers:

- The System.Globalization.CultureInfo class, which returns either a NumberFormatInfo object for formatting numeric values, or a DateTimeFormatInfo object for formatting date and time values.
- The System.Globalization.NumberFormatInfo class, which returns an instance of itself for formatting numeric values.
- The System.Globalization.DateTimeFormatInfo class, which returns an instance of itself for formatting date and time values.

In addition, you can define your own custom format providers to supply culture-specific, profession-specific, or industry-specific information used in formatting. For more information about implementing custom formatting by using a custom format provider, see ICustomFormatter.

The IFormattable interface defines a single method, ToString, that supplies formatting services for the implementing type. The ToString method can be called directly. In addition, it is called automatically by the Convert.ToString(Object) and

Convert.ToString(Object, IFormatProvider) methods, and by methods that use the composite formatting feature in the .NET Framework. Such methods include Console.WriteLine(String, Object), String.Format, and StringBuilder.AppendFormat(String, Object), among others. The ToString method is called for each format item in the method's format string.

The IFormattable interface is implemented by the base data types.

Notes to Implementers

Classes that require more control over the formatting of strings than ToString() provides should implement IFormattable.

A class that implements IFormattable must support the "G" (general) format specifier. Besides the "G" specifier, the class can define the list of format specifiers that it supports. In addition, the class must be prepared to handle a format specifier that is `null`. For more information about formatting and formatting codes, see Formatting Types

IFormattable.ToString(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Formats the value of the current instance using the specified format.

C#

```
public string ToString (string? format, IFormatProvider? formatProvider);
```

Parameters

`format` String

The format to use.

-or-

A null reference (`Nothing` in Visual Basic) to use the default format defined for the type of the IFormattable implementation.

`formatProvider` IFormatProvider

The provider to use to format the value.

-or-

A null reference (`Nothing` in Visual Basic) to obtain the numeric format information from the current locale setting of the operating system.

Returns

String

The value of the current instance in the specified format.

Examples

The following example demonstrates a `Temperature` class that implements the ToString method. This code example is part of a larger example provided for the IFormattable class.

C#

```
using System;
using System.Globalization;

public class Temperature : IFormattable
{
   private decimal temp;

   public Temperature(decimal temperature)
   {
      if (temperature < -273.15m)
        throw new ArgumentOutOfRangeException(String.Format("{0} is less
than absolute zero.",
                                                 temperature));
      this.temp = temperature;
   }

   public decimal Celsius
   {
      get { return temp; }
   }

   public decimal Fahrenheit
   {
      get { return temp * 9 / 5 + 32; }
   }

   public decimal Kelvin
   {
      get { return temp + 273.15m; }
   }

   public override string ToString()
   {
      return this.ToString("G", CultureInfo.CurrentCulture);
   }

   public string ToString(string format)
   {
      return this.ToString(format, CultureInfo.CurrentCulture);
   }

   public string ToString(string format, IFormatProvider provider)
   {
      if (String.IsNullOrEmpty(format)) format = "G";
      if (provider == null) provider = CultureInfo.CurrentCulture;

      switch (format.ToUpperInvariant())
```

```
        {
            case "G":
            case "C":
                return temp.ToString("F2", provider) + " °C";
            case "F":
                return Fahrenheit.ToString("F2", provider) + " °F";
            case "K":
                return Kelvin.ToString("F2", provider) + " K";
            default:
                throw new FormatException(String.Format("The {0} format string
is not supported.", format));
        }
    }
}
```

Remarks

The ToString method converts a value to a string representation that can be expressed in multiple ways. Its precise format depends on specific symbols or a specified order defined by specific cultures, professions, or industries. You can call the method directly. It is also called automatically by the Convert.ToString(Object) and Convert.ToString(Object, IFormatProvider) methods, and by methods that use the composite formatting feature in the .NET Framework, such as String.Format(String, Object[]), Console.WriteLine(String, Object[]), and StringBuilder.AppendFormat(String, Object[]). (For more information, see Composite Formatting.)

Composite formatting methods call the ToString method once for each format item in a format string. The parameters passed to the method depend on the specific formatting method that is called and on the content of the format item, as follows:

- If the format item does not include a format string (for example, if the format item is simply `{0}`), it is passed `null` as the value of the System.String parameter.
- If the format item includes a format string (for example, `{0:G}`), that format string is passed as the value of the System.String parameter.
- If the original method call does not include an System.IFormatProvider parameter, CultureInfo.CurrentCulture is passed as the value of the System.IFormatProvider parameter.
- If the original method call includes an System.IFormatProvider parameter, the provider that is supplied in the method call is passed as the value of the System.IFormatProvider parameter.

> **Note**
>
> An object's **ToString** implementation is called by composite formatting methods only if they are not passed an **ICustomFormatter** format provider, or if the **Format** method of the custom format provider returns `null`.

The .NET Framework includes three format providers, all of which implement the IFormatProvider interface:

- NumberFormatInfo supplies numeric formatting information, such as the characters to use for decimal and group separators, and the spelling and placement of currency symbols in monetary values.
- DateTimeFormatInfo supplies date-related and time-related formatting information, such as the position of the month, the day, and the year in a date pattern.
- CultureInfo contains the default formatting information in a specific culture, including the numeric format information, and date-related and time-related formatting information.

In addition, you can define your own custom format provider.

Notes to Implementers

The ToString(String, IFormatProvider) method must support the "G" (general) format specifier. Besides the "G" specifier, the class can define the list of format specifiers that it supports. In addition, the class must be prepared to handle a format specifier that is `null`. For more information about formatting and formatting codes, see Formatting Types.

Index Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a type that can be used to index a collection either from the beginning or the end.

```
C#

public readonly struct Index : IEquatable<Index>
```

Inheritance Object → ValueType → Index

Implements IEquatable<Index>

Remarks

`Index` is used by the C# compiler to support the `^` or "index from end" operator:

```
C#

int[] someArray = new int[5] { 1, 2, 3, 4, 5 };
int lastElement = someArray[^1]; // lastElement = 5
```

Constructors

Expand table

Index(Int32, Boolean)	Initializes a new Index with a specified index position and a value that indicates if the index is from the beginning or the end of a collection.

Properties

Expand table

End	Gets an Index that points beyond the last element.
IsFromEnd	Gets a value that indicates whether the index is from the start or the end.
Start	Gets an Index that points to the first element of a collection.
Value	Gets the index value.

Methods

Expand table

Equals(Index)	Returns a value that indicates whether the current object is equal to another Index object.
Equals(Object)	Indicates whether the current Index object is equal to a specified object.
FromEnd(Int32)	Creates an Index from the end of a collection at a specified index position.
From Start(Int32)	Creates an Index from the specified index at the start of a collection.
GetHashCode()	Returns the hash code for this instance.
GetOffset(Int32)	Calculates the offset from the start of the collection using the specified collection length.
ToString()	Returns the string representation of the current Index instance.

Operators

Expand table

Implicit(Int32 to Index)	Converts an integer number to an Index.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index(Int32, Boolean) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new Index with a specified index position and a value that indicates if the index is from the beginning or the end of a collection.

```
C#
public Index (int value, bool fromEnd = false);
```

Parameters

`value` Int32

The index value. It has to be greater then or equal to zero.

`fromEnd` Boolean

`true` to index from the end of the collection, or `false` to index from the beginning of the collection.

Remarks

If the Index is constructed from the end, an index value of 1 points to the last element, and an index value of 0 points beyond the last element.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.End Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an Index that points beyond the last element.

C#

```
public static Index End { get; }
```

Property Value

Index

An index that points beyond the last element.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.IsFromEnd Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the index is from the start or the end.

C#

```
public bool IsFromEnd { get; }
```

Property Value

Boolean

`true` if the Index is from the end; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.Start Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an Index that points to the first element of a collection.

C#

```
public static Index Start { get; }
```

Property Value

Index

An instance that points to the first element of a collection.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the index value.

```
C#
public int Value { get; }
```

Property Value

Int32

The index value.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Index)	Returns a value that indicates whether the current object is equal to another Index object.
Equals(Object)	Indicates whether the current Index object is equal to a specified object.

Equals(Index)

Returns a value that indicates whether the current object is equal to another Index object.

```
C#

public bool Equals (Index other);
```

Parameters

`other` Index

The object to compare with this instance.

Returns

Boolean

`true` if the current Index object is equal to `other`; `false` otherwise.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Equals(Object)

Indicates whether the current Index object is equal to a specified object.

C#

```
public override bool Equals (object? value);
```

Parameters

`value` Object

An object to compare with this instance.

Returns

Boolean

`true` if `value` is of type Index and is equal to the current instance; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Index.FromEnd(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an Index from the end of a collection at a specified index position.

C#

```
public static Index FromEnd (int value);
```

Parameters

`value` Int32

The index value from the end of a collection.

Returns

Index

The index value.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Index.FromStart(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an Index from the specified index at the start of a collection.

C#

```
public static Index FromStart (int value);
```

Parameters

`value` Int32

The index position from the start of a collection.

Returns

Index

The index value.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Index.GetOffset(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the offset from the start of the collection using the specified collection length.

```
C#
public int GetOffset (int length);
```

Parameters

`length` Int32

The length of the collection that the Index will be used with. Must be a positive value.

Returns

Int32

The offset.

Remarks

For performance reasons, this method does not validate if `length` or the returned value are negative. It also doesn't validate if the returned value is greater than `length`.

Collections are not expected to have a negative length/count. If this method's returned offset is negative and is then used to index a collection, the runtime will throw ArgumentOutOfRangeException, which will have the same effect as validation.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Index.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of the current Index instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the Index.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Index.Implicit(Int32 to Index) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts an integer number to an Index.

```
C#
public static implicit operator Index (int value);
```

Parameters

`value` Int32

The integer to convert.

Returns

Index

An index representing the integer.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOutOfRangeException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt is made to access an element of an array or collection with an index that is outside its bounds.

C#

```
public sealed class IndexOutOfRangeException : SystemException
```

Inheritance Object → Exception → SystemException → IndexOutOfRangeException

Remarks

An IndexOutOfRangeException exception is thrown when an invalid index is used to access a member of an array or a collection, or to read or write from a particular location in a buffer. This exception inherits from the Exception class but adds no unique members.

Typically, an IndexOutOfRangeException exception is thrown as a result of developer error. Instead of handling the exception, you should diagnose the cause of the error and correct your code. The most common causes of the error are:

- Forgetting that the upper bound of a collection or a zero-based array is one less than its number of members or elements, as the following example illustrates.

  C#

  ```
  using System;
  using System.Collections.Generic;

  public class Example
  {
     public static void Main()
     {
        List<Char> characters = new List<Char>();
        characters.InsertRange(0, new Char[] { 'a', 'b', 'c', 'd', 'e',
  'f' } );
  ```

```
      for (int ctr = 0; ctr <= characters.Count; ctr++)
         Console.Write("'{0}'    ", characters[ctr]);
   }
}
// The example displays the following output:
//    'a'    'b'    'c'    'd'    'e'    'f'
//    Unhandled Exception:
//    System.ArgumentOutOfRangeException:
//    Index was out of range. Must be non-negative and less than the
size of the collection.
//    Parameter name: index
//       at Example.Main()
```

To correct the error, you can use code like the following.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      List<Char> characters = new List<Char>();
      characters.InsertRange(0, new Char[] { 'a', 'b', 'c', 'd', 'e',
'f' } );
      for (int ctr = 0; ctr < characters.Count; ctr++)
         Console.Write("'{0}'    ", characters[ctr]);
   }
}
// The example displays the following output:
//        'a'    'b'    'c'    'd'    'e'    'f'
```

Alternately, instead of iterating all the elements in the array by their index, you can use the `foreach` statement (in C#), the `for...in` statement (in F#), or the `For Each` statement (in Visual Basic).

- Attempting to assign an array element to another array that has not been adequately dimensioned and that has fewer elements than the original array. The following example attempts to assign the last element in the `value1` array to the same element in the `value2` array. However, the `value2` array has been incorrectly dimensioned to have six instead of seven elements. As a result, the assignment throws an IndexOutOfRangeException exception.

C#

```
public class Example
{
```

```
    public static void Main()
    {
       int[] values1 = { 3, 6, 9, 12, 15, 18, 21 };
       int[] values2 = new int[6];

       // Assign last element of the array to the new array.
       values2[values1.Length - 1] = values1[values1.Length - 1];
    }
}
// The example displays the following output:
//       Unhandled Exception:
//       System.IndexOutOfRangeException:
//       Index was outside the bounds of the array.
//       at Example.Main()
```

- Using a value returned by a search method to iterate a portion of an array or collection starting at a particular index position. If you forget to check whether the search operation found a match, the runtime throws an IndexOutOfRangeException exception, as shown in this example.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   static List<int> numbers = new List<int>();

   public static void Main()
   {
      int startValue;
      string[] args = Environment.GetCommandLineArgs();
      if (args.Length < 2)
         startValue = 2;
      else
         if (! Int32.TryParse(args[1], out startValue))
            startValue = 2;

      ShowValues(startValue);
   }

   private static void ShowValues(int startValue)
   {
      // Create a collection with numeric values.
      if (numbers.Count == 0)
         numbers.AddRange( new int[] { 2, 4, 6, 8, 10, 12, 14, 16, 18,
20, 22} );

      // Get the index of a startValue.
      Console.WriteLine("Displaying values greater than or equal to
{0}:",
```

```
                        startValue);
      int startIndex = numbers.IndexOf(startValue);
      // Display all numbers from startIndex on.
      for (int ctr = startIndex; ctr < numbers.Count; ctr++)
         Console.Write("    {0}", numbers[ctr]);
   }
}
// The example displays the following output if the user supplies
// 7 as a command-line parameter:
//    Displaying values greater than or equal to 7:
//
//    Unhandled Exception: System.ArgumentOutOfRangeException:
//    Index was out of range. Must be non-negative and less than the
size of the collection.
//    Parameter name: index
//       at System.Collections.Generic.List`1.get_Item(Int32 index)
//       at Example.ShowValues(Int32 startValue)
//       at Example.Main()
```

In this case, the List<T>.IndexOf method returns -1, which is an invalid index value, when it fails to find a match. To correct this error, check the search method's return value before iterating the array, as shown in this example.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   static List<int> numbers = new List<int>();

   public static void Main()
   {
      int startValue;
      string[] args = Environment.GetCommandLineArgs();
      if (args.Length < 2)
         startValue = 2;
      else
         if (! Int32.TryParse(args[1], out startValue))
            startValue = 2;

      ShowValues(startValue);
   }

   private static void ShowValues(int startValue)
   {
      // Create a collection with numeric values.
      if (numbers.Count == 0)
         numbers.AddRange( new int[] { 2, 4, 6, 8, 10, 12, 14, 16, 18,
20, 22} );
```

```
      // Get the index of startValue.
      int startIndex = numbers.IndexOf(startValue);
      if (startIndex < 0) {
         Console.WriteLine("Unable to find {0} in the collection.",
startValue);
      }
      else {
         // Display all numbers from startIndex on.
         Console.WriteLine("Displaying values greater than or equal to
{0}:",
                           startValue);
         for (int ctr = startIndex; ctr < numbers.Count; ctr++)
            Console.Write("    {0}", numbers[ctr]);
      }
   }
}
// The example displays the following output if the user supplies
// 7 as a command-line parameter:
//      Unable to find 7 in the collection.
```

- Trying to use or enumerate a result set, collection, or array returned by a query without testing whether the returned object has any valid data.

- Using a computed value to define the starting index, the ending index, or the number of items to be iterated. If the result of the computation is unexpected, it might result in an IndexOutOfRangeException exception. You should check your program's logic in calculating the index value and validate the value before iterating the array or collection. The following conditions must all be true; otherwise, an IndexOutOfRangeException exception is thrown:

  - The starting index must be greater than or equal to Array.GetLowerBound for the dimension of the array that you want to iterate, or greater than or equal to 0 for a collection.

  - The ending index cannot exceed Array.GetUpperBound for the dimension of the array that you want to iterate, or cannot be greater than or equal to the `Count` property of a collection.

  - The following equation must be true for the dimension of the array that you want to iterate:

    ```
    start_index >= lower_bound And start_index + items_to_iterate - 1 <=
    upper_bound
    ```

    For a collection, the following equation must be true:

```
start_index >= 0 And start_index + items_to_iterate <= Count
```

> **Tip**
>
> The starting index of an array or collection can never be a negative number.

- Assuming that an array must be zero-based. Arrays that are not zero-based can be created by the Array.CreateInstance(Type, Int32[], Int32[]) method and can be returned by COM interop, although they aren't CLS-compliant. The following example illustrates the IndexOutOfRangeException that is thrown when you try to iterate a non-zero-based array created by the Array.CreateInstance(Type, Int32[], Int32[]) method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Array values = Array.CreateInstance(typeof(int), new int[] { 10
},
                                          new int[] { 1 });
      int value = 2;
      // Assign values.
      for (int ctr = 0; ctr < values.Length; ctr++) {
         values.SetValue(value, ctr);
         value *= 2;
      }

      // Display values.
      for (int ctr = 0; ctr < values.Length; ctr++)
         Console.Write("{0}    ", values.GetValue(ctr));
   }
}
// The example displays the following output:
//    Unhandled Exception:
//    System.IndexOutOfRangeException: Index was outside the bounds of
the array.
//       at System.Array.InternalGetReference(Void* elemRef, Int32
rank, Int32* pIndices)
//       at System.Array.SetValue(Object value, Int32 index)
//       at Example.Main()
```

To correct the error, as the following example does, you can call the GetLowerBound method instead of making assumptions about the starting index of an array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Array values = Array.CreateInstance(typeof(int), new int[] { 10
},
                                          new int[] { 1 });
      int value = 2;
      // Assign values.
      for (int ctr = values.GetLowerBound(0); ctr <=
values.GetUpperBound(0); ctr++) {
         values.SetValue(value, ctr);
         value *= 2;
      }

      // Display values.
      for (int ctr = values.GetLowerBound(0); ctr <=
values.GetUpperBound(0); ctr++)
         Console.Write("{0}    ", values.GetValue(ctr));
   }
}
// The example displays the following output:
//        2    4    8    16    32    64    128    256    512    1024
```

Note that when you call the GetLowerBound method to get the starting index of an array, you should also call the Array.GetUpperBound(Int32) method to get its ending index.

- Confusing an index and the value at that index in a numeric array or collection. This issue usually occurs when using the `foreach` statement (in C#), the `for...in` statement (in F#), or the `For Each` statement (in Visual Basic). The following example illustrates the problem.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Generate array of random values.
```

```
        int[] values = PopulateArray(5, 10);
        // Display each element in the array.
        foreach (var value in values)
           Console.Write("{0}   ", values[value]);
    }

    private static int[] PopulateArray(int items, int maxValue)
    {
        int[] values = new int[items];
        Random rnd = new Random();
        for (int ctr = 0; ctr < items; ctr++)
           values[ctr] = rnd.Next(0, maxValue + 1);

        return values;
    }
}
// The example displays output like the following:
//    6   4   4
//    Unhandled Exception: System.IndexOutOfRangeException:
//    Index was outside the bounds of the array.
//       at Example.Main()
```

The iteration construct returns each value in an array or collection, not its index. To eliminate the exception, use this code.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        // Generate array of random values.
        int[] values = PopulateArray(5, 10);
        // Display each element in the array.
        foreach (var value in values)
           Console.Write("{0}   ", value);
    }

    private static int[] PopulateArray(int items, int maxValue)
    {
        int[] values = new int[items];
        Random rnd = new Random();
        for (int ctr = 0; ctr < items; ctr++)
           values[ctr] = rnd.Next(0, maxValue + 1);

        return values;
    }
}
// The example displays output like the following:
//        10   6   7   5   8
```

- Providing an invalid column name to the DataView.Sort property.
- Violating thread safety. Operations such as reading from the same StreamReader object, writing to the same StreamWriter object from multiple threads, or enumerating the objects in a Hashtable from different threads can throw an IndexOutOfRangeException if the object isn't accessed in a thread-safe way. This exception is typically intermittent because it relies on a race condition.

Using hard-coded index values to manipulate an array is likely to throw an exception if the index value is incorrect or invalid, or if the size of the array being manipulation is unexpected. To prevent an operation from throwing an IndexOutOfRangeException exception, you can do the following:

- Iterate the elements of the array using the foreach statement (in C#), the for...in statement (in F#), or the For Each...Next construct (in Visual Basic) instead of iterating elements by index.
- Iterate the elements by index starting with the index returned by the Array.GetLowerBound method and ending with the index returned by the Array.GetUpperBound method.
- If you are assigning elements in one array to another, ensure that the target array has at least as many elements as the source array by comparing their Array.Length properties.

For a list of initial property values for an instance of IndexOutOfRangeException, see the IndexOutOfRangeException constructors.

The following intermediate language (IL) instructions throw IndexOutOfRangeException:

- ldelem.<type>
- ldelema
- stelem.<type>

IndexOutOfRangeException uses the HRESULT COR_E_INDEXOUTOFRANGE, which has the value 0x80131508.

Constructors

Expand table

IndexOutOfRangeException()	Initializes a new instance of the IndexOutOfRangeException class.
IndexOutOfRangeException(String)	Initializes a new instance of the IndexOutOfRangeException class with a specified error message.
IndexOutOfRangeException(String, Exception)	Initializes a new instance of the IndexOutOfRangeException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object.

	(Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IndexOutOfRangeException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the IndexOutOfRangeException class.

Overloads

Expand table

IndexOutOfRangeException()	Initializes a new instance of the IndexOutOfRangeException class.
IndexOutOfRangeException(String)	Initializes a new instance of the IndexOutOfRangeException class with a specified error message.
IndexOutOfRangeException(String, Exception)	Initializes a new instance of the IndexOutOfRangeException class with a specified error message and a reference to the inner exception that is the cause of this exception.

IndexOutOfRangeException()

Initializes a new instance of the IndexOutOfRangeException class.

C#

```
public IndexOutOfRangeException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "An array index is out of range."

This message takes into account the current system culture.

The following table shows the initial property values for an instance of IndexOutOfRangeException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IndexOutOfRangeException(String)

Initializes a new instance of the IndexOutOfRangeException class with a specified error message.

C#

```
public IndexOutOfRangeException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of IndexOutOfRangeException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IndexOutOfRangeException(String, Exception)

Initializes a new instance of the IndexOutOfRangeException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public IndexOutOfRangeException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The `InnerException` property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the `InnerException` property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of IndexOutOfRangeException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

InsufficientExecutionStackException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is insufficient execution stack available to allow most methods to execute.

C#

```
public sealed class InsufficientExecutionStackException : SystemException
```

Inheritance Object → Exception → SystemException → InsufficientExecutionStackException

Constructors

Expand table

InsufficientExecutionStackException()	Initializes a new instance of the InsufficientExecutionStackException class.
InsufficientExecutionStackException(String)	Initializes a new instance of the InsufficientExecutionStackException class with a specified error message.
InsufficientExecutionStackException(String, Exception)	Initializes a new instance of the InsufficientExecutionStackException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InsufficientExecutionStackException(String)

Initializes a new instance of the InsufficientExecutionStackException class with a specified error message.

C#

```
public InsufficientExecutionStackException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InsufficientExecutionStackException(String, Exception)

Initializes a new instance of the InsufficientExecutionStackException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public InsufficientExecutionStackException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Applies to

InsufficientMemoryException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a check for sufficient available memory fails. This class cannot be inherited.

C#

```
public sealed class InsufficientMemoryException : OutOfMemoryException
```

Inheritance Object → Exception → SystemException → OutOfMemoryException → InsufficientMemoryException

Remarks

Unlike OutOfMemoryException, InsufficientMemoryException is thrown before starting an operation, and thus does not imply state corruption. An application can catch this exception, throttle back its memory usage, and avoid actual out of memory conditions and their potential for corrupting program state.

This exception is thrown by the MemoryFailPoint constructor when you specify a projected memory allocation larger than the amount of currently available memory. Your program can catch the exception and either delay the task that needs the memory or execute it in smaller steps that require less memory.

See the MemoryFailPoint class for a code example.

> **Note**
>
> This exception is not included in the **.NET for Windows Store apps** or the **Portable Class Library**, but it is thrown by some members that are. To catch the exception in that case, write a `catch` statement for **OutOfMemoryException** instead.

Constructors

Expand table

InsufficientMemoryException()	Initializes a new instance of the InsufficientMemoryException class with a system-supplied message that describes the error.
InsufficientMemoryException(String)	Initializes a new instance of the InsufficientMemoryException class with a specified message that describes the error.
InsufficientMemoryException(String, Exception)	Initializes a new instance of the InsufficientMemoryException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
InnerException	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

InsufficientMemoryException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the InsufficientMemoryException class.

Overloads

Expand table

InsufficientMemoryException()	Initializes a new instance of the InsufficientMemoryException class with a system-supplied message that describes the error.
InsufficientMemoryException(String)	Initializes a new instance of the InsufficientMemoryException class with a specified message that describes the error.
InsufficientMemoryException(String, Exception)	Initializes a new instance of the InsufficientMemoryException class with a specified error message and a reference to the inner exception that is the cause of this exception.

InsufficientMemoryException()

Initializes a new instance of the InsufficientMemoryException class with a system-supplied message that describes the error.

C#

```
public InsufficientMemoryException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Insufficient available memory to meet the expected demands of an operation at this time. Please try again later." This message takes into account the current system culture.

The following table shows the initial property values for an instance of InsufficientMemoryException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

See also

- Handling and Throwing Exceptions

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

InsufficientMemoryException(String)

Initializes a new instance of the InsufficientMemoryException class with a specified message that describes the error.

C#

```
public InsufficientMemoryException (string? message);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of InsufficientMemoryException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string specified in `message`.

See also

- Handling and Throwing Exceptions

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

InsufficientMemoryException(String, Exception)

Initializes a new instance of the InsufficientMemoryException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public InsufficientMemoryException (string? message, Exception?
```

```
innerException);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of InsufficientMemoryException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string specified in `message`.

Int128 Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 128-bit signed integer.

C#

```
public readonly struct Int128 : IComparable<Int128>, IEquatable<Int128>,
IParsable<Int128>, ISpanParsable<Int128>, IUtf8SpanParsable<Int128>,
System.Numerics.IAdditionOperators<Int128,Int128,Int128>,
System.Numerics.IAdditiveIdentity<Int128,Int128>,
System.Numerics.IBinaryInteger<Int128>,
System.Numerics.IBinaryNumber<Int128>,
System.Numerics.IBitwiseOperators<Int128,Int128,Int128>,
System.Numerics.IComparisonOperators<Int128,Int128,bool>,
System.Numerics.IDecrementOperators<Int128>,
System.Numerics.IDivisionOperators<Int128,Int128,Int128>,

Constructors

Expand table

Int128(UInt64, UInt64)	Initializes a new instance of the Int128 struct.

Properties

Expand table

MaxValue	Gets the maximum value of the current type.
MinValue	Gets the minimum value of the current type.
NegativeOne	Gets the value `-1` for the type.
One	Gets the value `1` for the type.
Zero	Gets the value `0` for the type.

Methods

Expand table

Abs(Int128)	Computes the absolute of a value.
Clamp(Int128, Int128, Int128)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Int128)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CopySign(Int128, Int128)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(Int128, Int128)	Computes the quotient and remainder of two values.

Equals(Int128)	Indicates whether the current object is equal to another object of the same type.
Equals(Object)	Determines whether the specified object is equal to the current object.
GetHashCode()	Serves as the default hash function.
IsEvenInteger(Int128)	Determines if a value represents an even integral number.
IsNegative(Int128)	Determines if a value is negative.
IsOddInteger(Int128)	Determines if a value represents an odd integral number.
IsPositive(Int128)	Determines if a value is positive.
IsPow2(Int128)	Determines if a value is a power of two.
LeadingZeroCount(Int128)	Computes the number of leading zeros in a value.
Log2(Int128)	Computes the log2 of a value.
Max(Int128, Int128)	Compares two values to compute which is greater.
MaxMagnitude(Int128, Int128)	Compares two values to compute which is greater.
Min(Int128, Int128)	Compares two values to compute which is lesser.
MinMagnitude(Int128, Int128)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Parses a span of characters into a value.
Parse(String)	Parses a string into a value.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(String, NumberStyles)	Parses a string into a value.
Parse(String, NumberStyles, IFormatProvider)	Parses a string into a value.
PopCount(Int128)	Computes the number of bits that are set in a value.

RotateLeft(Int128, Int32)	Rotates a value left by a given amount.
RotateRight(Int128, Int32)	Rotates a value right by a given amount.
Sign(Int128)	Computes the sign of a value.
ToString()	Returns a string that represents the current object.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
TrailingZeroCount(Int128)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int128)	Tries to convert a UTF-8 character span containing the string representation of a number to its 128-bit signed integer equivalent.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, Int128)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int128)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Int128)	Tries to parse a string into a value.

TryParse(String, Int128)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, Int128)	Tries to parse a string into a value.

Operators

Expand table

Addition(Int128, Int128)	Adds two values together to compute their sum.
BitwiseAnd(Int128, Int128)	Computes the bitwise-and of two values.
BitwiseOr(Int128, Int128)	Computes the bitwise-or of two values.
CheckedAddition(Int128, Int128)	Adds two values together to compute their sum.
CheckedDecrement(Int128)	Decrements a value.
CheckedDivision(Int128, Int128)	Divides two values together to compute their quotient.
CheckedExplicit(Double)	
CheckedExplicit(Int128)	
CheckedExplicit(Single)	
CheckedIncrement(Int128)	Increments a value.
CheckedMultiply(Int128, Int128)	Multiplies two values together to compute their product.
CheckedSubtraction(Int128, Int128)	Subtracts two values to compute their difference.
CheckedUnaryNegation(Int128)	Computes the unary negation of a value.
Decrement(Int128)	Decrements a value.
Division(Int128, Int128)	Divides two values together to compute their quotient.
Equality(Int128, Int128)	Compares two values to determine equality.
ExclusiveOr(Int128, Int128)	Computes the exclusive-or of two values.
Explicit(Decimal to Int128)	Explicitly converts a Decimal value to a 128-bit signed integer.
Explicit(Double to Int128)	Explicitly converts a Double value to a 128-bit signed integer.
Explicit(Int128 to Byte)	Explicitly converts a 128-bit signed integer to a Byte value.

Explicit(Int128 to Char)	Explicitly converts a 128-bit signed integer to a Char value.
Explicit(Int128 to Decimal)	Explicitly converts a 128-bit signed integer to a Decimal value.
Explicit(Int128 to Double)	Explicitly converts a 128-bit signed integer to a Double value.
Explicit(Int128 to Half)	Explicitly converts a 128-bit signed integer to a Half value.
Explicit(Int128 to Int16)	Explicitly converts a 128-bit signed integer to a Int16 value.
Explicit(Int128 to Int32)	Explicitly converts a 128-bit signed integer to a Int32 value.
Explicit(Int128 to Int64)	Explicitly converts a 128-bit signed integer to a Int64 value.
Explicit(Int128 to IntPtr)	Explicitly converts a 128-bit signed integer to a IntPtr value.
Explicit(Int128 to SByte)	Explicitly converts a 128-bit signed integer to a SByte value.
Explicit(Int128 to Single)	Explicitly converts a 128-bit signed integer to a Single value.
Explicit(Int128 to UInt128)	Explicitly converts a 128-bit signed integer to a UInt128 value.
Explicit(Int128 to UInt16)	Explicitly converts a 128-bit signed integer to a UInt16 value.
Explicit(Int128 to UInt32)	Explicitly converts a 128-bit signed integer to a UInt32 value.
Explicit(Int128 to UInt64)	Explicitly converts a 128-bit signed integer to a UInt64 value.
Explicit(Int128 to UIntPtr)	Explicitly converts a 128-bit signed integer to a UIntPtr value.
Explicit(Single to Int128)	Explicitly converts a Single value to a 128-bit signed integer.
GreaterThan(Int128, Int128)	Compares two values to determine which is greater.
GreaterThanOrEqual(Int128, Int128)	Compares two values to determine which is greater or equal.
Implicit(Byte to Int128)	Implicitly converts a Byte value to a 128-bit signed integer.
Implicit(Char to Int128)	Implicitly converts a Char value to a 128-bit signed integer.
Implicit(Int16 to Int128)	Implicitly converts a Int16 value to a 128-bit signed integer.
Implicit(Int32 to Int128)	Implicitly converts a Int32 value to a 128-bit signed integer.
Implicit(Int64 to Int128)	Implicitly converts a Int64 value to a 128-bit signed integer.
Implicit(IntPtr to Int128)	Implicitly converts a IntPtr value to a 128-bit signed integer.
Implicit(SByte to Int128)	Implicitly converts a SByte value to a 128-bit signed integer.

Implicit(UInt16 to Int128)	Implicitly converts a UInt16 value to a 128-bit signed integer.
Implicit(UInt32 to Int128)	Implicitly converts a UInt32 value to a 128-bit signed integer.
Implicit(UInt64 to Int128)	Implicitly converts a UInt64 value to a 128-bit signed integer.
Implicit(UIntPtr to Int128)	Implicitly converts a UIntPtr value to a 128-bit signed integer.
Increment(Int128)	Increments a value.
Inequality(Int128, Int128)	Compares two values to determine inequality.
LeftShift(Int128, Int32)	Shifts a value left by a given amount.
LessThan(Int128, Int128)	Compares two values to determine which is less.
LessThanOrEqual(Int128, Int128)	Compares two values to determine which is less or equal.
Modulus(Int128, Int128)	Divides two values together to compute their modulus or remainder.
Multiply(Int128, Int128)	Multiplies two values together to compute their product.
OnesComplement(Int128)	Computes the ones-complement representation of a given value.
RightShift(Int128, Int32)	Shifts a value right by a given amount.
Subtraction(Int128, Int128)	Subtracts two values to compute their difference.
UnaryNegation(Int128)	Computes the unary negation of a value.
UnaryPlus(Int128)	Computes the unary plus of a value.
UnsignedRightShift(Int128, Int32)	Shifts a value right by a given amount.

Explicit Interface Implementations

Expand table

IAdditiveIdentity<Int128,Int128>.Additive Identity	Gets the additive identity of the current type.
IBinaryInteger<Int128>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<Int128>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<Int128>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, Int128)	

IBinaryInteger<Int128>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, Int128)	
IBinaryInteger<Int128>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<Int128>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<Int128>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IMultiplicativeIdentity<Int128,Int128>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
INumber<Int128>.MaxNumber(Int128, Int128)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<Int128>.MinNumber(Int128, Int128)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<Int128>.IsCanonical(Int128)	Determines if a value is in its canonical representation.
INumberBase<Int128>.IsComplexNumber(Int128)	Determines if a value represents a complex number.
INumberBase<Int128>.IsFinite(Int128)	Determines if a value is finite.
INumberBase<Int128>.IsImaginaryNumber(Int128)	Determines if a value represents a pure imaginary number.
INumberBase<Int128>.IsInfinity(Int128)	Determines if a value is infinite.
INumberBase<Int128>.IsInteger(Int128)	Determines if a value represents an integral number.
INumberBase<Int128>.IsNaN(Int128)	Determines if a value is NaN.
INumberBase<Int128>.IsNegativeInfinity(Int128)	Determines if a value is negative infinity.
INumberBase<Int128>.IsNormal(Int128)	Determines if a value is normal.
INumberBase<Int128>.IsPositiveInfinity(Int128)	Determines if a value is positive infinity.
INumberBase<Int128>.IsRealNumber(Int128)	Determines if a value represents a real number.
INumberBase<Int128>.IsSubnormal(Int128)	Determines if a value is subnormal.
INumberBase<Int128>.IsZero(Int128)	Determines if a value is zero.

INumberBase<Int128>.MaxMagnitudeNumber(Int128, Int128)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Int128>.MinMagnitudeNumber(Int128, Int128)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<Int128>.Radix	Gets the radix, or base, for the type.
INumberBase<Int128>.TryConvertFromChecked<TOther>(TOther, Int128)	
INumberBase<Int128>.TryConvertFromSaturating<TOther>(TOther, Int128)	
INumberBase<Int128>.TryConvertFromTruncating<TOther>(TOther, Int128)	
INumberBase<Int128>.TryConvertToChecked<TOther>(Int128, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Int128>.TryConvertToSaturating<TOther>(Int128, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Int128>.TryConvertToTruncating<TOther>(Int128, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

Int128(UInt64, UInt64) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the Int128 struct.

```
C#

[System.CLSCompliant(false)]
public Int128 (ulong upper, ulong lower);
```

Parameters

upper UInt64

The upper 64-bits of the 128-bit value.

lower UInt64

The lower 64-bits of the 128-bit value.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	7, 8, 9

Int128.Abs(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static Int128 Abs (Int128 value);
```

Parameters

`value` Int128

The value for which to get its absolute.

Returns

Int128

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.Clamp(Int128, Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static Int128 Clamp (Int128 value, Int128 min, Int128 max);
```

Parameters

`value` Int128

The value to clamp.

`min` Int128

The inclusive minimum to which `value` should clamp.

`max` Int128

The inclusive maximum to which `value` should clamp.

Returns

Int128

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(Int128)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

CompareTo(Int128)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (Int128 value);
```

Parameters

`value` Int128

An object to compare with this instance.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CompareTo(Object)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare with this instance.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Int128.CopySign(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
public static Int128 CopySign (Int128 value, Int128 sign);
```

Parameters

`value` Int128

The value whose magnitude is used in the result.

`sign` Int128

The value whose sign is used in the result.

Returns

Int128

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static Int128 CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int128

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static Int128 CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

Int128

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static Int128 CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

Int128

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.DivRem(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (Int128 Quotient, Int128 Remainder) DivRem (Int128 left,
Int128 right);
```

Parameters

`left` Int128

The value which `right` divides.

`right` Int128

The value which divides `left`.

Returns

ValueTuple<Int128,Int128>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Int128)	Indicates whether the current object is equal to another object of the same type.
Equals(Object)	Determines whether the specified object is equal to the current object.

Equals(Int128)

Indicates whether the current object is equal to another object of the same type.

```
C#

public bool Equals (Int128 other);
```

Parameters

other Int128

An object to compare with this object.

Returns

Boolean

`true` if the current object is equal to the `other` parameter; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Equals(Object)

Determines whether the specified object is equal to the current object.

```
C#
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare with the current object.

Returns

Boolean

`true` if the specified object is equal to the current object; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as the default hash function.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A hash code for the current object.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.IsEvenInteger(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (Int128 value);
```

Parameters

value Int128

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.IsNegative(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.IsOddInteger(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (Int128 value);
```

Parameters

value Int128

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.IsPositive(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.IsPow2(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.LeadingZeroCount(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

```
C#
public static Int128 LeadingZeroCount (Int128 value);
```

Parameters

`value` Int128

The value whose leading zeroes are to be counted.

Returns

Int128

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.Log2(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static Int128 Log2 (Int128 value);
```

Parameters

`value` Int128

The value whose log2 is to be computed.

Returns

Int128

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Int128.Max(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static Int128 Max (Int128 x, Int128 y);
```

Parameters

x Int128

The value to compare with `y`.

y Int128

The value to compare with `x`.

Returns

Int128

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.MaxMagnitude(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static Int128 MaxMagnitude (Int128 x, Int128 y);
```

Parameters

x Int128

The value to compare with `y`.

y Int128

The value to compare with `x`.

Returns

Int128

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.Min(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static Int128 Min (Int128 x, Int128 y);
```

Parameters

x Int128

The value to compare with `y`.

y Int128

The value to compare with `x`.

Returns

Int128

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Parses a string into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String)	Parses a string into a value.
Parse(String, NumberStyles)	Parses a string into a value.

Parse(String, NumberStyles, IFormatProvider)

Parses a string into a value.

C#

```
public static Int128 Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int128

The result of parsing `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static Int128 Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int128

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static Int128 Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int128

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Parses a string into a value.

C#

```
public static Int128 Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int128

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static Int128 Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int128

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static Int128 Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int128

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String)

Parses a string into a value.

C#

```
public static Int128 Parse (string s);
```

Parameters

s String

A string containing a number to parse.

Returns

Int128

The result of parsing `s`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, NumberStyles)

Parses a string into a value.

C#

```
public static Int128 Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string containing a number to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

Returns

Int128

The result of parsing `s`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Int128.PopCount(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static Int128 PopCount (Int128 value);
```

Parameters

`value` Int128

The value whose set bits are to be counted.

Returns

Int128

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.RotateLeft(Int128, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static Int128 RotateLeft (Int128 value, int rotateAmount);
```

Parameters

`value` Int128

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

Int128

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.RotateRight(Int128, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

```
C#
public static Int128 RotateRight (Int128 value, int rotateAmount);
```

Parameters

`value` Int128

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

Int128

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.Sign(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (Int128 value);
```

Parameters

`value` Int128

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Int128.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
ToString()	Returns a string that represents the current object.

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

The format to use, or a `null` reference to use the default format defined for the type of the IFormattable implementation.

Returns

String

The string representation of the value of this instance as specified by `format`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ToString(String, IFormatProvider)

Formats the value of the current instance using the specified format.

```
C#
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

The format to use, or a `null` reference to use the default format defined for the type of the IFormattable implementation.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ToString()

Returns a string that represents the current object.

```
C#
```

```
public override string ToString ();
```

Returns

String

A string that represents the current object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Int128.TrailingZeroCount(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

```
C#
public static Int128 TrailingZeroCount (Int128 value);
```

Parameters

`value` Int128

The value whose trailing zeroes are to be counted.

Returns

Int128

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Int128.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(String, Int128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, Int128)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Byte>, Int128)	Tries to convert a UTF-8 character span containing the string representation of a number to its 128-bit signed integer equivalent.
TryParse(String, NumberStyles, IFormatProvider, Int128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int128)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Int128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int128)	Tries to parse a string into a value.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int128)

Tries to parse a span of UTF-8 characters into a value.

```
C#
```

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out Int128 result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int128

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, Int128)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, out Int128 result);
```

Parameters

`s` String

The string to parse.

`result` Int128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, Int128)

Tries to parse a span of characters into a value.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out Int128 result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`result` Int128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, Int128)

Tries to convert a UTF-8 character span containing the string representation of a number to its 128-bit signed integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out Int128
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` Int128

When this method returns, contains the 128-bit signed integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, NumberStyles, IFormatProvider, Int128)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out Int128 result);
```

Parameters

`s` String

The string to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int128)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
Int128 result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int128

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int128)

Tries to parse a span of characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
Int128 result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Int128)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
Int128 result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, Int128)

Tries to parse a string into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out Int128 result);
```

Parameters

`s` ReadOnlySpan<Char>

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Int128.Addition(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#
public static Int128 operator + (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to which `right` is added.

`right` Int128

The value which is added to `left`.

Returns

Int128

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.BitwiseAnd(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#
public static Int128 operator & (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to `and` with `right`.

`right` Int128

The value to `and` with `left`.

Returns

Int128

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.BitwiseOr(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#
public static Int128 operator | (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to `or` with `right`.

`right` Int128

The value to `or` with `left`.

Returns

Int128

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.CheckedAddition(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#
public static Int128 op_CheckedAddition (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to which `right` is added.

`right` Int128

The value which is added to `left`.

Returns

Int128

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.CheckedDecrement(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
public static Int128 op_CheckedDecrement (Int128 value);
```

Parameters

`value` Int128

The value to decrement.

Returns

Int128

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.CheckedDivision(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their quotient.

```
C#
public static Int128 op_CheckedDivision (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value which `right` divides.

`right` Int128

The value which divides `left`.

Returns

Int128

The quotient of `left` divided-by `right`.

Implements

CheckedDivision(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.CheckedExplicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CheckedExplicit(Single)
CheckedExplicit(Int128)
CheckedExplicit(Double)

CheckedExplicit(Single)

C#

```
public static Int128 op_CheckedExplicit (float value);
```

Parameters

`value` Single

Returns

Int128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Int128)

C#

```
public static byte op_CheckedExplicit (Int128 value);
```

Parameters

`value` Int128

Returns

Byte

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Double)

C#

```
public static Int128 op_CheckedExplicit (double value);
```

Parameters

`value` Double

Returns

Int128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.CheckedIncrement(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
public static Int128 op_CheckedIncrement (Int128 value);
```

Parameters

`value` Int128

The value to increment.

Returns

Int128

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.CheckedMultiply(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#
public static Int128 op_CheckedMultiply (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value which `right` multiplies.

`right` Int128

The value which multiplies `left`.

Returns

Int128

The product of `left` multiplied-by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.CheckedSubtraction(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#
public static Int128 op_CheckedSubtraction (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value from which `right` is subtracted.

`right` Int128

The value which is subtracted from `left`.

Returns

Int128

The difference of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.CheckedUnaryNegation(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
public static Int128 op_CheckedUnaryNegation (Int128 value);
```

Parameters

`value` Int128

The value for which to compute the unary negation.

Returns

Int128

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.Decrement(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
public static Int128 operator -- (Int128 value);
```

Parameters

`value` Int128

The value to decrement.

Returns

Int128

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.Division(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their quotient.

```
C#
public static Int128 operator / (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value which `right` divides.

`right` Int128

The value which divides `left`.

Returns

Int128

The quotient of `left` divided-by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.Equality(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#
public static bool operator == (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to compare with `right`.

`right` Int128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.ExclusiveOr(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#
public static Int128 operator ^ (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to xor with `right`.

`right` Int128

The value to xor with `left`.

Returns

Int128

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Assembly: System.Runtime.dll

Overloads

Expand table

Explicit(Single to Int128)	Explicitly converts a Single value to a 128-bit signed integer.
Explicit(Int128 to UIntPtr)	Explicitly converts a 128-bit signed integer to a UIntPtr value.
Explicit(Int128 to UInt64)	Explicitly converts a 128-bit signed integer to a UInt64 value.
Explicit(Int128 to UInt32)	Explicitly converts a 128-bit signed integer to a UInt32 value.
Explicit(Int128 to UInt16)	Explicitly converts a 128-bit signed integer to a UInt16 value.
Explicit(Int128 to UInt128)	Explicitly converts a 128-bit signed integer to a UInt128 value.
Explicit(Int128 to Single)	Explicitly converts a 128-bit signed integer to a Single value.
Explicit(Int128 to SByte)	Explicitly converts a 128-bit signed integer to a SByte value.
Explicit(Int128 to IntPtr)	Explicitly converts a 128-bit signed integer to a IntPtr value.
Explicit(Int128 to Int32)	Explicitly converts a 128-bit signed integer to a Int32 value.
Explicit(Int128 to Int16)	Explicitly converts a 128-bit signed integer to a Int16 value.
Explicit(Int128 to Half)	Explicitly converts a 128-bit signed integer to a Half value.
Explicit(Int128 to Double)	Explicitly converts a 128-bit signed integer to a Double value.
Explicit(Int128 to Decimal)	Explicitly converts a 128-bit signed integer to a Decimal value.
Explicit(Int128 to Char)	Explicitly converts a 128-bit signed integer to a Char value.
Explicit(Int128 to Byte)	Explicitly converts a 128-bit signed integer to a Byte value.
Explicit(Double to Int128)	Explicitly converts a Double value to a 128-bit signed integer.
Explicit(Decimal to Int128)	Explicitly converts a Decimal value to a 128-bit signed integer.

Explicit(Int128 to Int64)	Explicitly converts a 128-bit signed integer to a Int64 value.

Explicit(Single to Int128)

Explicitly converts a Single value to a 128-bit signed integer.

C#

```
public static explicit operator Int128 (float value);
```

Parameters

`value` Single

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to UIntPtr)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit signed integer to a UIntPtr value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator UIntPtr (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

UIntPtr

`value` converted to a UIntPtr.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to UInt64)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit signed integer to a UInt64 value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator ulong (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

UInt64

`value` converted to a UInt64.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to UInt32)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit signed integer to a UInt32 value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator uint (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

UInt32

`value` converted to a UInt32.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to UInt16)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit signed integer to a UInt16 value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator ushort (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

UInt16

`value` converted to a UInt16.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to UInt128)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit signed integer to a UInt128 value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator UInt128 (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

UInt128

`value` converted to a UInt128.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Single)

Explicitly converts a 128-bit signed integer to a Single value.

```
C#

public static explicit operator float (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Single

`value` converted to a Single.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to SByte)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit signed integer to a SByte value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator sbyte (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

SByte

`value` converted to a SByte.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to IntPtr)

Explicitly converts a 128-bit signed integer to a IntPtr value.

```
C#

public static explicit operator IntPtr (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

IntPtr

`value` converted to a IntPtr.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Int32)

Explicitly converts a 128-bit signed integer to a Int32 value.

```
C#
public static explicit operator int (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Int32

`value` converted to a Int32.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Int16)

Explicitly converts a 128-bit signed integer to a Int16 value.

```
C#
public static explicit operator short (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Int16

`value` converted to a Int16.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Half)

Explicitly converts a 128-bit signed integer to a Half value.

```
C#
public static explicit operator Half (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Half

`value` converted to a Half.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Double)

Explicitly converts a 128-bit signed integer to a Double value.

```
C#
public static explicit operator double (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Double

`value` converted to a Double.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Decimal)

Explicitly converts a 128-bit signed integer to a Decimal value.

```
C#
public static explicit operator decimal (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Decimal

`value` converted to a Decimal.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Char)

Explicitly converts a 128-bit signed integer to a Char value.

```
C#
public static explicit operator char (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Char

`value` converted to a Char.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Byte)

Explicitly converts a 128-bit signed integer to a Byte value.

```
C#
public static explicit operator byte (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Byte

`value` converted to a Byte.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Double to Int128)

Explicitly converts a Double value to a 128-bit signed integer.

```
C#
public static explicit operator Int128 (double value);
```

Parameters

`value` Double

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Decimal to Int128)

Explicitly converts a Decimal value to a 128-bit signed integer.

```
C#
public static explicit operator Int128 (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int128 to Int64)

Explicitly converts a 128-bit signed integer to a Int64 value.

```
C#
public static explicit operator long (Int128 value);
```

Parameters

`value` Int128

The value to convert.

Returns

Int64

`value` converted to a Int64.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Int128.GreaterThan(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#
public static bool operator > (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to compare with `right`.

`right` Int128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.GreaterThanOrEqual(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#
public static bool operator >= (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to compare with `right`.

`right` Int128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(SByte to Int128)	Implicitly converts a SByte value to a 128-bit signed integer.
Implicit(UIntPtr to Int128)	Implicitly converts a UIntPtr value to a 128-bit signed integer.
Implicit(UInt32 to Int128)	Implicitly converts a UInt32 value to a 128-bit signed integer.
Implicit(UInt16 to Int128)	Implicitly converts a UInt16 value to a 128-bit signed integer.
Implicit(IntPtr to Int128)	Implicitly converts a IntPtr value to a 128-bit signed integer.
Implicit(UInt64 to Int128)	Implicitly converts a UInt64 value to a 128-bit signed integer.
Implicit(Int32 to Int128)	Implicitly converts a Int32 value to a 128-bit signed integer.
Implicit(Int16 to Int128)	Implicitly converts a Int16 value to a 128-bit signed integer.
Implicit(Char to Int128)	Implicitly converts a Char value to a 128-bit signed integer.
Implicit(Int64 to Int128)	Implicitly converts a Int64 value to a 128-bit signed integer.
Implicit(Byte to Int128)	Implicitly converts a Byte value to a 128-bit signed integer.

Implicit(SByte to Int128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a SByte value to a 128-bit signed integer.

```
C#

[System.CLSCompliant(false)]
public static implicit operator Int128 (sbyte value);
```

Parameters

`value` SByte

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UIntPtr to Int128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a UIntPtr value to a 128-bit signed integer.

```
C#

[System.CLSCompliant(false)]
public static implicit operator Int128 (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UInt32 to Int128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a UInt32 value to a 128-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator Int128 (uint value);
```

Parameters

`value` UInt32

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UInt16 to Int128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a UInt16 value to a 128-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator Int128 (ushort value);
```

Parameters

`value` UInt16

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(IntPtr to Int128)

Implicitly converts a IntPtr value to a 128-bit signed integer.

```
C#
public static implicit operator Int128 (IntPtr value);
```

Parameters

`value` IntPtr

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UInt64 to Int128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a UInt64 value to a 128-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator Int128 (ulong value);
```

Parameters

`value` UInt64

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Int32 to Int128)

Implicitly converts a Int32 value to a 128-bit signed integer.

C#

```
public static implicit operator Int128 (int value);
```

Parameters

`value` Int32

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Int16 to Int128)

Implicitly converts a Int16 value to a 128-bit signed integer.

```
C#
public static implicit operator Int128 (short value);
```

Parameters

`value` Int16

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Char to Int128)

Implicitly converts a Char value to a 128-bit signed integer.

```
C#
public static implicit operator Int128 (char value);
```

Parameters

`value` Char

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Int64 to Int128)

Implicitly converts a Int64 value to a 128-bit signed integer.

```
C#
public static implicit operator Int128 (long value);
```

Parameters

`value` Int64

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Byte to Int128)

Implicitly converts a Byte value to a 128-bit signed integer.

C#

```
public static implicit operator Int128 (byte value);
```

Parameters

`value` Byte

The value to convert.

Returns

Int128

`value` converted to a 128-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Int128.Increment(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
public static Int128 operator ++ (Int128 value);
```

Parameters

`value` Int128

The value to increment.

Returns

Int128

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.Inequality(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#
public static bool operator != (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to compare with `right`.

`right` Int128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.LeftShift(Int128, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

C#

```
public static Int128 operator << (Int128 value, int shiftAmount);
```

Parameters

`value` Int128

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

Int128

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.LessThan(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#
public static bool operator < (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to compare with `right`.

`right` Int128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.LessThanOrEqual(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#
public static bool operator <= (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value to compare with `right`.

`right` Int128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.Modulus(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#
public static Int128 operator % (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value which `right` divides.

`right` Int128

The value which divides `left`.

Returns

Int128

The modulus or remainder of `left` divided-by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.Multiply(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#
public static Int128 operator * (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value which `right` multiplies.

`right` Int128

The value which multiplies `left`.

Returns

Int128

The product of `left` multiplied-by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.OnesComplement(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
public static Int128 operator ~ (Int128 value);
```

Parameters

`value` Int128

The value for which to compute the ones-complement.

Returns

Int128

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

.NET feedback

- Provide product feedback

Int128.RightShift(Int128, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#
public static Int128 operator >> (Int128 value, int shiftAmount);
```

Parameters

`value` Int128

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int128

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Remarks

This operation is meant to perform a signed (otherwise known as an arithmetic) right shift on signed types.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.Subtraction(Int128, Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#
public static Int128 operator - (Int128 left, Int128 right);
```

Parameters

`left` Int128

The value from which `right` is subtracted.

`right` Int128

The value which is subtracted from `left`.

Returns

Int128

The difference of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.UnaryNegation(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
public static Int128 operator - (Int128 value);
```

Parameters

`value` Int128

The value for which to compute the unary negation.

Returns

Int128

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.UnaryPlus(Int128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
public static Int128 operator + (Int128 value);
```

Parameters

`value` Int128

The value for which to compute the unary plus.

Returns

Int128

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.UnsignedRightShift(Int128, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#
public static Int128 op_UnsignedRightShift (Int128 value, int shiftAmount);
```

Parameters

`value` Int128

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int128

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Remarks

This operation is meant to perform n unsigned (otherwise known as a logical) right shift on all types.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.IAdditiveIdentity<Int128,Int128>.AdditiveIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the additive identity of the current type.

C#

```
static Int128
System.Numerics.IAdditiveIdentity<System.Int128,System.Int128>.AdditiveIdentity { get; }
```

Property Value

Int128

Implements

AdditiveIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Int128.IBinaryInteger<Int128>.GetByteCount Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).

C#

```
int IBinaryInteger<Int128>.GetByteCount ();
```

Returns

Int32

The number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).

Implements

GetByteCount()

Applies to

Product	Versions
.NET	7, 8, 9

Int128.IBinaryInteger<Int128>.GetShortestBitLength Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the length, in bits, of the shortest two's complement representation of the current value.

```
C#
int IBinaryInteger<Int128>.GetShortestBitLength ();
```

Returns

Int32

The length, in bits, of the shortest two's complement representation of the current value.

Implements

GetShortestBitLength()

Applies to

Product	Versions
.NET	7, 8, 9

Int128.IBinaryInteger<Int128>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<Int128>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.IBinaryInteger<Int128>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<Int128>.TryWriteLittleEndian (Span<byte> destination,
out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteLittleEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.IBinaryNumber<Int128>.AllBits Set Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an instance of the binary type in which all bits are set.

C#

```
static Int128 System.Numerics.IBinaryNumber<System.Int128>.AllBitsSet { get;
}
```

Property Value

Int128

Implements

AllBitsSet

Applies to

Product	Versions
.NET	7, 8, 9

Int128.INumber<Int128>.MaxNumber(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static Int128 INumber<Int128>.MaxNumber (Int128 x, Int128 y);
```

Parameters

x Int128

The value to compare with `y`.

y Int128

The value to compare with `x`.

Returns

Int128

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumber<Int128>.MinNumber(Int128, Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static Int128 INumber<Int128>.MinNumber (Int128 x, Int128 y);
```

Parameters

x Int128

The value to compare with `y`.

y Int128

The value to compare with `x`.

Returns

Int128

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsCanonical(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<Int128>.IsCanonical (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsComplexNumber(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<Int128>.IsComplexNumber (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsFinite(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<Int128>.IsFinite (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsImaginaryNumber(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<Int128>.IsImaginaryNumber (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsInfinity(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<Int128>.IsInfinity (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsInteger(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<Int128>.IsInteger (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.INumberBase<Int128>.IsNaN(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<Int128>.IsNaN (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.INumberBase<Int128>.IsNegativeInfinity(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

```
C#
static bool INumberBase<Int128>.IsNegativeInfinity (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.IsNormal(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<Int128>.IsNormal (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int128.INumberBase<Int128>.IsRealNumber(Int128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<Int128>.IsRealNumber (Int128 value);
```

Parameters

`value` Int128

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int128.INumberBase<Int128>.TryConvertFromTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<Int128>.TryConvertFromTruncating<TOther> (TOther
value, out Int128 result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Int128

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

Int128.INumberBase<Int128>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<Int128>.TryConvertToChecked<TOther> (Int128 value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int128

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.INumberBase<Int128>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<Int128>.TryConvertToSaturating<TOther> (Int128
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int128

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int128.INumberBase<Int128>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<Int128>.TryConvertToTruncating<TOther> (Int128
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int128

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Remarks

The Int16 value type represents signed integers with values ranging from negative 32768 through positive 32767.

This type provides methods to convert the value of an instance of this type to its string representation, to convert the string representation of a number to an instance of this type, and to compare instances of this type.

You can also call the members of the Math class to perform a wide range of numeric operations, including getting the absolute value of a number, calculating the quotient and remainder from integral division, determining the maximum or minimum value of two integers, getting the sign of a number, and rounding a number.

For information about how format specification codes control the string representation of value types, see Formatting Types.

Fields

Expand table

MaxValue	Represents the largest possible value of an Int16. This field is constant.
MinValue	Represents the smallest possible value of Int16. This field is constant.

Methods

Expand table

Abs(Int16)	Computes the absolute of a value.
Clamp(Int16, Int16, Int16)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Int16)	Compares this instance to a specified 16-bit signed integer and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified 16-bit signed integer.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the object.
CopySign(Int16, Int16)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(Int16, Int16)	Computes the quotient and remainder of two values.
Equals(Int16)	Returns a value indicating whether this instance is equal to a specified Int16 value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type Int16.
IsEvenInteger(Int16)	Determines if a value represents an even integral number.
IsNegative(Int16)	Determines if a value is negative.
IsOddInteger(Int16)	Determines if a value represents an odd integral number.
IsPositive(Int16)	Determines if a value is positive.
IsPow2(Int16)	Determines if a value is a power of two.
LeadingZeroCount(Int16)	Computes the number of leading zeros in a value.
Log2(Int16)	Computes the log2 of a value.
Max(Int16, Int16)	Compares two values to compute which is greater.
MaxMagnitude(Int16, Int16)	Compares two values to compute which is greater.
Min(Int16, Int16)	Compares two values to compute which is lesser.
MinMagnitude(Int16, Int16)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer

	equivalent.
Parse(String)	Converts the string representation of a number to its 16-bit signed integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 16-bit signed integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 16-bit signed integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent.
PopCount(Int16)	Computes the number of bits that are set in a value.
RotateLeft(Int16, Int32)	Rotates a value left by a given amount.
RotateRight(Int16, Int32)	Rotates a value right by a given amount.
Sign(Int16)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific formatting information.
TrailingZeroCount(Int16)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current short number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int16)	Tries to convert a UTF-8 character span containing the string representation of a number to its 16-bit signed integer

	equivalent.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int16)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, Int16)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int16)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, Int16)	Tries to parse a string into a value.
TryParse(String, Int16)	Converts the string representation of a number to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Int16)	Converts the string representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<Int16,Int16,Int16>.Addition(Int16, Int16)	Adds two values together to compute their sum.
IAdditionOperators<Int16,Int16,Int16>.CheckedAddition(Int16, Int16)	Adds two values together to compute their sum.
IAdditiveIdentity<Int16,Int16>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<Int16>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).

IBinaryInteger<Int16>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<Int16>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, Int16)	
IBinaryInteger<Int16>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, Int16)	
IBinaryInteger<Int16>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<Int16>.TryWriteLittle Endian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<Int16>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<Int16,Int16,Int16>.BitwiseAnd(Int16, Int16)	Computes the bitwise-and of two values.
IBitwiseOperators<Int16,Int16,Int16>.BitwiseOr(Int16, Int16)	Computes the bitwise-or of two values.
IBitwiseOperators<Int16,Int16,Int16>.ExclusiveOr(Int16, Int16)	Computes the exclusive-or of two values.
IBitwiseOperators<Int16,Int16,Int16>.Ones Complement(Int16)	Computes the ones-complement representation of a given value.
IComparisonOperators<Int16,Int16,Boolean>.Greater Than(Int16, Int16)	Compares two values to determine which is greater.
IComparisonOperators<Int16,Int16,Boolean>.Greater ThanOrEqual(Int16, Int16)	Compares two values to determine which is greater or equal.
IComparisonOperators<Int16,Int16,Boolean>.Less Than(Int16, Int16)	Compares two values to determine which is less.
IComparisonOperators<Int16,Int16,Boolean>.LessThan OrEqual(Int16, Int16)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws

	an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<Int16>.Checked Decrement(Int16)	Decrements a value.
IDecrementOperators<Int16>.Decrement(Int16)	Decrements a value.
IDivisionOperators<Int16,Int16,Int16>.Division(Int16, Int16)	Divides one value by another to compute their quotient.
IEquality Operators<Int16,Int16,Boolean>.Equality(Int16, Int16)	Compares two values to determine equality.
IEquality Operators<Int16,Int16,Boolean>.Inequality(Int16, Int16)	Compares two values to determine inequality.
IIncrementOperators<Int16>.CheckedIncrement(Int16)	Increments a value.
IIncrementOperators<Int16>.Increment(Int16)	Increments a value.

IMinMaxValue<Int16>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Int16>.MinValue	Gets the minimum value of the current type.
IModulusOperators<Int16,Int16,Int16>.Modulus(Int16, Int16)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Int16,Int16>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
IMultiplyOperators<Int16,Int16,Int16>.CheckedMultiply(Int16, Int16)	Multiplies two values together to compute their product.
IMultiplyOperators<Int16,Int16,Int16>.Multiply(Int16, Int16)	Multiplies two values together to compute their product.
INumber<Int16>.MaxNumber(Int16, Int16)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<Int16>.MinNumber(Int16, Int16)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<Int16>.IsCanonical(Int16)	Determines if a value is in its canonical representation.
INumberBase<Int16>.IsComplexNumber(Int16)	Determines if a value represents a complex number.
INumberBase<Int16>.IsFinite(Int16)	Determines if a value is finite.
INumberBase<Int16>.IsImaginaryNumber(Int16)	Determines if a value represents a pure imaginary number.
INumberBase<Int16>.IsInfinity(Int16)	Determines if a value is infinite.
INumberBase<Int16>.IsInteger(Int16)	Determines if a value represents an integral number.
INumberBase<Int16>.IsNaN(Int16)	Determines if a value is NaN.
INumberBase<Int16>.IsNegativeInfinity(Int16)	Determines if a value is negative infinity.
INumberBase<Int16>.IsNormal(Int16)	Determines if a value is normal.
INumberBase<Int16>.IsPositiveInfinity(Int16)	Determines if a value is positive infinity.

INumberBase<Int16>.IsRealNumber(Int16)	Determines if a value represents a real number.
INumberBase<Int16>.IsSubnormal(Int16)	Determines if a value is subnormal.
INumberBase<Int16>.IsZero(Int16)	Determines if a value is zero.
INumberBase<Int16>.MaxMagnitudeNumber(Int16, Int16)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Int16>.MinMagnitudeNumber(Int16, Int16)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<Int16>.One	Gets the value `1` for the type.
INumberBase<Int16>.Radix	Gets the radix, or base, for the type.
INumberBase<Int16>.TryConvertFromChecked<TOther>(TOther, Int16)	
INumberBase<Int16>.TryConvertFromSaturating<TOther>(TOther, Int16)	
INumberBase<Int16>.TryConvertFromTruncating<TOther>(TOther, Int16)	
INumberBase<Int16>.TryConvertToChecked<TOther>(Int16, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Int16>.TryConvertToSaturating<TOther>(Int16, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Int16>.TryConvertToTruncating<TOther>(Int16, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Int16>.Zero	Gets the value `0` for the type.
IShiftOperators<Int16,Int32,Int16>.LeftShift(Int16, Int32)	Shifts a value left by a given amount.
IShiftOperators<Int16,Int32,Int16>.RightShift(Int16, Int32)	Shifts a value right by a given amount.
IShiftOperators<Int16,Int32,Int16>.UnsignedRightShift(Int16, Int32)	Shifts a value right by a given amount.

ISignedNumber<Int16>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<Int16,Int16,Int16>.Checked Subtraction(Int16, Int16)	Subtracts two values to compute their difference.
ISubtraction Operators<Int16,Int16,Int16>.Subtraction(Int16, Int16)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Int16,Int16>.CheckedUnary Negation(Int16)	Computes the checked unary negation of a value.
IUnaryNegationOperators<Int16,Int16>.Unary Negation(Int16)	Computes the unary negation of a value.
IUnaryPlusOperators<Int16,Int16>.UnaryPlus(Int16)	Computes the unary plus of a value.

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Int16.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of an Int16. This field is constant.

C#

```
public const short MaxValue = 32767;
```

Field Value

Value* = *32767

Int16

Examples

The following example uses the MaxValue property to prevent an OverflowException when converting to an Int16 value.

C#

```
long[] numbersToConvert = {162345, 32183, -54000};
short newNumber;
foreach (long number in numbersToConvert)
{
   if (number >= Int16.MinValue && number <= Int16.MaxValue)
   {
      newNumber = Convert.ToInt16(number);
      Console.WriteLine($"Successfully converted {newNumber} to an Int16.");
   }
   else
   {
      Console.WriteLine($"Unable to convert {number} to an Int16.");
   }
}
// The example displays the following output to the console:
//       Unable to convert 162345 to an Int16.
```

```
//       Successfully converted 32183 to an Int16.
//       Unable to convert -54000 to an Int16.
```

Remarks

The value of this constant is 32767; that is, hexadecimal 0x7FFF.

The MaxValue property is typically used to prevent an OverflowException when converting from a numeric type with a greater upper range (such as a UInt16 or a Int32) to an Int16. The example illustrates this usage.

Int16.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of Int16. This field is constant.

C#

```
public const short MinValue = -32768;
```

Field Value

***Value* = -32768**

Int16

Examples

The following example uses the MinValue property to prevent an OverflowException when converting to an Int16 value.

C#

```
long[] numbersToConvert = {162345, 32183, -54000};
short newNumber;
foreach (long number in numbersToConvert)
{
   if (number >= Int16.MinValue && number <= Int16.MaxValue)
   {
      newNumber = Convert.ToInt16(number);
      Console.WriteLine($"Successfully converted {newNumber} to an Int16.");
   }
   else
   {
      Console.WriteLine($"Unable to convert {number} to an Int16.");
   }
}
// The example displays the following output to the console:
//       Unable to convert 162345 to an Int16.
```

```
//       Successfully converted 32183 to an Int16.
//       Unable to convert -54000 to an Int16.
```

Remarks

The value of this constant is -32768; that is, hexadecimal 0x8000.

The MinValue property is typically used to prevent an OverflowException when converting from a numeric type with a greater lower range (such as an Int32 or an Int64) to an Int16. The example illustrates this usage.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int16.Abs(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static short Abs (short value);
```

Parameters

`value` Int16

The value for which to get its absolute.

Returns

Int16

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.Clamp(Int16, Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

C#

```
public static short Clamp (short value, short min, short max);
```

Parameters

`value` Int16

The value to clamp.

`min` Int16

The inclusive minimum to which `value` should clamp.

`max` Int16

The inclusive maximum to which `value` should clamp.

Returns

Int16

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or another Int16 instance and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object or the other Int16 instance.

Overloads

Expand table

CompareTo(Int16)	Compares this instance to a specified 16-bit signed integer and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified 16-bit signed integer.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the object.

CompareTo(Int16)

Compares this instance to a specified 16-bit signed integer and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified 16-bit signed integer.

C#

```
public int CompareTo (short value);
```

Parameters

`value` Int16

An integer to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
```

```
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;
    Int16    c1 = -2,    c2 = 2;
    Int32    d1 = 3,     d2 = 3;
    Int64    e1 = 4,     e2 = -4;
    Decimal  f1 = -5.5m, f2 = 5.5m;

x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
```

```
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Int16.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not an Int16.

Remarks

An Int16, regardless of its value, is considered greater than a null reference.

The `value` parameter must be `null` or an instance of Int16; otherwise, an exception is thrown.

Int16.CopySign(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
public static short CopySign (short value, short sign);
```

Parameters

value Int16

The value whose magnitude is used in the result.

sign Int16

The value whose sign is used in the result.

Returns

Int16

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

public static short CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int16

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static short CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int16

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.CreateTruncating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static short CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int16

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.DivRem(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (short Quotient, short Remainder) DivRem (short left, short
right);
```

Parameters

`left` Int16

The value which `right` divides.

`right` Int16

The value which divides `left`.

Returns

ValueTuple<Int16,Int16>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or Int16.

Overloads

Expand table

Equals(Int16)	Returns a value indicating whether this instance is equal to a specified Int16 value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(Int16)

Returns a value indicating whether this instance is equal to a specified Int16 value.

C#

```
public bool Equals (short obj);
```

Parameters

obj Int16

An Int16 value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Int16) method overloads. If an implicit conversion between the `obj` argument and an Int16 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(Int16) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not an Int16 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte and SByte values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Int16) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static short value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,15}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,17}", value.Equals(int1));
      TestObjectForEquality(int1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,15}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);

      ushort ushort1 = 112;
      Console.WriteLine("value = ushort1: {0,15}",
```

```
value.Equals(ushort1));
      TestObjectForEquality(ushort1);

      decimal dec1 = 112m;
      Console.WriteLine("value = dec1: {0,20}", value.Equals(dec1));
      TestObjectForEquality(dec1);

      double dbl1 = 112;
      Console.WriteLine("value = dbl1: {0,19}", value.Equals(dbl1));
      TestObjectForEquality(dbl1);
   }

   private static void TestObjectForEquality(Object obj)
   {
      Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                        value, value.GetType().Name,
                        obj, obj.GetType().Name,
                        value.Equals(obj));
   }
}
// The example displays the following output:
//       value = byte1:            True
//       112 (Int16) = 112 (Byte): False
//
//       value = int1:             False
//       112 (Int16) = 112 (Int32): False
//
//       value = sbyte1:            True
//       112 (Int16) = 112 (SByte): False
//
//       value = ushort1:            False
//       112 (Int16) = 112 (UInt16): False
//
//       value = dec1:                False
//       112 (Int16) = 112 (Decimal): False
//
//       value = dbl1:               False
//       112 (Int16) = 112 (Double): False
```

.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

```
C#

public override bool Equals (object? obj);
```

Parameters

`obj` Object

An object to compare to this instance.

Returns

Boolean

`true` if `obj` is an instance of Int16 and equals the value of this instance; otherwise, `false`.

Examples

The following code example illustrates the use of `Equals` in the context of `Int16`, comparing two short values and returning `true` if they represent the same number, or `false` if they do not.

```
C#

Int16 myVariable1 = 20;
Int16 myVariable2 = 20;

// Get and display the declaring type.
```

```
Console.WriteLine("\nType of 'myVariable1' is '{0}' and"+
     " value is :{1}",myVariable1.GetType(), myVariable1);
Console.WriteLine("Type of 'myVariable2' is '{0}' and"+
     " value is :{1}",myVariable2.GetType(), myVariable2);

// Compare 'myVariable1' instance with 'myVariable2' Object.
if( myVariable1.Equals( myVariable2 ) )
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are equal");
else
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are not equal");
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Int16) method overloads. If an implicit conversion between the `obj` argument and an Int16 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(Int16) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not an Int16 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte and SByte values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Int16) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static short value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,15}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,17}", value.Equals(int1));
      TestObjectForEquality(int1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,15}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);
```

```
        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,15}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,20}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,19}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:            True
//       112 (Int16) = 112 (Byte): False
//
//       value = int1:             False
//       112 (Int16) = 112 (Int32): False
//
//       value = sbyte1:            True
//       112 (Int16) = 112 (SByte): False
//
//       value = ushort1:            False
//       112 (Int16) = 112 (UInt16): False
//
//       value = dec1:                False
//       112 (Int16) = 112 (Decimal): False
//
//       value = dbl1:               False
//       112 (Int16) = 112 (Double): False
```

Int16.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int16.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Int16.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Int16.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Int16.IsEvenInteger(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Int16.IsNegative(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Int16.IsOddInteger(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Int16.IsPositive(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Int16.IsPow2(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.LeadingZeroCount(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static short LeadingZeroCount (short value);
```

Parameters

`value` Int16

The value whose leading zeroes are to be counted.

Returns

Int16

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Int16.Log2(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

```
C#
public static short Log2 (short value);
```

Parameters

`value` Int16

The value whose log2 is to be computed.

Returns

Int16

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Int16.Max(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static short Max (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.MaxMagnitude(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static short MaxMagnitude (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Int16.Min(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static short Min (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Int16.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 16-bit signed integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 16-bit signed integer equivalent.
Parse(String)	Converts the string representation of a number to its 16-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 16-bit signed integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent.

```
C#

public static short Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information about `s`.

Returns

Int16

A 16-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than Int16.MinValue or greater than Int16.MaxValue.

-or-

`s` includes non-zero fractional digits.

Examples

The following example uses a variety of `style` and `provider` parameters to parse the string representations of Int16 values.

C#

```
string value;
short number;
NumberStyles style;
CultureInfo provider;

// Parse string using "." as the thousands separator
// and " " as the decimal separator.
value = "19 694,00";
style = NumberStyles.AllowDecimalPoint | NumberStyles.AllowThousands;
provider = new CultureInfo("fr-FR");

number = Int16.Parse(value, style, provider);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '19 694,00' converted to 19694.

try
{
   number = Int16.Parse(value, style, CultureInfo.InvariantCulture);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '19 694,00'.

// Parse string using "$" as the currency symbol for en_GB and
// en-US cultures.
value = "$6,032.00";
style = NumberStyles.Number | NumberStyles.AllowCurrencySymbol;
provider = new CultureInfo("en-GB");
```

```
try
{
   number = Int16.Parse(value, style, CultureInfo.InvariantCulture);
   Console.WriteLine("'{0}' converted to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", value);
}
// Displays:
//    Unable to parse '$6,032.00'.

provider = new CultureInfo("en-US");
number = Int16.Parse(value, style, provider);
Console.WriteLine("'{0}' converted to {1}.", value, number);
// Displays:
//    '$6,032.00' converted to 6032.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern and NumberFormatInfo.CurrencyNegativePattern property of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.

Element	Description
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
,	A culture-specific thousands separator symbol. The current culture's thousands separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	A sequence of the 0 digit. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. If any digit other than 0 appears in *fractional_digits*, the method throws an OverflowException.
e	The 'e' or 'E' character, which indicates that `s` can be represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag. However, the `s` parameter must represent a number in the range of the Int16 data type and cannot have a non-zero fractional component.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with *digits* only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The . and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or an OverflowException is thrown.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The , element.
NumberStyles.AllowCurrencySymbol	The *$* element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be the string representation of a hexadecimal value without a prefix. For example, "9AF3" parses successfully, but "0x9AF3" does not.. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation whose GetFormat method obtains a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `s`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent.

C#

```
public static short Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information about `s`.

Returns

Int16

A 16-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static short Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int16

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its 16-bit signed integer equivalent.

```
C#

public static short Parse (string s, IFormatProvider? provider);
```

Parameters

s String

A string containing a number to convert.

provider IFormatProvider

An IFormatProvider that supplies culture-specific formatting information about `s`.

Returns

Int16

A 16-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example parses string representations of Int16 values with the Int16.Parse(String, IFormatProvider) method.

C#

```
string stringToConvert;
short number;

stringToConvert = " 214 ";
try
{
   number = Int16.Parse(stringToConvert, CultureInfo.InvariantCulture);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert);
}
catch (OverflowException)
{
   Console.WriteLine("'{0'} is out of range of the Int16 data type.",
                     stringToConvert);
}

stringToConvert = " + 214";
try
{
   number = Int16.Parse(stringToConvert, CultureInfo.InvariantCulture);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert);
```

```
}
catch (OverflowException)
{
   Console.WriteLine("'{0'} is out of range of the Int16 data type.",
                     stringToConvert);
}

stringToConvert = " +214 ";
try
{
   number = Int16.Parse(stringToConvert, CultureInfo.InvariantCulture);
   Console.WriteLine("Converted '{0}' to {1}.", stringToConvert, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to parse '{0}'.", stringToConvert);
}
catch (OverflowException)
{
   Console.WriteLine("'{0'} is out of range of the Int16 data type.",
                     stringToConvert);
}
// The example displays the following output to the console:
//       Converted ' 214 ' to 214.
//       Unable to parse ' + 214'.
//       Converted ' +214 ' to 214.
```

Remarks

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	An optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to decimal digits, only leading and trailing spaces together with a leading sign are allowed in `s`. To explicitly define the style elements together with the culture-specific

formatting information that can be present in `s`, use the Int16.Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation that obtains a NumberFormatInfo object. The NumberFormatInfo provides culture-specific information about the format of `s`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

UWP	10.0

Parse(String)

Converts the string representation of a number to its 16-bit signed integer equivalent.

C#

```
public static short Parse (string s);
```

Parameters

s String

A string containing a number to convert.

Returns

Int16

A 16-bit signed integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Int16.MinValue or greater than Int16.MaxValue.

Examples

The following example demonstrates how to convert a string value into a 16-bit signed integer value using the Int16.Parse(String) method. The resulting integer value is then displayed to the console.

C#

```
string value;
short number;

value = " 12603 ";
try
{
   number = Int16.Parse(value);
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to convert '{0}' to a 16-bit signed
integer.",
                     value);
}

value = " 16,054";
try
{
   number = Int16.Parse(value);
```

```
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to convert '{0}' to a 16-bit signed
integer.",
                     value);
}

value = " -17264";
try
{
   number = Int16.Parse(value);
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
}
catch (FormatException)
{
   Console.WriteLine("Unable to convert '{0}' to a 16-bit signed
integer.",
                     value);
}
// The example displays the following output to the console:
//       Converted ' 12603 ' to 12603.
//       Unable to convert ' 16,054' to a 16-bit signed integer.
//       Converted ' -17264' to -17264.
```

Remarks

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to the integer value's decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements that can be present in `s`, use either the Int16.Parse(String, NumberStyles) or the Parse method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see CurrentInfo. To parse a string using the formatting information of some other culture, use the Int16.Parse(String, IFormatProvider) or the Int16.Parse(String, NumberStyles, IFormatProvider) method.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static short Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int16

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static short Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int16

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its 16-bit signed integer equivalent.

```
C#

public static short Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

Returns

Int16

A 16-bit signed integer equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than Int16.MinValue or greater than Int16.MaxValue.

-or-

`s` includes non-zero fractional digits.

Examples

The following example uses the Int16.Parse(String, NumberStyles) method to parse the string representations of Int16 values using the en-US culture.

C#

```
using System;
using System.Globalization;

public class ParseSample
{
   public static void Main()
   {
      string value;
      NumberStyles style;

      // Parse a number with a thousands separator (throws an exception).
      value = "14,644";
      style = NumberStyles.None;
      ParseToInt16(value, style);

      style = NumberStyles.AllowThousands;
      ParseToInt16(value, style);

      // Parse a number with a thousands separator and decimal point.
      value = "14,644.00";
      style = NumberStyles.AllowThousands | NumberStyles.Integer |
              NumberStyles.AllowDecimalPoint;
      ParseToInt16(value, style);
```

```
      // Parse a number with a fractional component (throws an
exception).
      value = "14,644.001";
      ParseToInt16(value, style);

      // Parse a number in exponential notation.
      value = "145E02";
      style = style | NumberStyles.AllowExponent;
      ParseToInt16(value, style);

      // Parse a number in exponential notation with a positive sign.
      value = "145E+02";
      ParseToInt16(value, style);

      // Parse a number in exponential notation with a negative sign
      // (throws an exception).
      value = "145E-02";
      ParseToInt16(value, style);
   }

   private static void ParseToInt16(string value, NumberStyles style)
   {
      try
      {
         short number = Int16.Parse(value, style);
         Console.WriteLine("Converted '{0}' to {1}.", value, number);
      }
      catch (FormatException)
      {
         Console.WriteLine("Unable to parse '{0}' with style {1}.",
value,
                           style.ToString());
      }
      catch (OverflowException)
      {
         Console.WriteLine("'{0}' is out of range of the Int16 type.",
value);
      }
   }
}
// The example displays the following output to the console:
//       Unable to parse '14,644' with style None.
//       Converted '14,644' to 14644.
//       Converted '14,644.00' to 14644.
//       '14,644.001' is out of range of the Int16 type.
//       Converted '145E02' to 14500.
//       Converted '145E+02' to 14500.
//       '145E-02' is out of range of the Int16 type.
```

Remarks

The `style` parameter defines the style elements (such as white space or a sign symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern and NumberFormatInfo.CurrencyNegativePattern property of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
,	A culture-specific thousands separator symbol. The current culture's thousands separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	A sequence of the 0 digit. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. If any digit other than 0 appears in *fractional_digits*, the method throws an OverflowException.

Element	Description
e	The 'e' or 'E' character, which indicates that `s` can be represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag. However, the `s` parameter must represent a number in the range of the Int16 data type and cannot have a non-zero fractional component.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with *digits* only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The . and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or an OverflowException is thrown.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The , element.

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.AllowCurrencySymbol	The $ element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be the string representation of a hexadecimal value without a prefix. For example, "9AF3" parses successfully, but "0x9AF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse `s` using the formatting information of a specific culture, call the Int16.Parse(String, NumberStyles, IFormatProvider) method.

Int16.PopCount(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static short PopCount (short value);
```

Parameters

`value` Int16

The value whose set bits are to be counted.

Returns

Int16

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.RotateLeft(Int16, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static short RotateLeft (short value, int rotateAmount);
```

Parameters

`value` Int16

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

Int16

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.RotateRight(Int16, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

C#

```
public static short RotateRight (short value, int rotateAmount);
```

Parameters

`value` Int16

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

Int16

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.Sign(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (short value);
```

Parameters

`value` Int16

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific formatting information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, consisting of a minus sign if the value is negative, and a sequence of digits ranging from 0 to 9 with no leading zeroes.

Examples

The following example uses the ToString() method to display an array of Int16 values to the console.

C#

```
short[] numbers = {0, 14624, 13982, short.MaxValue,
                   short.MinValue, -16667};
foreach (short number in numbers)
{
   Console.WriteLine(number.ToString());
}
// The example displays the following output to the console:
//       0
//       14624
//       13982
//       32767
//       -32768
//       -16667
```

Remarks

The ToString() method formats an Int16 value in the default ("G", or general) format by using the NumberFormatInfo object of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example iterates an array of Int16 values and displays each of them to the console by calling the Int16.ToString(IFormatProvider) method with different format providers. Because of the simple formatting defined by the default "G" format specifier, the formatted strings produced for each Int16 value are identical regardless of the value of the `provider` parameter.

C#

```
short[] numbers = {-23092, 0, 14894, Int16.MaxValue};
CultureInfo[] providers = {new CultureInfo("en-us"),
                           new CultureInfo("fr-fr"),
                           new CultureInfo("de-de"),
                           new CultureInfo("es-es")};
foreach (Int16 int16Value in numbers)
{
   foreach (CultureInfo provider in providers)
   {
      Console.Write("{0, 6} ({1})     ",
                    int16Value.ToString(provider),
                    provider.Name);
   }
   Console.WriteLine();
}
// The example displays the following output to the console:
//       -23092 (en-US)     -23092 (fr-FR)     -23092 (de-DE)     -23092
(es-ES)
//            0 (en-US)          0 (fr-FR)          0 (de-DE)          0
(es-ES)
//        14894 (en-US)      14894 (fr-FR)      14894 (de-DE)      14894
(es-ES)
//        32767 (en-US)      32767 (fr-FR)      32767 (de-DE)      32767
(es-ES)
```

Remarks

The ToString(IFormatProvider) method formats an Int16 value in the default ("G", or general) format by using the NumberFormatInfo object of a specified culture. If you

want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose IFormatProvider.GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a NumberFormatInfo object or a CultureInfo object. The NumberFormatInfo object provides culture-specific information about the format of the string returned by this method. If `provider` is `null`, this instance is formatted with the NumberFormatInfo object for the current culture.

UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Examples

The following example initializes two Int16 values and displays them to the console using each of the supported standard format strings and several custom format strings. The example is run with en-US as the current culture.

C#

```
Int16[] values = {-23805, 32194};
string[] formats = {"C4", "D6", "e1", "E2", "F1", "G", "N1",
                    "P0", "X4", "000000.0000", "##000.0"};
foreach (string format in formats)
{
   Console.WriteLine("'{0,2}' format specifier: {1,17}   {2,17}",
                     format,
                     values[0].ToString(format),
                     values[1].ToString(format));
```

```
}
// The example displays the following output to the console:
//    'C4' format specifier:    ($23,805.0000)        $32,194.0000
//    'D6' format specifier:           -023805              032194
//    'e1' format specifier:         -2.4e+004            3.2e+004
//    'E2' format specifier:        -2.38E+004           3.22E+004
//    'F1' format specifier:          -23805.0             32194.0
//    ' G' format specifier:            -23805               32194
//    'N1' format specifier:         -23,805.0            32,194.0
//    'P0' format specifier:      -2,380,500 %         3,219,400 %
//    'X4' format specifier:              A303                 7DC2
//    '000000.0000' format specifier:      -023805.0000
032194.0000
//    '##000.0' format specifier:          -23805.0             32194.0
```

Remarks

The ToString(String) method formats an Int16 value in a specified format by using a NumberFormatInfo object that represents the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be either a standard or a custom numeric format string. All standard numeric format strings other than "R" (or "r") are supported, as are all custom numeric format characters. If `format` is `null` or an empty string, the return value of this instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The return value of this instance is formatted with the NumberFormatInfo for the current culture.

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific formatting information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Examples

The following example displays an Int16 value using each of the supported standard format strings in four different cultures.

C#

```
Int16 value = 14603;
string[] formats = {"C", "D6", "e1", "E2", "F1", "G", "N1",
                    "P0", "X4", "000000.0000", "##000.0"};
CultureInfo[] providers = {new CultureInfo("en-us"),
                           new CultureInfo("fr-fr"),
                           new CultureInfo("de-de"),
                           new CultureInfo("es-es")};
// Display header.
Console.WriteLine("{0,24}{1,14}{2,14}{3,14}", providers[0], providers[1],
                  providers[2], providers[3]);
Console.WriteLine();
// Display a value using each format string.
foreach (string format in formats)
{
   // Display the value for each provider on the same line.
   Console.Write("{0,-12}", format);
   foreach (CultureInfo provider in providers)
   {
      Console.Write("{0,12}  ",
                    value.ToString(format, provider));
   }
   Console.WriteLine();
}
// The example displays the following output to the console:
//                        en-US         fr-FR         de-DE         es-ES
//
//    C             $14,603.00   14 603,00 €   14.603,00 €   14.603,00 €
//    D6                014603        014603        014603        014603
//    e1              1.5e+004      1,5e+004      1,5e+004      1,5e+004
//    E2             1.46E+004     1,46E+004     1,46E+004     1,46E+004
//    F1               14603.0       14603,0       14603,0       14603,0
//    G                  14603         14603         14603         14603
```

```
//    N1              14,603.0      14 603,0      14.603,0      14.603,0
//    P0           1,460,300 %   1 460 300 %    1.460.300%   1.460.300 %
//    X4                  390B          390B          390B          390B
//    000000.0000  014603.0000   014603,0000   014603,0000   014603,0000
//    ##000.0          14603.0       14603,0       14603,0       14603,0
```

Remarks

The ToString(String, IFormatProvider) method formats an Int16 value in a specified format by using the NumberFormatInfo object of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be either a standard or a custom numeric format string. All standard numeric format strings other than "R" (or "r") are supported, as are all custom numeric format characters. If `format` is `null` or an empty string (""), the string returned by this method is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.

- A NumberFormatInfo object that contains specific numeric formatting information for this value.
- A custom object that implements IFormatProvider.

If `provider` is `null`, or a NumberFormatInfo object cannot be obtained from `provider`, the return value is formatted with the NumberFormatInfo for the current culture.

Int16.TrailingZeroCount(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static short TrailingZeroCount (short value);
```

Parameters

`value` Int16

The value whose trailing zeroes are to be counted.

Returns

Int16

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current short number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current short number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Int16.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Int16)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Int16)	Converts the string representation of a number to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int16)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Int16)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int16)	Tries to convert a UTF-8 character span containing the string representation of a number to its 16-bit signed integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int16)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(String, NumberStyles, IFormatProvider, Int16)	Converts the string representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int16)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out short result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int16

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, Int16)

Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out short result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert.

`result` Int16

When this method returns, contains the 16-bit signed integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int16.MinValue or greater than Int16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Int16)

Converts the string representation of a number to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

```C#
public static bool TryParse (string? s, out short result);
```

Parameters

`s` String

A string containing a number to convert.

`result` Int16

When this method returns, contains the 16-bit signed integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than Int16.MinValue or greater than Int16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the Int16.TryParse(String, Int16) method with a number of different string values.

```C#
using System;

public class StringParsing
{
   public static void Main()
   {
      TryToParse(null);
      TryToParse("16051");
      TryToParse("9432.0");
      TryToParse("16,667");
      TryToParse("   -322   ");
```

```
        TryToParse("+4302");
        TryToParse("(100);");
        TryToParse("01FA");
    }

    private static void TryToParse(string value)
    {
        short number;
        bool result = Int16.TryParse(value, out number);
        if (result)
        {
            Console.WriteLine("Converted '{0}' to {1}.", value, number);
        }
        else
        {
            if (value == null) value = "";
            Console.WriteLine("Attempted conversion of '{0}' failed.",
value);
        }
    }
}
// The example displays the following output to the console:
//       Attempted conversion of '' failed.
//       Converted '16051' to 16051.
//       Attempted conversion of '9432.0' failed.
//       Attempted conversion of '16,667' failed.
//       Converted '   -322   ' to -322.
//       Converted '+4302' to 4302.
//       Attempted conversion of '(100)' failed.
//       Attempted conversion of '01FA' failed.
```

Some of the strings that the TryParse(String, Int16) method is unable to convert in this example are:

- "9432.0". The conversion fails because the string cannot contain a decimal separator; it must contain integral digits only.
- "16,667". The conversion fails because the string cannot contain group separators; it must contain integral digits only.
- "(100)". The conversion fails because the string cannot contain a negative sign other than the one defined by the current culture's NumberFormatInfo.NegativeSign and NumberFormatInfo.NumberNegativePattern properties.
- "01FA". The conversion fails because the string cannot contain hexadecimal digits; it must contain decimal digits only.

Remarks

The Int16.TryParse(String, Int16) method differs from the Int16.Parse(String) method by returning a Boolean value that indicates whether the parse operation succeeded instead of returning the parsed Int16 value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `s` parameter should be the string representation of a number in the form:

[ws][sign]digits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Int16.TryParse(String, NumberStyles, IFormatProvider, Int16) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see CurrentInfo.

This overload of the TryParse method interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the Int16.TryParse(String, NumberStyles, IFormatProvider, Int16) overload.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, Int16)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out short result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int16

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Int16)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider, out
short result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int16

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int16)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
short result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int16

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, Int16)

Tries to convert a UTF-8 character span containing the string representation of a number to its 16-bit signed integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out short
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` Int16

When this method returns, contains the 16-bit signed integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int16)

Converts the span representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
short result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert. The span is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Int16

When this method returns, contains the 16-bit signed integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int16.MinValue or greater than Int16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Int16)

Converts the string representation of a number in a specified style and culture-specific format to its 16-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out short result);
```

Parameters

`s` String

A string containing a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Int16

When this method returns, contains the 16-bit signed integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int16.MinValue or greater than

Int16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the Int16.TryParse(String, NumberStyles, IFormatProvider, Int16) method with a number of different string values.

C#

```
using System;
using System.Globalization;

public class StringParsing
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      numericString = "10677";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      numericString = "-30677";
      styles = NumberStyles.None;
      CallTryParse(numericString, styles);

      numericString = "10345.00";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "10345.72";
```

```
        styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
        CallTryParse(numericString, styles);

        numericString = "22,593";
        styles = NumberStyles.Integer | NumberStyles.AllowThousands;
        CallTryParse(numericString, styles);

        numericString = "12E-01";
        styles = NumberStyles.Integer | NumberStyles.AllowExponent;
        CallTryParse(numericString, styles);

        numericString = "12E03";
        CallTryParse(numericString, styles);

        numericString = "80c1";
        CallTryParse(numericString, NumberStyles.HexNumber);

        numericString = "0x80C1";
        CallTryParse(numericString, NumberStyles.HexNumber);
    }

    private static void CallTryParse(string stringToConvert, NumberStyles
styles)
    {
        short number;
        bool result = Int16.TryParse(stringToConvert, styles,
                                     CultureInfo.InvariantCulture, out
number);
        if (result)
            Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
        else
            Console.WriteLine($"Attempted conversion of '{stringToConvert}'
failed.");
    }
}
// The example displays the following output to the console:
//       Converted '10677' to 10677.
//       Attempted conversion of '-30677' failed.
//       Converted '10345.00' to 10345.
//       Attempted conversion of '10345.72' failed.
//       Converted '22,593' to 22593.
//       Attempted conversion of '12E-01' failed.
//       Converted '12E03' to 12000.
//       Converted '80c1' to -32575.
//       Attempted conversion of '0x80C1' failed.
```

Remarks

The Int16.TryParse(String, NumberStyles, IFormatProvider, Int16) method differs from the Int16.Parse(String, NumberStyles, IFormatProvider) method by returning a Boolean value that indicates whether the parse operation succeeded instead of

returning the parsed Int16 value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of style, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]digits][ws]

Or, if the `style` parameter includes NumberStyles.AllowHexSpecifier:

[ws]hexdigits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign.
digits	A sequence of digits from 0 through 9.
,	A culture-specific thousands separator. The thousands separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.

Element	Description
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The . and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or the method returns `false`.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation. If `s` represents a number in exponential notation, it must represent an integer within the range of the Int16 data type without a non-zero fractional component.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of *s*.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of *s*.
NumberStyles.AllowLeadingSign	A sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing

Non-composite NumberStyles values	Elements permitted in s in addition to digits
	the numeric value.
NumberStyles.AllowThousands	The , element.
NumberStyles.AllowCurrencySymbol	The *$* element.
NumberStyles.Currency	All elements. The *s* parameter cannot represent a hexadecimal number or a number in exponential notation.
NumberStyles.Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the . symbol. The `s` parameter can also use exponential notation.
NumberStyles.Number	The *ws*, *sign*, thousands separator (,), and decimal point (.) elements.
NumberStyles.Any	All styles, except `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "9AF3" parses successfully, but "0x9AF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a CultureInfo object or a NumberFormatInfo object, whose GetFormat method returns a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `s`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Int16.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int16.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

```
C#
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(Int16) method.

Applies to

Product	Versions

Int16.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(Int16) method.

Applies to

Product	Versions

Int16.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, unchanged.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int16.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int16.IConvertible.To Int64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int16.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToSByte(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int16.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int16.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The type to which to convert this Int16 value.

`provider` IFormatProvider

An IFormatProvider implementation that supplies information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int16.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, unchanged.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt16(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int16.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt32(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int16.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int16 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt64(Int16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int16.IAdditionOperators<Int16,Int16,Int16>.AdditionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static short IAdditionOperators<short,short,short>.operator + (short left,
short right);
```

Parameters

left Int16

The value to which `right` is added.

right Int16

The value that's added to `left`.

Returns

Int16

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IBinaryInteger<Int16>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<short>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Int16.IComparisonOperators<Int16,Int16,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<short,short,bool>.operator >= (short left,
short right);
```

Parameters

`left` Int16

The value to compare with `right`.

`right` Int16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.IComparisonOperators<Int16,Int16,Boolean>.Less Than Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<short,short,bool>.operator < (short left,
short right);
```

Parameters

`left` Int16

The value to compare with `right`.

`right` Int16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IComparisonOperators<Int16,Int16,Boolean>.LessThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<short,short,bool>.operator <= (short left,
short right);
```

Parameters

`left` Int16

The value to compare with `right`.

`right` Int16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IDecrementOperators<Int16>.CheckedDecrement(Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static short IDecrementOperators<short>.op_CheckedDecrement (short value);
```

Parameters

`value` Int16

The value to decrement.

Returns

Int16

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IDecrementOperators<Int16>.Decrement(Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static short IDecrementOperators<short>.operator -- (short value);
```

Parameters

`value` Int16

The value to decrement.

Returns

Int16

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IDivisionOperators<Int16,Int16,Int16>.DivisionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static short IDivisionOperators<short,short,short>.operator / (short left,
short right);
```

Parameters

`left` Int16

The value that `right` divides.

`right` Int16

The value that divides `left`.

Returns

Int16

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IEqualityOperators<Int16,Int16,Boolean>.EqualityOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<short,short,bool>.operator == (short left,
short right);
```

Parameters

`left` Int16

The value to compare with `right`.

`right` Int16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IEqualityOperators<Int16,Int16,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<short,short,bool>.operator != (short left,
short right);
```

Parameters

`left` Int16

The value to compare with `right`.

`right` Int16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IIncrementOperators<Int16>.CheckedIncrement(Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static short IIncrementOperators<short>.op_CheckedIncrement (short value);
```

Parameters

`value` Int16

The value to increment.

Returns

Int16

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IIncrementOperators<Int16>.Increment(Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static short IIncrementOperators<short>.operator ++ (short value);
```

Parameters

`value` Int16

The value to increment.

Returns

Int16

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IMinMaxValue<Int16>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static short System.Numerics.IMinMaxValue<System.Int16>.MaxValue { get; }
```

Property Value

Int16

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IMinMaxValue<Int16>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static short System.Numerics.IMinMaxValue<System.Int16>.MinValue { get; }
```

Property Value

Int16

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IModulusOperators<Int16,Int16,Int16>.Modulus(Int16, Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static short IModulusOperators<short,short,short>.operator % (short left,
short right);
```

Parameters

left Int16

The value that `right` divides.

right Int16

The value that divides `left`.

Returns

Int16

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IMultiplicativeIdentity<Int16,Int16>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static short
System.Numerics.IMultiplicativeIdentity<System.Int16,System.Int16>.MultiplicativeIdentity { get; }
```

Property Value

Int16

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IMultiplyOperators<Int16,Int16,Int16>.CheckedMultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static short IMultiplyOperators<short,short,short>.op_CheckedMultiply (short
left, short right);
```

Parameters

left Int16

The value that `right` multiplies.

right Int16

The value that multiplies `left`.

Returns

Int16

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.IMultiplyOperators<Int16,Int16,Int16>.MultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static short IMultiplyOperators<short,short,short>.operator * (short left,
short right);
```

Parameters

left Int16

The value that `right` multiplies.

right Int16

The value that multiplies `left`.

Returns

Int16

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumber<Int16>.MaxNumber(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static short INumber<short>.MaxNumber (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumber<Int16>.MinNumber(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static short INumber<short>.MinNumber (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.IsCanonical(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<short>.IsCanonical (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsComplexNumber(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<short>.IsComplexNumber (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.IsFinite(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<short>.IsFinite (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsImaginaryNumber(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

```
C#
static bool INumberBase<short>.IsImaginaryNumber (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.IsInfinity(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<short>.IsInfinity (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsInteger(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<short>.IsInteger (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsNaN(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<short>.IsNaN (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsNegativeInfinity(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

```
C#
static bool INumberBase<short>.IsNegativeInfinity (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsNormal(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<short>.IsNormal (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.IsPositiveInfinity(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive infinity.

```
C#
static bool INumberBase<short>.IsPositiveInfinity (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is positive infinity; otherwise, `false`.

Implements

IsPositiveInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.IsRealNumber(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<short>.IsRealNumber (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.IsSubnormal(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is subnormal.

```
C#
static bool INumberBase<short>.IsSubnormal (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is subnormal; otherwise, `false`.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.IsZero(Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<short>.IsZero (short value);
```

Parameters

`value` Int16

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.MaxMagnitudeNumber(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

C#

```
static short INumberBase<short>.MaxMagnitudeNumber (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.INumberBase<Int16>.MinMagnitudeNumber(Int16, Int16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

```
C#
static short INumberBase<short>.MinMagnitudeNumber (short x, short y);
```

Parameters

x Int16

The value to compare with `y`.

y Int16

The value to compare with `x`.

Returns

Int16

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.INumberBase<Int16>.TryConvertFromChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<short>.TryConvertFromChecked<TOther> (TOther value,
out short result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Int16

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

Int16.INumberBase<Int16>.TryConvertFromSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<short>.TryConvertFromSaturating<TOther> (TOther
value, out short result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Int16

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

Int16.INumberBase<Int16>.TryConvertFromTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<short>.TryConvertFromTruncating<TOther> (TOther
value, out short result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Int16

Returns

Boolean

Int16.INumberBase<Int16>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<short>.TryConvertToChecked<TOther> (short value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int16

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.INumberBase<Int16>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<short>.TryConvertToSaturating<TOther> (short value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int16

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.INumberBase<Int16>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<short>.TryConvertToTruncating<TOther> (short value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int16

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int16.INumberBase<Int16>.Zero Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `0` for the type.

C#

```
static short System.Numerics.INumberBase<System.Int16>.Zero { get; }
```

Property Value

Int16

Implements

Zero

Applies to

Product	Versions
.NET	7, 8, 9

Int16.IShift Operators<Int16,Int32,Int16>.Left Shift(Int16, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static short IShiftOperators<short,int,short>.operator << (short value, int
shiftAmount);
```

Parameters

`value` Int16

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

Int16

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IShift Operators<Int16,Int32,Int16>.RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static short IShiftOperators<short,int,short>.operator >> (short value, int
shiftAmount);
```

Parameters

`value` Int16

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int16

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IShift Operators<Int16,Int32,Int16>.Unsigned RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static short IShiftOperators<short,int,short>.op_UnsignedRightShift (short
value, int shiftAmount);
```

Parameters

`value` Int16

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int16

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.ISignedNumber<Int16>.NegativeOne Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `-1` for the type.

```
C#

static short System.Numerics.ISignedNumber<System.Int16>.NegativeOne { get;
}
```

Property Value

Int16

Implements

NegativeOne

Applies to

Product	Versions
.NET	7, 8, 9

Int16.ISubtractionOperators<Int16,Int16,Int16>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static short ISubtractionOperators<short,short,short>.op_CheckedSubtraction
(short left, short right);
```

Parameters

`left` Int16

The value from which `right` is subtracted.

`right` Int16

The value that's subtracted from `left`.

Returns

Int16

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int16.ISubtractionOperators<Int16,Int16,Int16>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static short ISubtractionOperators<short,short,short>.operator - (short
left, short right);
```

Parameters

`left` Int16

The value from which `right` is subtracted.

`right` Int16

The value that's subtracted from `left`.

Returns

Int16

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IUnaryNegationOperators<Int16,Int16>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static short IUnaryNegationOperators<short,short>.op_CheckedUnaryNegation
(short value);
```

Parameters

`value` Int16

The value for which to compute the unary negation.

Returns

Int16

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IUnaryNegationOperators<Int16,Int16>.UnaryNegation(Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static short IUnaryNegationOperators<short,short>.operator - (short value);
```

Parameters

`value` Int16

The value for which to compute the unary negation.

Returns

Int16

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int16.IUnaryPlusOperators<Int16,Int16>.UnaryPlus(Int16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static short IUnaryPlusOperators<short,short>.operator + (short value);
```

Parameters

`value` Int16

The value for which to compute the unary plus.

Returns

Int16

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Fields

Expand table

MaxValue	Represents the largest possible value of an Int32. This field is constant.
MinValue	Represents the smallest possible value of Int32. This field is constant.

Methods

Expand table

Abs(Int32)	Computes the absolute of a value.
Clamp(Int32, Int32, Int32)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Int32)	Compares this instance to a specified 32-bit signed integer and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CopySign(Int32, Int32)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(Int32, Int32)	Computes the quotient and remainder of two values.
Equals(Int32)	Returns a value indicating whether this instance is equal to a specified Int32 value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type Int32.
IsEvenInteger(Int32)	Determines if a value represents an even integral number.

IsNegative(Int32)	Determines if a value is negative.
IsOddInteger(Int32)	Determines if a value represents an odd integral number.
IsPositive(Int32)	Determines if a value is positive.
IsPow2(Int32)	Determines if a value is a power of two.
LeadingZeroCount(Int32)	Computes the number of leading zeros in a value.
Log2(Int32)	Computes the log2 of a value.
Max(Int32, Int32)	Compares two values to compute which is greater.
MaxMagnitude(Int32, Int32)	Compares two values to compute which is greater.
Min(Int32, Int32)	Compares two values to compute which is lesser.
MinMagnitude(Int32, Int32)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent.
Parse(String)	Converts the string representation of a number to its 32-bit signed integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 32-bit signed integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 32-bit signed integer equivalent.
Parse(String, NumberStyles, IFormat Provider)	Converts the string representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent.
PopCount(Int32)	Computes the number of bits that are set in a value.
RotateLeft(Int32, Int32)	Rotates a value left by a given amount.
RotateRight(Int32, Int32)	Rotates a value right by a given amount.

Sign(Int32)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
TrailingZeroCount(Int32)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current integer number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int32)	Tries to convert a UTF-8 character span containing the string representation of a number to its 32-bit signed integer equivalent.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int32)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, Int32)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int32)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, Int32)	Tries to parse a string into a value.

TryParse(String, Int32)	Converts the string representation of a number to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, NumberStyles, IFormatProvider, Int32)	Converts the string representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.

Explicit Interface Implementations

Expand table

IAdditionOperators<Int32,Int32,Int32>.Addition(Int32, Int32)	Adds two values together to compute their sum.
IAdditionOperators<Int32,Int32,Int32>.CheckedAddition(Int32, Int32)	Adds two values together to compute their sum.
IAdditiveIdentity<Int32,Int32>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<Int32>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<Int32>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<Int32>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, Int32)	
IBinaryInteger<Int32>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, Int32)	
IBinaryInteger<Int32>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<Int32>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<Int32>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<Int32,Int32,Int32>.BitwiseAnd(Int32, Int32)	Computes the bitwise-and of two values.
IBitwiseOperators<Int32,Int32,Int32>.BitwiseOr(Int32, Int32)	Computes the bitwise-or of two values.

IBitwiseOperators<Int32,Int32,Int32>.ExclusiveOr(Int32, Int32)	Computes the exclusive-or of two values.
IBitwiseOperators<Int32,Int32,Int32>.Ones Complement(Int32)	Computes the ones-complement representation of a given value.
IComparisonOperators<Int32,Int32,Boolean>.Greater Than(Int32, Int32)	Compares two values to determine which is greater.
IComparisonOperators<Int32,Int32,Boolean>.Greater ThanOrEqual(Int32, Int32)	Compares two values to determine which is greater or equal.
IComparisonOperators<Int32,Int32,Boolean>.Less Than(Int32, Int32)	Compares two values to determine which is less.
IComparisonOperators<Int32,Int32,Boolean>.LessThan OrEqual(Int32, Int32)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).

IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<Int32>.Checked Decrement(Int32)	Decrements a value.
IDecrementOperators<Int32>.Decrement(Int32)	Decrements a value.
IDivisionOperators<Int32,Int32,Int32>.Division(Int32, Int32)	Divides one value by another to compute their quotient.
IEquality Operators<Int32,Int32,Boolean>.Equality(Int32, Int32)	Compares two values to determine equality.
IEquality Operators<Int32,Int32,Boolean>.Inequality(Int32, Int32)	Compares two values to determine inequality.
IIncrementOperators<Int32>.CheckedIncrement(Int32)	Increments a value.
IIncrementOperators<Int32>.Increment(Int32)	Increments a value.
IMinMaxValue<Int32>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Int32>.MinValue	Gets the minimum value of the current type.
IModulusOperators<Int32,Int32,Int32>.Modulus(Int32, Int32)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Int32,Int32>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiplyOperators<Int32,Int32,Int32>.Checked Multiply(Int32, Int32)	Multiplies two values together to compute their product.
IMultiplyOperators<Int32,Int32,Int32>.Multiply(Int32, Int32)	Multiplies two values together to compute their product.
INumber<Int32>.MaxNumber(Int32, Int32)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.

INumber<Int32>.MinNumber(Int32, Int32)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<Int32>.IsCanonical(Int32)	Determines if a value is in its canonical representation.
INumberBase<Int32>.IsComplexNumber(Int32)	Determines if a value represents a complex number.
INumberBase<Int32>.IsFinite(Int32)	Determines if a value is finite.
INumberBase<Int32>.IsImaginaryNumber(Int32)	Determines if a value represents a pure imaginary number.
INumberBase<Int32>.IsInfinity(Int32)	Determines if a value is infinite.
INumberBase<Int32>.IsInteger(Int32)	Determines if a value represents an integral number.
INumberBase<Int32>.IsNaN(Int32)	Determines if a value is NaN.
INumberBase<Int32>.IsNegativeInfinity(Int32)	Determines if a value is negative infinity.
INumberBase<Int32>.IsNormal(Int32)	Determines if a value is normal.
INumberBase<Int32>.IsPositiveInfinity(Int32)	Determines if a value is positive infinity.
INumberBase<Int32>.IsRealNumber(Int32)	Determines if a value represents a real number.
INumberBase<Int32>.IsSubnormal(Int32)	Determines if a value is subnormal.
INumberBase<Int32>.IsZero(Int32)	Determines if a value is zero.
INumberBase<Int32>.MaxMagnitudeNumber(Int32, Int32)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Int32>.MinMagnitudeNumber(Int32, Int32)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<Int32>.One	Gets the value `1` for the type.
INumberBase<Int32>.Radix	Gets the radix, or base, for the type.
INumberBase<Int32>.TryConvertFromChecked<TOther>(TOther, Int32)	
INumberBase<Int32>.TryConvertFromSaturating<TOther>(TOther, Int32)	

INumberBase<Int32>.TryConvertFromTruncating<TOther>(TOther, Int32)	
INumberBase<Int32>.TryConvertToChecked<TOther>(Int32, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Int32>.TryConvertToSaturating<TOther>(Int32, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Int32>.TryConvertToTruncating<TOther>(Int32, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Int32>.Zero	Gets the value `0` for the type.
IShiftOperators<Int32,Int32,Int32>.LeftShift(Int32, Int32)	Shifts a value left by a given amount.
IShiftOperators<Int32,Int32,Int32>.RightShift(Int32, Int32)	Shifts a value right by a given amount.
IShiftOperators<Int32,Int32,Int32>.UnsignedRightShift(Int32, Int32)	Shifts a value right by a given amount.
ISignedNumber<Int32>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<Int32,Int32,Int32>.CheckedSubtraction(Int32, Int32)	Subtracts two values to compute their difference.
ISubtractionOperators<Int32,Int32,Int32>.Subtraction(Int32, Int32)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Int32,Int32>.CheckedUnaryNegation(Int32)	Computes the checked unary negation of a value.
IUnaryNegationOperators<Int32,Int32>.UnaryNegation(Int32)	Computes the unary negation of a value.
IUnaryPlusOperators<Int32,Int32>.UnaryPlus(Int32)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Int32.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of an Int32. This field is constant.

C#

```
public const int MaxValue = 2147483647;
```

Field Value

Value* = *2147483647

Int32

Examples

The following example uses the MaxValue property to prevent an OverflowException when converting to an Int32 value.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      long[] numbersToConvert = { 162345, 32183, -54000, Int64.MaxValue/2 };
      int newNumber;
      foreach (long number in numbersToConvert)
      {
         if (number >= Int32.MinValue && number <= Int32.MaxValue)
         {
            newNumber = Convert.ToInt32(number);
            Console.WriteLine($"Successfully converted {newNumber} to an
Int32.");
         }
         else
         {
```

```
            Console.WriteLine($"Unable to convert {number} to an Int32.");
        }
    }
  }
}
// The example displays the following output to the console:
//    Successfully converted 162345 to an Int32.
//    Successfully converted 32183 to an Int32.
//    Successfully converted -54000 to an Int32.
//    Unable to convert 4611686018427387903 to an Int32.
```

Remarks

The value of this constant is 2,147,483,647; that is, hexadecimal 0x7FFFFFFF.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int32.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of Int32. This field is constant.

C#

```
public const int MinValue = -2147483648;
```

Field Value

***Value* = -2147483648**

Int32

Examples

The following example uses the MinValue property to prevent an OverflowException when converting to an Int32 value.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      long[] numbersToConvert = { 162345, 32183, -54000, Int64.MaxValue/2 };
      int newNumber;
      foreach (long number in numbersToConvert)
      {
         if (number >= Int32.MinValue && number <= Int32.MaxValue)
         {
            newNumber = Convert.ToInt32(number);
            Console.WriteLine($"Successfully converted {newNumber} to an
Int32.");
         }
         else
         {
```

```
            Console.WriteLine($"Unable to convert {number} to an Int32.");
        }
    }
  }
}
// The example displays the following output to the console:
//    Successfully converted 162345 to an Int32.
//    Successfully converted 32183 to an Int32.
//    Successfully converted -54000 to an Int32.
//    Unable to convert 4611686018427387903 to an Int32.
```

Remarks

The value of this constant is -2,147,483,648; that is, hexadecimal 0x80000000.

Int32.Abs(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static int Abs (int value);
```

Parameters

`value` Int32

The value for which to get its absolute.

Returns

Int32

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.Clamp(Int32, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static int Clamp (int value, int min, int max);
```

Parameters

`value` Int32

The value to clamp.

`min` Int32

The inclusive minimum to which `value` should clamp.

`max` Int32

The inclusive maximum to which `value` should clamp.

Returns

Int32

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified 32-bit signed integer and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Int32)	Compares this instance to a specified 32-bit signed integer and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.

CompareTo(Int32)

Compares this instance to a specified 32-bit signed integer and returns an indication of their relative values.

C#

```
public int CompareTo (int value);
```

Parameters

`value` Int32

An integer to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following example demonstrates the Int32.CompareTo(Int32) method. In addition to displaying the value returned by the method for four different comparisons, it converts the return value to a member of the custom `Comparison` enumeration, whose value it also displays.

C#

```
using System;

enum Comparison {
   LessThan=-1, Equal=0, GreaterThan=1};

public class ValueComparison
{
   public static void Main()
   {
      int mainValue = 16325;
      int zeroValue = 0;
      int negativeValue = -1934;
      int positiveValue = 903624;
      int sameValue = 16325;

      Console.WriteLine("Comparing {0} and {1}: {2} ({3}).",
                        mainValue, zeroValue,
                        mainValue.CompareTo(zeroValue),
                        (Comparison) mainValue.CompareTo(zeroValue));

      Console.WriteLine("Comparing {0} and {1}: {2} ({3}).",
                        mainValue, sameValue,
                        mainValue.CompareTo(sameValue),
```

```
                        (Comparison) mainValue.CompareTo(sameValue));

        Console.WriteLine("Comparing {0} and {1}: {2} ({3}).",
                          mainValue, negativeValue,
                          mainValue.CompareTo(negativeValue),
                          (Comparison) mainValue.CompareTo(negativeValue));

        Console.WriteLine("Comparing {0} and {1}: {2} ({3}).",
                          mainValue, positiveValue,
                          mainValue.CompareTo(positiveValue),
                          (Comparison) mainValue.CompareTo(positiveValue));
    }
}
// The example displays the following output:
//       Comparing 16325 and 0: 1 (GreaterThan).
//       Comparing 16325 and 16325: 0 (Equal).
//       Comparing 16325 and -1934: 1 (GreaterThan).
//       Comparing 16325 and 903624: -1 (LessThan).
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Int32.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not an Int32.

Remarks

Any instance of Int32, regardless of its value, is considered greater than `null`.

`value` must be `null` or an instance of Int32; otherwise, an exception is thrown.

Int32.CopySign(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

```
C#
public static int CopySign (int value, int sign);
```

Parameters

`value` Int32

The value whose magnitude is used in the result.

`sign` Int32

The value whose sign is used in the result.

Returns

Int32

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

public static int CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int32

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static int CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int32

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.CreateTruncating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static int CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int32

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.DivRem(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#
public static (int Quotient, int Remainder) DivRem (int left, int right);
```

Parameters

`left` Int32

The value which `right` divides.

`right` Int32

The value which divides `left`.

Returns

ValueTuple<Int32,Int32>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified Int32 value.

Overloads

Expand table

Equals(Int32)	Returns a value indicating whether this instance is equal to a specified Int32 value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(Int32)

Returns a value indicating whether this instance is equal to a specified Int32 value.

C#

```
public bool Equals (int obj);
```

Parameters

obj Int32

An Int32 value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Int32.Equals(Object) because it does not have to convert the `obj` parameter to an object.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Int32) method overloads. If an implicit conversion between the `obj` argument and an Int32 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(Int32) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not an Int32 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte, Int16, SByte, and UInt16 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Int32) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static int value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,15}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,15}", value.Equals(short1));
      TestObjectForEquality(short1);

      long long1 = 112;
      Console.WriteLine("value = long1: {0,17}", value.Equals(long1));
      TestObjectForEquality(long1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,15}", value.Equals(sbyte1));
```

```
      TestObjectForEquality(sbyte1);

      ushort ushort1 = 112;
      Console.WriteLine("value = ushort1: {0,15}",
value.Equals(ushort1));
      TestObjectForEquality(ushort1);

      ulong ulong1 = 112;
      Console.WriteLine("value = ulong1: {0,17}", value.Equals(ulong1));
      TestObjectForEquality(ulong1);

      decimal dec1 = 112m;
      Console.WriteLine("value = dec1: {0,20}", value.Equals(dec1));
      TestObjectForEquality(dec1);

      double dbl1 = 112;
      Console.WriteLine("value = dbl1: {0,19}", value.Equals(dbl1));
      TestObjectForEquality(dbl1);
   }

   private static void TestObjectForEquality(Object obj)
   {
      Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                        value, value.GetType().Name,
                        obj, obj.GetType().Name,
                        value.Equals(obj));
   }
}
// The example displays the following output:
//       value = byte1:            True
//       112 (Int32) = 112 (Byte): False
//
//       value = short1:            True
//       112 (Int32) = 112 (Int16): False
//
//       value = long1:             False
//       112 (Int32) = 112 (Int64): False
//
//       value = sbyte1:            True
//       112 (Int32) = 112 (SByte): False
//
//       value = ushort1:            True
//       112 (Int32) = 112 (UInt16): False
//
//       value = ulong1:             False
//       112 (Int32) = 112 (UInt64): False
//
//       value = dec1:                False
//       112 (Int32) = 112 (Decimal): False
//
//       value = dbl1:               False
//       112 (Int32) = 112 (Double): False
```

UWP	10.0

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is an instance of Int32 and equals the value of this instance; otherwise, `false`.

Examples

The following example illustrates the use of `Equals` in the context of `Int32`, comparing two `int` values and returning `true` if they represent the same number, or `false` if they do not.

C#

```
Int32 myVariable1 = 60;
Int32 myVariable2 = 60;

// Get and display the declaring type.
Console.WriteLine("\nType of 'myVariable1' is '{0}' and"+
     " value is :{1}",myVariable1.GetType(), myVariable1);
Console.WriteLine("Type of 'myVariable2' is '{0}' and"+
     " value is :{1}",myVariable2.GetType(), myVariable2);

// Compare 'myVariable1' instance with 'myVariable2' Object.
if( myVariable1.Equals( myVariable2 ) )
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are equal");
else
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are not equal");
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Int32) method overloads. If an implicit conversion between the `obj` argument and an Int32 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(Int32) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not an Int32 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte, Int16, SByte, and UInt16 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Int32) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static int value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,15}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,15}", value.Equals(short1));
```

```
        TestObjectForEquality(short1);

        long long1 = 112;
        Console.WriteLine("value = long1: {0,17}", value.Equals(long1));
        TestObjectForEquality(long1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,15}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,15}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,17}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,20}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,19}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:            True
//       112 (Int32) = 112 (Byte): False
//
//       value = short1:            True
//       112 (Int32) = 112 (Int16): False
//
//       value = long1:             False
//       112 (Int32) = 112 (Int64): False
//
//       value = sbyte1:            True
//       112 (Int32) = 112 (SByte): False
//
//       value = ushort1:            True
//       112 (Int32) = 112 (UInt16): False
//
//       value = ulong1:             False
//       112 (Int32) = 112 (UInt64): False
//
```

```
//       value = dec1:                 False
//       112 (Int32) = 112 (Decimal): False
//
//       value = dbl1:                False
//       112 (Int32) = 112 (Double): False
```

Int32.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int32.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Int32.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Int32.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Int32.IsEvenInteger(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IsNegative(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IsOddInteger(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (int value);
```

Parameters

value Int32

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Int32.IsPositive(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Int32.IsPow2(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.LeadingZeroCount(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static int LeadingZeroCount (int value);
```

Parameters

`value` Int32

The value whose leading zeroes are to be counted.

Returns

Int32

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.Log2(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static int Log2 (int value);
```

Parameters

`value` Int32

The value whose log2 is to be computed.

Returns

Int32

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.Max(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static int Max (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.MaxMagnitude(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static int MaxMagnitude (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Int32.Min(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static int Min (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Int32.MinMagnitude(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static int MinMagnitude (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `minimumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Int32.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 32-bit signed integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 32-bit signed integer equivalent.
Parse(String)	Converts the string representation of a number to its 32-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 32-bit signed integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent.

```C#
public static int Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific information about the format of `s`.

Returns

Int32

A 32-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than Int32.MinValue or greater than Int32.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example uses a variety of `style` and `provider` parameters to parse the string representations of Int32 values. It also illustrates some of the different ways the same string can be interpreted depending on the culture whose formatting information is used for the parsing operation.

C#

```
using System;
using System.Globalization;

public class ParseInt32
{
   public static void Main()
   {
      Convert("12,000", NumberStyles.Float | NumberStyles.AllowThousands,
              new CultureInfo("en-GB"));
      Convert("12,000", NumberStyles.Float | NumberStyles.AllowThousands,
              new CultureInfo("fr-FR"));
      Convert("12,000", NumberStyles.Float, new CultureInfo("en-US"));

      Convert("12 425,00", NumberStyles.Float |
NumberStyles.AllowThousands,
              new CultureInfo("sv-SE"));
      Convert("12,425.00", NumberStyles.Float |
NumberStyles.AllowThousands,
              NumberFormatInfo.InvariantInfo);
      Convert("631,900", NumberStyles.Integer |
NumberStyles.AllowDecimalPoint,
              new CultureInfo("fr-FR"));
      Convert("631,900", NumberStyles.Integer |
NumberStyles.AllowDecimalPoint,
              new CultureInfo("en-US"));
      Convert("631,900", NumberStyles.Integer |
NumberStyles.AllowThousands,
              new CultureInfo("en-US"));
   }
```

```
    private static void Convert(string value, NumberStyles style,
                                IFormatProvider provider)
    {
       try
       {
          int number = Int32.Parse(value, style, provider);
          Console.WriteLine("Converted '{0}' to {1}.", value, number);
       }
       catch (FormatException)
       {
          Console.WriteLine("Unable to convert '{0}'.", value);
       }
       catch (OverflowException)
       {
          Console.WriteLine("'{0}' is out of range of the Int32 type.",
value);
       }
    }
}
// This example displays the following output to the console:
//       Converted '12,000' to 12000.
//       Converted '12,000' to 12.
//       Unable to convert '12,000'.
//       Converted '12 425,00' to 12425.
//       Converted '12,425.00' to 12425.
//       '631,900' is out of range of the Int32 type.
//       Unable to convert '631,900'.
//       Converted '631,900' to 631900.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digist][e[sign]exponential_digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag or at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.
,	A culture-specific thousands separator symbol. The thousands separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, an OverflowException is thrown.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

Note

Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Int32 type. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements. However, *fractional-digits* must consist of only one or more 0 digits or an OverflowException is thrown.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation. If `s` represents a number in exponential notation, it must represent an integer within the range of the Int32 data type without a non-zero, fractional component.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A positive sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A positive sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The thousands separator (,) element.
NumberStyles.AllowCurrencySymbol	The *$* element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "C9AF3" parses successfully, but "0xC9AF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-

specific information used in parsing. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent.

C#

```
public static int Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific information about the format of `s`.

Returns

Int32

A 32-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static int Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int32

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its 32-bit signed integer equivalent.

C#

```
public static int Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Int32

A 32-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not of the correct format.

OverflowException

`s` represents a number less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to an Int32 value.

C#

```
protected void OkToInteger_Click(object sender, EventArgs e)
{
    string locale;
    int number;
    CultureInfo culture;

    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;
```

```
    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = Int32.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
        return;
    }
    catch (Exception)
    {
        return;
    }
    // Output number to label on web form
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

This overload of the Parse(String, IFormatProvider) method is typically used to convert text that can be formatted in a variety of ways to an Int32 value. For example, it can be used to convert the text entered by a user into an HTML text box to a numeric value.

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.

Element	Description
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements that can be present in `s`, use the Int32.Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information about the format of `s`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Parse(String)

Converts the string representation of a number to its 32-bit signed integer equivalent.

```C#
public static int Parse (string s);
```

Parameters

s String

A string containing a number to convert.

Returns

Int32

A 32-bit signed integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Int32.MinValue or greater than Int32.MaxValue.

Examples

The following example demonstrates how to convert a string value into a 32-bit signed integer value using the Int32.Parse(String) method. The resulting integer value is then displayed to the console.

```C#
using System;

public class Example
{
   public static void Main()
   {
      string[] values = { "+13230", "-0", "1,390,146",
"$190,235,421,127",
                          "0xFA1B", "163042", "-10", "007", "2147483647",
                          "2147483648", "16e07", "134985.0", "-12034",
```

```
                                "-2147483648", "-2147483649" };
        foreach (string value in values)
        {
           try {
              int number = Int32.Parse(value);
              Console.WriteLine("{0} --> {1}", value, number);
           }
           catch (FormatException) {
              Console.WriteLine("{0}: Bad Format", value);
           }
           catch (OverflowException) {
              Console.WriteLine("{0}: Overflow", value);
           }
        }
     }
  }
  // The example displays the following output:
  //       +13230 --> 13230
  //       -0 --> 0
  //       1,390,146: Bad Format
  //       $190,235,421,127: Bad Format
  //       0xFA1B: Bad Format
  //       163042 --> 163042
  //       -10 --> -10
  //       007 --> 7
  //       2147483647 --> 2147483647
  //       2147483648: Overflow
  //       16e07: Bad Format
  //       134985.0: Bad Format
  //       -12034 --> -12034
  //       -2147483648 --> -2147483648
  //       -2147483649: Overflow
```

Remarks

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.

Element	Description
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements that can be present in `s`, use either the Int32.Parse(String, NumberStyles) or the Int32.Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object initialized for the current system culture. For more information, see CurrentInfo. To parse a string using the formatting information of some other culture, use the Int32.Parse(String, NumberStyles, IFormatProvider) method.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#
```

```
public static int Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int32

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static int Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int32

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its 32-bit signed integer equivalent.

```
C#

public static int Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

Returns

Int32

A 32-bit signed integer equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than Int32.MinValue or greater than Int32.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example uses the Int32.Parse(String, NumberStyles) method to parse the string representations of several Int32 values. The current culture for the example is en-US.

C#

```
using System;
using System.Globalization;

public class ParseInt32
{
```

```
    public static void Main()
    {
       Convert("104.0", NumberStyles.AllowDecimalPoint);
       Convert("104.9", NumberStyles.AllowDecimalPoint);
       Convert(" $17,198,064.42", NumberStyles.AllowCurrencySymbol |
                                  NumberStyles.Number);
       Convert("103E06", NumberStyles.AllowExponent);
       Convert("-1,345,791", NumberStyles.AllowThousands);
       Convert("(1,345,791)", NumberStyles.AllowThousands |
                              NumberStyles.AllowParentheses);
    }

    private static void Convert(string value, NumberStyles style)
    {
       try
       {
          int number = Int32.Parse(value, style);
          Console.WriteLine("Converted '{0}' to {1}.", value, number);
       }
       catch (FormatException)
       {
          Console.WriteLine("Unable to convert '{0}'.", value);
       }
       catch (OverflowException)
       {
          Console.WriteLine("'{0}' is out of range of the Int32 type.",
value);
       }
    }
}
// The example displays the following output to the console:
//       Converted '104.0' to 104.
//       '104.9' is out of range of the Int32 type.
//       ' $17,198,064.42' is out of range of the Int32 type.
//       Converted '103E06' to 103000000.
//       Unable to convert '-1,345,791'.
//       Converted '(1,345,791)' to -1345791.
```

Remarks

The `style` parameter defines the style elements (such as white space, the positive or negative sign symbol, or the thousands separator symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]exponential_digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.
,	A culture-specific thousands separator symbol. The current culture's thousands separator can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, an OverflowException is thrown.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfull if it is in the range of the Int32 type. Most of the remaining NumberStyles members control elements that may be but are not required to be present in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in s in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The `s` parameter can also use exponential notation.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The thousands separator (,) element.
AllowCurrencySymbol	The *$* element.
Currency	All. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, thousands separator (,), and decimal point (.) elements.
Any	All styles, except `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "C9AF3" parses successfully, but "0xC9AF3" does not. The only other flags that can be combined with the `s` parameter it are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To specify the culture whose formatting information is used for the parse operation, call the Int32.Parse(String, NumberStyles, IFormatProvider) overload.

Int32.PopCount(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static int PopCount (int value);
```

Parameters

`value` Int32

The value whose set bits are to be counted.

Returns

Int32

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.RotateLeft(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static int RotateLeft (int value, int rotateAmount);
```

Parameters

`value` Int32

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

Int32

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.RotateRight(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

```
C#
public static int RotateRight (int value, int rotateAmount);
```

Parameters

`value` Int32

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

Int32

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.Sign(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (int value);
```

Parameters

`value` Int32

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, consisting of a negative sign if the value is negative, and a sequence of digits ranging from 0 to 9 with no leading zeroes.

Examples

The following example displays an Int32 value using the default ToString() method. It also displays the string representations of the Int32 value that results from using a number of standard format specifiers. The examples are displayed using the formatting conventions of the en-US culture.

C#

```
int value = -16325;
// Display value using default ToString method.
Console.WriteLine(value.ToString());            // Displays -16325
// Display value using some standard format specifiers.
Console.WriteLine(value.ToString("G"));         // Displays -16325
Console.WriteLine(value.ToString("C"));         // Displays ($16,325.00)
Console.WriteLine(value.ToString("D"));         // Displays -16325
Console.WriteLine(value.ToString("F"));         // Displays -16325.00
Console.WriteLine(value.ToString("N"));         // Displays -16,325.00
Console.WriteLine(value.ToString("X"));         // Displays FFFFC03B
```

Remarks

The ToString() method formats an Int32 value in the default ("G", or general) format by using the NumberFormatInfo object of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

See also

- Parse(String)
- String

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example displays the string representation of an Int32 value using CultureInfo objects that represent several different cultures.

C#

```
int value = -16325;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));
// This example displays the following output to the console:
//       -16325
//       -16325
//       -16325
```

Remarks

The ToString(IFormatProvider) method formats an Int32 value in the default ("G", or general) format by using the NumberFormatInfo object of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `provider` parameter is an object that implements the IFormatProvider interface. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.
- A NumberFormatInfo object that contains specific numeric formatting information for this value.
- A custom object that implements IFormatProvider and whose GetFormat method returns a NumberFormatInfo object that provides formatting information.

If `provider` is `null` or a NumberFormatInfo object cannot be obtained from `provider`, the return value is formatted using the NumberFormatInfo object for the thread current culture. For information about the thread current culture, see Thread.CurrentCulture.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

See also

- Parse(String)
- String
- Formatting Types in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A standard or custom numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid or not supported.

Examples

The following example displays an Int32 value using each of the supported standard numeric format specifiers, together with two custom numeric format strings. In converting the numeric values to strings, the example uses the formatting conventions of the en-US culture.

C#

```
int value = -16325;
string specifier;

// Use standard numeric format specifier.
specifier = "G";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    G: -16325
specifier = "C";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    C: ($16,325.00)
specifier = "D8";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    D8: -00016325
specifier = "E4";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    E4: -1.6325E+004
specifier = "e3";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    e3: -1.633e+004
specifier = "F";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    F: -16325.00
specifier = "N";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    N: -16,325.00
specifier = "P";
Console.WriteLine("{0}: {1}", specifier,
(value/100000).ToString(specifier));
// Displays:    P: -16.33 %
specifier = "X";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    X: FFFFC03B

// Use custom numeric format specifiers.
specifier = "0,0.000";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    0,0.000: -16,325.000
specifier = "#,#.00#;(#,#.00#)";
Console.WriteLine("{0}: {1}", specifier, (value*-1).ToString(specifier));
// Displays:    #,#.00#;(#,#.00#): 16,325.00
```

Remarks

The ToString(String) method formats an Int32 value in a specified format by using a NumberFormatInfo object that represents the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be any valid standard numeric format specifier except for "R", as well as any combination of custom numeric format specifiers. If `format` is `null` or an empty string (""), the return value of this instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The return value of this instance is formatted with the NumberFormatInfo for the current culture.

UWP	10.0

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A standard or custom numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` is invalid or not supported.

Examples

The following example displays a positive and a negative value using each of the supported standard numeric format specifiers for three different cultures.

C#

```
// Define cultures whose formatting conventions are to be used.
CultureInfo[] cultures = {CultureInfo.CreateSpecificCulture("en-US"),
                          CultureInfo.CreateSpecificCulture("fr-FR"),
                          CultureInfo.CreateSpecificCulture("es-ES") };
int positiveNumber = 1679;
int negativeNumber = -3045;
string[] specifiers = {"G", "C", "D8", "E2", "F", "N", "P", "X8"};

foreach (string specifier in specifiers)
{
   foreach (CultureInfo culture in cultures)
   {
      // Display values with "G" format specifier.
      Console.WriteLine("{0} format using {1} culture: {2, 16} {3, 16}",
                        specifier, culture.Name,
                        positiveNumber.ToString(specifier, culture),
                        negativeNumber.ToString(specifier, culture));
   }
   Console.WriteLine();
}
// The example displays the following output:
//       G format using en-US culture:             1679            -3045
//       G format using fr-FR culture:             1679            -3045
//       G format using es-ES culture:             1679            -3045
//
//       C format using en-US culture:        $1,679.00      ($3,045.00)
//       C format using fr-FR culture:       1 679,00 €      -3 045,00 €

//       E2 format using es-ES culture:        1,68E+003       -3,05E+003
//
//       F format using en-US culture:          1679.00         -3045.00
//       F format using fr-FR culture:          1679,00         -3045,00
//       F format using es-ES culture:          1679,00         -3045,00
//
//       N format using en-US culture:         1,679.00        -3,045.00
//       N format using fr-FR culture:         1 679,00        -3 045,00
//       N format using es-ES culture:         1.679,00        -3.045,00
//
//       P format using en-US culture:     167,900.00 %    -304,500.00 %
//       P format using fr-FR culture:     167 900,00 %    -304 500,00 %
//       P format using es-ES culture:     167.900,00 %    -304.500,00 %
//
```

```
//       X8 format using en-US culture:         0000068F         FFFFF41B
//       X8 format using fr-FR culture:         0000068F         FFFFF41B
//       X8 format using es-ES culture:         0000068F         FFFFF41B
```

Remarks

The ToString(String, IFormatProvider) method formats an Int32 value in a specified format by using the NumberFormatInfo object of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be either a standard or a custom numeric format string. All standard numeric format strings other than "R" (or "r") are supported, as are all custom numeric format characters. If `format` is `null` or an empty string (""), the return value for this instance is formatted with the general numeric format specifier ("G").

The `provider` parameter is an object that implements the IFormatProvider interface. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific format information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.
- A NumberFormatInfo object that contains specific numeric formatting information for this value.
- A custom object that implements IFormatProvider and whose GetFormat method returns a NumberFormatInfo object that provides formatting information.

If `provider` is `null` or a NumberFormatInfo object cannot be obtained from `provider`, the return value for this instance is formatted with the NumberFormatInfo

for the current culture.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

Int32.TrailingZeroCount(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static int TrailingZeroCount (int value);
```

Parameters

`value` Int32

The value whose trailing zeroes are to be counted.

Returns

Int32

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current integer number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current integer number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Int32.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 32-bit signed integer equivalent. A return value indicates whether the operation succeeded.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Int32)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, Int32)	Converts the string representation of a number to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int32)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Int32)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int32)	Tries to convert a UTF-8 character span containing the string representation of a number to its 32-bit signed integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int32)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.

TryParse(String, NumberStyles, IFormatProvider, Int32)	Converts the string representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int32)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out int result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int32

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, Int32)

Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out int result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert.

`result` Int32

When this method returns, contains the 32-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int32.MinValue or greater than Int32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Int32)

Converts the string representation of a number to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.

```C#
public static bool TryParse (string? s, out int result);
```

Parameters

`s` String

A string containing a number to convert.

`result` Int32

When this method returns, contains the 32-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than Int32.MinValue or greater than Int32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the Int32.TryParse(String, Int32) method with a number of different string values.

```C#
using System;

public class Example
{
   public static void Main()
   {
      string[] values = { null, "160519", "9432.0", "16,667",
                          "   -322   ", "+4302", "(100);", "01FA" };
      foreach (var value in values)
      {
         int number;
```

```
            bool success = int.TryParse(value, out number);
            if (success)
            {
               Console.WriteLine($"Converted '{value}' to {number}.");
            }
            else
            {
               Console.WriteLine($"Attempted conversion of '{value ?? "
<null>"}' failed.");
            }
         }
      }
   }
// The example displays the following output:
//       Attempted conversion of '<null>' failed.
//       Converted '160519' to 160519.
//       Attempted conversion of '9432.0' failed.
//       Attempted conversion of '16,667' failed.
//       Converted '   -322   ' to -322.
//       Converted '+4302' to 4302.
//       Attempted conversion of '(100);' failed.
//       Attempted conversion of '01FA' failed.
```

Some of the strings that the TryParse(String, Int32) method is unable to convert in this example are:

- "9432.0". The conversion fails because the string cannot contain a decimal separator; it must contain integral digits only.
- "16,667". The conversion fails because the string cannot contain group separators; it must contain integral digits only.
- "(100)". The conversion fails because the string cannot contain a negative sign other than the one defined by the current culture's NumberFormatInfo.NegativeSign and NumberFormatInfo.NumberNegativePattern properties.
- "01FA". The conversion fails because the string cannot contain hexadecimal digits; it must contain decimal digits only.

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Int32.TryParse(String, NumberStyles, IFormatProvider, Int32) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object initialized for the current system culture. For more information, see CurrentInfo.

This overload of the TryParse method interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the Int32.TryParse(String, NumberStyles, IFormatProvider, Int32) overload.

UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, Int32)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out int result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int32

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Int32)

Tries to parse a string into a value.

```
C#
public static bool TryParse (string? s, IFormatProvider? provider, out
int result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int32

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int32)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
int result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int32

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, Int32)

Tries to convert a UTF-8 character span containing the string representation of a number to its 32-bit signed integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out int
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` Int32

When this method returns, contains the 32-bit signed integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int32)

Converts the span representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates

whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
int result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Int32

When this method returns, contains the 32-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int32.MinValue or greater than Int32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Int32)

Converts the string representation of a number in a specified style and culture-specific format to its 32-bit signed integer equivalent. A return value indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out int result);
```

Parameters

`s` String

A string containing a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Int32

When this method returns, contains the 32-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int32.MinValue or greater than Int32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the Int32.TryParse(String, NumberStyles, IFormatProvider, Int32) method with a number of different string and NumberStyles values.

C#

```
using System;
using System.Globalization;

public class StringParsing
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      numericString = "106779";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      numericString = "-30677";
      styles = NumberStyles.None;
      CallTryParse(numericString, styles);

      styles = NumberStyles.AllowLeadingSign;
      CallTryParse(numericString, styles);

      numericString = "301677-";
      CallTryParse(numericString, styles);

      styles = styles | NumberStyles.AllowTrailingSign;
      CallTryParse(numericString, styles);

      numericString = "$10634";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      styles = NumberStyles.Integer | NumberStyles.AllowCurrencySymbol;
```

```
      CallTryParse(numericString, styles);

      numericString = "10345.00";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "10345.72";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "22,593";
      styles = NumberStyles.Integer | NumberStyles.AllowThousands;
      CallTryParse(numericString, styles);

      numericString = "12E-01";
      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(numericString, styles);

      numericString = "12E03";
      CallTryParse(numericString, styles);

      numericString = "80c1";
      CallTryParse(numericString, NumberStyles.HexNumber);

      numericString = "0x80C1";
      CallTryParse(numericString, NumberStyles.HexNumber);
   }

   private static void CallTryParse(string stringToConvert, NumberStyles
styles)
   {
      CultureInfo provider;

      // If currency symbol is allowed, use en-US culture.
      if ((styles & NumberStyles.AllowCurrencySymbol) > 0)
         provider = new CultureInfo("en-US");
      else
         provider = CultureInfo.InvariantCulture;

      bool success = int.TryParse(stringToConvert, styles,
                                  provider, out int number);
      if (success)
         Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
      else
         Console.WriteLine($"Attempted conversion of '{stringToConvert}'
failed.");
   }
}
// The example displays the following output to the console:
//       Converted '106779' to 106779.
//       Attempted conversion of '-30677' failed.
//       Converted '-30677' to -30677.
//       Attempted conversion of '301677-' failed.
//       Converted '301677-' to -301677.
```

```
//       Attempted conversion of '$10634' failed.
//       Converted '$10634' to 10634.
//       Converted '10345.00' to 10345.
//       Attempted conversion of '10345.72' failed.
//       Converted '22,593' to 22593.
//       Attempted conversion of '12E-01' failed.
//       Converted '12E03' to 12000.
//       Converted '80c1' to 32961.
//       Attempted conversion of '0x80C1' failed.
```

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be parsed successfully.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]digits][ws]

Or, if the `style` parameter includes AllowHexSpecifier:

[ws]hexdigits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.

Element	Description
sign	An optional sign. A sign symbol can appear in `s` if `style` includes the NumberStyles.AllowLeadingSign or NumberStyles.AllowTrailingSign flags.
digits	A sequence of digits from 0 through 9.
,	A culture-specific thousands separator. The thousands separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or the method returns `false`.

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation. If `s` represents a number in exponential notation, it must represent an integer within the range of the Int32 data type without a non-zero, fractional component.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The thousands separator (,) element.
NumberStyles.AllowCurrencySymbol	The *$* element.
NumberStyles.Currency	All elements. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
NumberStyles.Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
NumberStyles.Number	The *ws*, *sign*, thousands separator (,), and decimal point (.) elements.
NumberStyles.Any	All styles, except `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "C9AF3" parses successfully, but "0xC9AF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a CultureInfo object or a NumberFormatInfo object, whose GetFormat method returns a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific

information about the format of `s`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Int32.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int32.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int32.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

```
C#
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int32.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Int32.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

```
C#
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int32.IConvertible.To Double(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int32.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int32.IConvertible.To Int32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, unchanged.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int32.IConvertible.To Int64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int32.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToSByte(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int32.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int32.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

```
C#
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The type to which to convert this Int32 value.

`provider` IFormatProvider

An object that provides information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method instead.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int32.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt16(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int32 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt32(Int32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int32.IAdditionOperators<Int32,Int32,Int32>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#
static int IAdditionOperators<int,int,int>.operator + (int left, int right);
```

Parameters

`left` Int32

The value to which `right` is added.

`right` Int32

The value that's added to `left`.

Returns

Int32

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.IBinaryInteger<Int32>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<int>.TryWriteBigEndian (Span<byte> destination, out int
bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IBinaryInteger<Int32>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<int>.TryWriteLittleEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteLittleEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IBinaryNumber<Int32>.AllBitsSet Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an instance of the binary type in which all bits are set.

C#

```
static int System.Numerics.IBinaryNumber<System.Int32>.AllBitsSet { get; }
```

Property Value

Int32

Implements

AllBitsSet

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IBitwiseOperators<Int32,Int32,Int32>.Bitwise And Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#
static int IBitwiseOperators<int,int,int>.operator & (int left, int right);
```

Parameters

`left` Int32

The value to `and` with `right`.

`right` Int32

The value to `and` with `left`.

Returns

Int32

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IBitwiseOperators<Int32,Int32,Int32>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#
static int IBitwiseOperators<int,int,int>.operator | (int left, int right);
```

Parameters

`left` Int32

The value to `or` with `right`.

`right` Int32

The value to `or` with `left`.

Returns

Int32

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IBitwise Operators<Int32,Int32,Int32>.Exclusive Or Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#
static int IBitwiseOperators<int,int,int>.operator ^ (int left, int right);
```

Parameters

`left` Int32

The value to xor with `right`.

`right` Int32

The value to xor with `left`.

Returns

Int32

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IBitwiseOperators<Int32,Int32,Int32>.OnesComplement(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
static int IBitwiseOperators<int,int,int>.operator ~ (int value);
```

Parameters

`value` Int32

The value for which to compute the ones-complement.

Returns

Int32

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IComparisonOperators<Int32,Int32,Boolean>.GreaterThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<int,int,bool>.operator > (int left, int right);
```

Parameters

`left` Int32

The value to compare with `right`.

`right` Int32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IComparisonOperators<Int32,Int32,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<int,int,bool>.operator >= (int left, int right);
```

Parameters

`left` Int32

The value to compare with `right`.

`right` Int32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IComparisonOperators<Int32,Int32,Boolean>.Less Than Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<int,int,bool>.operator < (int left, int right);
```

Parameters

`left` Int32

The value to compare with `right`.

`right` Int32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IComparisonOperators<Int32,Int32,Boolean>.LessThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<int,int,bool>.operator <= (int left, int right);
```

Parameters

`left` Int32

The value to compare with `right`.

`right` Int32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IDecrementOperators<Int32>.CheckedDecrement(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static int IDecrementOperators<int>.op_CheckedDecrement (int value);
```

Parameters

`value` Int32

The value to decrement.

Returns

Int32

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IDecrementOperators<Int32>.Decrement(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static int IDecrementOperators<int>.operator -- (int value);
```

Parameters

`value` Int32

The value to decrement.

Returns

Int32

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IDivisionOperators<Int32,Int32,Int32>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#
static int IDivisionOperators<int,int,int>.operator / (int left, int right);
```

Parameters

`left` Int32

The value that `right` divides.

`right` Int32

The value that divides `left`.

Returns

Int32

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IEqualityOperators<Int32,Int32,Boolean>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<int,int,bool>.operator == (int left, int right);
```

Parameters

`left` Int32

The value to compare with `right`.

`right` Int32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IEqualityOperators<Int32,Int32,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<int,int,bool>.operator != (int left, int right);
```

Parameters

`left` Int32

The value to compare with `right`.

`right` Int32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IIncrementOperators<Int32>.CheckedIncrement(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static int IIncrementOperators<int>.op_CheckedIncrement (int value);
```

Parameters

`value` Int32

The value to increment.

Returns

Int32

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IIncrementOperators<Int32>.Increment(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static int IIncrementOperators<int>.operator ++ (int value);
```

Parameters

`value` Int32

The value to increment.

Returns

Int32

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IMinMaxValue<Int32>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static int System.Numerics.IMinMaxValue<System.Int32>.MaxValue { get; }
```

Property Value

Int32

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IMinMaxValue<Int32>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static int System.Numerics.IMinMaxValue<System.Int32>.MinValue { get; }
```

Property Value

Int32

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IModulusOperators<Int32,Int32,Int32>.Modulus(Int32, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#
static int IModulusOperators<int,int,int>.operator % (int left, int right);
```

Parameters

`left` Int32

The value that `right` divides.

`right` Int32

The value that divides `left`.

Returns

Int32

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IMultiplyOperators<Int32,Int32,Int32>.CheckedMultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static int IMultiplyOperators<int,int,int>.op_CheckedMultiply (int left, int
right);
```

Parameters

left Int32

The value that `right` multiplies.

right Int32

The value that multiplies `left`.

Returns

Int32

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IMultiplyOperators<Int32,Int32,Int32>.MultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#
static int IMultiplyOperators<int,int,int>.operator * (int left, int right);
```

Parameters

`left` Int32

The value that `right` multiplies.

`right` Int32

The value that multiplies `left`.

Returns

Int32

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumber<Int32>.MaxNumber(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static int INumber<int>.MaxNumber (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.INumber<Int32>.MinNumber(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static int INumber<int>.MinNumber (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsCanonical(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<int>.IsCanonical (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsComplexNumber(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<int>.IsComplexNumber (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsFinite(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<int>.IsFinite (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsImaginaryNumber(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

```
C#
static bool INumberBase<int>.IsImaginaryNumber (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsInfinity(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<int>.IsInfinity (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsInteger(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<int>.IsInteger (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsNaN(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<int>.IsNaN (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsNegativeInfinity(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

```
C#
static bool INumberBase<int>.IsNegativeInfinity (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsNormal(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<int>.IsNormal (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsPositiveInfinity(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive infinity.

```
C#
static bool INumberBase<int>.IsPositiveInfinity (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is positive infinity; otherwise, `false`.

Implements

IsPositiveInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsRealNumber(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<int>.IsRealNumber (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsSubnormal(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is subnormal.

```
C#
static bool INumberBase<int>.IsSubnormal (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is subnormal; otherwise, `false`.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.IsZero(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<int>.IsZero (int value);
```

Parameters

`value` Int32

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.INumberBase<Int32>.MaxMagnitudeNumber(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#

static int INumberBase<int>.MaxMagnitudeNumber (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.MinMagnitudeNumber(Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

```
C#

static int INumberBase<int>.MinMagnitudeNumber (int x, int y);
```

Parameters

x Int32

The value to compare with `y`.

y Int32

The value to compare with `x`.

Returns

Int32

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.One Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `1` for the type.

```
C#
static int System.Numerics.INumberBase<System.Int32>.One { get; }
```

Property Value

Int32

Implements

One

Applies to

Product	Versions
.NET	7, 8, 9

Int32.INumberBase<Int32>.Radix Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the radix, or base, for the type.

C#

```
static int System.Numerics.INumberBase<System.Int32>.Radix { get; }
```

Property Value

Int32

Implements

Radix

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.INumberBase<Int32>.TryConvertFromChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<int>.TryConvertFromChecked<TOther> (TOther value,
out int result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Int32

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

Int32.INumberBase<Int32>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<int>.TryConvertToChecked<TOther> (int value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int32

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.INumberBase<Int32>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<int>.TryConvertToSaturating<TOther> (int value, out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int32

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.INumberBase<Int32>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<int>.TryConvertToTruncating<TOther> (int value, out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int32

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int32.IShift Operators<Int32,Int32,Int32>.Left Shift(Int32, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static int IShiftOperators<int,int,int>.operator << (int value, int
shiftAmount);
```

Parameters

`value` Int32

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

Int32

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IShift Operators<Int32,Int32,Int32>.RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static int IShiftOperators<int,int,int>.operator >> (int value, int
shiftAmount);
```

Parameters

`value` Int32

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int32

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IShift Operators<Int32,Int32,Int32>.Unsigned RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static int IShiftOperators<int,int,int>.op_UnsignedRightShift (int value,
int shiftAmount);
```

Parameters

`value` Int32

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int32

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.ISubtractionOperators<Int32,Int32,Int32>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static int ISubtractionOperators<int,int,int>.op_CheckedSubtraction (int
left, int right);
```

Parameters

`left` Int32

The value from which `right` is subtracted.

`right` Int32

The value that's subtracted from `left`.

Returns

Int32

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.ISubtractionOperators<Int32,Int32,Int32>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static int ISubtractionOperators<int,int,int>.operator - (int left, int
right);
```

Parameters

`left` Int32

The value from which `right` is subtracted.

`right` Int32

The value that's subtracted from `left`.

Returns

Int32

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IUnaryNegationOperators<Int32,Int32>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static int IUnaryNegationOperators<int,int>.op_CheckedUnaryNegation (int
value);
```

Parameters

`value` Int32

The value for which to compute the unary negation.

Returns

Int32

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int32.IUnaryNegationOperators<Int32,Int32>.UnaryNegation(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static int IUnaryNegationOperators<int,int>.operator - (int value);
```

Parameters

`value` Int32

The value for which to compute the unary negation.

Returns

Int32

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int32.IUnaryPlusOperators<Int32,Int32>.UnaryPlus(Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static int IUnaryPlusOperators<int,int>.operator + (int value);
```

Parameters

`value` Int32

The value for which to compute the unary plus.

Returns

Int32

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Remarks

For more information about this API, see Supplemental API remarks for Int64.

Fields

Expand table

MaxValue	Represents the largest possible value of an Int64. This field is constant.
MinValue	Represents the smallest possible value of an Int64. This field is constant.

Methods

Expand table

Abs(Int64)	Computes the absolute of a value.
Clamp(Int64, Int64, Int64)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Int64)	Compares this instance to a specified 64-bit signed integer and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CopySign(Int64, Int64)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(Int64, Int64)	Computes the quotient and remainder of two values.
Equals(Int64)	Returns a value indicating whether this instance is equal to a specified Int64 value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type Int64.
IsEvenInteger(Int64)	Determines if a value represents an even integral number.

IsNegative(Int64)	Determines if a value is negative.
IsOddInteger(Int64)	Determines if a value represents an odd integral number.
IsPositive(Int64)	Determines if a value is positive.
IsPow2(Int64)	Determines if a value is a power of two.
LeadingZeroCount(Int64)	Computes the number of leading zeros in a value.
Log2(Int64)	Computes the log2 of a value.
Max(Int64, Int64)	Compares two values to compute which is greater.
MaxMagnitude(Int64, Int64)	Compares two values to compute which is greater.
Min(Int64, Int64)	Compares two values to compute which is lesser.
MinMagnitude(Int64, Int64)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent.
Parse(String)	Converts the string representation of a number to its 64-bit signed integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 64-bit signed integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 64-bit signed integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent.
PopCount(Int64)	Computes the number of bits that are set in a value.
RotateLeft(Int64, Int32)	Rotates a value left by a given amount.
RotateRight(Int64, Int32)	Rotates a value right by a given amount.

Sign(Int64)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
TrailingZeroCount(Int64)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current long number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int64)	Tries to convert a UTF-8 character span containing the string representation of a number to its 64-bit signed integer equivalent.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int64)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, Int64)	Converts the span representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int64)	Converts the span representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, Int64)	Tries to parse a string into a value.

TryParse(String, Int64)	Converts the string representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Int64)	Converts the string representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<Int64,Int64,Int64>.Addition(Int64, Int64)	Adds two values together to compute their sum.
IAdditionOperators<Int64,Int64,Int64>.Checked Addition(Int64, Int64)	Adds two values together to compute their sum.
IAdditiveIdentity<Int64,Int64>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<Int64>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<Int64>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<Int64>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, Int64)	
IBinaryInteger<Int64>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, Int64)	
IBinaryInteger<Int64>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<Int64>.TryWriteLittle Endian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<Int64>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<Int64,Int64,Int64>.BitwiseAnd(Int64, Int64)	Computes the bitwise-and of two values.
IBitwiseOperators<Int64,Int64,Int64>.BitwiseOr(Int64, Int64)	Computes the bitwise-or of two values.

IBitwiseOperators<Int64,Int64,Int64>.ExclusiveOr(Int64, Int64)	Computes the exclusive-or of two values.
IBitwiseOperators<Int64,Int64,Int64>.Ones Complement(Int64)	Computes the ones-complement representation of a given value.
IComparisonOperators<Int64,Int64,Boolean>.Greater Than(Int64, Int64)	Compares two values to determine which is greater.
IComparisonOperators<Int64,Int64,Boolean>.Greater ThanOrEqual(Int64, Int64)	Compares two values to determine which is greater or equal.
IComparisonOperators<Int64,Int64,Boolean>.Less Than(Int64, Int64)	Compares two values to determine which is less.
IComparisonOperators<Int64,Int64,Boolean>.LessThan OrEqual(Int64, Int64)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).

IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<Int64>.Checked Decrement(Int64)	Decrements a value.
IDecrementOperators<Int64>.Decrement(Int64)	Decrements a value.
IDivisionOperators<Int64,Int64,Int64>.Division(Int64, Int64)	Divides one value by another to compute their quotient.
IEquality Operators<Int64,Int64,Boolean>.Equality(Int64, Int64)	Compares two values to determine equality.
IEquality Operators<Int64,Int64,Boolean>.Inequality(Int64, Int64)	Compares two values to determine inequality.
IIncrementOperators<Int64>.CheckedIncrement(Int64)	Increments a value.
IIncrementOperators<Int64>.Increment(Int64)	Increments a value.
IMinMaxValue<Int64>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Int64>.MinValue	Gets the minimum value of the current type.
IModulusOperators<Int64,Int64,Int64>.Modulus(Int64, Int64)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Int64,Int64>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiplyOperators<Int64,Int64,Int64>.Checked Multiply(Int64, Int64)	Multiplies two values together to compute their product.
IMultiplyOperators<Int64,Int64,Int64>.Multiply(Int64, Int64)	Multiplies two values together to compute their product.
INumber<Int64>.MaxNumber(Int64, Int64)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.

INumber<Int64>.MinNumber(Int64, Int64)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<Int64>.IsCanonical(Int64)	Determines if a value is in its canonical representation.
INumberBase<Int64>.IsComplexNumber(Int64)	Determines if a value represents a complex number.
INumberBase<Int64>.IsFinite(Int64)	Determines if a value is finite.
INumberBase<Int64>.IsImaginaryNumber(Int64)	Determines if a value represents a pure imaginary number.
INumberBase<Int64>.IsInfinity(Int64)	Determines if a value is infinite.
INumberBase<Int64>.IsInteger(Int64)	Determines if a value represents an integral number.
INumberBase<Int64>.IsNaN(Int64)	Determines if a value is NaN.
INumberBase<Int64>.IsNegativeInfinity(Int64)	Determines if a value is negative infinity.
INumberBase<Int64>.IsNormal(Int64)	Determines if a value is normal.
INumberBase<Int64>.IsPositiveInfinity(Int64)	Determines if a value is positive infinity.
INumberBase<Int64>.IsRealNumber(Int64)	Determines if a value represents a real number.
INumberBase<Int64>.IsSubnormal(Int64)	Determines if a value is subnormal.
INumberBase<Int64>.IsZero(Int64)	Determines if a value is zero.
INumberBase<Int64>.MaxMagnitudeNumber(Int64, Int64)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<Int64>.MinMagnitudeNumber(Int64, Int64)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<Int64>.One	Gets the value `1` for the type.
INumberBase<Int64>.Radix	Gets the radix, or base, for the type.
INumberBase<Int64>.TryConvertFromChecked<TOther>(TOther, Int64)	
INumberBase<Int64>.TryConvertFromSaturating<TOther>(TOther, Int64)	

INumberBase<Int64>.TryConvertFromTruncating<TOther>(TOther, Int64)	
INumberBase<Int64>.TryConvertToChecked<TOther>(Int64, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Int64>.TryConvertToSaturating<TOther>(Int64, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<Int64>.TryConvertToTruncating<TOther>(Int64, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Int64>.Zero	Gets the value `0` for the type.
IShiftOperators<Int64,Int32,Int64>.LeftShift(Int64, Int32)	Shifts a value left by a given amount.
IShiftOperators<Int64,Int32,Int64>.RightShift(Int64, Int32)	Shifts a value right by a given amount.
IShiftOperators<Int64,Int32,Int64>.UnsignedRightShift(Int64, Int32)	Shifts a value right by a given amount.
ISignedNumber<Int64>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<Int64,Int64,Int64>.CheckedSubtraction(Int64, Int64)	Subtracts two values to compute their difference.
ISubtractionOperators<Int64,Int64,Int64>.Subtraction(Int64, Int64)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Int64,Int64>.CheckedUnaryNegation(Int64)	Computes the checked unary negation of a value.
IUnaryNegationOperators<Int64,Int64>.UnaryNegation(Int64)	Computes the unary negation of a value.
IUnaryPlusOperators<Int64,Int64>.UnaryPlus(Int64)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Int64.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of an Int64. This field is constant.

```
C#
public const long MaxValue = 9223372036854775807;
```

Field Value

Value = 9223372036854775807

Int64

Remarks

The value of this constant is 9,223,372,036,854,775,807; that is, hexadecimal 0x7FFFFFFFFFFFFFFF.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int64.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of an Int64. This field is constant.

C#

```
public const long MinValue = -9223372036854775808;
```

Field Value

***Value* = -9223372036854775808**

Int64

Remarks

The value of this constant is negative 9,223,372,036,854,775,808; that is, hexadecimal 0x8000000000000000.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.Abs(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static long Abs (long value);
```

Parameters

`value` Int64

The value for which to get its absolute.

Returns

Int64

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.Clamp(Int64, Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static long Clamp (long value, long min, long max);
```

Parameters

`value` Int64

The value to clamp.

`min` Int64

The inclusive minimum to which `value` should clamp.

`max` Int64

The inclusive maximum to which `value` should clamp.

Returns

Int64

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or Int64 and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Int64)	Compares this instance to a specified 64-bit signed integer and returns an indication of their relative values.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.

CompareTo(Int64)

Compares this instance to a specified 64-bit signed integer and returns an indication of their relative values.

C#

```
public int CompareTo (long value);
```

Parameters

`value` Int64

An integer to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");
```

```

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                            resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
```

```
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the Int64.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.

Return Value	Description
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not an Int64.

Remarks

An Int64, regardless of its value, is considered greater than a null reference.

The `value` parameter must be `null` or an instance of Int64; otherwise, an exception is thrown.

Int64.CopySign(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

```
C#
public static long CopySign (long value, long sign);
```

Parameters

`value` Int64

The value whose magnitude is used in the result.

`sign` Int64

The value whose sign is used in the result.

Returns

Int64

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static long CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int64

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static long CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int64

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.CreateTruncating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static long CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Int64

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.DivRem(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (long Quotient, long Remainder) DivRem (long left, long
right);
```

Parameters

`left` Int64

The value which `right` divides.

`right` Int64

The value which divides `left`.

Returns

ValueTuple<Int64,Int64>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or Int64.

Overloads

Expand table

Equals(Int64)	Returns a value indicating whether this instance is equal to a specified Int64 value.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(Int64)

Returns a value indicating whether this instance is equal to a specified Int64 value.

C#

```
public bool Equals (long obj);
```

Parameters

obj Int64

An Int64 value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Int64) method overloads. If an implicit conversion between the `obj` argument and an Int64 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(Int64) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not an Int64 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte, SByte, Int16, UInt16, Int32, and UInt32 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Int64) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static long value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,15}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,15}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,17}", value.Equals(int1));
      TestObjectForEquality(int1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,15}", value.Equals(sbyte1));
```

```
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,15}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,17}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,20}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,19}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:            True
//       112 (Int64) = 112 (Byte): False
//
//       value = short1:            True
//       112 (Int64) = 112 (Int16): False
//
//       value = int1:              True
//       112 (Int64) = 112 (Int32): False
//
//       value = sbyte1:            True
//       112 (Int64) = 112 (SByte): False
//
//       value = ushort1:            True
//       112 (Int64) = 112 (UInt16): False
//
//       value = uint1:              True
//       112 (Int64) = 112 (UInt32): False
//
//       value = dec1:                False
//       112 (Int64) = 112 (Decimal): False
//
//       value = dbl1:               False
//       112 (Int64) = 112 (Double): False
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is an instance of an Int64 and equals the value of this instance; otherwise, `false`.

Examples

The following code example illustrates the use of `Equals` in the context of `Int64`, comparing two long values and returning `true` if they represent the same number, or `false` if they do not.

C#

```
Int64 myVariable1 = 80;
Int64 myVariable2 = 80;

// Get and display the declaring type.
Console.WriteLine("\nType of 'myVariable1' is '{0}' and"+
     " value is :{1}",myVariable1.GetType(), myVariable1);
Console.WriteLine("Type of 'myVariable2' is '{0}' and"+
     " value is :{1}",myVariable2.GetType(), myVariable2);

// Compare 'myVariable1' instance with 'myVariable2' Object.
if( myVariable1.Equals( myVariable2 ) )
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are equal");
else
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are not equal");
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Int64) method overloads. If an implicit conversion between the `obj` argument and an Int64 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(Int64) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not an Int64 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte, SByte, Int16, UInt16, Int32, and UInt32 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Int64) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static long value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,15}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,15}", value.Equals(short1));
```

```
        TestObjectForEquality(short1);

        int int1 = 112;
        Console.WriteLine("value = int1: {0,17}", value.Equals(int1));
        TestObjectForEquality(int1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,15}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,15}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,17}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,20}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,19}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:            True
//       112 (Int64) = 112 (Byte): False
//
//       value = short1:            True
//       112 (Int64) = 112 (Int16): False
//
//       value = int1:              True
//       112 (Int64) = 112 (Int32): False
//
//       value = sbyte1:            True
//       112 (Int64) = 112 (SByte): False
//
//       value = ushort1:            True
//       112 (Int64) = 112 (UInt16): False
//
//       value = uint1:              True
//       112 (Int64) = 112 (UInt32): False
//
```

```
//       value = dec1:                 False
//       112 (Int64) = 112 (Decimal): False
//
//       value = dbl1:                False
//       112 (Int64) = 112 (Double): False
```

Int64.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Int64.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Int64.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int64.IsEvenInteger(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IsNegative(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Int64.IsOddInteger(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (long value);
```

Parameters

value Int64

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Int64.IsPositive(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Int64.IsPow2(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.LeadingZeroCount(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static long LeadingZeroCount (long value);
```

Parameters

`value` Int64

The value whose leading zeroes are to be counted.

Returns

Int64

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.Log2(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static long Log2 (long value);
```

Parameters

`value` Int64

The value whose log2 is to be computed.

Returns

Int64

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.Max(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static long Max (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.MaxMagnitude(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static long MaxMagnitude (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.Min(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static long Min (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Int64.MinMagnitude(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static long MinMagnitude (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `minimumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Int64.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 64-bit signed integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 64-bit signed integer equivalent.
Parse(String)	Converts the string representation of a number to its 64-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 64-bit signed integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent.

```
C#

public static long Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information about `s`.

Returns

Int64

A 64-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than Int64.MinValue or greater than Int64.MaxValue.

-or-

`style` supports fractional digits, but `s` includes non-zero fractional digits.

Examples

The following example uses a variety of `style` and `provider` parameters to parse the string representations of Int64 values. It also illustrates some of the different ways the same string can be interpreted depending on the culture whose formatting information is used for the parsing operation.

C#

```
using System;
using System.Globalization;

public class ParseInt64
{
   public static void Main()
   {
      Convert("12,000", NumberStyles.Float | NumberStyles.AllowThousands,
              new CultureInfo("en-GB"));
      Convert("12,000", NumberStyles.Float | NumberStyles.AllowThousands,
              new CultureInfo("fr-FR"));
      Convert("12,000", NumberStyles.Float, new CultureInfo("en-US"));

      Convert("12 425,00", NumberStyles.Float |
NumberStyles.AllowThousands,
              new CultureInfo("sv-SE"));
      Convert("12,425.00", NumberStyles.Float |
NumberStyles.AllowThousands,
              NumberFormatInfo.InvariantInfo);
      Convert("631,900", NumberStyles.Integer |
NumberStyles.AllowDecimalPoint,
              new CultureInfo("fr-FR"));
      Convert("631,900", NumberStyles.Integer |
NumberStyles.AllowDecimalPoint,
              new CultureInfo("en-US"));
      Convert("631,900", NumberStyles.Integer |
NumberStyles.AllowThousands,
              new CultureInfo("en-US"));
   }
```

```
    private static void Convert(string value, NumberStyles style,
                                IFormatProvider provider)
    {
       try
       {
          long number = Int64.Parse(value, style, provider);
          Console.WriteLine("Converted '{0}' to {1}.", value, number);
       }
       catch (FormatException)
       {
          Console.WriteLine("Unable to convert '{0}'.", value);
       }
       catch (OverflowException)
       {
          Console.WriteLine("'{0}' is out of range of the Int64 type.",
value);
       }
    }
}
// This example displays the following output to the console:
//       Converted '12,000' to 12000.
//       Converted '12,000' to 12.
//       Unable to convert '12,000'.
//       Converted '12 425,00' to 12425.
//       Converted '12,425.00' to 12425.
//       '631,900' is out of range of the Int64 type.
//       Unable to convert '631,900'.
//       Converted '631,900' to 631900.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]exponential_digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag or at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9.
,	A culture-specific thousands separator symbol. The thousands separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, an OverflowException is thrown.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

Note

Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Int64 type. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements. However, *fractional-digits* must consist of only one or more 0 digits or an OverflowException is thrown.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The thousands separator (,) element.
NumberStyles.AllowCurrencySymbol	The *$* element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "C9AF3" parses successfully, but "0xC9AF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information used in parsing. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the span representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent.

C#

```
public static long Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information about `s`.

Returns

Int64

A 64-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static long Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int64

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its 64-bit signed integer equivalent.

```
C#
public static long Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Int64

A 64-bit signed integer equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to an Int64 value.

C#

```
protected void OkToLong_Click(object sender, EventArgs e)
{
    string locale;
    long number;
    CultureInfo culture;

    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;

    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
```

```
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = Int64.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
        return;
    }
    catch (Exception)
    {
        return;
    }
    // Output number to label on web form
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

This overload of the Parse(String, IFormatProvider) method is typically used to convert text that can be formatted in a variety of ways to an Int64 value. For example, it can be used to convert the text entered by a user into an HTML text box to a numeric value.

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Items in square brackets ([and]) are optional, and other items are as follows.

ws An optional white space.

sign An optional sign.

digits A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements that can be present in `s`, use the Int64.Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation, such as a NumberFormatInfo or CultureInfo object. The `provider` parameter supplies culture-specific information about the format of `s`. If `provider` is `null`, the NumberFormatInfo for the current culture is used.

UWP	10.0

Parse(String)

Converts the string representation of a number to its 64-bit signed integer equivalent.

C#

```
public static long Parse (string s);
```

Parameters

s String

A string containing a number to convert.

Returns

Int64

A 64-bit signed integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than Int64.MinValue or greater than Int64.MaxValue.

Examples

The following example demonstrates how to convert a string value into a 64-bit signed integer value using the Int64.Parse(String) method. It then displays the resulting long integer value.

C#

```
using System;

public class ParseInt64
{
   public static void Main()
   {
      Convert("  179042  ");
      Convert(" -2041326 ");
      Convert(" +8091522 ");
      Convert("   1064.0   ");
      Convert("  178.3");
      Convert(String.Empty);
      Convert(((decimal) Int64.MaxValue) + 1.ToString());
   }

   private static void Convert(string value)
   {
      try
      {
         long number = Int64.Parse(value);
         Console.WriteLine("Converted '{0}' to {1}.", value, number);
      }
      catch (FormatException)
```

```
        {
            Console.WriteLine("Unable to convert '{0}'.", value);
        }
        catch (OverflowException)
        {
            Console.WriteLine("'{0}' is out of range.", value);
        }
    }
}
// This example displays the following output to the console:
//       Converted '   179042   ' to 179042.
//       Converted ' -2041326 ' to -2041326.
//       Converted ' +8091522 ' to 8091522.
//       Unable to convert '    1064.0    '.
//       Unable to convert '   178.3'.
//       Unable to convert ''.
//       '92233720368547758071' is out of range.
```

Remarks

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements that can be present in `s`, use either the Int64.Parse(String, NumberStyles) or the Int64.Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To parse a string using the formatting information of some other culture, use the Int64.Parse(String, NumberStyles, IFormatProvider) method.

- ToString()
- Parsing Numeric Strings in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#

public static long Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Int64

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static long Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Int64

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its 64-bit signed integer equivalent.

C#

```
public static long Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of NumberStyles values that indicates the permitted format of `s`. A typical value to specify is Integer.

Returns

Int64

A 64-bit signed integer equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than Int64.MinValue or greater than Int64.MaxValue.

-or-

`style` supports fractional digits but `s` includes non-zero fractional digits.

Examples

The following example uses the Int64.Parse(String, NumberStyles) method to parse the string representations of several Int64 values. The current culture for the example is en-US.

C#

```
using System;
using System.Globalization;

public class ParseInt32
{
   public static void Main()
   {
      Convert("104.0", NumberStyles.AllowDecimalPoint);
      Convert("104.9", NumberStyles.AllowDecimalPoint);
      Convert (" 106034", NumberStyles.None);
      Convert(" $17,198,064.42", NumberStyles.AllowCurrencySymbol |
                                 NumberStyles.Number);
      Convert(" $17,198,064.00", NumberStyles.AllowCurrencySymbol |
                                 NumberStyles.Number);
      Convert("103E06", NumberStyles.AllowExponent);
      Convert("1200E-02", NumberStyles.AllowExponent);
      Convert("1200E-03", NumberStyles.AllowExponent);
      Convert("-1,345,791", NumberStyles.AllowThousands);
      Convert("(1,345,791)", NumberStyles.AllowThousands |
                             NumberStyles.AllowParentheses);
      Convert("FFCA00A0", NumberStyles.HexNumber);
      Convert("0xFFCA00A0", NumberStyles.HexNumber);
   }

   private static void Convert(string value, NumberStyles style)
   {
      try
      {
         long number = Int64.Parse(value, style);
         Console.WriteLine("Converted '{0}' to {1}.", value, number);
      }
      catch (FormatException)
```

```
        {
            Console.WriteLine("Unable to convert '{0}'.", value);
        }
        catch (OverflowException)
        {
            Console.WriteLine("'{0}' is out of range of the Int64 type.",
value);
        }
    }
}
// The example displays the following output to the console:
//       Converted '104.0' to 104.
//       '104.9' is out of range of the Int64 type.
//       Unable to convert ' 106034'.
//       ' $17,198,064.42' is out of range of the Int64 type.
//       Converted ' $17,198,064.00' to 17198064.
//       Converted '103E06' to 103000000.
//       Converted '1200E-02' to 12.
//       '1200E-03' is out of range of the Int64 type.
//       Unable to convert '-1,345,791'.
//       Converted '(1,345,791)' to -1345791.
//       Converted 'FFCA00A0' to 4291428512.
//       Unable to convert '0xFFCA00A0'.
```

Remarks

The `style` parameter defines the style elements (such as white space, the positive or negative sign symbol, or the thousands separator symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may contain the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]exponential_digits][ws]

Or, if `style` includes AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can

Element	Description
	appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.
,	A culture-specific thousands separator symbol. The current culture's thousands separator can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, an OverflowException is thrown.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Int64 type. Most of the remaining NumberStyles members control elements that may be but are not required to be

present in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in s in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The `s` parameter can also use exponential notation. If `s` represents a number in exponential notation, the resulting numeric value cannot include any non-zero fractional digits.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The thousands separator (,) element.
AllowCurrencySymbol	The *$* element.
Currency	All. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The *ws*, *sign*, thousands separator (,), and decimal point (.) elements.
Any	All styles, except `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "C9AF3" parses successfully, but "0xC9AF3" does not. The only other flags that can be combined with the `s` parameter are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white space flags.)

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To specify the culture whose formatting information is used for the parse operation, call the Int64.Parse(String, NumberStyles, IFormatProvider) overload.

Int64.PopCount(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static long PopCount (long value);
```

Parameters

`value` Int64

The value whose set bits are to be counted.

Returns

Int64

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.RotateLeft(Int64, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

C#

```
public static long RotateLeft (long value, int rotateAmount);
```

Parameters

`value` Int64

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

Int64

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.RotateRight(Int64, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

C#

```
public static long RotateRight (long value, int rotateAmount);
```

Parameters

`value` Int64

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

Int64

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.Sign(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (long value);
```

Parameters

`value` Int64

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, consisting of a minus sign if the value is negative, and a sequence of digits ranging from 0 to 9 with no leading zeroes.

Examples

The following example displays an Int64 value using the default ToString() method. It also displays the string representations of the Int64 value that results from using a number of standard format specifiers. The examples are displayed using the formatting conventions of the en-US culture.

C#

```
long value = -16325091;
// Display value using default ToString method.
Console.WriteLine(value.ToString());            // Displays -16325091
// Display value using some standard format specifiers.
Console.WriteLine(value.ToString("G"));         // Displays -16325091
Console.WriteLine(value.ToString("C"));         // Displays
($16,325,091.00)
Console.WriteLine(value.ToString("D"));         // Displays -16325091
Console.WriteLine(value.ToString("F"));         // Displays -16325091.00
Console.WriteLine(value.ToString("N"));         // Displays
-16,325,091.00
Console.WriteLine(value.ToString("N0"));         // Displays -16,325,091
Console.WriteLine(value.ToString("X"));         // Displays
FFFFFFFFFF06E61D
```

Remarks

The ToString() method formats an Int64 value in the default ("G", or general) format by using the NumberFormatInfo object of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

See also

- Parse(String)
- String
- Formatting Types in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An IFormatProvider that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example displays the string representation of an Int64 value using CultureInfo objects that represent several different cultures.

C#

```
long value = -16325901;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));
// This example displays the following output to the console:
//       -16325901
//       -16325901
//       -16325901
```

Remarks

The ToString(IFormatProvider) method formats an Int64 value in the default ("G", or general) format by using the NumberFormatInfo object of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)

To use format	For culture	Use the overload
A specific format	A specific culture	ToString(String, IFormatProvider)

The `provider` parameter is an object that implements the IFormatProvider interface. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.
- A NumberFormatInfo object that contains specific numeric formatting information for this value.
- A custom object that implements IFormatProvider and whose GetFormat method returns a NumberFormatInfo object that provides formatting information.

If `provider` is `null` or a NumberFormatInfo object cannot be obtained from `provider`, the return value is formatted with the NumberFormatInfo object for the current culture.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

See also

- Parse(String)
- String
- Formatting Types in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

```
C#
public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid or not supported.

Examples

The following example displays an Int64 value using each of the supported standard numeric format specifiers together with two custom numeric format strings. In converting the numeric values to strings, the example uses the formatting conventions of the en-US culture.

C#

```
long value = -16325;
string specifier;

// Use standard numeric format specifier.
specifier = "G";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    G: -16325
specifier = "C";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    C: ($16,325.00)
specifier = "D8";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    D8: -00016325
specifier = "E4";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    E4: -1.6325E+004
specifier = "e3";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    e3: -1.633e+004
specifier = "F";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    F: -16325.00
specifier = "N";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    N: -16,325.00
specifier = "P";
Console.WriteLine("{0}: {1}", specifier,
(value/100000.0).ToString(specifier));
// Displays:    P: -16.33 %
specifier = "X";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    X: FFFFFFFFFFFFC03B

// Use custom numeric format specifiers.
specifier = "0,0.000";
Console.WriteLine("{0}: {1}", specifier, value.ToString(specifier));
// Displays:    0,0.000: -16,325.000
specifier = "#,#.00#;(#,#.00#)";
Console.WriteLine("{0}: {1}", specifier, (value*-1).ToString(specifier));
// Displays:    #,#.00#;(#,#.00#): 16,325.00
```

Remarks

The ToString(String) method formats an Int64 value in a specified format by using a NumberFormatInfo object that represents the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be any valid standard numeric format specifier except for "R", as well as any combination of custom numeric format specifiers. If `format` is `null` or an empty string (""), the return value of this instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The return value of this instance is formatted with the NumberFormatInfo for the current culture.

UWP	10.0

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about this instance.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` is invalid or not supported.

Examples

The following example displays a positive and a negative value using each of the supported standard numeric format specifiers for three different cultures.

C#

```
// Define cultures whose formatting conventions are to be used.
CultureInfo[] cultures = {CultureInfo.CreateSpecificCulture("en-US"),
                          CultureInfo.CreateSpecificCulture("fr-FR"),
                          CultureInfo.CreateSpecificCulture("es-ES") };
long positiveNumber = 1679;
long negativeNumber = -3045;
string[] specifiers = {"G", "C", "D8", "E2", "F", "N", "N0", "P", "X8"};

foreach (string specifier in specifiers)
{
   foreach (CultureInfo culture in cultures)
   {
      // Display values with "G" format specifier.
      Console.WriteLine("{0} format using {1} culture: {2, 16} {3, 16}",
                        specifier, culture.Name,
                        positiveNumber.ToString(specifier, culture),
                        negativeNumber.ToString(specifier, culture));
   }
   Console.WriteLine();
}
// The example displays the following output to the console:
//    G format using en-US culture:             1679            -3045
//    G format using fr-FR culture:             1679            -3045
//    G format using es-ES culture:             1679            -3045
//
//    C format using en-US culture:        $1,679.00      ($3,045.00)
//    C format using fr-FR culture:       1 679,00 €      -3 045,00 €
//    C format using es-ES culture:       1.679,00 €      -3.045,00 €
//
//    D8 format using en-US culture:         00001679        -00003045
//    D8 format using fr-FR culture:         00001679        -00003045
//    D8 format using es-ES culture:         00001679        -00003045
//
//    E2 format using en-US culture:        1.68E+003       -3.05E+003
//    E2 format using fr-FR culture:        1,68E+003       -3,05E+003
//    E2 format using es-ES culture:        1,68E+003       -3,05E+003
//
//    F format using en-US culture:          1679.00         -3045.00
//    F format using fr-FR culture:          1679,00         -3045,00
//    F format using es-ES culture:          1679,00         -3045,00
//
//    N format using en-US culture:         1,679.00        -3,045.00
//    N format using fr-FR culture:         1 679,00        -3 045,00
//    N format using es-ES culture:         1.679,00        -3.045,00
//
//    N0 format using en-US culture:         1,679           -3,045
```

```
//    N0 format using fr-FR culture:         1 679           -3 045
//    N0 format using es-ES culture:         1.679           -3.045
//
//    P format using en-US culture:      167,900.00%     -304,500.00%
//    P format using fr-FR culture:     167 900,00 %    -304 500,00 %
//    P format using es-ES culture:     167.900,00 %    -304.500,00 %
//
//    X8 format using en-US culture:         0000068F FFFFFFFFFFFFF41B
//    X8 format using fr-FR culture:         0000068F FFFFFFFFFFFFF41B
//    X8 format using es-ES culture:         0000068F FFFFFFFFFFFFF41B
```

Remarks

The ToString(String, IFormatProvider) method formats an Int64 value in a specified format by using the NumberFormatInfo object of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be either a standard or a custom numeric format string. All standard numeric format strings other than "R" (or "r") are supported, as are all custom numeric format characters. If `format` is `null` or an empty string (""), the return value for this instance is formatted with the general numeric format specifier ("G").

The `provider` parameter is an object that implements the IFormatProvider interface. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string that is returned by this method. The object that implements IFormatProvider can be any of the following:

- A CultureInfo object that represents the culture whose formatting rules are to be used.
- A NumberFormatInfo object that contains specific numeric formatting information for this value.

- A custom object that implements IFormatProvider and whose GetFormat method returns a NumberFormatInfo object that provides formatting information.

If `provider` is `null` or a NumberFormatInfo object cannot be obtained from `provider`, the return value for this instance is formatted with the NumberFormatInfo for the current culture.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.

- For more information about formatting, see Formatting Types.

Int64.TrailingZeroCount(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static long TrailingZeroCount (long value);
```

Parameters

`value` Int64

The value whose trailing zeroes are to be counted.

Returns

Int64

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current long number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current long number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Int64.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, Int64)	Converts the span representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Int64)	Converts the string representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Int64)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, Int64)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Int64)	Tries to convert a UTF-8 character span containing the string representation of a number to its 64-bit signed integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int64)	Converts the span representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Int64)	Converts the string representation of a number in a specified style and culture-specific format to its 64-bit

	signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Int64)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out long result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int64

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, Int64)

Converts the span representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out long result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`result` Int64

When this method returns, contains the 64-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than Int64.MinValue or greater than Int64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Int64)

Converts the string representation of a number to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (string? s, out long result);
```

Parameters

s String

A string containing a number to convert.

result Int64

When this method returns, contains the 64-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than Int64.MinValue or greater than Int64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the Int64.TryParse(String, Int64) method with a number of different string values.

```
C#

using System;

public class StringParsing
{
   public static void Main()
   {
      TryToParse(null);
      TryToParse("160519");
      TryToParse("9432.0");
      TryToParse("16,667");
      TryToParse("   -322   ");
      TryToParse("+4302");
      TryToParse("(100);");
      TryToParse("01FA");
   }
```

```
    private static void TryToParse(string value)
    {
       bool success = Int64.TryParse(value, out long number);
       if (success)
       {
          Console.WriteLine("Converted '{0}' to {1}.", value, number);
       }
       else
       {
          if (value == null) value = "";
          Console.WriteLine("Attempted conversion of '{0}' failed.",
value);
       }
    }
}
// The example displays the following output to the console:
//       Attempted conversion of '' failed.
//       Converted '160519' to 160519.
//       Attempted conversion of '9432.0' failed.
//       Attempted conversion of '16,667' failed.
//       Converted '   -322   ' to -322.
//       Converted '+4302' to 4302.
//       Attempted conversion of '(100);' failed.
//       Attempted conversion of '01FA' failed.
```

Some of the strings that the TryParse(String, Int64) method is unable to convert in this example are:

- "9432.0". The conversion fails because the string cannot contain a decimal separator; it must contain integral digits only.
- "16,667". The conversion fails because the string cannot contain group separators; it must contain integral digits only.
- "(100)". The conversion fails because the string cannot contain a negative sign other than the one defined by the current culture's NumberFormatInfo.NegativeSign and NumberFormatInfo.NumberNegativePattern properties.
- "01FA". The conversion fails because the string cannot contain hexadecimal digits; it must contain decimal digits only.

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails. It eliminates the need to use exception

handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	An optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces together with a leading sign are allowed. To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the TryParse(String, NumberStyles, IFormatProvider, Int64) method.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object initialized for the current system culture. For more information, see CurrentInfo.

This overload of the TryParse method interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the TryParse(String, NumberStyles, IFormatProvider, Int64) overload.

TryParse(ReadOnlySpan<Char>, IFormatProvider, Int64)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out long result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int64

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, Int64)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
long result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Int64

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Int64)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
long result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Int64

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, Int64)

Tries to convert a UTF-8 character span containing the string representation of a number to its 64-bit signed integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out long
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` Int64

When this method returns, contains the 64-bit signed integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Int64)

Converts the span representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
long result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the characters representing the number to convert. The span is interpreted using the style specified by `style`.

style NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

provider IFormatProvider

An object that supplies culture-specific formatting information about `s`.

result Int64

When this method returns, contains the 64-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int64.MinValue or greater than Int64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Int64)

Converts the string representation of a number in a specified style and culture-specific format to its 64-bit signed integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out long result);
```

Parameters

`s` String

A string containing a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Int64

When this method returns, contains the 64-bit signed integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than Int64.MinValue or greater than

Int64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the TryParse(String, NumberStyles, IFormatProvider, Int64) method with a number of different string and NumberStyles values.

C#

```
using System;
using System.Globalization;

public class StringParsing
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(numericString, styles);

      numericString = "12E03";
      CallTryParse(numericString, styles);

      numericString = "80c1";
      CallTryParse(numericString, NumberStyles.HexNumber);

      numericString = "0x80C1";
      CallTryParse(numericString, NumberStyles.HexNumber);
   }

   private static void CallTryParse(string stringToConvert, NumberStyles
styles)
   {
      CultureInfo provider;

      // If currency symbol is allowed, use en-US culture.
      if ((styles & NumberStyles.AllowCurrencySymbol) > 0)
         provider = new CultureInfo("en-US");
      else
         provider = CultureInfo.InvariantCulture;

      bool success = Int64.TryParse(stringToConvert, styles,
                                    provider, out long number);
      if (success)
         Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
      else
         Console.WriteLine($"Attempted conversion of '{stringToConvert}'
```

```
failed.");
    }
}
// The example displays the following output to the console:
//       Converted '106779' to 106779.
//       Attempted conversion of '-30677' failed.
//       Converted '-30677' to -30677.
//       Attempted conversion of '301677-' failed.
//       Converted '301677-' to -301677.
//       Attempted conversion of '$10634' failed.
//       Converted '$10634' to 10634.
//       Converted '10345.00' to 10345.
//       Attempted conversion of '10345.72' failed.
//       Converted '22,593' to 22593.
//       Attempted conversion of '12E-01' failed.
//       Converted '12E03' to 12000.
//       Converted '80c1' to 32961.
//       Attempted conversion of '0x80C1' failed.
```

Remarks

The TryParse method is like the Parse method, except the TryParse method does not throw an exception if the conversion fails. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be parsed successfully.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`,the `s` parameter may include the following elements:

[ws][$][sign][digits,]digits[.fractional_digits][e[sign]exponential_digits][ws]

Or, if the `style` parameter includes NumberStyles.AllowHexSpecifier:

[ws]hexdigits[ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end

Element	Description
	of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. A sign symbol can appear in `s` if `style` includes the NumberStyles.AllowLeadingSign or NumberStyles.AllowTrailingSign flags.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.
,	A culture-specific thousands separator. The thousands separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The 'e' or 'E' character, which indicates that the value is represented in exponential notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be but are not required to be present in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in s in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits or the method returns `false`.
NumberStyles.AllowExponent	The `s` parameter can also use exponential notation. The `s` parameter must represent an integer within the range of the Int64 data type without a non-zero fractional component.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign can appear before *digits*.
NumberStyles.AllowTrailingSign	A sign can appear after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The thousands separator (,) element.
NumberStyles.AllowCurrencySymbol	The *$* element.
NumberStyles.Currency	All elements. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
NumberStyles.Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
NumberStyles.Number	The *ws*, *sign*, thousands separator (,), and decimal point (.) elements.
NumberStyles.Any	All styles, except `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value without a prefix. For example, "C9AF3" parses successfully, but "0xC9AF3" does not. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, NumberStyles.HexNumber, that includes both white space flags.)

The `provider` parameter is an IFormatProvider implementation, such as a CultureInfo object or a NumberFormatInfo object, whose GetFormat method returns a NumberFormatInfo object. The NumberFormatInfo object provides culture-specific information about the format of `s`. If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Int64.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int64.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

```
C#
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.To Decimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.To Double(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

```
C#
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Int64.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The type to which to convert this Int64 value.

`provider` IFormatProvider

An IFormatProvider implementation that provides information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int64.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt16(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt32(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Int64.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Int64 instance is cast to an IConvertible interface. The recommended alternative is to

call the Convert.ToUInt64(Int64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Int64.IAdditionOperators<Int64,Int64,Int64>.AdditionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static long IAdditionOperators<long,long,long>.operator + (long left, long
right);
```

Parameters

`left` Int64

The value to which `right` is added.

`right` Int64

The value that's added to `left`.

Returns

Int64

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IAdditionOperators<Int64,Int64,Int64>.CheckedAdditionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static long IAdditionOperators<long,long,long>.op_CheckedAddition (long
left, long right);
```

Parameters

`left` Int64

The value to which `right` is added.

`right` Int64

The value that's added to `left`.

Returns

Int64

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.IBinaryInteger<Int64>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<long>.TryWriteBigEndian (Span<byte> destination, out int
bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IBinaryInteger<Int64>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<long>.TryWriteLittleEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteLittleEndian(Span<Byte>, Int32)

Applies to

Int64.IBitwiseOperators<Int64,Int64,Int64>.BitwiseAndOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static long IBitwiseOperators<long,long,long>.operator & (long left, long
right);
```

Parameters

`left` Int64

The value to `and` with `right`.

`right` Int64

The value to `and` with `left`.

Returns

Int64

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IBitwiseOperators<Int64,Int64,Int64>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static long IBitwiseOperators<long,long,long>.operator | (long left, long
right);
```

Parameters

`left` Int64

The value to `or` with `right`.

`right` Int64

The value to `or` with `left`.

Returns

Int64

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IBitwiseOperators<Int64,Int64,Int64>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static long IBitwiseOperators<long,long,long>.operator ^ (long left, long
right);
```

Parameters

`left` Int64

The value to xor with `right`.

`right` Int64

The value to xor with `left`.

Returns

Int64

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IBitwiseOperators<Int64,Int64,Int64>.OnesComplement(Int64) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
static long IBitwiseOperators<long,long,long>.operator ~ (long value);
```

Parameters

`value` Int64

The value for which to compute the ones-complement.

Returns

Int64

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IComparisonOperators<Int64,Int64,Boolean>.GreaterThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<long,long,bool>.operator > (long left, long right);
```

Parameters

`left` Int64

The value to compare with `right`.

`right` Int64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IComparisonOperators<Int64,Int64,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<long,long,bool>.operator >= (long left,
long right);
```

Parameters

`left` Int64

The value to compare with `right`.

`right` Int64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IComparisonOperators<Int64,Int64,Boolean>.Less Than Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<long,long,bool>.operator < (long left, long right);
```

Parameters

`left` Int64

The value to compare with `right`.

`right` Int64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IComparisonOperators<Int64,Int64,Boolean>.LessThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<long,long,bool>.operator <= (long left,
long right);
```

Parameters

`left` Int64

The value to compare with `right`.

`right` Int64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IDivisionOperators<Int64,Int64,Int64>.DivisionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static long IDivisionOperators<long,long,long>.operator / (long left, long right);
```

Parameters

`left` Int64

The value that `right` divides.

`right` Int64

The value that divides `left`.

Returns

Int64

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IEqualityOperators<Int64,Int64,Boolean>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<long,long,bool>.operator == (long left, long right);
```

Parameters

`left` Int64

The value to compare with `right`.

`right` Int64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IEqualityOperators<Int64,Int64,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<long,long,bool>.operator != (long left, long right);
```

Parameters

`left` Int64

The value to compare with `right`.

`right` Int64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IMinMaxValue<Int64>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static long System.Numerics.IMinMaxValue<System.Int64>.MinValue { get; }
```

Property Value

Int64

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.IModulusOperators<Int64,Int64,Int64>.Modulus(Int64, Int64) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static long IModulusOperators<long,long,long>.operator % (long left, long
right);
```

Parameters

`left` Int64

The value that `right` divides.

`right` Int64

The value that divides `left`.

Returns

Int64

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.IMultiplicativeIdentity<Int64,Int64>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static long
System.Numerics.IMultiplicativeIdentity<System.Int64,System.Int64>.MultiplicativeIdentity { get; }
```

Property Value

Int64

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IMultiplyOperators<Int64,Int64,Int64>.CheckedMultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static long IMultiplyOperators<long,long,long>.op_CheckedMultiply (long
left, long right);
```

Parameters

`left` Int64

The value that `right` multiplies.

`right` Int64

The value that multiplies `left`.

Returns

Int64

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.IMultiplyOperators<Int64,Int64,Int64>.MultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static long IMultiplyOperators<long,long,long>.operator * (long left, long right);
```

Parameters

`left` Int64

The value that `right` multiplies.

`right` Int64

The value that multiplies `left`.

Returns

Int64

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumber<Int64>.MaxNumber(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static long INumber<long>.MaxNumber (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumber<Int64>.MinNumber(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static long INumber<long>.MinNumber (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsCanonical(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<long>.IsCanonical (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsComplexNumber(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<long>.IsComplexNumber (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsFinite(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<long>.IsFinite (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsImaginaryNumber(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

```
C#
static bool INumberBase<long>.IsImaginaryNumber (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsInfinity(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<long>.IsInfinity (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsInteger(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<long>.IsInteger (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsNaN(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<long>.IsNaN (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.IsNegativeInfinity(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

C#

```
static bool INumberBase<long>.IsNegativeInfinity (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.IsNormal(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<long>.IsNormal (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsPositiveInfinity(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive infinity.

C#

```
static bool INumberBase<long>.IsPositiveInfinity (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is positive infinity; otherwise, `false`.

Implements

IsPositiveInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.IsRealNumber(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<long>.IsRealNumber (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.IsSubnormal(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is subnormal.

```
C#
static bool INumberBase<long>.IsSubnormal (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is subnormal; otherwise, `false`.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.IsZero(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<long>.IsZero (long value);
```

Parameters

`value` Int64

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.MaxMagnitudeNumber(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#
static long INumberBase<long>.MaxMagnitudeNumber (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.INumberBase<Int64>.MinMagnitudeNumber(Int64, Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

```
C#

static long INumberBase<long>.MinMagnitudeNumber (long x, long y);
```

Parameters

x Int64

The value to compare with `y`.

y Int64

The value to compare with `x`.

Returns

Int64

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<long>.TryConvertToChecked<TOther> (long value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int64

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<long>.TryConvertToSaturating<TOther> (long value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int64

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.INumberBase<Int64>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<long>.TryConvertToTruncating<TOther> (long value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Int64

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.IShift Operators<Int64,Int32,Int64>.Left Shift(Int64, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static long IShiftOperators<long,int,long>.operator << (long value, int
shiftAmount);
```

Parameters

`value` Int64

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

Int64

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.IShift Operators<Int64,Int32,Int64>.RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static long IShiftOperators<long,int,long>.operator >> (long value, int
shiftAmount);
```

Parameters

`value` Int64

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int64

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.IShift Operators<Int64,Int32,Int64>.Unsigned RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static long IShiftOperators<long,int,long>.op_UnsignedRightShift (long
value, int shiftAmount);
```

Parameters

`value` Int64

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

Int64

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Int64.ISignedNumber<Int64>.NegativeOne Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `-1` for the type.

C#

```
static long System.Numerics.ISignedNumber<System.Int64>.NegativeOne { get; }
```

Property Value

Int64

Implements

NegativeOne

Applies to

Product	Versions
.NET	7, 8, 9

Int64.ISubtractionOperators<Int64,Int64,Int64>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static long ISubtractionOperators<long,long,long>.op_CheckedSubtraction
(long left, long right);
```

Parameters

`left` Int64

The value from which `right` is subtracted.

`right` Int64

The value that's subtracted from `left`.

Returns

Int64

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.ISubtractionOperators<Int64,Int64,Int64>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static long ISubtractionOperators<long,long,long>.operator - (long left,
long right);
```

Parameters

`left` Int64

The value from which `right` is subtracted.

`right` Int64

The value that's subtracted from `left`.

Returns

Int64

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IUnaryNegationOperators<Int64,Int64>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static long IUnaryNegationOperators<long,long>.op_CheckedUnaryNegation (long
value);
```

Parameters

`value` Int64

The value for which to compute the unary negation.

Returns

Int64

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Int64.IUnaryNegationOperators<Int64,Int64>.UnaryNegation(Int64) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static long IUnaryNegationOperators<long,long>.operator - (long value);
```

Parameters

`value` Int64

The value for which to compute the unary negation.

Returns

Int64

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Int64.IUnaryPlusOperators<Int64,Int64>.UnaryPlus(Int64) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static long IUnaryPlusOperators<long,long>.operator + (long value);
```

Parameters

`value` Int64

The value for which to compute the unary plus.

Returns

Int64

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Examples

The following example uses managed pointers to reverse the characters in an array. After it initializes a String object and gets its length, it does the following:

1. Calls the Marshal.StringToHGlobalAnsi method to copy the Unicode string to unmanaged memory as an ANSI (one-byte) character. The method returns an IntPtr object that points to the beginning of the unmanaged string. The Visual Basic example uses this pointer directly; in the C++, F# and C# examples, it is cast to a pointer to a byte.

2. Calls the Marshal.AllocHGlobal method to allocate the same number of bytes as the unmanaged string occupies. The method returns an IntPtr object that points to the beginning of the unmanaged block of memory. The Visual Basic example uses this pointer directly; in the C++, F# and C# examples, it is cast to a pointer to a byte.

3. The Visual Basic example defines a variable named `offset` that is equal to the length of the ANSI string. It is used to determine the offset into unmanaged memory to which the next character in the ANSI string is copied. Because its starting value is the length of the string, the copy operation will copy a character from the start of the string to the end of the memory block.

   The C#, F# and C++ examples call the ToPointer method to get an unmanaged pointer to the starting address of the string and the unmanaged block of memory, and they add one less than the length of the string to the starting address of the ANSI string. Because the unmanaged string pointer now points to the end of the string, the copy operation will copy a character from the end of the string to the start of the memory block.

4. Uses a loop to copy each character from the string to the unmanaged block of memory.

   The Visual Basic example calls the Marshal.ReadByte(IntPtr, Int32) method to read the byte (or one-byte character) at a specified offset from the managed pointer to the ANSI string. The offset is incremented with each iteration of the loop. It then calls the Marshal.WriteByte(IntPtr, Int32, Byte) method to write the byte to the memory address defined by the starting address of the unmanaged block of memory plus `offset`. It then decrements `offset`.

   The C#, F# and C++ examples perform the copy operation, then decrement the pointer to the address of the next location in the unmanaged ANSI string and increment the pointer to the next address in the unmanaged block.

5. All examples call the Marshal.PtrToStringAnsi to convert the unmanaged memory block containing the copied ANSI string to a managed Unicode String object.

6. After displaying the original and reversed strings, all examples call the FreeHGlobal method to free the memory allocated for the unmanaged ANSI string and the unmanaged block of memory.

C#

```
using System;
using System.Runtime.InteropServices;

class NotTooSafeStringReverse
{
    static public void Main()
    {
        string stringA = "I seem to be turned around!";
        int copylen = stringA.Length;

        // Allocate HGlobal memory for source and destination strings
        IntPtr sptr = Marshal.StringToHGlobalAnsi(stringA);
        IntPtr dptr = Marshal.AllocHGlobal(copylen + 1);

        // The unsafe section where byte pointers are used.
        unsafe
        {
            byte *src = (byte *)sptr.ToPointer();
            byte *dst = (byte *)dptr.ToPointer();

            if (copylen > 0)
            {
                // set the source pointer to the end of the string
                // to do a reverse copy.
                src += copylen - 1;

                while (copylen-- > 0)
                {
                    *dst++ = *src--;
                }
                *dst = 0;
            }
        }
        string stringB = Marshal.PtrToStringAnsi(dptr);

        Console.WriteLine("Original:\n{0}\n", stringA);
        Console.WriteLine("Reversed:\n{0}", stringB);

        // Free HGlobal memory
        Marshal.FreeHGlobal(dptr);
        Marshal.FreeHGlobal(sptr);
    }
}

// The progam has the following output:
//
// Original:
```

```
// I seem to be turned around!
//
// Reversed:
// !dnuora denrut eb ot mees I
```

Remarks

The IntPtr type is designed to be an integer whose size is the same as a pointer. That is, an instance of this type is expected to be 32 bits in a 32-bit process and 64 bits in a 64-bit process.

The IntPtr type can be used by languages that support pointers and as a common means of referring to data between languages that do and do not support pointers.

IntPtr objects can also be used to hold handles. For example, instances of IntPtr are used extensively in the System.IO.FileStream class to hold file handles.

> **Note**
>
> Using **IntPtr** as a pointer or a handle is error prone and unsafe. It is simply an integer type that can be used as an interchange format for pointers and handles due to being the same size. Outside of specific interchange requirements, such as for passing data to a language that doesn't support pointers, a correctly typed pointer should be used to represent pointers and **SafeHandle** should be used to represent handles.

This type implements the ISerializable. In .NET 5 and later versions, this type also implements the IFormattable interfaces. In .NET 7 and later versions, this type also implements the IBinaryInteger<TSelf>, IMinMaxValue<TSelf>, and ISignedNumber<TSelf> interfaces.

In C# starting from version 9.0, you can use the built-in `nint` type to define native-sized integers. This type is represented by the IntPtr type internally and provides operations and conversions that are appropriate for integer types. For more information, see nint and nuint types.

In C# starting from version 11 and when targeting the .NET 7 or later runtime, `nint` is an alias for IntPtr in the same way that `int` is an alias for Int32.

Constructors

Expand table

IntPtr(Int32)	Initializes a new instance of IntPtr using the specified 32-bit signed integer.
IntPtr(Int64)	Initializes a new instance of IntPtr using the specified 64-bit signed integer.
Int Ptr(Void*)	Initializes a new instance of IntPtr using the specified pointer to an unspecified type.

Fields

Expand table

Zero	A read-only field that represents a signed integer that has been initialized to zero.

Properties

Expand table

MaxValue	Gets the largest possible value of IntPtr.
MinValue	Gets the smallest possible value of IntPtr.
Size	Gets the size of this instance.

Methods

Expand table

Abs(IntPtr)	Computes the absolute of a value.
Add(IntPtr, Int32)	Adds an offset to a signed integer.
Clamp(IntPtr, IntPtr, IntPtr)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(IntPtr)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the

	current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CopySign(IntPtr, IntPtr)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(IntPtr, IntPtr)	Computes the quotient and remainder of two values.
Equals(IntPtr)	Indicates whether the current object is equal to another object of the same type.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
GetHashCode()	Returns the hash code for this instance.
IsEvenInteger(IntPtr)	Determines if a value represents an even integral number.
IsNegative(IntPtr)	Determines if a value is negative.
IsOddInteger(IntPtr)	Determines if a value represents an odd integral number.
IsPositive(IntPtr)	Determines if a value is positive.
IsPow2(IntPtr)	Determines if a value is a power of two.
LeadingZeroCount(IntPtr)	Computes the number of leading zeros in a value.
Log2(IntPtr)	Computes the log2 of a value.
Max(IntPtr, IntPtr)	Compares two values to compute which is greater.
MaxMagnitude(IntPtr, IntPtr)	Compares two values to compute which is greater.
Min(IntPtr, IntPtr)	Compares two values to compute which is lesser.
MinMagnitude(IntPtr, IntPtr)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its signed native integer equivalent.
Parse(String)	Converts the string representation of a number to its signed native integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its signed native integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its signed native integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its signed native integer equivalent.
PopCount(IntPtr)	Computes the number of bits that are set in a value.
RotateLeft(IntPtr, Int32)	Rotates a value left by a given amount.
RotateRight(IntPtr, Int32)	Rotates a value right by a given amount.
Sign(IntPtr)	Computes the sign of a value.
Subtract(IntPtr, Int32)	Subtracts an offset from a signed integer.
ToInt32()	Converts the value of this instance to a 32-bit signed integer.
ToInt64()	Converts the value of this instance to a 64-bit signed integer.
ToPointer()	Converts the value of this instance to a pointer to an unspecified type.
ToString()	Converts the numeric value of the current IntPtr object to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString(String)	Converts the numeric value of the current IntPtr object to its equivalent string representation.

ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
TrailingZeroCount(IntPtr)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, IntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, IntPtr)	Tries to convert a UTF-8 character span containing the string representation of a number to its signed integer equivalent.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, IntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, IntPtr)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, IntPtr)	Converts the read-only span of characters representation of a number to its signed native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, IntPtr)	Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its signed native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, IntPtr)	Tries to parse a string into a value.
TryParse(String, IntPtr)	Converts the string representation of a number to its signed native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, NumberStyles, IFormatProvider, IntPtr)	Converts the string representation of a number in a specified style and culture-specific format to its signed native integer equivalent. A return value indicates whether the conversion succeeded.

Operators

Expand table

Addition(IntPtr, Int32)	Adds an offset to a signed integer.
Equality(IntPtr, IntPtr)	Determines whether two specified instances of IntPtr are equal.
Explicit(Int32 to IntPtr)	Converts the value of a 32-bit signed integer to an IntPtr.
Explicit(Int64 to IntPtr)	Converts the value of a 64-bit signed integer to an IntPtr.
Explicit(IntPtr to Int32)	Converts the value of the specified IntPtr to a 32-bit signed integer.
Explicit(IntPtr to Int64)	Converts the value of the specified IntPtr to a 64-bit signed integer.
Explicit(IntPtr to Void*)	Converts the value of the specified IntPtr to a pointer to an unspecified type. This API is not CLS-compliant.
Explicit(Void* to IntPtr)	Converts the specified pointer to an unspecified type to an IntPtr. This API is not CLS-compliant.
Inequality(IntPtr, IntPtr)	Determines whether two specified instances of IntPtr are not equal.
Subtraction(IntPtr, Int32)	Subtracts an offset from a signed integer.

Explicit Interface Implementations

Expand table

IAdditionOperators<IntPtr,IntPtr,IntPtr>.Addition(IntPtr, IntPtr)	Adds two values together to compute their sum.
IAdditionOperators<IntPtr,IntPtr,IntPtr>.CheckedAddition(IntPtr, IntPtr)	Adds two values together to compute their sum.
IAdditiveIdentity<IntPtr,IntPtr>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<IntPtr>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<IntPtr>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<IntPtr>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, IntPtr)	
IBinaryInteger<IntPtr>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, IntPtr)	

IBinaryInteger<IntPtr>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<IntPtr>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<IntPtr>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<IntPtr,IntPtr,IntPtr>.BitwiseAnd(IntPtr, IntPtr)	Computes the bitwise-and of two values.
IBitwiseOperators<IntPtr,IntPtr,IntPtr>.BitwiseOr(IntPtr, IntPtr)	Computes the bitwise-or of two values.
IBitwiseOperators<IntPtr,IntPtr,IntPtr>.ExclusiveOr(IntPtr, IntPtr)	Computes the exclusive-or of two values.
IBitwiseOperators<IntPtr,IntPtr,IntPtr>.OnesComplement(IntPtr)	Computes the ones-complement representation of a given value.
IComparisonOperators<IntPtr,IntPtr,Boolean>.GreaterThan(IntPtr, IntPtr)	Compares two values to determine which is greater.
IComparisonOperators<IntPtr,IntPtr,Boolean>.GreaterThanOrEqual(IntPtr, IntPtr)	Compares two values to determine which is greater or equal.
IComparisonOperators<IntPtr,IntPtr,Boolean>.LessThan(IntPtr, IntPtr)	Compares two values to determine which is less.
IComparisonOperators<IntPtr,IntPtr,Boolean>.LessThanOrEqual(IntPtr, IntPtr)	Compares two values to determine which is less or equal.
IDecrementOperators<IntPtr>.CheckedDecrement(IntPtr)	Decrements a value.
IDecrementOperators<IntPtr>.Decrement(IntPtr)	Decrements a value.
IDivisionOperators<IntPtr,IntPtr,IntPtr>.Division(IntPtr, IntPtr)	Divides one value by another to compute their quotient.
IIncrementOperators<IntPtr>.CheckedIncrement(IntPtr)	Increments a value.
IIncrementOperators<IntPtr>.Increment(IntPtr)	Increments a value.
IMinMaxValue<IntPtr>.MaxValue	Gets the maximum value of the current type.

IMinMaxValue<IntPtr>.MinValue	Gets the minimum value of the current type.
IModulusOperators<IntPtr,IntPtr,IntPtr>.Modulus(IntPtr, IntPtr)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<IntPtr,IntPtr>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
IMultiplyOperators<IntPtr,IntPtr,IntPtr>.CheckedMultiply(IntPtr, IntPtr)	Multiplies two values together to compute their product.
IMultiplyOperators<IntPtr,IntPtr,IntPtr>.Multiply(IntPtr, IntPtr)	Multiplies two values together to compute their product.
INumber<IntPtr>.MaxNumber(IntPtr, IntPtr)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<IntPtr>.MinNumber(IntPtr, IntPtr)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<IntPtr>.IsCanonical(IntPtr)	Determines if a value is in its canonical representation.
INumberBase<IntPtr>.IsComplexNumber(IntPtr)	Determines if a value represents a complex number.
INumberBase<IntPtr>.IsFinite(IntPtr)	Determines if a value is finite.
INumberBase<IntPtr>.IsImaginaryNumber(IntPtr)	Determines if a value represents a pure imaginary number.
INumberBase<IntPtr>.IsInfinity(IntPtr)	Determines if a value is infinite.
INumberBase<IntPtr>.IsInteger(IntPtr)	Determines if a value represents an integral number.
INumberBase<IntPtr>.IsNaN(IntPtr)	Determines if a value is NaN.
INumberBase<IntPtr>.IsNegativeInfinity(IntPtr)	Determines if a value is negative infinity.
INumberBase<IntPtr>.IsNormal(IntPtr)	Determines if a value is normal.
INumberBase<IntPtr>.IsPositiveInfinity(IntPtr)	Determines if a value is positive infinity.
INumberBase<IntPtr>.IsRealNumber(IntPtr)	Determines if a value represents a real number.
INumberBase<IntPtr>.IsSubnormal(IntPtr)	Determines if a value is subnormal.
INumberBase<IntPtr>.IsZero(IntPtr)	Determines if a value is zero.

INumberBase<IntPtr>.MaxMagnitudeNumber(IntPtr, IntPtr)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<IntPtr>.MinMagnitudeNumber(IntPtr, IntPtr)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<IntPtr>.One	Gets the value `1` for the type.
INumberBase<IntPtr>.Radix	Gets the radix, or base, for the type.
INumberBase<IntPtr>.TryConvertFromChecked<TOther>(TOther, IntPtr)	
INumberBase<IntPtr>.TryConvertFromSaturating<TOther>(TOther, IntPtr)	
INumberBase<IntPtr>.TryConvertFromTruncating<TOther>(TOther, IntPtr)	
INumberBase<IntPtr>.TryConvertToChecked<TOther>(IntPtr, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<IntPtr>.TryConvertToSaturating<TOther>(IntPtr, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<IntPtr>.TryConvertToTruncating<TOther>(IntPtr, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<IntPtr>.Zero	Gets the value `0` for the type.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo object with the data needed to serialize the current IntPtr object.
IShiftOperators<IntPtr,Int32,IntPtr>.LeftShift(IntPtr, Int32)	Shifts a value left by a given amount.
IShiftOperators<IntPtr,Int32,IntPtr>.RightShift(IntPtr, Int32)	Shifts a value right by a given amount.
IShiftOperators<IntPtr,Int32,IntPtr>.UnsignedRightShift(IntPtr, Int32)	Shifts a value right by a given amount.
ISignedNumber<IntPtr>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<IntPtr,IntPtr,IntPtr>.CheckedSubtraction(IntPtr, IntPtr)	Subtracts two values to compute their difference.
ISubtractionOperators<IntPtr,IntPtr,IntPtr>.Subtraction(IntPtr, IntPtr)	Subtracts two values to compute their difference.

IUnaryNegationOperators<IntPtr,IntPtr>.CheckedUnaryNegation(IntPtr)	Computes the checked unary negation of a value.
IUnaryNegationOperators<IntPtr,IntPtr>.UnaryNegation(IntPtr)	Computes the unary negation of a value.
IUnaryPlusOperators<IntPtr,IntPtr>.UnaryPlus(IntPtr)	Computes the unary plus of a value.

IntPtr Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of IntPtr.

Overloads

Expand table

IntPtr(Int32)	Initializes a new instance of IntPtr using the specified 32-bit signed integer.
IntPtr(Int64)	Initializes a new instance of IntPtr using the specified 64-bit signed integer.
IntPtr(Void*)	Initializes a new instance of IntPtr using the specified pointer to an unspecified type.

IntPtr(Int32)

Initializes a new instance of IntPtr using the specified 32-bit signed integer.

C#

```
public IntPtr (int value);
```

Parameters

`value` Int32

A 32-bit signed integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IntPtr(Int64)

Initializes a new instance of IntPtr using the specified 64-bit signed integer.

C#

```
public IntPtr (long value);
```

Parameters

`value` Int64

A 64-bit signed integer.

Exceptions

OverflowException

In a 32-bit process, `value` is too large or too small to represent as an IntPtr.

Remarks

An exception is only thrown if the value of `value` requires more bits than the executing process supports.

Applies to

▼ .NET 9 and other versions

Product	Versions

UWP	10.0

IntPtr(Void*)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of IntPtr using the specified pointer to an unspecified type.

C#

```
[System.CLSCompliant(false)]
public IntPtr (void* value);
```

Parameters

`value` Void*

A pointer to an unspecified type.

Attributes CLSCompliantAttribute

IntPtr.Zero Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A read-only field that represents a signed integer that has been initialized to zero.

```
C#

public static readonly IntPtr Zero;
```

Field Value

IntPtr

Remarks

The value of this field is not equivalent to `null`. Use this field to efficiently determine whether an instance of IntPtr has been set to a value other than zero.

For example, assume the variable, ip, is an instance of IntPtr. You can determine if it has been set by comparing it to the value returned by a constructor, for example: " `if ip != new IntPtr(0)...` ". However, invoking a constructor to get an uninitialized pointer is inefficient. It is better to code either " `if ip != IntPtr.Zero...` ", or " `if !IntPtr.Zero.Equals(ip)...` ".

When calling the Windows API from managed code, you can pass IntPtr.Zero instead of `null` if an argument is expected to be either a pointer or a `null`. For example, the following call to the Windows `CreateFile` function supplies IntPtr.Zero for the `pSecurityAttributes` and `hTemplateFile` argument values.

```
C#

using Microsoft.Win32.SafeHandles;
using System;
using System.Runtime.InteropServices;

public class Example
```

```
{
   private const uint GENERIC_READ = 0x80000000;
   private const uint OPEN_EXISTING = 3;
   private const uint FILE_ATTRIBUTE_NORMAL = 128;
   private const uint FILE_FLAG_OVERLAPPED = 0x40000000;

   [DllImport("kernel32.dll", SetLastError = true, CharSet =
CharSet.Unicode)]
   private static extern Microsoft.Win32.SafeHandles.SafeFileHandle
CreateFile(
            string lpFileName, System.UInt32 dwDesiredAccess, System.UInt32
dwShareMode,
            IntPtr pSecurityAttributes, System.UInt32 dwCreationDisposition,
            System.UInt32 dwFlagsAndAttributes, IntPtr hTemplateFile);

   public static void Main()
   {
      SafeFileHandle hnd = CreateFile("CallOfTheWild.txt", GENERIC_READ, 0,
                                      IntPtr.Zero, OPEN_EXISTING,
                                      FILE_ATTRIBUTE_NORMAL |
FILE_FLAG_OVERLAPPED,
                                      IntPtr.Zero);
      if (hnd.IsInvalid) {
            Exception ex =
Marshal.GetExceptionForHR(Marshal.GetHRForLastWin32Error());
            Console.WriteLine("Attempt to open file failed:");
            Console.WriteLine("  {0}", ex.Message);
            return;
      }
      else {
         Console.WriteLine("File successfully opened.");
         hnd.Close();
      }
   }
}
// If the file cannot be found, the example displays the following output:
//    Attempt to open file failed:
//      The system cannot find the file specified. (Exception from HRESULT:
0x80070002)
```

> **Note**
>
> Although **Zero** is equivalent to `null` for Windows API functions with parameters or return values that can be either pointers or `null`, **Zero** is not equivalent to `null`. Passing `null` to the `IntPtr.Zero.Equals` method always returns `false`.

You can also test for a `null` return value from Windows API function calls that return either a pointer or a `null` by comparing the returned value with IntPtr.Zero. For example, the call to the `GetWindow` function in the following example tries to retrieve the

handle of a non-existent window. If it were called from unmanaged code, the function would return `null`, but when it is called from managed code, it returns IntPtr.Zero.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
   private const int GW_OWNER = 4;

   [DllImport("user32", CharSet=CharSet.Auto, SetLastError=true,
ExactSpelling=true)]
   public static extern IntPtr GetWindow(IntPtr hwnd, int wFlag);

   public static void Main()
   {
      IntPtr hwnd = new IntPtr(3);
      IntPtr hOwner = GetWindow(hwnd, GW_OWNER);
      if (hOwner == IntPtr.Zero)
         Console.WriteLine("Window not found.");
   }
}
// The example displays the following output:
//        Window not found.
```

IntPtr.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the largest possible value of IntPtr.

```
C#
public static IntPtr MaxValue { get; }
```

Property Value

IntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxValue

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

IntPtr.Size Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the size of this instance.

C#

```
public static int Size { get; }
```

Property Value

Int32

The size of a signed integer in the executing process, measured in bytes. The value of this property is 4 in a 32-bit process, and 8 in a 64-bit process. You can define the process type by setting the `/platform` switch when you compile your code with the C# and Visual Basic compilers.

Applies to

Product	Versions

IntPtr.Abs(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
public static IntPtr Abs (IntPtr value);
```

Parameters

`value` IntPtr

The value for which to get its absolute.

Returns

IntPtr

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.Add(IntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds an offset to a signed integer.

C#

```
public static IntPtr Add (IntPtr pointer, int offset);
```

Parameters

pointer IntPtr

The signed integer to add the offset to.

offset Int32

The offset to add.

Returns

IntPtr

A new signed integer that reflects the addition of `offset` to `pointer`.

Examples

The following example instantiates an IntPtr object that points to the beginning of a ten-element array, and then calls the Add method to iterate the elements in the array.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
   public static void Main()
   {
```

```
        int[] arr = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
        unsafe {
           fixed(int* parr = arr) {
              IntPtr ptr = new IntPtr(parr);
              // Get the size of an array element.
              int size = sizeof(int);
              for (int ctr = 0; ctr < arr.Length; ctr++)
              {
                 IntPtr newPtr = IntPtr.Add(ptr, ctr * size);
                 Console.Write("{0}   ", Marshal.ReadInt32(newPtr));
              }
           }
        }
     }
  }
  // The example displays the following output:
  //       2   4   6   8   10   12   14   16   18   20
```

Remarks

The Add method does not throw an exception if the result is too large to represent as a signed integer in the executing process. Instead, the addition operation is performed in an unchecked context.

Languages that do not support operator overloading or custom operators can use this method to add an offset to the value of a pointer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IntPtr.Clamp(IntPtr, IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static IntPtr Clamp (IntPtr value, IntPtr min, IntPtr max);
```

Parameters

`value` IntPtr

The value to clamp.

`min` IntPtr

The inclusive minimum to which `value` should clamp.

`max` IntPtr

The inclusive maximum to which `value` should clamp.

Returns

IntPtr

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(IntPtr)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

CompareTo(IntPtr)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (IntPtr value);
```

Parameters

`value` IntPtr

A signed native integer to compare.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

CompareTo(Object)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

IntPtr.CopySign(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

```
C#
public static IntPtr CopySign (IntPtr value, IntPtr sign);
```

Parameters

`value` IntPtr

The value whose magnitude is used in the result.

`sign` IntPtr

The value whose sign is used in the result.

Returns

IntPtr

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static IntPtr CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

IntPtr

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static IntPtr CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

IntPtr

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

```
C#

public static IntPtr CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

IntPtr

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.DivRem(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (IntPtr Quotient, IntPtr Remainder) DivRem (IntPtr left,
IntPtr right);
```

Parameters

`left` IntPtr

The value which `right` divides.

`right` IntPtr

The value which divides `left`.

Returns

ValueTuple<IntPtr,IntPtr>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(IntPtr)	Indicates whether the current object is equal to another object of the same type.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(IntPtr)

Indicates whether the current object is equal to another object of the same type.

C#

```
public bool Equals (IntPtr other);
```

Parameters

other IntPtr

An object to compare with this object.

Returns

Boolean

`true` if the current object is equal to `other`; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

```
C#
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance or `null`.

Returns

Boolean

`true` if `obj` is an instance of IntPtr and equals the value of this instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IntPtr.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

IntPtr.IsEvenInteger(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IsNegative(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IsOddInteger(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.IsPositive(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.IsPow2(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.LeadingZeroCount(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static IntPtr LeadingZeroCount (IntPtr value);
```

Parameters

`value` IntPtr

The value whose leading zeroes are to be counted.

Returns

IntPtr

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

IntPtr.Log2(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

```
C#
public static IntPtr Log2 (IntPtr value);
```

Parameters

`value` IntPtr

The value whose log2 is to be computed.

Returns

IntPtr

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

IntPtr.Max(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static IntPtr Max (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.MaxMagnitude(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static IntPtr MaxMagnitude (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

IntPtr.Min(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static IntPtr Min (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its signed native integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its signed native integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its signed native integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its signed native integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String)	Converts the string representation of a number to its signed native integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its signed native integer equivalent.

```
C#

public static IntPtr Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

IntPtr

A signed native integer equivalent to the number contained in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value or `style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its signed native integer equivalent.

C#

```
public static IntPtr Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

IntPtr

A signed native integer equivalent to the number contained in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Exceptions

ArgumentException

`style` is not a NumberStyles value or `style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static IntPtr Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

IntPtr

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its signed native integer equivalent.

C#

```
public static IntPtr Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

IntPtr

A signed native integer equivalent to the number contained in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its signed native integer equivalent.

```C#
public static IntPtr Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

s String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`.

Returns

IntPtr

A signed native integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value or `style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#
```

```
public static IntPtr Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

IntPtr

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static IntPtr Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

IntPtr

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String)

Converts the string representation of a number to its signed native integer equivalent.

C#

```
public static IntPtr Parse (string s);
```

Parameters

`s` String

A string containing a number to convert.

Returns

IntPtr

A signed native integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

IntPtr.PopCount(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static IntPtr PopCount (IntPtr value);
```

Parameters

`value` IntPtr

The value whose set bits are to be counted.

Returns

IntPtr

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.RotateLeft(IntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static IntPtr RotateLeft (IntPtr value, int rotateAmount);
```

Parameters

`value` IntPtr

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

IntPtr

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.RotateRight(IntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

C#

```
public static IntPtr RotateRight (IntPtr value, int rotateAmount);
```

Parameters

`value` IntPtr

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

IntPtr

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.Sign(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (IntPtr value);
```

Parameters

`value` IntPtr

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.Subtract(IntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts an offset from a signed integer.

C#

```
public static IntPtr Subtract (IntPtr pointer, int offset);
```

Parameters

`pointer` IntPtr

The signed integer to subtract the offset from.

`offset` Int32

The offset to subtract.

Returns

IntPtr

A new signed integer that reflects the subtraction of `offset` from `pointer`.

Examples

The following example instantiates an IntPtr object that points to the end of a ten-element array, and then calls the Subtract method to iterate the elements in the array in reverse order.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
```

```
    public static void Main()
    {
       int[] arr = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20};
       // Get the size of a single array element.
       int size = sizeof(int);
       unsafe {
          fixed(int* pend = &arr[arr.GetUpperBound(0)]) {
             IntPtr ptr = new IntPtr(pend);
             for (int ctr = 0; ctr < arr.Length; ctr++)
             {
                IntPtr newPtr = IntPtr.Subtract(ptr, ctr * size);
                Console.Write("{0}   ", Marshal.ReadInt32(newPtr));
             }
          }
       }
    }
 }
 // The example displays the following output:
 //       20   18   16   14   12   10   8   6   4   2
```

Remarks

The Subtract method does not throw an exception if the result is too small to represent as a signed integer in the executing process. Instead, the subtraction operation is performed in an unchecked context.

Languages that do not support operator overloading or custom operators can use this method to subtract an offset from the value of a pointer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IntPtr.ToInt32 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to a 32-bit signed integer.

C#

```
public int ToInt32 ();
```

Returns

Int32

A 32-bit signed integer equal to the value of this instance.

Exceptions

OverflowException

In a 64-bit process, the value of this instance is too large or too small to represent as a 32-bit signed integer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IntPtr.ToInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to a 64-bit signed integer.

C#

```
public long ToInt64 ();
```

Returns

Int64

A 64-bit signed integer equal to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IntPtr.ToPointer Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the value of this instance to a pointer to an unspecified type.

C#

```
[System.CLSCompliant(false)]
public void* ToPointer ();
```

Returns

Void*

A pointer to Void; that is, a pointer to memory containing data of an unspecified type.

Attributes CLSCompliantAttribute

Examples

The following example uses managed pointers to reverse the characters in an array. After it initializes a String object and gets its length, it does the following:

- Calls the Marshal.StringToHGlobalAnsi method to copy the Unicode string to unmanaged memory as ANSI (one-byte) characters. The method returns an IntPtr object that points to the beginning of the unmanaged string.
- Calls the Marshal.AllocHGlobal method to allocate the same number of bytes as the unmanaged string occupies. The method returns an IntPtr object that points to the beginning of the unmanaged block of memory.

- Calls the ToPointer method to get an unmanaged pointer to the starting address of the string and the unmanaged block of memory, and adds one less than the length of the string to the starting address of the ANSI string. Because the unmanaged string pointer now points to the end of the string, the copy operation will copy a character from the end of the string to the start of the memory block.

- Uses a loop to copy each character from the string to the unmanaged block of memory. After each copy operation, it decrements the pointer to the address of the next location in the unmanaged ANSI string and increments the pointer to the next address in the unmanaged block.

- Calls the Marshal.PtrToStringAnsi to convert the unmanaged memory block containing the copied ANSI string to a managed Unicode String object.

- After displaying the original and reversed strings, calls the Marshal.FreeHGlobal method to free the memory allocated for the unmanaged ANSI string and the unmanaged block of memory.

C#

```
using System;
using System.Runtime.InteropServices;

class NotTooSafeStringReverse
{
    static public void Main()
    {
        string stringA = "I seem to be turned around!";
        int copylen = stringA.Length;

        // Allocate HGlobal memory for source and destination strings
        IntPtr sptr = Marshal.StringToHGlobalAnsi(stringA);
        IntPtr dptr = Marshal.AllocHGlobal(copylen + 1);

        // The unsafe section where byte pointers are used.
        unsafe
        {
            byte *src = (byte *)sptr.ToPointer();
            byte *dst = (byte *)dptr.ToPointer();

            if (copylen > 0)
            {
                // set the source pointer to the end of the string
                // to do a reverse copy.
                src += copylen - 1;

                while (copylen-- > 0)
                {
                    *dst++ = *src--;
                }
```

```
                *dst = 0;
            }
        }
        string stringB = Marshal.PtrToStringAnsi(dptr);

        Console.WriteLine("Original:\n{0}\n", stringA);
        Console.WriteLine("Reversed:\n{0}", stringB);

        // Free HGlobal memory
        Marshal.FreeHGlobal(dptr);
        Marshal.FreeHGlobal(sptr);
    }
}

// The progam has the following output:
//
// Original:
// I seem to be turned around!
//
// Reversed:
// !dnuora denrut eb ot mees I
```

IntPtr.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of the current IntPtr object to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of the current IntPtr object to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString(String)	Converts the numeric value of the current IntPtr object to its equivalent string representation.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.

ToString()

Converts the numeric value of the current IntPtr object to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance.

Remarks

If the value of the Size property for this instance is 4, then this method is equivalent to Int32.ToString; otherwise, this method is equivalent to Int64.ToString.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToString(String)

Converts the numeric value of the current IntPtr object to its equivalent string representation.

```
C#
public string ToString (string? format);
```

Parameters

`format` String

A format specification that governs how the current IntPtr object is converted.

Returns

String

The string representation of the value of the current IntPtr object.

Exceptions

FormatException

`format` is invalid or not supported.

Remarks

If the `format` parameter is `null` or an empty string ("), the return value is formatted with the general format specifier ("G"). For more information about numeric format specifiers, see the Standard Numeric Format Strings topic.

The return value is formatted using the invariant culture.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String, IFormatProvider)

Formats the value of the current instance using the specified format.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

The format to use. -or- A `null` reference (`Nothing` in Visual Basic) to use the default format defined for the type of the IFormattable implementation.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Applies to

IntPtr.TrailingZeroCount(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static IntPtr TrailingZeroCount (IntPtr value);
```

Parameters

`value` IntPtr

The value whose trailing zeroes are to be counted.

Returns

IntPtr

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span where this instance's value formatted as a span of characters should be written.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

The characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

IntPtr.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IntPtr)	Tries to convert a UTF-8 character span containing the string representation of a number to its signed integer equivalent.
TryParse(ReadOnlySpan<Char>, IntPtr)	Converts the read-only span of characters representation of a number to its signed native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, IntPtr)	Converts the string representation of a number to its signed native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, IntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, IntPtr)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, IntPtr)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, IntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(String, NumberStyles, IFormatProvider, IntPtr)	Converts the string representation of a number in a specified style and culture-specific format to its signed native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, IntPtr)	Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its signed native integer

	equivalent. A return value indicates whether the conversion succeeded.

TryParse(ReadOnlySpan<Byte>, IntPtr)

Tries to convert a UTF-8 character span containing the string representation of a number to its signed integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out IntPtr
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` IntPtr

When this method returns, contains the signed integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, IntPtr)

Converts the read-only span of characters representation of a number to its signed native integer equivalent. A return value indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out IntPtr result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert.

`result` IntPtr

When this method returns, contains the signed native integer equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(String, IntPtr)

Converts the string representation of a number to its signed native integer equivalent. A return value indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParse (string? s, out IntPtr result);
```

Parameters

`s` String

A string containing a number to convert.

`result` IntPtr

When this method returns, contains the signed native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryParse(ReadOnlySpan<Byte>, IFormatProvider, IntPtr)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out IntPtr result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` IntPtr

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, IntPtr)

Tries to parse a string into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out IntPtr result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` IntPtr

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, IntPtr)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
IntPtr result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` IntPtr

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, IntPtr)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
IntPtr result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` IntPtr

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, NumberStyles, IFormatProvider, IntPtr)

Converts the string representation of a number in a specified style and culture-specific format to its signed native integer equivalent. A return value indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out IntPtr result);
```

Parameters

`s` String

A string containing a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` IntPtr

When this method returns, contains the signed native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, IntPtr)

Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its signed native integer equivalent. A return value indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
IntPtr result);
```

Parameters

s ReadOnlySpan<Char>

A read-only span of characters containing a number to convert. The string is interpreted using the style specified by `style`.

style NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` IntPtr

When this method returns, contains the signed native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

IntPtr.Addition(IntPtr, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds an offset to a signed integer.

```
C#

public static IntPtr operator + (IntPtr pointer, int offset);
```

Parameters

`pointer` IntPtr

The signed integer to add the offset to.

`offset` Int32

The offset to add.

Returns

IntPtr

A new signed integer that reflects the addition of `offset` to `pointer`.

Remarks

The Addition method defines the addition operation for IntPtr objects. It enables code such as the following.

```
C#

int[] arr = {2, 4, 6, 8, 10, 12, 14, 16, 18, 20 };
unsafe {
   fixed(int* parr = arr)
   {
       IntPtr ptr = new IntPtr(parr);
       for (int ctr = 0; ctr < arr.Length; ctr++)
       {
```

```
            IntPtr newPtr = ptr + ctr * sizeof(Int32);
            Console.Write("{0}   ", Marshal.ReadInt32(newPtr));
        }
    }
}
// The example displays the following output:
//       2   4   6   8   10   12   14   16   18   20
```

Languages that do not support custom operators can call the Add method instead.

The addition operation does not throw an exception if the result is too large to represent as a signed integer in the executing process. Instead, it is performed in an unchecked context.

In C# starting from version 11 and when targeting the .NET 7 or later runtime, this API is only accessible via reflection. The addition operator is directly recognized by the language and will follow the normal language behavior for addition operations, including overflowing in a `checked` context if the result is too large to represent.

The equivalent method for this operator is IntPtr.Add(IntPtr, Int32)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IntPtr.Equality(IntPtr, IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of IntPtr are equal.

```
C#
public static bool operator == (IntPtr value1, IntPtr value2);
```

Parameters

`value1` IntPtr

The first signed integer to compare.

`value2` IntPtr

The second signed integer to compare.

Returns

Boolean

`true` if `value1` equals `value2`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Remarks

The equivalent method for this operator is IntPtr.Equals(Object)

Applies to

Product	Versions

IntPtr.Explicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified data type to an IntPtr value, or an IntPtr value to a specified data type.

Overloads

Expand table

Explicit(Void* to IntPtr)	Converts the specified pointer to an unspecified type to an IntPtr. This API is not CLS-compliant.
Explicit(IntPtr to Int64)	Converts the value of the specified IntPtr to a 64-bit signed integer.
Explicit(IntPtr to Void*)	Converts the value of the specified IntPtr to a pointer to an unspecified type. This API is not CLS-compliant.
Explicit(Int64 to IntPtr)	Converts the value of a 64-bit signed integer to an IntPtr.
Explicit(IntPtr to Int32)	Converts the value of the specified IntPtr to a 32-bit signed integer.
Explicit(Int32 to IntPtr)	Converts the value of a 32-bit signed integer to an IntPtr.

Explicit(Void* to IntPtr)

> Important
>
> This API is not CLS-compliant.

Converts the specified pointer to an unspecified type to an IntPtr.

This API is not CLS-compliant.

```
C#

[System.CLSCompliant(false)]
public static explicit operator IntPtr (void* value);
```

Parameters

`value` Void*

A pointer to an unspecified type.

Returns

IntPtr

A new instance of IntPtr initialized to `value`.

Attributes CLSCompliantAttribute

UWP	10.0

Explicit(IntPtr to Int64)

Converts the value of the specified IntPtr to a 64-bit signed integer.

```
C#
public static explicit operator long (IntPtr value);
```

Parameters

`value` IntPtr

The signed integer to convert.

Returns

Int64

The contents of `value`.

UWP	10.0

Explicit(IntPtr to Void*)

> Important
>
> This API is not CLS-compliant.

Converts the value of the specified IntPtr to a pointer to an unspecified type.

This API is not CLS-compliant.

```
C#

[System.CLSCompliant(false)]
public static explicit operator void* (IntPtr value);
```

Parameters

`value` IntPtr

The signed integer to convert.

Returns

Void*

The contents of `value`.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Explicit(Int64 to IntPtr)

Converts the value of a 64-bit signed integer to an IntPtr.

```
C#
public static explicit operator IntPtr (long value);
```

Parameters

`value` Int64

A 64-bit signed integer.

Returns

IntPtr

A new instance of IntPtr initialized to `value`.

Exceptions

OverflowException

In a 32-bit process, `value` is too large to represent as an IntPtr.

- IntPtr

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Explicit(IntPtr to Int32)

Converts the value of the specified IntPtr to a 32-bit signed integer.

```
C#
public static explicit operator int (IntPtr value);
```

Parameters

`value` IntPtr

The signed integer to convert.

Returns

Int32

The contents of `value`.

Exceptions

OverflowException

In a 64-bit process, the value of `value` is too large to represent as a 32-bit signed integer.

Remarks

An exception is only thrown if the value of `value` requires more bits than the executing process supports.

IntPtr.Inequality(IntPtr, IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of IntPtr are not equal.

```
C#
public static bool operator != (IntPtr value1, IntPtr value2);
```

Parameters

`value1` IntPtr

The first signed integer to compare.

`value2` IntPtr

The second signed integer to compare.

Returns

Boolean

`true` if `value1` does not equal `value2`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Remarks

The equivalent method for this operator is IntPtr.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

IntPtr.Subtraction(IntPtr, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts an offset from a signed integer.

```
C#

public static IntPtr operator - (IntPtr pointer, int offset);
```

Parameters

`pointer` IntPtr

The signed integer to subtract the offset from.

`offset` Int32

The offset to subtract.

Returns

IntPtr

A new signed integer that reflects the subtraction of `offset` from `pointer`.

Remarks

The Subtraction method defines the subtraction operation for IntPtr objects. It enables code such as the following.

```
C#

int[] arr = { 2, 4, 6, 8, 10, 12, 14, 16, 18, 20};
unsafe {
   fixed(int* parr = &arr[arr.GetUpperBound(0)])
   {
      IntPtr ptr = new IntPtr(parr);
      for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++)
      {
```

```
            IntPtr newPtr = ptr - ctr * sizeof(Int32);
            Console.Write("{0}   ", Marshal.ReadInt32(newPtr));
        }
    }
}
// The example displays the following output:
//       20   18   16   14   12   10   8   6   4   2
```

Languages that do not support custom operators can call the Subtract method instead.

The subtraction operation does not throw an exception if the result is too small to represent as a signed integer in the executing process. Instead, it is performed in an unchecked context.

In C# starting from version 11 and when targeting the .NET 7 or later runtime, this API is only accessible via reflection. The subtraction operator is directly recognized by the language and will follow the normal language behavior for subtraction operations, including overflowing in a `checked` context if the result is too small to represent.

The equivalent method for this operator is IntPtr.Subtract(IntPtr, Int32)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IntPtr.IAdditionOperators<IntPtr,IntPtr,IntPtr>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static IntPtr IAdditionOperators<IntPtr,IntPtr,IntPtr>.operator + (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value to which `right` is added.

`right` IntPtr

The value that's added to `left`.

Returns

IntPtr

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.IAdditionOperators<IntPtr,IntPtr,IntPtr>.CheckedAddition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static IntPtr IAdditionOperators<IntPtr,IntPtr,IntPtr>.op_CheckedAddition
(IntPtr left, IntPtr right);
```

Parameters

`left` IntPtr

The value to which `right` is added.

`right` IntPtr

The value that's added to `left`.

Returns

IntPtr

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

IntPtr.IBinaryInteger<IntPtr>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<IntPtr>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

IntPtr.IComparisonOperators<IntPtr,IntPtr,Boolean>.LessThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<IntPtr,IntPtr,bool>.operator < (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value to compare with `right`.

`right` IntPtr

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions

IntPtr.IComparisonOperators<IntPtr,IntPtr,Boolean>.LessThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<IntPtr,IntPtr,bool>.operator <= (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value to compare with `right`.

`right` IntPtr

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IDecrementOperators<IntPtr>.CheckedDecrement(IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#

static IntPtr IDecrementOperators<IntPtr>.op_CheckedDecrement (IntPtr
value);
```

Parameters

`value` IntPtr

The value to decrement.

Returns

IntPtr

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IDecrementOperators<IntPtr>.Decrement(IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static IntPtr IDecrementOperators<IntPtr>.operator -- (IntPtr value);
```

Parameters

`value` IntPtr

The value to decrement.

Returns

IntPtr

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IDivisionOperators<IntPtr,IntPtr,IntPtr>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static IntPtr IDivisionOperators<IntPtr,IntPtr,IntPtr>.operator / (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value that `right` divides.

`right` IntPtr

The value that divides `left`.

Returns

IntPtr

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IIncrementOperators<IntPtr>.CheckedIncrement(IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#

static IntPtr IIncrementOperators<IntPtr>.op_CheckedIncrement (IntPtr
value);
```

Parameters

`value` IntPtr

The value to increment.

Returns

IntPtr

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IIncrementOperators<IntPtr>.Increment(IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static IntPtr IIncrementOperators<IntPtr>.operator ++ (IntPtr value);
```

Parameters

`value` IntPtr

The value to increment.

Returns

IntPtr

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IMinMaxValue<IntPtr>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static IntPtr System.Numerics.IMinMaxValue<System.IntPtr>.MaxValue { get; }
```

Property Value

IntPtr

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IMinMaxValue<IntPtr>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static IntPtr System.Numerics.IMinMaxValue<System.IntPtr>.MinValue { get; }
```

Property Value

IntPtr

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IModulusOperators<IntPtr,IntPtr,IntPtr>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static IntPtr IModulusOperators<IntPtr,IntPtr,IntPtr>.operator % (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value that `right` divides.

`right` IntPtr

The value that divides `left`.

Returns

IntPtr

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IMultiplicativeIdentity<IntPtr,IntPtr>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static IntPtr
System.Numerics.IMultiplicativeIdentity<System.IntPtr,System.IntPtr>.Multipl
icativeIdentity { get; }
```

Property Value

IntPtr

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IMultiplyOperators<IntPtr,IntPtr,IntPtr>.CheckedMultiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

C#

```
static IntPtr IMultiplyOperators<IntPtr,IntPtr,IntPtr>.op_CheckedMultiply
(IntPtr left, IntPtr right);
```

Parameters

left IntPtr

The value that `right` multiplies.

right IntPtr

The value that multiplies `left`.

Returns

IntPtr

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IMultiplyOperators<IntPtr,IntPtr,IntPtr>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static IntPtr IMultiplyOperators<IntPtr,IntPtr,IntPtr>.operator * (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value that `right` multiplies.

`right` IntPtr

The value that multiplies `left`.

Returns

IntPtr

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumber<IntPtr>.MaxNumber(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static IntPtr INumber<IntPtr>.MaxNumber (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumber<IntPtr>.MinNumber(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static IntPtr INumber<IntPtr>.MinNumber (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.IsCanonical(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<IntPtr>.IsCanonical (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.IsComplexNumber(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<IntPtr>.IsComplexNumber (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.IsFinite(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

C#

```
static bool INumberBase<IntPtr>.IsFinite (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsImaginaryNumber(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<IntPtr>.IsImaginaryNumber (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.IsInfinity(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<IntPtr>.IsInfinity (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsInteger(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<IntPtr>.IsInteger (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsNaN(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<IntPtr>.IsNaN (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsNegativeInfinity(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

C#

```
static bool INumberBase<IntPtr>.IsNegativeInfinity (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsNormal(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<IntPtr>.IsNormal (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsPositiveInfinity(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive infinity.

C#

```
static bool INumberBase<IntPtr>.IsPositiveInfinity (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is positive infinity; otherwise, `false`.

Implements

IsPositiveInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.INumberBase<IntPtr>.IsRealNumber(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<IntPtr>.IsRealNumber (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.IsSubnormal(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is subnormal.

```
C#
static bool INumberBase<IntPtr>.IsSubnormal (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is subnormal; otherwise, `false`.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.IsZero(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<IntPtr>.IsZero (IntPtr value);
```

Parameters

`value` IntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.MaxMagnitudeNumber(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#
static IntPtr INumberBase<IntPtr>.MaxMagnitudeNumber (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.MinMagnitudeNumber(IntPtr, IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

```
C#

static IntPtr INumberBase<IntPtr>.MinMagnitudeNumber (IntPtr x, IntPtr y);
```

Parameters

x IntPtr

The value to compare with `y`.

y IntPtr

The value to compare with `x`.

Returns

IntPtr

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.INumberBase<IntPtr>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<IntPtr>.TryConvertToChecked<TOther> (IntPtr value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` IntPtr

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<IntPtr>.TryConvertToSaturating<TOther> (IntPtr
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` IntPtr

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.INumberBase<IntPtr>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<IntPtr>.TryConvertToTruncating<TOther> (IntPtr
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` IntPtr

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.INumberBase<IntPtr>.Zero Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `0` for the type.

C#

```
static IntPtr System.Numerics.INumberBase<System.IntPtr>.Zero { get; }
```

Property Value

IntPtr

Implements

Zero

Applies to

Product	Versions
.NET	7, 8, 9

IntPtr.IShiftOperators<IntPtr,Int32,IntPtr>.LeftShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

C#

```
static IntPtr IShiftOperators<IntPtr,int,IntPtr>.operator << (IntPtr value,
int shiftAmount);
```

Parameters

`value` IntPtr

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

IntPtr

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IShiftOperators<IntPtr,Int32,IntPtr>.RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

C#

```
static IntPtr IShiftOperators<IntPtr,int,IntPtr>.operator >> (IntPtr value,
int shiftAmount);
```

Parameters

`value` IntPtr

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

IntPtr

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IShiftOperators<IntPtr,Int32,IntPtr>.UnsignedRightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

C#

```
static IntPtr IShiftOperators<IntPtr,int,IntPtr>.op_UnsignedRightShift
(IntPtr value, int shiftAmount);
```

Parameters

value IntPtr

The value that is shifted right by `shiftAmount`.

shiftAmount Int32

The amount by which `value` is shifted right.

Returns

IntPtr

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.ISubtractionOperators<IntPtr,IntPtr,IntPtr>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static IntPtr
ISubtractionOperators<IntPtr,IntPtr,IntPtr>.op_CheckedSubtraction (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value from which `right` is subtracted.

`right` IntPtr

The value that's subtracted from `left`.

Returns

IntPtr

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.ISubtractionOperators<IntPtr,IntPtr,IntPtr>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static IntPtr ISubtractionOperators<IntPtr,IntPtr,IntPtr>.operator - (IntPtr
left, IntPtr right);
```

Parameters

`left` IntPtr

The value from which `right` is subtracted.

`right` IntPtr

The value that's subtracted from `left`.

Returns

IntPtr

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IUnaryNegationOperators<IntPtr,IntPtr>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static IntPtr IUnaryNegationOperators<IntPtr,IntPtr>.op_CheckedUnaryNegation
(IntPtr value);
```

Parameters

`value` IntPtr

The value for which to compute the unary negation.

Returns

IntPtr

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IntPtr.IUnaryNegationOperators<IntPtr,IntPtr>.UnaryNegation Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#

static IntPtr IUnaryNegationOperators<IntPtr,IntPtr>.operator - (IntPtr
value);
```

Parameters

`value` IntPtr

The value for which to compute the unary negation.

Returns

IntPtr

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.IUnaryPlusOperators<IntPtr,IntPtr>.UnaryPlus(IntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

C#

```
static IntPtr IUnaryPlusOperators<IntPtr,IntPtr>.operator + (IntPtr value);
```

Parameters

`value` IntPtr

The value for which to compute the unary plus.

Returns

IntPtr

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IntPtr.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data needed to serialize the current IntPtr object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo object to populate with data.

`context` StreamingContext

The destination for this serialization. (This parameter is not used; specify `null`.)

Implements

GetObjectData(SerializationInfo, StreamingContext)

Exceptions

ArgumentNullException

`info` is `null`.

Remarks

This method populates the `info` parameter with the value of the current IntPtr object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

InvalidCastException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown for invalid casting or explicit conversion.

C#

```
public class InvalidCastException : SystemException
```

Inheritance Object → Exception → SystemException → InvalidCastException

Remarks

For more information about this API, see Supplemental API remarks for InvalidCastException.

Constructors

Expand table

InvalidCastException()	Initializes a new instance of the InvalidCastException class.
InvalidCastException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the InvalidCastException class with serialized data.
InvalidCastException(String)	Initializes a new instance of the InvalidCastException class with a specified error message.
InvalidCastException(String, Exception)	Initializes a new instance of the InvalidCastException class with a specified error message and a reference to the inner exception that is the cause of this exception.
InvalidCastException(String, Int32)	Initializes a new instance of the InvalidCastException class with a specified message and error code.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.**

	When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidCastException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the InvalidCastException class.

Overloads

Expand table

InvalidCastException()	Initializes a new instance of the InvalidCastException class.
InvalidCastException(String)	Initializes a new instance of the InvalidCastException class with a specified error message.
InvalidCastException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the InvalidCastException class with serialized data.
InvalidCastException(String, Exception)	Initializes a new instance of the InvalidCastException class with a specified error message and a reference to the inner exception that is the cause of this exception.
InvalidCastException(String, Int32)	Initializes a new instance of the InvalidCastException class with a specified message and error code.

InvalidCastException()

Initializes a new instance of the InvalidCastException class.

C#

```
public InvalidCastException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Cannot cast from source type to destination type." This message takes into account the current system culture.

The following table shows the initial property values for an instance of InvalidCastException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidCastException(String)

Initializes a new instance of the InvalidCastException class with a specified error message.

C#

```
public InvalidCastException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of InvalidCastException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidCastException(SerializationInfo, StreamingContext)

⊗ Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the InvalidCastException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected InvalidCastException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions *(Obsolete)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

InvalidCastException(String, Exception)

Initializes a new instance of the InvalidCastException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public InvalidCastException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or returns `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of InvalidCastException.

Expand table

Property	Value
InnerException	The inner exception reference.

Property	Value
Message	The error message string.

See also

- Exception
- Handling and Throwing Exceptions

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidCastException(String, Int32)

Initializes a new instance of the InvalidCastException class with a specified message and error code.

C#

```
public InvalidCastException (string? message, int errorCode);
```

Parameters

`message` String

The message that indicates the reason the exception occurred.

`errorCode` Int32

The error code (HRESULT) value associated with the exception.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

This constructor supplies an HRESULT value that is accessible to inheritors of the InvalidCastException class, via the protected HResult property of the Exception class.

The following table shows the initial property values for an instance of InvalidCastException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

InvalidOperationException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a method call is invalid for the object's current state.

C#

```
public class InvalidOperationException : SystemException
```

Inheritance Object → Exception → SystemException → InvalidOperationException

Derived System.Data.Linq.DuplicateKeyException
System.Data.Linq.ForeignKeyReferenceAlreadyHasValueException
System.Data.Services.Client.DataServiceClientException
System.Data.Services.Client.DataServiceQueryException
System.Data.Services.Client.DataServiceRequestException
More...

Remarks

For more information about this API, see Supplemental API remarks for InvalidOperationException.

Constructors

Expand table

InvalidOperationException()	Initializes a new instance of the InvalidOperationException class.
InvalidOperationException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the InvalidOperationException class with serialized data.

InvalidOperationException(String)	Initializes a new instance of the InvalidOperationException class with a specified error message.
InvalidOperationException(String, Exception)	Initializes a new instance of the InvalidOperationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)

GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The requested operation cannot be performed." This message takes into account the current system culture.

The following table shows the initial property values for an instance of InvalidOperationException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidOperationException(String)

Initializes a new instance of the InvalidOperationException class with a specified error message.

C#

```
public InvalidOperationException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of InvalidOperationException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidOperationException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the InvalidOperationException class with serialized data.

```
C#

[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected InvalidOperationException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

InvalidOperationException(String, Exception)

Initializes a new instance of the InvalidOperationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public InvalidOperationException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of InvalidOperationException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

InvalidProgramException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a program contains invalid Microsoft intermediate language (MSIL) or metadata. Generally this indicates a bug in the compiler that generated the program. This exception is also thrown when internal runtime implementation limits have been exceeded by the program.

C#

```
public sealed class InvalidProgramException : SystemException
```

Inheritance Object → Exception → SystemException → InvalidProgramException

Remarks

InvalidProgramException uses the HRESULT `COR_E_INVALIDPROGRAM`, which has the value 0x8013153A.

For a list of initial property values for an instance of InvalidProgramException, see the InvalidProgramException constructors.

Constructors

Expand table

InvalidProgramException()	Initializes a new instance of the InvalidProgramException class with default properties.
InvalidProgram Exception(String)	Initializes a new instance of the InvalidProgramException class with a specified error message.
InvalidProgram Exception(String, Exception)	Initializes a new instance of the InvalidProgramException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.**

	When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

InvalidProgramException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the InvalidProgramException class.

Overloads

Expand table

InvalidProgramException()	Initializes a new instance of the InvalidProgramException class with default properties.
InvalidProgramException(String)	Initializes a new instance of the InvalidProgramException class with a specified error message.
InvalidProgramException(String, Exception)	Initializes a new instance of the InvalidProgramException class with a specified error message and a reference to the inner exception that is the cause of this exception.

InvalidProgramException()

Initializes a new instance of the InvalidProgramException class with default properties.

C#

```
public InvalidProgramException ();
```

Remarks

The constructor initializes the Exception.Message property of the new exception to a system-supplied message that describes the error, such as "Metadata is incorrect." This message takes into account the current system culture.

The following table shows the initial property values for an instance of InvalidProgramException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidProgramException(String)

Initializes a new instance of the InvalidProgramException class with a specified error message.

C#

```
public InvalidProgramException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Remarks

This constructor initializes the Exception.Message property of the new exception using the `message` parameter. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of InvalidProgramException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidProgramException(String, Exception)

Initializes a new instance of the InvalidProgramException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public InvalidProgramException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The `InnerException` property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the `InnerException` property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of InvalidProgramException.

InvalidTimeZoneException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when time zone information is invalid.

C#

```
public class InvalidTimeZoneException : Exception
```

Inheritance Object → Exception → InvalidTimeZoneException

Remarks

This exception is thrown when a TimeZoneInfo object contains invalid, incomplete, or missing data. It is thrown by the FindSystemTimeZoneById method when a time zone is found in the registry but contains corrupted data. It can also be thrown by the CreateCustomTimeZone method under any of the following conditions:

- The adjustment rules overlap.
- The adjustment rules contain one or more null elements.
- The sum of the Coordinated Universal Time (UTC) offset and daylight delta is out of range. (It is either greater than 14 hours or less than -14 hours.)
- A single date has multiple adjustment rules applied to it.

This exception is not thrown to indicate that the time zone is not defined on a particular system; the TimeZoneNotFoundException is used for this purpose.

Constructors

Expand table

InvalidTimeZoneException()	Initializes a new instance of the InvalidTimeZoneException class with a system-supplied message.
InvalidTimeZone Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the InvalidTimeZoneException class from serialized data.
InvalidTimeZoneException(String)	Initializes a new instance of the InvalidTimeZoneException class with the specified message string.
InvalidTimeZoneException(String, Exception)	Initializes a new instance of the InvalidTimeZoneException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

InvalidTimeZoneException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the InvalidTimeZoneException class.

Overloads

Expand table

InvalidTimeZoneException()	Initializes a new instance of the InvalidTimeZoneException class with a system-supplied message.
InvalidTimeZoneException(String)	Initializes a new instance of the InvalidTimeZoneException class with the specified message string.
InvalidTimeZoneException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the InvalidTimeZoneException class from serialized data.
InvalidTimeZoneException(String, Exception)	Initializes a new instance of the InvalidTimeZoneException class with a specified error message and a reference to the inner exception that is the cause of this exception.

InvalidTimeZoneException()

Initializes a new instance of the InvalidTimeZoneException class with a system-supplied message.

C#

```
public InvalidTimeZoneException ();
```

Remarks

This is the parameterless constructor of the InvalidTimeZoneException class. It initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Exception of type 'System.InvalidTimeZoneException' was thrown." This message is localized for the current system culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidTimeZoneException(String)

Initializes a new instance of the InvalidTimeZoneException class with the specified message string.

C#

```
public InvalidTimeZoneException (string? message);
```

Parameters

`message` String

A string that describes the exception.

Remarks

The string supplied as the `message` parameter is assigned to the Message property. It should be localized for the current culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

InvalidTimeZoneException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the InvalidTimeZoneException class from serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected InvalidTimeZoneException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that contains the serialized data.

`context` StreamingContext

The stream that contains the serialized data.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` parameter is `null`.

-or-

The `context` parameter is `null`.

Remarks

This constructor is not called directly by your code to instantiate the InvalidTimeZoneException object. Instead, it is called by the IFormatter object's Deserialize method when deserializing the InvalidTimeZoneException object from a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

InvalidTimeZoneException(String, Exception)

Initializes a new instance of the InvalidTimeZoneException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public InvalidTimeZoneException (string? message, Exception?
innerException);
```

Parameters

`message` String

A string that describes the exception.

`innerException` Exception

The exception that is the cause of the current exception.

Examples

The following code tries to retrieve a TimeZoneInfo object that represents the Central Standard Time zone. If an InvalidTimeZoneException occurs in the `RetrieveTimeZone` method call, the exception handler wraps the exception in a new InvalidTimeZoneException object, which it returns to the caller. The caller's exception handler then displays information about both the outer and inner exceptions.

C#

```
private void HandleInnerException()
{
   string timeZoneName = "Any Standard Time";
   TimeZoneInfo tz;
   try
   {
      tz = RetrieveTimeZone(timeZoneName);
      Console.WriteLine("The time zone display name is {0}.",
tz.DisplayName);
   }
   catch (TimeZoneNotFoundException e)
   {
      Console.WriteLine("{0} thrown by application", e.GetType().Name);
      Console.WriteLine("   Message: {0}", e.Message);
      if (e.InnerException != null)
      {
         Console.WriteLine("   Inner Exception Information:");
         Exception innerEx = e.InnerException;
         while (innerEx != null)
         {
            Console.WriteLine("      {0}: {1}", innerEx.GetType().Name,
innerEx.Message);
            innerEx = innerEx.InnerException;
         }
      }
   }
}

private TimeZoneInfo RetrieveTimeZone(string tzName)
{
   try
   {
```

```
        return TimeZoneInfo.FindSystemTimeZoneById(tzName);
    }
    catch (TimeZoneNotFoundException ex1)
    {
        throw new TimeZoneNotFoundException(
              String.Format("The time zone '{0}' cannot be found.",
tzName),
              ex1);
    }
    catch (InvalidTimeZoneException ex2)
    {
        throw new InvalidTimeZoneException(
              String.Format("The time zone {0} contains invalid data.",
tzName),
              ex2);
    }
}
```

Remarks

Typically, you use this overload of the InvalidTimeZoneException class to handle an exception in a `try`...`catch` block. The `innerException` parameter should be a reference to the exception object handled in the `catch` block, or it can be `null`. This value is then assigned to the InvalidTimeZoneException object's InnerException property.

The `message` string is assigned to the Message property. The string should be localized for the current culture.

Applies to

IObservable<T> Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a provider for push-based notification.

C#

```
public interface IObservable<out T>
```

Type Parameters

T

The object that provides notification information.
This type parameter is covariant. That is, you can use either the type you specified or any type that is more derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Derived System.Diagnostics.DiagnosticListener
System.Web.Hosting.AspNetMemoryMonitor

Examples

The following example illustrates the observer design pattern. It defines a `Location` class that contains latitude and longitude information.

C#

```
public struct Location
{
   double lat, lon;

   public Location(double latitude, double longitude)
   {
      this.lat = latitude;
      this.lon = longitude;
   }
```

```
    public double Latitude
    { get { return this.lat; } }

    public double Longitude
    { get { return this.lon; } }
}
```

The `LocationTracker` class provides the IObservable<T> implementation. Its `TrackLocation` method is passed a nullable `Location` object that contains the latitude and longitude data. If the `Location` value is not `null`, the `TrackLocation` method calls the OnNext method of each observer.

C#

```
public class LocationTracker : IObservable<Location>
{
    public LocationTracker()
    {
        observers = new List<IObserver<Location>>();
    }

    private List<IObserver<Location>> observers;

    public IDisposable Subscribe(IObserver<Location> observer)
    {
        if (! observers.Contains(observer))
            observers.Add(observer);
        return new Unsubscriber(observers, observer);
    }

    private class Unsubscriber : IDisposable
    {
        private List<IObserver<Location>>_observers;
        private IObserver<Location> _observer;

        public Unsubscriber(List<IObserver<Location>> observers,
IObserver<Location> observer)
        {
            this._observers = observers;
            this._observer = observer;
        }

        public void Dispose()
        {
            if (_observer != null && _observers.Contains(_observer))
                _observers.Remove(_observer);
        }
    }

    public void TrackLocation(Nullable<Location> loc)
    {
        foreach (var observer in observers) {
```

```
            if (! loc.HasValue)
               observer.OnError(new LocationUnknownException());
            else
               observer.OnNext(loc.Value);
         }
      }

      public void EndTransmission()
      {
         foreach (var observer in observers.ToArray())
            if (observers.Contains(observer))
               observer.OnCompleted();

         observers.Clear();
      }
   }
```

If the `Location` value is `null`, the `TrackLocation` method instantiates a `LocationUnknownException` object, which is shown in the following example. It then calls each observer's OnError method and passes it the `LocationUnknownException` object. Note that `LocationUnknownException` derives from Exception, but does not add any new members.

C#

```
public class LocationUnknownException : Exception
{
   internal LocationUnknownException()
   { }
}
```

Observers register to receive notifications from a `LocationTracker` object by calling its IObservable<T>.Subscribe method, which assigns a reference to the observer object to a private generic List<T> object. The method returns an `Unsubscriber` object, which is an IDisposable implementation that enables observers to stop receiving notifications. The `LocationTracker` class also includes an `EndTransmission` method. When no further location data is available, the method calls each observer's OnCompleted method and then clears the internal list of observers.

In this example, the `LocationReporter` class provides the IObserver<T> implementation. It displays information about the current location to the console. Its constructor includes a `name` parameter, which enables the `LocationReporter` instance to identify itself in its string output. It also includes a `Subscribe` method, which wraps a call to the provider's Subscribe method. This allows the method to assign the returned IDisposable reference to a private variable. The `LocationReporter` class also includes an `Unsubscribe` method,

which calls the IDisposable.Dispose method of the object that is returned by the IObservable<T>.Subscribe method. The following code defines the `LocationReporter` class.

C#

```
using System;

public class LocationReporter : IObserver<Location>
{
   private IDisposable unsubscriber;
   private string instName;

   public LocationReporter(string name)
   {
      this.instName = name;
   }

   public string Name
   {  get{ return this.instName; } }

   public virtual void Subscribe(IObservable<Location> provider)
   {
      if (provider != null)
         unsubscriber = provider.Subscribe(this);
   }

   public virtual void OnCompleted()
   {
      Console.WriteLine("The Location Tracker has completed transmitting
data to {0}.", this.Name);
      this.Unsubscribe();
   }

   public virtual void OnError(Exception e)
   {
      Console.WriteLine("{0}: The location cannot be determined.",
this.Name);
   }

   public virtual void OnNext(Location value)
   {
      Console.WriteLine("{2}: The current location is {0}, {1}",
value.Latitude, value.Longitude, this.Name);
   }

   public virtual void Unsubscribe()
   {
      unsubscriber.Dispose();
   }
}
```

The following code then instantiates the provider and the observer.

```C#
using System;

class Program
{
   static void Main(string[] args)
   {
      // Define a provider and two observers.
      LocationTracker provider = new LocationTracker();
      LocationReporter reporter1 = new LocationReporter("FixedGPS");
      reporter1.Subscribe(provider);
      LocationReporter reporter2 = new LocationReporter("MobileGPS");
      reporter2.Subscribe(provider);

      provider.TrackLocation(new Location(47.6456, -122.1312));
      reporter1.Unsubscribe();
      provider.TrackLocation(new Location(47.6677, -122.1199));
      provider.TrackLocation(null);
      provider.EndTransmission();
   }
}
// The example displays output similar to the following:
//      FixedGPS: The current location is 47.6456, -122.1312
//      MobileGPS: The current location is 47.6456, -122.1312
//      MobileGPS: The current location is 47.6677, -122.1199
//      MobileGPS: The location cannot be determined.
//      The Location Tracker has completed transmitting data to MobileGPS.
```

Remarks

The IObserver<T> and IObservable<T> interfaces provide a generalized mechanism for push-based notification, also known as the observer design pattern. The IObservable<T> interface represents the class that sends notifications (the provider); the IObserver<T> interface represents the class that receives them (the observer). `T` represents the class that provides the notification information. In some push-based notifications, the IObserver<T> implementation and `T` can represent the same type.

The provider must implement a single method, Subscribe, that indicates that an observer wants to receive push-based notifications. Callers to the method pass an instance of the observer. The method returns an IDisposable implementation that enables observers to cancel notifications at any time before the provider has stopped sending them.

At any given time, a given provider may have zero, one, or multiple observers. The provider is responsible for storing references to observers and ensuring that they are valid before it sends notifications. The IObservable<T> interface does not make any assumptions about the number of observers or the order in which notifications are sent.

The provider sends the following three kinds of notifications to the observer by calling IObserver<T> methods:

- The current data. The provider can call the IObserver<T>.OnNext method to pass the observer a `T` object that has current data, changed data, or fresh data.
- An error condition. The provider can call the IObserver<T>.OnError method to notify the observer that some error condition has occurred.
- No further data. The provider can call the IObserver<T>.OnCompleted method to notify the observer that it has finished sending notifications.

Methods

Expand table

Subscribe(IObserver<T>)	Notifies the provider that an observer is to receive notifications.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IObservable<T>.Subscribe(IObserver<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Notifies the provider that an observer is to receive notifications.

C#

```
public IDisposable Subscribe (IObserver<out T> observer);
```

Parameters

observer IObserver<T>

The object that is to receive notifications.

Returns

IDisposable

A reference to an interface that allows observers to stop receiving notifications before the provider has finished sending them.

Examples

The following example illustrates the Subscribe method for an application that reports latitude and longitude information. It defines an IList<T> collection object that stores references to all observers. It also returns a private class named `Unsubscriber` that implements the IDisposable interface and enables subscribers to stop receiving event notifications. See the Example section of the IObservable<T> topic for the complete example.

C#

```
private List<IObserver<Location>> observers;
```

```
public IDisposable Subscribe(IObserver<Location> observer)
{
   if (! observers.Contains(observer))
      observers.Add(observer);
   return new Unsubscriber(observers, observer);
}

private class Unsubscriber : IDisposable
{
   private List<IObserver<Location>>_observers;
   private IObserver<Location> _observer;

   public Unsubscriber(List<IObserver<Location>> observers,
IObserver<Location> observer)
   {
      this._observers = observers;
      this._observer = observer;
   }

   public void Dispose()
   {
      if (_observer != null && _observers.Contains(_observer))
         _observers.Remove(_observer);
   }
}
```

Remarks

The Subscribe method must be called to register an observer for push-based notifications. A typical implementation of the Subscribe method does the following:

- It stores a reference to the observer in a collection object, such as a List<T> object.
- It returns a reference to an IDisposable interface. This enables observers to unsubscribe (that is, to stop receiving notifications) before the provider has finished sending them and called the subscriber's OnCompleted method.

At any given time, a particular instance of an IObservable<T> implementation is responsible for handling all subscriptions and notifying all subscribers. Unless the documentation for a particular IObservable<T> implementation indicates otherwise, observers should make no assumptions about the IObservable<T> implementation, such as the order of notifications that multiple observers will receive.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

IObserver<T> Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a mechanism for receiving push-based notifications.

C#

```
public interface IObserver<in T>
```

Type Parameters

T

The object that provides notification information.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Derived Microsoft.Extensions.DiagnosticAdapter.DiagnosticSourceAdapter
System.Web.Hosting.LowPhysicalMemoryObserver
System.Web.Hosting.RecycleLimitObserver

Examples

The following example illustrates the observer design pattern. It defines a `Location` class that contains latitude and longitude information.

C#

```
public struct Location
{
   double lat, lon;

   public Location(double latitude, double longitude)
   {
      this.lat = latitude;
      this.lon = longitude;
   }
```

```
    public double Latitude
    { get { return this.lat; } }

    public double Longitude
    { get { return this.lon; } }
}
```

The `LocationReporter` class provides the IObserver<T> implementation. It displays information about the current location to the console. Its constructor includes a `name` parameter, which allows the `LocationReporter` instance to identify itself in its string output. It also includes a `Subscribe` method, which wraps a call to the provider's Subscribe method. This enables the method to assign the returned IDisposable reference to a private variable. The `LocationReporter` class also includes an `Unsubscribe` method, which calls the IDisposable.Dispose method of the object returned by the IObservable<T>.Subscribe method. The following code defines the `LocationReporter` class.

C#

```
using System;

public class LocationReporter : IObserver<Location>
{
    private IDisposable unsubscriber;
    private string instName;

    public LocationReporter(string name)
    {
        this.instName = name;
    }

    public string Name
    {  get{ return this.instName; } }

    public virtual void Subscribe(IObservable<Location> provider)
    {
        if (provider != null)
            unsubscriber = provider.Subscribe(this);
    }

    public virtual void OnCompleted()
    {
        Console.WriteLine("The Location Tracker has completed transmitting
data to {0}.", this.Name);
        this.Unsubscribe();
    }

    public virtual void OnError(Exception e)
    {
```

```
      Console.WriteLine("{0}: The location cannot be determined.",
this.Name);
   }

   public virtual void OnNext(Location value)
   {
      Console.WriteLine("{2}: The current location is {0}, {1}",
value.Latitude, value.Longitude, this.Name);
   }

   public virtual void Unsubscribe()
   {
      unsubscriber.Dispose();
   }
}
```

The `LocationTracker` class provides the IObservable<T> implementation. Its `TrackLocation` method is passed a nullable `Location` object that contains the latitude and longitude data. If the `Location` value is not `null`, the `TrackLocation` method calls the OnNext method of each observer.

C#

```
public class LocationTracker : IObservable<Location>
{
   public LocationTracker()
   {
      observers = new List<IObserver<Location>>();
   }

   private List<IObserver<Location>> observers;

   public IDisposable Subscribe(IObserver<Location> observer)
   {
      if (! observers.Contains(observer))
         observers.Add(observer);
      return new Unsubscriber(observers, observer);
   }

   private class Unsubscriber : IDisposable
   {
      private List<IObserver<Location>>_observers;
      private IObserver<Location> _observer;

      public Unsubscriber(List<IObserver<Location>> observers,
IObserver<Location> observer)
      {
         this._observers = observers;
         this._observer = observer;
      }

      public void Dispose()
```

```
        {
            if (_observer != null && _observers.Contains(_observer))
                _observers.Remove(_observer);
        }
    }

    public void TrackLocation(Nullable<Location> loc)
    {
        foreach (var observer in observers) {
            if (! loc.HasValue)
                observer.OnError(new LocationUnknownException());
            else
                observer.OnNext(loc.Value);
        }
    }

    public void EndTransmission()
    {
        foreach (var observer in observers.ToArray())
            if (observers.Contains(observer))
                observer.OnCompleted();

        observers.Clear();
    }
}
```

If the `Location` value is `null`, the `TrackLocation` method instantiates a `LocationNotFoundException` object, which is shown in the following example. It then calls each observer's OnError method and passes it the `LocationNotFoundException` object. Note that `LocationNotFoundException` derives from Exception but does not add any new members.

C#

```
public class LocationUnknownException : Exception
{
    internal LocationUnknownException()
    { }
}
```

Observers register to receive notifications from a `TrackLocation` object by calling its IObservable<T>.Subscribe method, which assigns a reference to the observer object to a private generic List<T> object. The method returns an `Unsubscriber` object, which is an IDisposable implementation that enables observers to stop receiving notifications. The `LocationTracker` class also includes an `EndTransmission` method. When no further location data is available, the method calls each observer's OnCompleted method and then clears the internal list of observers.

The following code then instantiates the provider and the observer.

C#

```
using System;

class Program
{
   static void Main(string[] args)
   {
      // Define a provider and two observers.
      LocationTracker provider = new LocationTracker();
      LocationReporter reporter1 = new LocationReporter("FixedGPS");
      reporter1.Subscribe(provider);
      LocationReporter reporter2 = new LocationReporter("MobileGPS");
      reporter2.Subscribe(provider);

      provider.TrackLocation(new Location(47.6456, -122.1312));
      reporter1.Unsubscribe();
      provider.TrackLocation(new Location(47.6677, -122.1199));
      provider.TrackLocation(null);
      provider.EndTransmission();
   }
}
// The example displays output similar to the following:
//      FixedGPS: The current location is 47.6456, -122.1312
//      MobileGPS: The current location is 47.6456, -122.1312
//      MobileGPS: The current location is 47.6677, -122.1199
//      MobileGPS: The location cannot be determined.
//      The Location Tracker has completed transmitting data to MobileGPS.
```

Remarks

The IObserver<T> and IObservable<T> interfaces provide a generalized mechanism for push-based notification, also known as the observer design pattern. The IObservable<T> interface represents the class that sends notifications (the provider); the IObserver<T> interface represents the class that receives them (the observer). `T` represents the class that provides the notification information.

An IObserver<T> implementation arranges to receive notifications from a provider (an IObservable<T> implementation) by passing an instance of itself to the provider's IObservable<T>.Subscribe method. This method returns an IDisposable object that can be used to unsubscribe the observer before the provider finishes sending notifications.

The IObserver<T> interface defines the following three methods that the observer must implement:

- The OnNext method, which is typically called by the provider to supply the observer with new data or state information.
- The OnError method, which is typically called by the provider to indicate that data is unavailable, inaccessible, or corrupted, or that the provider has experienced some other error condition.
- The OnCompleted method, which is typically called by the provider to indicate that it has finished sending notifications to observers.

Methods

Expand table

OnCompleted()	Notifies the observer that the provider has finished sending push-based notifications.
On Error(Exception)	Notifies the observer that the provider has experienced an error condition.
OnNext(T)	Provides the observer with new data.

Applies to

Product	Versions

IObserver<T>.OnCompleted Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Notifies the observer that the provider has finished sending push-based notifications.

C#

```
public void OnCompleted ();
```

Examples

The following example provides an implementation of the OnCompleted method in a latitude/longitude tracking application. The method simply reports that no further data is available and calls the provider's IDisposable.Dispose implementation. See the Example section of the IObserver<T> topic for the complete example.

C#

```
public virtual void OnCompleted()
{
   Console.WriteLine("The Location Tracker has completed transmitting data
to {0}.", this.Name);
   this.Unsubscribe();
}
```

Remarks

When the observer's OnCompleted implementation is called, the OnCompleted method can optionally call the Dispose method of the IDisposable object that was returned to the observer when it called the IObservable<T>.Subscribe method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

IObserver<T>.OnError(Exception) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Notifies the observer that the provider has experienced an error condition.

```
C#

public void OnError (Exception error);
```

Parameters

`error` Exception

An object that provides additional information about the error.

Examples

The following example provides an implementation of the OnError method in a latitude/longitude tracking application. The method simply reports that data is currently unavailable; it does not make use of the Exception object passed to it as a parameter. See the Example section of the IObserver<T> topic for the complete example.

```
C#

public virtual void OnError(Exception e)
{
   Console.WriteLine("{0}: The location cannot be determined.", this.Name);
}
```

Remarks

Although `error` is an object that is derived from System.Exception, it does not necessarily represent an exception that is thrown by the provider. It can also represent a routine or expected error condition, such as data that is missing or unavailable. The

OnError method should be seen as informational, and the provider should not expect the observer to provide error handling.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IObserver<T>.OnNext(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides the observer with new data.

```
C#

public void OnNext (T value);
```

Parameters

`value` T

The current notification information.

Examples

The following example provides an implementation of the OnNext method in a latitude/longitude tracking application. See the Example section of the IObserver<T> topic for the complete example.

```
C#

public virtual void OnNext(Location value)
{
   Console.WriteLine("{2}: The current location is {0}, {1}",
value.Latitude, value.Longitude, this.Name);
}
```

Remarks

After an observer has called a provider's IObservable<T>.Subscribe method, the provider calls the observer's OnNext method to provide notifications.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IParsable<TSelf>.Parse(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a string into a value.

```
C#
public static abstract TSelf Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

TSelf

The result of parsing `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` is not representable by `TSelf`.

Applies to

Product	Versions
.NET	7, 8, 9

IParsable<TSelf>.TryParse(String, IFormatProvider, TSelf) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to parse a string into a value.

```
C#

public static abstract bool TryParse (string? s, IFormatProvider? provider,
out TSelf result);
```

Parameters

s String

The string to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

result TSelf

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

IProgress<T> Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a provider for progress updates.

C#

```
public interface IProgress<in T>
```

Type Parameters

T

The type of progress update value.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Derived System.Progress<T>

Methods

Expand table

Report(T)	Reports a progress update.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

IProgress<T>.Report(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reports a progress update.

C#

```
public void Report (T value);
```

Parameters

`value` T

The value of the updated progress.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

IServiceProvider Interface

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.dll

Defines a mechanism for retrieving a service object; that is, an object that provides custom support to other objects.

C#

```
public interface IServiceProvider
```

Derived Microsoft.Extensions.DependencyInjection.IKeyedServiceProvider
Microsoft.Extensions.DependencyInjection.ServiceProvider
System.Activities.Presentation.ServiceManager
System.CommandLine.Binding.BindingContext
System.ComponentModel.DataAnnotations.ValidationContext
More...

Remarks

This interface is implemented by a class or value type that provides a service to other objects.

The GetService method of this interface obtains the object that provides the service.

The IServiceProvider interface is implemented by a number of types, including System.Web.HttpContext, System.ComponentModel.LicenseContext, System.ComponentModel.MarshalByValueComponent, and System.ComponentModel.Design.ServiceContainer.

Methods

Expand table

GetService(Type)	Gets the service object of the specified type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1
UWP	10.0

IServiceProvider.GetService(Type) Method

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.dll

Gets the service object of the specified type.

```
C#
public object? GetService (Type serviceType);
```

Parameters

`serviceType` Type

An object that specifies the type of service object to get.

Returns

Object

A service object of type `serviceType`.

-or-

`null` if there is no service object of type `serviceType`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1
UWP	10.0

ISpanFormattable Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides functionality to format the string representation of an object into a span.

C#

```
public interface ISpanFormattable : IFormattable
```

Derived System.Byte
System.Char
System.DateOnly
System.DateTime
System.DateTimeOffset
More...

Implements IFormattable

Methods

Expand table

ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format. (Inherited from IFormattable)
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

ISpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format, IFormatProvider? provider);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Remarks

- An implementation of this interface should produce the same string of characters as an implementation of ToString(String, IFormatProvider) on the same type.
- TryFormat should return false only if there is not enough space in the destination buffer. Any other failures should throw an exception.

Applies to

Product	Versions
.NET	6, 7, 8, 9

ISpanParsable<TSelf> Interface

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a mechanism for parsing a span of characters to a value.

C#

```
public interface ISpanParsable<TSelf> : IParsable<TSelf> where TSelf :
ISpanParsable<TSelf>
```

Type Parameters

TSelf

The type that implements this interface.

Derived System.Boolean
System.Byte
System.Char
System.DateOnly
System.DateTime
More...

Implements IParsable<TSelf>

Methods

Expand table

Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, TSelf)	Tries to parse a span of characters into a value.

ISpanParsable<TSelf>.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a span of characters into a value.

```
C#

public static abstract TSelf Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

TSelf

The result of parsing `s`.

Exceptions

FormatException

`s` is not in the correct format.

OverflowException

`s` is not representable by `TSelf`.

Applies to

Product	Versions
.NET	7, 8, 9

ISpanParsable<TSelf>.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to parse a span of characters into a value.

C#

```
public static abstract bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out TSelf result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

result TSelf

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

Product	Versions
.NET	7, 8, 9

IUtf8SpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format, IFormatProvider? provider);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Remarks

An implementation of this interface should produce the same string of characters as an implementation of ToString(String, IFormatProvider) or TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider) on the same type. TryFormat should return `false` only if there is not enough space in the destination buffer; any other failures should throw an exception.

Lazy<T> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides support for lazy initialization.

```
C#
public class Lazy<T>
```

Type Parameters

T

The type of object that is being lazily initialized.

Inheritance Object → Lazy<T>

Derived System.Lazy<T,TMetadata>

Examples

The following example demonstrates the use of the Lazy<T> class to provide lazy initialization with access from multiple threads.

> **Note**
>
> The example uses the **Lazy<T>(Func<T>)** constructor. It also demonstrates the use of the **Lazy<T>(Func<T>, Boolean)** constructor (specifying `true` for `isThreadSafe`) and the **Lazy<T>(Func<T>, LazyThreadSafetyMode)** constructor (specifying **LazyThreadSafetyMode.ExecutionAndPublication** for `mode`). To switch to a different constructor, just change which constructors are commented out.
>
> For an example that demonstrates exception caching using the same constructors, see the **Lazy<T>(Func<T>)** constructor.

The example defines a `LargeObject` class that will be initialized lazily by one of several threads. The four key sections of code illustrate the creation of the initializer, the factory method, the actual initialization, and the constructor of the `LargeObject` class, which displays a message when the object is created. At the beginning of the `Main` method, the example creates the thread-safe lazy initializer for `LargeObject`:

C#

```
lazyLargeObject = new Lazy<LargeObject>(InitLargeObject);

// The following lines show how to use other constructors to achieve exactly
the
// same result as the previous line:
//lazyLargeObject = new Lazy<LargeObject>(InitLargeObject, true);
//lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
//
LazyThreadSafetyMode.ExecutionAndPublication);
```

The factory method shows the creation of the object, with a placeholder for further initialization:

C#

```
static LargeObject InitLargeObject()
{
    LargeObject large = new
LargeObject(Thread.CurrentThread.ManagedThreadId);
    // Perform additional initialization here.
    return large;
}
```

Note that the first two code sections could be combined by using a lambda function, as shown here:

C#

```
lazyLargeObject = new Lazy<LargeObject>(() =>
{
    LargeObject large = new
LargeObject(Thread.CurrentThread.ManagedThreadId);
    // Perform additional initialization here.
    return large;
});
```

The example pauses, to indicate that an indeterminate period may elapse before lazy initialization occurs. When you press the **Enter** key, the example creates and starts three

threads. The `ThreadProc` method that's used by all three threads calls the Value property. The first time this happens, the `LargeObject` instance is created:

C#

```
LargeObject large = lazyLargeObject.Value;

// IMPORTANT: Lazy initialization is thread-safe, but it doesn't protect the
//            object after creation. You must lock the object before
accessing it,
//            unless the type is thread safe. (LargeObject is not thread
safe.)
lock(large)
{
    large.Data[0] = Thread.CurrentThread.ManagedThreadId;
    Console.WriteLine("Initialized by thread {0}; last used by thread {1}.",
        large.InitializedBy, large.Data[0]);
}
```

The constructor of the `LargeObject` class, which includes the last key section of code, displays a message and records the identity of the initializing thread. The output from the program appears at the end of the full code listing.

C#

```
int initBy = 0;
public LargeObject(int initializedBy)
{
    initBy = initializedBy;
    Console.WriteLine("LargeObject was created on thread id {0}.", initBy);
}
```

> **Note**
>
> For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;
```

```
    static LargeObject InitLargeObject()
    {
        LargeObject large = new
LargeObject(Thread.CurrentThread.ManagedThreadId);
        // Perform additional initialization here.
        return large;
    }

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not created
until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>(InitLargeObject);

        // The following lines show how to use other constructors to achieve
exactly the
        // same result as the previous line:
        //lazyLargeObject = new Lazy<LargeObject>(InitLargeObject, true);
        //lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
        //
LazyThreadSafetyMode.ExecutionAndPublication);

        Console.WriteLine(
            "\r\nLargeObject is not created until you access the Value
property of the lazy" +
            "\r\ninitializer. Press Enter to create LargeObject.");
        Console.ReadLine();

        // Create and start 3 threads, each of which uses LargeObject.
        Thread[] threads = new Thread[3];
        for (int i = 0; i < 3; i++)
        {
            threads[i] = new Thread(ThreadProc);
            threads[i].Start();
        }

        // Wait for all 3 threads to finish.
        foreach (Thread t in threads)
        {
            t.Join();
        }

        Console.WriteLine("\r\nPress Enter to end the program");
        Console.ReadLine();
    }

    static void ThreadProc(object state)
    {
        LargeObject large = lazyLargeObject.Value;

        // IMPORTANT: Lazy initialization is thread-safe, but it doesn't
protect the
        //            object after creation. You must lock the object before
accessing it,
```

```
        //            unless the type is thread safe. (LargeObject is not
thread safe.)
        lock(large)
        {
            large.Data[0] = Thread.CurrentThread.ManagedThreadId;
            Console.WriteLine("Initialized by thread {0}; last used by
thread {1}.",
                large.InitializedBy, large.Data[0]);
        }
    }
}

class LargeObject
{
    public int InitializedBy { get { return initBy; } }

    int initBy = 0;
    public LargeObject(int initializedBy)
    {
        initBy = initializedBy;
        Console.WriteLine("LargeObject was created on thread id {0}.",
initBy);
    }

    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:

LargeObject is not created until you access the Value property of the lazy
initializer. Press Enter to create LargeObject.

LargeObject was created on thread id 3.
Initialized by thread 3; last used by thread 3.
Initialized by thread 3; last used by thread 4.
Initialized by thread 3; last used by thread 5.

Press Enter to end the program
 */
```

Remarks

Use lazy initialization to defer the creation of a large or resource-intensive object, or the execution of a resource-intensive task, particularly when such creation or execution might not occur during the lifetime of the program.

To prepare for lazy initialization, you create an instance of Lazy<T>. The type argument of the Lazy<T> object that you create specifies the type of the object that you want to initialize lazily. The constructor that you use to create the Lazy<T> object determines

the characteristics of the initialization. Lazy initialization occurs the first time the Lazy<T>.Value property is accessed.

In most cases, choosing a constructor depends on your answers to two questions:

- Will the lazily initialized object be accessed from more than one thread? If so, the Lazy<T> object might create it on any thread. You can use one of the simple constructors whose default behavior is to create a thread-safe Lazy<T> object, so that only one instance of the lazily instantiated object is created no matter how many threads try to access it. To create a Lazy<T> object that is not thread safe, you must use a constructor that enables you to specify no thread safety.

  > ⊗ **Caution**
  >
  > Making the **Lazy<T>** object thread safe does not protect the lazily initialized object. If multiple threads can access the lazily initialized object, you must make its properties and methods safe for multithreaded access.

- Does lazy initialization require a lot of code, or does the lazily initialized object have a parameterless constructor that does everything you need and doesn't throw exceptions? If you need to write initialization code or if exceptions need to be handled, use one of the constructors that takes a factory method. Write your initialization code in the factory method.

The following table shows which constructor to choose, based on these two factors:

Expand table

Object will be accessed by	If no initialization code is required (parameterless constructor), use	If initialization code is required, use
Multiple threads	Lazy<T>()	Lazy<T>(Func<T>)
One thread	Lazy<T>(Boolean) with `isThreadSafe` set to `false`.	Lazy<T>(Func<T>, Boolean) with `isThreadSafe` set to `false`.

You can use a lambda expression to specify the factory method. This keeps all the initialization code in one place. The lambda expression captures the context, including any arguments you pass to the lazily initialized object's constructor.

Exception caching When you use factory methods, exceptions are cached. That is, if the factory method throws an exception the first time a thread tries to access the Value property of the Lazy<T> object, the same exception is thrown on every subsequent

attempt. This ensures that every call to the Value property produces the same result and avoids subtle errors that might arise if different threads get different results. The Lazy<T> stands in for an actual `T` that otherwise would have been initialized at some earlier point, usually during startup. A failure at that earlier point is usually fatal. If there is a potential for a recoverable failure, we recommend that you build the retry logic into the initialization routine (in this case, the factory method), just as you would if you weren't using lazy initialization.

Alternative to locking In certain situations, you might want to avoid the overhead of the Lazy<T> object's default locking behavior. In rare situations, there might be a potential for deadlocks. In such cases, you can use the Lazy<T>(LazyThreadSafetyMode) or Lazy<T>(Func<T>, LazyThreadSafetyMode) constructor, and specify LazyThreadSafetyMode.PublicationOnly. This enables the Lazy<T> object to create a copy of the lazily initialized object on each of several threads if the threads call the Value property simultaneously. The Lazy<T> object ensures that all threads use the same instance of the lazily initialized object and discards the instances that are not used. Thus, the cost of reducing the locking overhead is that your program might sometimes create and discard extra copies of an expensive object. In most cases, this is unlikely. The examples for the Lazy<T>(LazyThreadSafetyMode) and Lazy<T>(Func<T>, LazyThreadSafetyMode) constructors demonstrate this behavior.

> **Important**
>
> When you specify **LazyThreadSafetyMode.PublicationOnly**, exceptions are never cached, even if you specify a factory method.

Equivalent constructors In addition to enabling the use of LazyThreadSafetyMode.PublicationOnly, the Lazy<T>(LazyThreadSafetyMode) and Lazy<T>(Func<T>, LazyThreadSafetyMode) constructors can duplicate the functionality of the other constructors. The following table shows the parameter values that produce equivalent behavior.

Expand table

Other capabilities For information about the use of Lazy<T> with thread-static fields, or as the backing store for properties, see Lazy Initialization.

Constructors

Expand table

Lazy<T>()	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the parameterless constructor of the target type is used.
Lazy<T>(Boolean)	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the parameterless constructor of the target type and the specified initialization mode are used.
Lazy<T>(Func<T>)	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the specified initialization function is used.
Lazy<T>(Func<T>, Boolean)	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the specified initialization function and initialization mode are used.
Lazy<T>(Func<T>, LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T> class that uses the specified initialization function and thread-safety mode.
Lazy<T>(LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T> class that uses the parameterless constructor of `T` and the specified thread-safety mode.
Lazy<T>(T)	Initializes a new instance of the Lazy<T> class that uses a preinitialized specified value.

Properties

Expand table

IsValueCreated	Gets a value that indicates whether a value has been created for this Lazy<T> instance.
Value	Gets the lazily initialized value of the current Lazy<T> instance.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the Value property for this instance.

UWP	10.0

Thread Safety

By default, all public and protected members of the Lazy<T> class are thread safe and may be used concurrently from multiple threads. These thread-safety guarantees may

be removed optionally and per instance, using parameters to the type's constructors.

Lazy<T> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Lazy<T> class.

Overloads

Expand table

Lazy<T>()	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the parameterless constructor of the target type is used.
Lazy<T>(Boolean)	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the parameterless constructor of the target type and the specified initialization mode are used.
Lazy<T>(Func<T>)	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the specified initialization function is used.
Lazy<T>(LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T> class that uses the parameterless constructor of `T` and the specified thread-safety mode.
Lazy<T>(T)	Initializes a new instance of the Lazy<T> class that uses a preinitialized specified value.
Lazy<T>(Func<T>, Boolean)	Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the specified initialization function and initialization mode are used.
Lazy<T>(Func<T>, LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T> class that uses the specified initialization function and thread-safety mode.

Lazy<T>()

Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the parameterless constructor of the target type is used.

```C#
public Lazy ();
```

Examples

The following example demonstrates the use of this constructor. It also illustrates the use of the Lazy<T>(Boolean) constructor (specifying `true` for `isThreadSafe`) and the Lazy<T>(LazyThreadSafetyMode) constructor (specifying LazyThreadSafetyMode.ExecutionAndPublication for `mode`). To switch to a different constructor, just change which constructors are commented out.

The example defines a `LargeObject` class that will be initialized lazily by one of several threads. The two key lines of code in this example are the creation of the initializer and the actual initialization. At the beginning of the `Main` method, the example creates the thread-safe lazy initializer for `LargeObject`:

```C#
lazyLargeObject = new Lazy<LargeObject>();

// The following lines show how to use other constructors to achieve
exactly the
// same result as the previous line:
//lazyLargeObject = new Lazy<LargeObject>(true);
//lazyLargeObject = new Lazy<LargeObject>
(LazyThreadSafetyMode.ExecutionAndPublication);
```

The example creates and starts three threads that block on a ManualResetEvent object, so that the example can release the threads all at once. The `ThreadProc` method that's used by all three threads calls the Value property to get the `LargeObject` instance:

```C#
LargeObject large = lazyLargeObject.Value;
```

The Lazy<T> class provides locking, so that only one thread is allowed to create the `LargeObject` instance. The example demonstrates that the other threads all get the same instance.

ⓘ **Note**

For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not
created until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>();

        // The following lines show how to use other constructors to
achieve exactly the
        // same result as the previous line:
        //lazyLargeObject = new Lazy<LargeObject>(true);
        //lazyLargeObject = new Lazy<LargeObject>
(LazyThreadSafetyMode.ExecutionAndPublication);

        Console.WriteLine(
            "\r\nLargeObject is not created until you access the Value
property of the lazy" +
            "\r\ninitializer. Press Enter to create LargeObject.");
        Console.ReadLine();

        // Create and start 3 threads, passing the same blocking event to
all of them.
        ManualResetEvent startingGate = new ManualResetEvent(false);
        Thread[] threads = { new Thread(ThreadProc), new
Thread(ThreadProc), new Thread(ThreadProc) };
        foreach (Thread t in threads)
        {
            t.Start(startingGate);
        }

        // Give all 3 threads time to start and wait, then release them
all at once.
        Thread.Sleep(100);
        startingGate.Set();

        // Wait for all 3 threads to finish. (The order doesn't matter.)
        foreach (Thread t in threads)
        {
            t.Join();
```

```
        }

        Console.WriteLine("\r\nPress Enter to end the program");
        Console.ReadLine();
    }

    static void ThreadProc(object state)
    {
        // Wait for the signal.
        ManualResetEvent waitForStart = (ManualResetEvent) state;
        waitForStart.WaitOne();

        LargeObject large = lazyLargeObject.Value;

        // The following line introduces an artificial delay to
exaggerate the race condition.
        Thread.Sleep(5);

        // IMPORTANT: Lazy initialization is thread-safe, but it doesn't
protect the
        //            object after creation. You must lock the object
before accessing it,
        //            unless the type is thread safe. (LargeObject is not
thread safe.)
        lock(large)
        {
            large.Data[0] = Thread.CurrentThread.ManagedThreadId;
            Console.WriteLine("Initialized by thread {0}; last used by
thread {1}.",
                large.InitializedBy, large.Data[0]);
        }
    }
}

class LargeObject
{
    int initBy = 0;
    public int InitializedBy { get { return initBy; } }

    public LargeObject()
    {
        initBy = Thread.CurrentThread.ManagedThreadId;
        Console.WriteLine("LargeObject was created on thread id {0}.",
initBy);
    }
    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:

LargeObject is not created until you access the Value property of the
lazy
initializer. Press Enter to create LargeObject.

LargeObject was created on thread id 4.
```

```
 Initialized by thread 4; last used by thread 3.
 Initialized by thread 4; last used by thread 4.
 Initialized by thread 4; last used by thread 5.

 Press Enter to end the program
  */
```

Remarks

An instance that is created with this constructor may be used concurrently from multiple threads.

The thread safety mode of a Lazy<T> instance that is initialized with this constructor is LazyThreadSafetyMode.ExecutionAndPublication. The thread safety mode describes the behavior when multiple threads try to initialize the Lazy<T> instance.

A Lazy<T> instance that is created with this constructor does not cache exceptions. For more information, see the Lazy<T> class or the System.Threading.LazyThreadSafetyMode enumeration.

UWP	10.0

Lazy<T>(Boolean)

Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the parameterless constructor of the target type and the specified initialization mode are used.

```
C#

public Lazy (bool isThreadSafe);
```

Parameters

`isThreadSafe` Boolean

`true` to make this instance usable concurrently by multiple threads; `false` to make the instance usable by only one thread at a time.

Examples

The following example demonstrates the use of this constructor to create a lazy initializer that is not thread safe, for scenarios where all access to the lazily initialized object occurs on the same thread. It also demonstrates the use of the Lazy<T> (LazyThreadSafetyMode) constructor (specifying LazyThreadSafetyMode.None for `mode`. To switch to a different constructor, just change which constructor is commented out.

> ⓘ **Note**
>
> For code that demonstrates how to use this constructor in multithreaded scenarios (specifying `true` for `isThreadSafe`), see the example for the **Lazy<T>()** constructor.

The example defines a `LargeObject` class that will be initialized lazily. In the `Main` method, the example creates a Lazy<T> instance and then pauses. When you press the **Enter** key, the example accesses the Value property of the Lazy<T> instance, which causes initialization to occur. The constructor of the `LargeObject` class displays a console message.

> ⓘ **Note**

For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not
created until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>(false);

        // The following lines show how to use other constructors to
achieve exactly the
        // same result as the previous line:
        //lazyLargeObject = new Lazy<LargeObject>
(LazyThreadSafetyMode.None);

        Console.WriteLine(
            "\r\nLargeObject is not created until you access the Value
property of the lazy" +
            "\r\ninitializer. Press Enter to create LargeObject.");
        Console.ReadLine();

        LargeObject large = lazyLargeObject.Value;

        large.Data[11] = 89;

        Console.WriteLine("\r\nPress Enter to end the program");
        Console.ReadLine();
    }
}

class LargeObject
{
    public LargeObject()
    {
        Console.WriteLine("LargeObject was created on thread id {0}.",
            Thread.CurrentThread.ManagedThreadId);
    }
    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:
```

```
LargeObject is not created until you access the Value property of the
lazy
initializer. Press Enter to create LargeObject.

LargeObject was created on thread id 1.

Press Enter to end the program
 */
```

Remarks

The thread safety mode of a Lazy<T> instance that is initialized with this constructor is LazyThreadSafetyMode.ExecutionAndPublication if `isThreadSafe` is `true`; otherwise, the mode is LazyThreadSafetyMode.None. The thread safety mode describes the behavior when multiple threads try to initialize the Lazy<T> instance. To specify the LazyThreadSafetyMode.PublicationOnly mode, use the Lazy<T>(Func<T>, LazyThreadSafetyMode) or Lazy<T>(LazyThreadSafetyMode) constructor.

A Lazy<T> instance that is created with this constructor does not cache exceptions. For more information, see the Lazy<T> class or the System.Threading.LazyThreadSafetyMode enumeration.

UWP	10.0

Lazy<T>(Func<T>)

Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the specified initialization function is used.

```
C#

public Lazy (Func<T> valueFactory);
```

Parameters

`valueFactory` Func<T>

The delegate that is invoked to produce the lazily initialized value when it is needed.

Exceptions

ArgumentNullException

`valueFactory` is `null`.

Examples

The following example demonstrates the use of this constructor to provide lazy initialization with exception caching. It also demonstrates the use of the Lazy<T> (Func<T>, Boolean) constructor (specifying `true` for `isThreadSafe`) and the Lazy<T> (Func<T>, LazyThreadSafetyMode) constructor (specifying LazyThreadSafetyMode.ExecutionAndPublication for `mode`). To switch to a different constructor, just change which constructors are commented out.

The example defines a `LargeObject` class that will be initialized lazily by one of several threads. The three key sections of code illustrate the creation of the initializer, the actual initialization, and the constructor of the `LargeObject` class, which demonstrates exception caching. At the beginning of the `Main` method, the example creates the thread-safe lazy initializer for `LargeObject`:

```
C#

lazyLargeObject = new Lazy<LargeObject>(InitLargeObject);

// The following lines show how to use other constructors to achieve
exactly the
// same result as the previous line:
//lazyLargeObject = new Lazy<LargeObject>(InitLargeObject, true);
//lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
LazyThreadSafetyMode.ExecutionAndPublication);
```

The example creates and starts three threads. The `ThreadProc` method that's used by all three threads calls the Value property to get the `LargeObject` instance:

```C#
try
{
    LargeObject large = lazyLargeObject.Value;

    // IMPORTANT: Lazy initialization is thread-safe, but it doesn't protect the
    //            object after creation. You must lock the object before accessing it,
    //            unless the type is thread safe. (LargeObject is not thread safe.)
    lock(large)
    {
        large.Data[0] = Thread.CurrentThread.ManagedThreadId;
        Console.WriteLine("Initialized by thread {0}; last used by thread {1}.",
            large.InitializedBy, large.Data[0]);
    }
}
catch (ApplicationException aex)
{
    Console.WriteLine("Exception: {0}", aex.Message);
}
```

In the constructor of the `LargeObject` class, the third key section of code throws an exception the first time a `LargeObject` instance is created, but thereafter allows instance creation to occur:

```C#
static int instanceCount = 0;
public LargeObject()
{
    if (1 == Interlocked.Increment(ref instanceCount))
    {
        throw new ApplicationException("Throw only ONCE.");
    }

    initBy = Thread.CurrentThread.ManagedThreadId;
    Console.WriteLine("LargeObject was created on thread id {0}.", initBy);
}
```

When the example is run, the first thread that tries to create an instance of `LargeObject` fails, and the exception is caught. You might expect that the next thread

would successfully create an instance, but the Lazy<T> object has cached the exception. Because of this, all three threads throw the exception.

> **Note**
>
> For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;

    static LargeObject InitLargeObject()
    {
        return new LargeObject();
    }

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not
created until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>(InitLargeObject);

        // The following lines show how to use other constructors to
achieve exactly the
        // same result as the previous line:
        //lazyLargeObject = new Lazy<LargeObject>(InitLargeObject, true);
        //lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
LazyThreadSafetyMode.ExecutionAndPublication);

        Console.WriteLine(
            "\r\nLargeObject is not created until you access the Value
property of the lazy" +
            "\r\ninitializer. Press Enter to create LargeObject.");
        Console.ReadLine();

        // Create and start 3 threads, each of which tries to use
LargeObject.
        Thread[] threads = { new Thread(ThreadProc), new
Thread(ThreadProc), new Thread(ThreadProc) };
        foreach (Thread t in threads)
        {
            t.Start();
        }
```

```
        // Wait for all 3 threads to finish. (The order doesn't matter.)
        foreach (Thread t in threads)
        {
            t.Join();
        }

        Console.WriteLine("\r\nPress Enter to end the program");
        Console.ReadLine();
    }

    static void ThreadProc(object state)
    {
        try
        {
            LargeObject large = lazyLargeObject.Value;

            // IMPORTANT: Lazy initialization is thread-safe, but it
doesn't protect the
            //            object after creation. You must lock the object
before accessing it,
            //            unless the type is thread safe. (LargeObject is
not thread safe.)
            lock(large)
            {
                large.Data[0] = Thread.CurrentThread.ManagedThreadId;
                Console.WriteLine("Initialized by thread {0}; last used
by thread {1}.",
                    large.InitializedBy, large.Data[0]);
            }
        }
        catch (ApplicationException aex)
        {
            Console.WriteLine("Exception: {0}", aex.Message);
        }
    }
}

class LargeObject
{
    int initBy = 0;
    public int InitializedBy { get { return initBy; } }

    static int instanceCount = 0;
    public LargeObject()
    {
        if (1 == Interlocked.Increment(ref instanceCount))
        {
            throw new ApplicationException("Throw only ONCE.");
        }

        initBy = Thread.CurrentThread.ManagedThreadId;
        Console.WriteLine("LargeObject was created on thread id {0}.",
initBy);
    }
```

```
    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:

LargeObject is not created until you access the Value property of the
lazy
initializer. Press Enter to create LargeObject.

Exception: Throw only ONCE.
Exception: Throw only ONCE.
Exception: Throw only ONCE.

Press Enter to end the program
 */
```

Remarks

An instance that is created with this constructor may be used concurrently from multiple threads.

The thread safety mode of a Lazy<T> instance that is initialized with this constructor is LazyThreadSafetyMode.ExecutionAndPublication. The thread safety mode describes the behavior when multiple threads try to initialize the Lazy<T> instance.

Exceptions that are thrown by `valueFactory` are cached. For more information, see the Lazy<T> class or the System.Threading.LazyThreadSafetyMode enumeration.

Lazy<T>(LazyThreadSafetyMode)

Initializes a new instance of the Lazy<T> class that uses the parameterless constructor of `T` and the specified thread-safety mode.

```
C#
public Lazy (System.Threading.LazyThreadSafetyMode mode);
```

Parameters

`mode` LazyThreadSafetyMode

One of the enumeration values that specifies the thread safety mode.

Exceptions

ArgumentOutOfRangeException

`mode` contains an invalid value.

Examples

The following example demonstrates the use of this constructor to create a lazy initializer that enables multiple threads to race to create an object lazily. Multiple threads might succeed in creating instances, but all threads use the instance that was created first.

> ⓘ **Note**
>
> For an example that demonstrates how to use this constructor in single-threaded scenarios (specifying **LazyThreadSafetyMode.None** for `mode`), see the **Lazy<T>(Boolean)** constructor. For an example that demonstrates how to use this constructor to provide locking instead of race conditions in multithreaded scenarios (specifying **LazyThreadSafetyMode.ExecutionAndPublication** for `mode`), see the **Lazy<T>()** constructor.

The example defines a `LargeObject` class that will be initialized lazily by any of several threads. The three key sections of code illustrate the creation of the initializer, the actual initialization, and the constructor and finalizer of the `LargeObject` class. At the beginning of the `Main` method, the example creates the Lazy<T> object that performs lazy initialization of the `LargeObject`:

```
C#

lazyLargeObject = new Lazy<LargeObject>
(LazyThreadSafetyMode.PublicationOnly);
```

The example creates and starts three threads that block on a ManualResetEvent object, so that the example can release the threads all at once. In the `ThreadProc` method that's used by all three threads, calling the Value property creates the `LargeObject` instance:

```
C#

LargeObject large = lazyLargeObject.Value;
```

Because the constructor for the Lazy<T> instance specified LazyThreadSafetyMode.PublicationOnly, all three threads are allowed to create `LargeObject` instances. The example demonstrates this by displaying console messages in the constructor and in the finalizer of the `LargeObject` class:

```
C#

public LargeObject()
{
    initBy = Thread.CurrentThread.ManagedThreadId;
    Console.WriteLine("Constructor: Instance initializing on thread {0}",
initBy);
}

~LargeObject()
{
    Console.WriteLine("Finalizer: Instance was initialized on {0}",
initBy);
}
```

However, the Lazy<T> object ensures that only one instance is used by all threads. The output from the example shows that all three threads use the same instance, and also shows that the other two instances can be reclaimed by garbage collection.

> **Note**
>
> For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not
created until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>
(LazyThreadSafetyMode.PublicationOnly);

        // Create and start 3 threads, passing the same blocking event to
all of them.
        ManualResetEvent startingGate = new ManualResetEvent(false);
        Thread[] threads = { new Thread(ThreadProc), new
Thread(ThreadProc), new Thread(ThreadProc) };
        foreach (Thread t in threads)
        {
            t.Start(startingGate);
        }

        // Give all 3 threads time to start and wait, then release them
all at once.
        Thread.Sleep(50);
        startingGate.Set();

        // Wait for all 3 threads to finish. (The order doesn't matter.)
        foreach (Thread t in threads)
        {
            t.Join();
        }

        Console.WriteLine(
            "\r\nThreads are complete. Running GC.Collect() to reclaim
the extra instances.");

        GC.Collect();

        // Allow time for garbage collection, which happens
```

```
asynchronously.
        Thread.Sleep(100);

        Console.WriteLine(
            "\r\nNote that all three threads used the instance that was
not collected.");
        Console.WriteLine("Press Enter to end the program");
        Console.ReadLine();
    }

    static void ThreadProc(object state)
    {
        // Wait for the signal.
        ManualResetEvent waitForStart = (ManualResetEvent) state;
        waitForStart.WaitOne();

        LargeObject large = lazyLargeObject.Value;

        // The following line introduces an artificial delay, to
exaggerate the race
        // condition.
        Thread.Sleep(5);

        // IMPORTANT: Lazy initialization is thread-safe, but it doesn't
protect the
        //            object after creation. You must lock the object
before accessing it,
        //            unless the type is thread safe. (LargeObject is not
thread safe.)
        lock(large)
        {
            large.Data[0] = Thread.CurrentThread.ManagedThreadId;
            Console.WriteLine("LargeObject was initialized by thread {0};
last used by thread {1}.",
                large.InitializedBy, large.Data[0]);
        }
    }
}

class LargeObject
{
    int initBy = -1;
    public int InitializedBy { get { return initBy; } }

    public LargeObject()
    {
        initBy = Thread.CurrentThread.ManagedThreadId;
        Console.WriteLine("Constructor: Instance initializing on thread
{0}", initBy);
    }

    ~LargeObject()
    {
        Console.WriteLine("Finalizer: Instance was initialized on {0}",
initBy);
```

```
    }

    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:

Constructor: Instance initializing on thread 4
Constructor: Instance initializing on thread 3
Constructor: Instance initializing on thread 5
LargeObject was initialized by thread 4; last used by thread 4.
LargeObject was initialized by thread 4; last used by thread 5.
LargeObject was initialized by thread 4; last used by thread 3.

Threads are complete. Running GC.Collect() to reclaim the extra
instances.
Finalizer: Instance was initialized on 3
Finalizer: Instance was initialized on 5

Note that all three threads used the instance that was not collected.
Press Enter to end the program

Instance finalizing; initialized on 4
 */
```

Remarks

The thread safety mode of a Lazy<T> instance describes the behavior when multiple threads try to initialize the Lazy<T> instance.

A Lazy<T> instance that is created with this constructor does not cache exceptions. For more information, see the Lazy<T> class or the System.Threading.LazyThreadSafetyMode enumeration.

Lazy<T>(T)

Initializes a new instance of the Lazy<T> class that uses a preinitialized specified value.

```
C#

public Lazy (T value);
```

Parameters

`value` T

The preinitialized value to be used.

Remarks

An instance created with this constructor is usable by multiple threads concurrently.

Lazy<T>(Func<T>, Boolean)

Initializes a new instance of the Lazy<T> class. When lazy initialization occurs, the specified initialization function and initialization mode are used.

```
C#
```

```
public Lazy (Func<T> valueFactory, bool isThreadSafe);
```

Parameters

`valueFactory` Func<T>

The delegate that is invoked to produce the lazily initialized value when it is needed.

`isThreadSafe` Boolean

`true` to make this instance usable concurrently by multiple threads; `false` to make this instance usable by only one thread at a time.

Exceptions

ArgumentNullException

`valueFactory` is `null`.

Examples

The following example demonstrates the use of this constructor to provide lazy initialization with exception caching, in a scenario with a single thread. It also demonstrates the use of the Lazy<T> constructor (specifying LazyThreadSafetyMode.None for `mode`). To switch to that constructor, just change which constructor is commented out.

> **Note**
>
> For code that demonstrates how to use this constructor in multithreaded scenarios (specifying `true` for `isThreadSafe`), see the example for the **Lazy<T> (Func<T>)** constructor.

The example defines a `LargeObject` class that will be initialized lazily by one of several threads. The three key sections of code illustrate the creation of the initializer, the actual initialization, and the constructor of the `LargeObject` class, which demonstrates exception caching. At the beginning of the `Main` method, the example creates the thread-safe lazy initializer for `LargeObject`:

```
C#
```

```
lazyLargeObject = new Lazy<LargeObject>(InitLargeObject, false);

// The following lines show how to use other constructors to achieve
exactly the
// same result as the previous line:
//lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
LazyThreadSafetyMode.None);
```

In the call to the constructor, the `isThreadSafe` parameter is `false`, so the Lazy<T> is not thread safe. Because it's not thread safe, the example calls the Value property three times on the same thread:

C#

```
for (int i = 0; i < 3; i++)
{
    try
    {
        LargeObject large = lazyLargeObject.Value;
        large.Data[11] = 89;
    }
    catch (ApplicationException aex)
    {
        Console.WriteLine("Exception: {0}", aex.Message);
    }
}
```

In the constructor of the `LargeObject` class, the third key section of code throws an exception the first time a `LargeObject` instance is created, but thereafter allows instance creation to occur:

C#

```
static bool pleaseThrow = true;
public LargeObject()
{
    if (pleaseThrow)
    {
        pleaseThrow = false;
        throw new ApplicationException("Throw only ONCE.");
    }

    Console.WriteLine("LargeObject was created on thread id {0}.",
        Thread.CurrentThread.ManagedThreadId);
}
```

When the example is run, the first attempt to create an instance of `LargeObject` fails, and the exception is caught. You might expect that the next attempt would succeed, but the Lazy<T> object has cached the exception. Because of this, all three attempts throw the exception.

> **Note**
>
> For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;

    static LargeObject InitLargeObject()
    {
        return new LargeObject();
    }

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not
created until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>(InitLargeObject, false);

        // The following lines show how to use other constructors to
achieve exactly the
        // same result as the previous line:
        //lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
LazyThreadSafetyMode.None);

        Console.WriteLine(
            "\r\nLargeObject is not created until you access the Value
property of the lazy" +
            "\r\ninitializer. Press Enter to create LargeObject (three
tries).");
        Console.ReadLine();

        for (int i = 0; i < 3; i++)
        {
            try
            {
                LargeObject large = lazyLargeObject.Value;
```

```
                large.Data[11] = 89;
            }
            catch (ApplicationException aex)
            {
                Console.WriteLine("Exception: {0}", aex.Message);
            }
        }

        Console.WriteLine("\r\nPress Enter to end the program");
        Console.ReadLine();
    }
}

class LargeObject
{
    static bool pleaseThrow = true;
    public LargeObject()
    {
        if (pleaseThrow)
        {
            pleaseThrow = false;
            throw new ApplicationException("Throw only ONCE.");
        }

        Console.WriteLine("LargeObject was created on thread id {0}.",
            Thread.CurrentThread.ManagedThreadId);
    }
    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:

LargeObject is not created until you access the Value property of the
lazy
initializer. Press Enter to create LargeObject (three tries).

Exception: Throw only ONCE.
Exception: Throw only ONCE.
Exception: Throw only ONCE.

Press Enter to end the program
 */
```

Remarks

The thread safety mode of a Lazy<T> instance that is initialized with this constructor is LazyThreadSafetyMode.ExecutionAndPublication if `isThreadSafe` is `true`; otherwise, the mode is LazyThreadSafetyMode.None. The thread safety mode describes the behavior when multiple threads try to initialize the Lazy<T> instance.

To specify the LazyThreadSafetyMode.PublicationOnly mode, use the Lazy<T>(Func<T>, LazyThreadSafetyMode) or Lazy<T>(LazyThreadSafetyMode) constructor.

Exceptions that are thrown by `valueFactory` are cached. For more information, see the Lazy<T> class or the System.Threading.LazyThreadSafetyMode enumeration.

Lazy<T>(Func<T>, LazyThreadSafetyMode)

Initializes a new instance of the Lazy<T> class that uses the specified initialization function and thread-safety mode.

C#

```
public Lazy (Func<T> valueFactory, System.Threading.LazyThreadSafetyMode
mode);
```

Parameters

`valueFactory` Func<T>

The delegate that is invoked to produce the lazily initialized value when it is needed.

`mode` LazyThreadSafetyMode

One of the enumeration values that specifies the thread safety mode.

Exceptions

ArgumentOutOfRangeException

`mode` contains an invalid value.

ArgumentNullException

`valueFactory` is `null`.

Examples

The following example demonstrates the use of this constructor to create a lazy initializer that enables multiple threads to race to create an object lazily. Multiple threads might succeed in creating instances, but all threads use the instance that was created first. In addition, the example demonstrates that exceptions are never cached when you specify LazyThreadSafetyMode.PublicationOnly, even if initialization is performed by a function instead of by the parameterless constructor of the lazily created type.

> ⓘ **Note**
>
> For an example that demonstrates how to use this constructor in single-threaded scenarios (specifying **LazyThreadSafetyMode.None** for `mode`), see the **Lazy<T>(Boolean)** constructor. For an example that demonstrates how to use this constructor to provide locking instead of race conditions in multithreaded scenarios (specifying **LazyThreadSafetyMode.ExecutionAndPublication** for `mode`), see the **Lazy<T>()** constructor.

The example defines a `LargeObject` class that will be initialized lazily by any of several threads. The four key sections of code illustrate the creation of the initializer, the actual initialization, the initialization function, and the constructor and finalizer of the `LargeObject` class. At the beginning of the `Main` method, the example creates the Lazy<T> object that performs lazy initialization of the `LargeObject`:

```C#
lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,
                                        LazyThreadSafetyMode.PublicationOnly);
```

The lazy initializer uses a function to perform the initialization. In this case, a function is required because there is no parameterless constructor for the `LargeObject` class.

The example creates and starts three threads that block on a ManualResetEvent object, so that the example can release the threads all at once. In the `ThreadProc` method that's used by all three threads, calling the Value property creates the `LargeObject` instance:

C#

```
LargeObject large = null;
try
{
    large = lazyLargeObject.Value;

    // The following line introduces an artificial delay to exaggerate
the race condition.
    Thread.Sleep(5);

    // IMPORTANT: Lazy initialization is thread-safe, but it doesn't
protect the
    //            object after creation. You must lock the object before
accessing it,
    //            unless the type is thread safe. (LargeObject is not
thread safe.)
    lock(large)
    {
        large.Data[0] = Thread.CurrentThread.ManagedThreadId;
        Console.WriteLine("LargeObject was initialized by thread {0};
last used by thread {1}.",
            large.InitializedBy, large.Data[0]);
    }
}
catch (ApplicationException ex)
{
    Console.WriteLine("ApplicationException: {0}", ex.Message);
}
```

In the third key section of code, the lazy initialization function is called to create the `LargeObject` instance. The function throws an exception the first time it's called:

C#

```
static int instanceCount = 0;
static LargeObject InitLargeObject()
{
    if (1 == Interlocked.Increment(ref instanceCount))
    {
        throw new ApplicationException(
            String.Format("Lazy initialization function failed on thread
{0}.",
            Thread.CurrentThread.ManagedThreadId));
    }
```

```
    return new LargeObject(Thread.CurrentThread.ManagedThreadId);
}
```

With any other LazyThreadSafetyMode setting, an unhandled exception in the initialization function would be cached. However, LazyThreadSafetyMode.PublicationOnly suppresses exception caching. The output from the example demonstrates that a subsequent attempt to initialize the object succeeds.

> **Note**
>
> The exception message usually appears after messages indicating that other threads have successfully initialized the object. This is because of the delay introduced by throwing and catching the exception.

Because the constructor for the Lazy<T> instance specified LazyThreadSafetyMode.PublicationOnly, all three threads are allowed to create `LargeObject` instances. The example demonstrates this by displaying console messages in the constructor and in the finalizer of the `LargeObject` class:

```C#
public LargeObject(int initializedBy)
{
    initBy = initializedBy;
    Console.WriteLine("Constructor: Instance initializing on thread {0}",
initBy);
}

~LargeObject()
{
    Console.WriteLine("Finalizer: Instance was initialized on {0}",
initBy);
}
```

The Lazy<T> object ensures that only one instance is used by all threads (except the thread where the initialization function throws an exception). The output from the example shows this.

> **Note**

For simplicity, this example uses a global instance of **Lazy<T>**, and all the methods are `static` (`Shared` in Visual Basic). These are not requirements for the use of lazy initialization.

C#

```
using System;
using System.Threading;

class Program
{
    static Lazy<LargeObject> lazyLargeObject = null;

    // Factory function for lazy initialization.
    static int instanceCount = 0;
    static LargeObject InitLargeObject()
    {
        if (1 == Interlocked.Increment(ref instanceCount))
        {
            throw new ApplicationException(
                String.Format("Lazy initialization function failed on
thread {0}.",
                Thread.CurrentThread.ManagedThreadId));
        }
        return new LargeObject(Thread.CurrentThread.ManagedThreadId);
    }

    static void Main()
    {
        // The lazy initializer is created here. LargeObject is not
created until the
        // ThreadProc method executes.
        lazyLargeObject = new Lazy<LargeObject>(InitLargeObject,

LazyThreadSafetyMode.PublicationOnly);

        // Create and start 3 threads, passing the same blocking event to
all of them.
        ManualResetEvent startingGate = new ManualResetEvent(false);
        Thread[] threads = { new Thread(ThreadProc), new
Thread(ThreadProc), new Thread(ThreadProc) };
        foreach (Thread t in threads)
        {
            t.Start(startingGate);
        }

        // Give all 3 threads time to start and wait, then release them
all at once.
        Thread.Sleep(50);
        startingGate.Set();

        // Wait for all 3 threads to finish. (The order doesn't matter.)
```

```
        foreach (Thread t in threads)
        {
            t.Join();
        }

        Console.WriteLine(
            "\r\nThreads are complete. Running GC.Collect() to reclaim
extra instances.");

        GC.Collect();

        // Allow time for garbage collection, which happens
asynchronously.
        Thread.Sleep(100);

        Console.WriteLine("\r\nNote that only one instance of LargeObject
was used.");
        Console.WriteLine("Press Enter to end the program");
        Console.ReadLine();
    }

    static void ThreadProc(object state)
    {
        // Wait for the signal.
        ManualResetEvent waitForStart = (ManualResetEvent) state;
        waitForStart.WaitOne();

        LargeObject large = null;
        try
        {
            large = lazyLargeObject.Value;

            // The following line introduces an artificial delay to
exaggerate the race condition.
            Thread.Sleep(5);

            // IMPORTANT: Lazy initialization is thread-safe, but it
doesn't protect the
            //            object after creation. You must lock the object
before accessing it,
            //            unless the type is thread safe. (LargeObject is
not thread safe.)
            lock(large)
            {
                large.Data[0] = Thread.CurrentThread.ManagedThreadId;
                Console.WriteLine("LargeObject was initialized by thread
{0}; last used by thread {1}.",
                    large.InitializedBy, large.Data[0]);
            }
        }
        catch (ApplicationException ex)
        {
            Console.WriteLine("ApplicationException: {0}", ex.Message);
        }
    }
```

```
}

class LargeObject
{
    int initBy = -1;
    public int InitializedBy { get { return initBy; } }

    public LargeObject(int initializedBy)
    {
        initBy = initializedBy;
        Console.WriteLine("Constructor: Instance initializing on thread
{0}", initBy);
    }

    ~LargeObject()
    {
        Console.WriteLine("Finalizer: Instance was initialized on {0}",
initBy);
    }

    public long[] Data = new long[100000000];
}

/* This example produces output similar to the following:

Constructor: Instance initializing on thread 5
Constructor: Instance initializing on thread 4
ApplicationException: Lazy initialization function failed on thread 3.
LargeObject was initialized by thread 5; last used by thread 5.
LargeObject was initialized by thread 5; last used by thread 4.

Threads are complete. Running GC.Collect() to reclaim extra instances.
Finalizer: Instance was initialized on 4

Note that only one instance of LargeObject was used.
Press Enter to end the program

Finalizer: Instance was initialized on 5
 */
```

Remarks

The thread safety mode of a Lazy<T> instance describes the behavior when multiple threads try to initialize the Lazy<T> instance.

Exceptions that are thrown by `valueFactory` are cached, unless `mode` is LazyThreadSafetyMode.PublicationOnly. For more information, see the Lazy<T> class or the System.Threading.LazyThreadSafetyMode enumeration.

Lazy<T>.IsValueCreated Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether a value has been created for this Lazy<T> instance.

```
C#
public bool IsValueCreated { get; }
```

Property Value

Boolean

`true` if a value has been created for this Lazy<T> instance; otherwise, `false`.

Remarks

When lazy initialization occurs for a Lazy<T> instance, it may result in either a value being created or an exception being thrown. If an exception is thrown, subsequent behavior of the Lazy<T> instance depends on whether exception caching is in effect. If the Lazy<T> instance was created by using a constructor that does not specify an initialization function, then exception caching is not in effect. A subsequent attempt to initialize the Lazy<T> might succeed, and after successful initialization the IsValueCreated property returns `true`. If the Lazy<T> instance was created with an initialization function (specified by the `valueFactory` parameter of the Lazy<T> constructor), then exception caching is controlled by the thread safety mode.

- If the mode is LazyThreadSafetyMode.ExecutionAndPublication or LazyThreadSafetyMode.None, there is no second chance to initialize the Lazy<T> instance. If an exception occurs and is unhandled in the initialization function, that exception is cached and rethrown on subsequent accesses of the Lazy<T>.Value property. No value is created if an exception is thrown, so in such cases IsValueCreated returns `false`.

- If the mode is LazyThreadSafetyMode.PublicationOnly, the first thread that succeeds in running the initialization function (or the parameterless constructor) creates the value for the Lazy<T> instance. If the initialization function throws an exception on one thread, other threads can still try to initialize the Lazy<T> instance. Until the value is created, the IsValueCreated property returns `false`.

Lazy<T>.Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the lazily initialized value of the current Lazy<T> instance.

```
C#
public T Value { get; }
```

Property Value

T

The lazily initialized value of the current Lazy<T> instance.

Exceptions

MemberAccessException

The Lazy<T> instance is initialized to use the parameterless constructor of the type that is being lazily initialized, and permissions to access the constructor are missing.

MissingMemberException

The Lazy<T> instance is initialized to use the parameterless constructor of the type that is being lazily initialized, and that type does not have a public, parameterless constructor.

InvalidOperationException

The initialization function tries to access Value on this instance.

Remarks

If the Lazy<T>.IsValueCreated property is `false`, accessing the Value property forces initialization.

In addition to the exceptions that are listed, the Value property can throw any unhandled exception that is thrown by the factory method that was passed to the `valueFactory` parameter of the Lazy<T>(Func<T>), Lazy<T>(Func<T>, LazyThreadSafetyMode), or Lazy<T>(Func<T>, Boolean) constructor.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates and returns a string representation of the Value property for this instance.

```
C#
public override string? ToString ();
```

Returns

String

The result of calling the ToString() method on the Value property for this instance, if the value has been created (that is, if the IsValueCreated property returns `true`). Otherwise, a string indicating that the value has not been created.

Exceptions

NullReferenceException

The Value property is `null`.

Remarks

Calling this method does not cause initialization.

The Lazy<T>.Value property can be `null` after lazy initialization if the factory method that was specified for the `valueFactory` parameter of the Lazy<T>(Func<T>), Lazy<T>(Func<T>, LazyThreadSafetyMode), or Lazy<T>(Func<T>, Boolean) constructor returns `null`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Lazy<T,TMetadata> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a lazy indirect reference to an object and its associated metadata for use by the Managed Extensibility Framework.

C#

```
public class Lazy<T,TMetadata> : Lazy<T>
```

Type Parameters

T

The type of the object referenced.

TMetadata

The type of the metadata.

Inheritance Object → Lazy<T> → Lazy<T,TMetadata>

Constructors

Expand table

Lazy<T,TMetadata>(Func<T>, TMetadata)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata that uses the specified function to get the referenced object.
Lazy<T,TMetadata>(Func<T>, TMetadata, Boolean)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread safety value that uses the specified function to get the referenced object.
Lazy<T,TMetadata>(Func<T>, TMetadata, LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread synchronization mode that uses the specified function to get the referenced object.

Lazy<T,TMetadata>(TMetadata)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata.
Lazy<T,TMetadata>(TMetadata, Boolean)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread safety value.
Lazy<T,TMetadata>(TMetadata, LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread synchronization mode.

Properties

Expand table

IsValueCreated	Gets a value that indicates whether a value has been created for this Lazy<T> instance. (Inherited from Lazy<T>)
Metadata	Gets the metadata associated with the referenced object.
Value	Gets the lazily initialized value of the current Lazy<T> instance. (Inherited from Lazy<T>)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the Value property for this instance. (Inherited from Lazy<T>)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T,TMetadata> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Lazy<T,TMetadata> class.

Overloads

Expand table

Lazy<T,TMetadata>(TMetadata)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata.
Lazy<T,TMetadata>(Func<T>, TMetadata)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata that uses the specified function to get the referenced object.
Lazy<T,TMetadata>(TMetadata, Boolean)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread safety value.
Lazy<T,TMetadata>(TMetadata, LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread synchronization mode.
Lazy<T,TMetadata>(Func<T>, TMetadata, Boolean)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread safety value that uses the specified function to get the referenced object.
Lazy<T,TMetadata>(Func<T>, TMetadata, LazyThreadSafetyMode)	Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread synchronization mode that uses the specified function to get the referenced object.

Lazy<T,TMetadata>(TMetadata)

Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata.

```
C#
public Lazy (TMetadata metadata);
```

Parameters

`metadata` TMetadata

The metadata associated with the referenced object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T,TMetadata>(Func<T>, TMetadata)

Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata that uses the specified function to get the referenced object.

```
C#
public Lazy (Func<T> valueFactory, TMetadata metadata);
```

Parameters

`valueFactory` Func<T>

A function that returns the referenced object.

`metadata` TMetadata

The metadata associated with the referenced object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T,TMetadata>(TMetadata, Boolean)

Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread safety value.

```
C#

public Lazy (TMetadata metadata, bool isThreadSafe);
```

Parameters

`metadata` TMetadata

The metadata associated with the referenced object.

`isThreadSafe` Boolean

Indicates whether the Lazy<T,TMetadata> object that is created will be thread-safe.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
Framework	
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T,TMetadata>(TMetadata, LazyThreadSafetyMode)

Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread synchronization mode.

C#

```
public Lazy (TMetadata metadata, System.Threading.LazyThreadSafetyMode
mode);
```

Parameters

`metadata` TMetadata

The metadata associated with the referenced object.

`mode` LazyThreadSafetyMode

The thread synchronization mode.

Remarks

See LazyThreadSafetyMode for more information on thread synchronization and Lazy<T,TMetadata>.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T,TMetadata>(Func<T>, TMetadata, Boolean)

Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread safety value that uses the specified function to get the referenced object.

C#

```
public Lazy (Func<T> valueFactory, TMetadata metadata, bool
isThreadSafe);
```

Parameters

`valueFactory` Func<T>

A function that returns the referenced object.

`metadata` TMetadata

The metadata associated with the referenced object.

`isThreadSafe` Boolean

Indicates whether the Lazy<T,TMetadata> object that is created will be thread-safe.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Lazy<T,TMetadata>(Func<T>, TMetadata, LazyThreadSafetyMode)

Initializes a new instance of the Lazy<T,TMetadata> class with the specified metadata and thread synchronization mode that uses the specified function to get the referenced object.

C#

```
public Lazy (Func<T> valueFactory, TMetadata metadata,
System.Threading.LazyThreadSafetyMode mode);
```

Parameters

`valueFactory` Func<T>

A function that returns the referenced object.

`metadata` TMetadata

The metadata associated with the referenced object.

`mode` LazyThreadSafetyMode

The thread synchronization mode.

Remarks

See LazyThreadSafetyMode for more information on thread synchronization and Lazy<T,TMetadata>.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

LdapStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser based on the Lightweight Directory Access Protocol (LDAP) scheme.

C#

```
public class LdapStyleUriParser : UriParser
```

Inheritance Object → UriParser → LdapStyleUriParser

Constructors

Expand table

LdapStyleUriParser()	Creates a customizable parser based on the Lightweight Directory Access Protocol (LDAP) scheme.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)

InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

LoaderOptimization Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

An enumeration used with the LoaderOptimizationAttribute class to specify loader optimizations for an executable.

C#

```
public enum LoaderOptimization
```

Inheritance Object → ValueType → Enum → LoaderOptimization

Fields

Expand table

DisallowBindings	4	Ignored by the common language runtime.
DomainMask	3	Do not use. This mask selects the domain-related values, screening out the unused DisallowBindings flag.
MultiDomain	2	Indicates that the application will probably have many domains that use the same code, and the loader must share maximal internal resources across application domains.
MultiDomainHost	3	Indicates that the application will probably host unique code in multiple domains, and the loader must share resources across application domains only for globally available (strong-named) assemblies that have been added to the global assembly cache.
NotSpecified	0	Indicates that no optimizations for sharing internal resources are specified. If the default domain or hosting interface specified an optimization, then the loader uses that; otherwise, the loader uses SingleDomain.
SingleDomain	1	Indicates that the application will probably have a single domain, and loader must not share internal resources across application domains.

Remarks

.NET Framework only: The meaning of `MultiDomainHost` changed starting with .NET Framework version 2.0. The loader now shares resources across application domains only for assemblies that have been added to the global assembly cache.

> **Note**
>
> **.NET Framework only:** If custom code access security policy is set for the **AppDomain**, by using the **SetAppDomainPolicy** property, and the **AppDomain** is created using the `MultiDomain` flag, the effect is the same as specifying the `MultiDomainHost` flag; that is, only assemblies in the GAC are shared. When this occurs, the loader does not throw an exception and the application does not experience the performance gains associated with the `MultiDomain` flag.

For more information on assembly sharing and domain-neutral assembly loading, see Application Domains and Assemblies.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

LoaderOptimizationAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Used to set the default loader optimization policy for the main method of an executable application.

C#

```
[System.AttributeUsage(System.AttributeTargets.Method)]
public sealed class LoaderOptimizationAttribute : Attribute
```

Inheritance Object → Attribute → LoaderOptimizationAttribute

Attributes AttributeUsageAttribute

Remarks

The LoaderOptimizationAttribute can only be set on the main method for an executable application and is ignored on all other methods.

The LoaderOptimizationAttribute attribute is specified with a LoaderOptimization enumeration value, which tells the loader what type of application to optimize for: `SingleDomain`, `MultiDomain`, or `MultiDomainHost`.

This attribute is only a hint to the loader and does not affect program behavior.

> **Note**
>
> If custom code access security policy is set for the **AppDomain**, by using the **SetAppDomainPolicy** property, and the **AppDomain** is created using the **MultiDomain** flag, the effect is the same as specifying the **MultiDomainHost** flag; that is, only assemblies in the GAC are shared. When this occurs, the loader does not throw an exception and the application does not experience the performance gains associated with the **MultiDomain** flag.

Constructors

Expand table

LoaderOptimizationAttribute(Byte)	Initializes a new instance of the LoaderOptimizationAttribute class to the specified value.
LoaderOptimizationAttribute(LoaderOptimization)	Initializes a new instance of the LoaderOptimizationAttribute class to the specified value.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)
Value	Gets the current LoaderOptimization value for this instance.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object.

(Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

LoaderOptimizationAttribute Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the LoaderOptimizationAttribute class.

Overloads

Expand table

LoaderOptimizationAttribute(Byte)	Initializes a new instance of the LoaderOptimizationAttribute class to the specified value.
LoaderOptimizationAttribute(LoaderOptimization)	Initializes a new instance of the LoaderOptimizationAttribute class to the specified value.

LoaderOptimizationAttribute(Byte)

Initializes a new instance of the LoaderOptimizationAttribute class to the specified value.

C#

```
public LoaderOptimizationAttribute (byte value);
```

Parameters

`value` Byte

A value equivalent to a LoaderOptimization constant.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

LoaderOptimizationAttribute(LoaderOptimization)

Initializes a new instance of the LoaderOptimizationAttribute class to the specified value.

C#

```
public LoaderOptimizationAttribute (LoaderOptimization value);
```

Parameters

`value` LoaderOptimization

A LoaderOptimization constant.

Applies to

▼ .NET 9 and other versions

LoaderOptimizationAttribute.Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current LoaderOptimization value for this instance.

C#

```
public LoaderOptimization Value { get; }
```

Property Value

LoaderOptimization

A LoaderOptimization constant.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

LocalDataStoreSlot Class

Reference

Definition

Namespace: System

Assembly: System.Threading.Thread.dll

Encapsulates a memory slot to store local data. This class cannot be inherited.

```
C#
public sealed class LocalDataStoreSlot
```

Inheritance Object → LocalDataStoreSlot

Remarks

The .NET Framework provides two mechanisms for using thread local storage (TLS): thread-relative static fields, and data slots.

- Thread-relative static fields are `static` fields (`Shared` fields in Visual Basic) that are marked with the ThreadStaticAttribute attribute. They provide better performance than data slots, and enable compile-time type checking.
- Data slots are slower and more awkward to use than thread-relative static fields. Also, data is stored as type Object, so you must cast it to the correct type before using it. However, you can use data slots when you have insufficient information at compile time to allocate static fields.

For more information about using TLS, see Thread Local Storage: Thread-Relative Static Fields and Data Slots.

Similarly, the .NET Framework provides two mechanisms for using context local storage: context-relative static fields and data slots. Context-relative static fields are static fields that are marked with the ContextStaticAttribute attribute. The trade-offs between using these two mechanisms are similar to the tradeoffs between using thread-relative static fields and data slots.

The LocalDataStoreSlot structure serves as a local store memory mechanism that threads and contexts can use to store thread-specific and context-specific data,

respectively. The common language runtime allocates a multi-slot data store array to each process when it is created. The thread or context calls various functions to allocate a data slot in the data store, to store and retrieve a data value in the slot, and to free a data slot for reuse after the thread or context object expires.

The data slots are unique per thread or context; their values are not shared between the thread or context objects. Data slots can be allocated by a name or by an index number.

For more information about storing local data, see Thread or Context. The LocalDataStoreSlot class is used with methods such as Thread.AllocateNamedDataSlot, Context.AllocateNamedDataSlot, Thread.GetData, and Context.GetData; it does not have any methods of its own that you need to use.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
Finalize()	Ensures that resources are freed and other cleanup operations are performed when the garbage collector reclaims the LocalDataStoreSlot object.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

LocalDataStoreSlot.Finalize Method

Reference

Definition

Namespace: System

Assembly: System.Threading.Thread.dll

Ensures that resources are freed and other cleanup operations are performed when the garbage collector reclaims the LocalDataStoreSlot object.

C#

```
~LocalDataStoreSlot ();
```

Remarks

The garbage collector calls Finalize when the current object is ready to be finalized.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

MarshalByRefObject Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Enables access to objects across application domain boundaries in applications that support remoting.

C#

```
public abstract class MarshalByRefObject
```

Inheritance Object → MarshalByRefObject

Derived IEHost.Execute.IEExecuteRemote
Microsoft.Win32.RegistryKey
System.AddIn.Pipeline.ContractBase
System.AppDomain
System.AppDomainManager
More...

Examples

This section contains two code examples. The first code example shows how to create an instance of a class in another application domain. The second code example shows a simple class that can be used for remoting.

Example 1

The following code example shows the simplest way to execute code in another application domain. The example defines a class named `Worker` that inherits MarshalByRefObject, with a method that displays the name of the application domain in which it is executing. The example creates instances of `Worker` in the default application domain and in a new application domain.

Note

The assembly that contains `Worker` must be loaded into both application domains, but it could load other assemblies that would exist only in the new application domain.

C#

```
using System;
using System.Reflection;

public class CreateInstanceWorker : MarshalByRefObject
{
    public void PrintDomain()
    {
        Console.WriteLine("Object is executing in AppDomain \"{0}\"",
            AppDomain.CurrentDomain.FriendlyName);
    }
}

class CreateInstanceAndUnwrapSourceSnippet
{
    public static void Main()
    {
        // Create an ordinary instance in the current AppDomain
        CreateInstanceWorker localWorker = new CreateInstanceWorker();
        localWorker.PrintDomain();

        // Create a new application domain, create an instance
        // of Worker in the application domain, and execute code
        // there.
        AppDomain ad = AppDomain.CreateDomain("New domain");
        CreateInstanceWorker remoteWorker = (CreateInstanceWorker)
ad.CreateInstanceAndUnwrap(
            typeof(CreateInstanceWorker).Assembly.FullName,
            "Worker");
        remoteWorker.PrintDomain();
    }
}

/* This code produces output similar to the following:

Object is executing in AppDomain "source.exe"
Object is executing in AppDomain "New domain"
 */
```

Example 2

The following example demonstrates a class derived from MarshalByRefObject that is used later in remoting.

C#

```
using System;
using System.Runtime.Remoting;

public class SetObjectUriForMarshalTest  {

    class TestClass : MarshalByRefObject {
    }

    public static void Main()  {

        TestClass obj = new TestClass();

        RemotingServices.SetObjectUriForMarshal(obj, "testUri");
        RemotingServices.Marshal(obj);

        Console.WriteLine(RemotingServices.GetObjectUri(obj));
    }
}
```

Remarks

An application domain is a partition in an operating system process where one or more applications reside. Objects in the same application domain communicate directly. Objects in different application domains communicate either by transporting copies of objects across application domain boundaries, or by using a proxy to exchange messages.

MarshalByRefObject is the base class for objects that communicate across application domain boundaries by exchanging messages using a proxy. Objects that do not inherit from MarshalByRefObject are implicitly marshal by value. When a remote application references a marshal by value object, a copy of the object is passed across application domain boundaries.

MarshalByRefObject objects are accessed directly within the boundaries of the local application domain. The first time an application in a remote application domain accesses a MarshalByRefObject, a proxy is passed to the remote application. Subsequent calls on the proxy are marshaled back to the object residing in the local application domain.

Types must inherit from MarshalByRefObject when the type is used across application domain boundaries, and the state of the object must not be copied because the members of the object are not usable outside the application domain where they were created.

When you derive an object from MarshalByRefObject for use across application domain boundaries, you should not override any of its members, nor should you call its methods directly. The runtime recognizes that classes derived from MarshalByRefObject should be marshaled across app domain boundaries.

Constructors

Expand table

MarshalByRefObject()	Initializes a new instance of the MarshalByRefObject class.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetLifetimeService()	**Obsolete.** Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeLifetimeService()	**Obsolete.** Obtains a lifetime service object to control the lifetime policy for this instance.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
MemberwiseClone(Boolean)	Creates a shallow copy of the current MarshalByRefObject object.
ToString()	Returns a string that represents the current object. (Inherited from Object)

MarshalByRefObject.GetLifetimeService Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This Remoting API is not supported and throws PlatformNotSupportedException.

Retrieves the current lifetime service object that controls the lifetime policy for this instance.

C#

```
[System.Obsolete("This Remoting API is not supported and throws
PlatformNotSupportedException.", DiagnosticId="SYSLIB0010",
UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public object GetLifetimeService ();
```

Returns

Object

An object of type ILease used to control the lifetime policy for this instance.

Attributes ObsoleteAttribute

Exceptions

SecurityException

The immediate caller does not have infrastructure permission.

PlatformNotSupportedException

.NET Core and .NET 5+ only: In all cases.

Remarks

This method is marked obsolete starting in .NET 5.

For more information about lifetime services, see the LifetimeServices class.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1 *(5, 6, 7, 8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

MarshalByRefObject.InitializeLifetimeService Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This Remoting API is not supported and throws PlatformNotSupportedException.

Obtains a lifetime service object to control the lifetime policy for this instance.

C#

```
[System.Obsolete("This Remoting API is not supported and throws
PlatformNotSupportedException.", DiagnosticId="SYSLIB0010",
UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public virtual object InitializeLifetimeService ();
```

Returns

Object

An object of type ILease used to control the lifetime policy for this instance. This is the current lifetime service object for this instance if one exists; otherwise, a new lifetime service object initialized to the value of the LeaseManagerPollTime property.

Attributes ObsoleteAttribute

Exceptions

SecurityException

The immediate caller does not have infrastructure permission.

PlatformNotSupportedException

.NET Core and .NET 5+ only: In all cases.

Examples

The following code example demonstrates creating a lease.

C#

```
public class MyClass : MarshalByRefObject
{
  public override Object InitializeLifetimeService()
  {
    ILease lease = (ILease)base.InitializeLifetimeService();
    if (lease.CurrentState == LeaseState.Initial)
    {
         lease.InitialLeaseTime = TimeSpan.FromMinutes(1);
         lease.SponsorshipTimeout = TimeSpan.FromMinutes(2);
          lease.RenewOnCallTime = TimeSpan.FromSeconds(2);
    }
      return lease;
  }
}
```

Remarks

This method is marked obsolete starting in .NET 5.

For more information about lifetime services, see the LifetimeServices class.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1 *(5, 6, 7, 8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MarshalByRefObject.MemberwiseClone(Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a shallow copy of the current MarshalByRefObject object.

```
C#
protected MarshalByRefObject MemberwiseClone (bool cloneIdentity);
```

Parameters

`cloneIdentity` Boolean

`false` to delete the current MarshalByRefObject object's identity, which will cause the object to be assigned a new identity when it is marshaled across a remoting boundary. A value of `false` is usually appropriate. `true` to copy the current MarshalByRefObject object's identity to its clone, which will cause remoting client calls to be routed to the remote server object.

Returns

MarshalByRefObject

A shallow copy of the current MarshalByRefObject object.

Remarks

The MemberwiseClone(Boolean) method creates a shallow copy by creating a new MarshalByRefObject object, and then copying the nonstatic fields of the current MarshalByRefObject object to the new object. If a field is a value type, a bit-by-bit copy of the field is performed. If a field is a reference type, the reference is copied but the referred object is not; therefore, the original object and its clone refer to the same object.

For example, consider a MarshalByRefObject object called X that references objects A and B. Object B, in turn, references object C. A shallow copy of X creates new object X2 that also references objects A and B. In contrast, a deep copy of X creates a new object X2 that references the new objects A2 and B2, which are copies of A and B. B2, in turn, references the new object C2, which is a copy C. Use a class that implements the ICloneable interface to perform a deep or shallow copy of an object.

The identity of a MarshalByRefObject object is defined as the remote server object that is the target of a remoting client call. By default, the memberwise clone of a MarshalByRefObject object has the same identity as the original object, which is typically not the correct behavior for clones of server-side objects that are marshaled across a remoting boundary to the client side. Specify `false`, which is usually appropriate, to delete the identity of the clone and cause a new identity to be assigned when the clone is marshaled across a remoting boundary, or `true` to cause the clone to retain the identity of the original MarshalByRefObject object. The MemberwiseClone(Boolean) method is intended to be used by developers implementing remote server objects.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides constants and static methods for trigonometric, logarithmic, and other common mathematical functions.

C#

```
public static class Math
```

Inheritance Object → Math

Examples

The following example uses several mathematical and trigonometric functions from the Math class to calculate the inner angles of a trapezoid.

C#

```
/// <summary>
/// The following class represents simple functionality of the trapezoid.
/// </summary>
using System;

namespace MathClassCS
{
    class MathTrapezoidSample
    {
        private double m_longBase;
        private double m_shortBase;
        private double m_leftLeg;
        private double m_rightLeg;

        public MathTrapezoidSample(double longbase, double shortbase, double
leftLeg, double rightLeg)
        {
            m_longBase = Math.Abs(longbase);
            m_shortBase = Math.Abs(shortbase);
            m_leftLeg = Math.Abs(leftLeg);
            m_rightLeg = Math.Abs(rightLeg);
```

```
        }

        private double GetRightSmallBase()
        {
            return (Math.Pow(m_rightLeg,2.0) - Math.Pow(m_leftLeg,2.0) +
Math.Pow(m_longBase,2.0) + Math.Pow(m_shortBase,2.0) - 2* m_shortBase *
m_longBase)/ (2*(m_longBase - m_shortBase));
        }

        public double GetHeight()
        {
            double x = GetRightSmallBase();
            return Math.Sqrt(Math.Pow(m_rightLeg,2.0) - Math.Pow(x,2.0));
        }

        public double GetSquare()
        {
            return GetHeight() * m_longBase / 2.0;
        }

        public double GetLeftBaseRadianAngle()
        {
            double sinX = GetHeight()/m_leftLeg;
            return Math.Round(Math.Asin(sinX),2);
        }

        public double GetRightBaseRadianAngle()
        {
            double x = GetRightSmallBase();
            double cosX = (Math.Pow(m_rightLeg,2.0) + Math.Pow(x,2.0) -
Math.Pow(GetHeight(),2.0))/(2*x*m_rightLeg);
            return Math.Round(Math.Acos(cosX),2);
        }

        public double GetLeftBaseDegreeAngle()
        {
            double x = GetLeftBaseRadianAngle() * 180/ Math.PI;
            return Math.Round(x,2);
        }

        public double GetRightBaseDegreeAngle()
        {
            double x = GetRightBaseRadianAngle() * 180/ Math.PI;
            return Math.Round(x,2);
        }

        static void Main(string[] args)
        {
            MathTrapezoidSample trpz = new MathTrapezoidSample(20.0, 10.0,
8.0, 6.0);
            Console.WriteLine("The trapezoid's bases are 20.0 and 10.0, the
trapezoid's legs are 8.0 and 6.0");
            double h = trpz.GetHeight();
            Console.WriteLine("Trapezoid height is: " + h.ToString());
            double dxR = trpz.GetLeftBaseRadianAngle();
```

```
            Console.WriteLine("Trapezoid left base angle is: " +
dxR.ToString() + " Radians");
            double dyR = trpz.GetRightBaseRadianAngle();
            Console.WriteLine("Trapezoid right base angle is: " +
dyR.ToString() + " Radians");
            double dxD = trpz.GetLeftBaseDegreeAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dxD.ToString() + " Degrees");
            double dyD = trpz.GetRightBaseDegreeAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dyD.ToString() + " Degrees");
        }
    }
}
```

Fields

Expand table

E	Represents the natural logarithmic base, specified by the constant, `e`.
PI	Represents the ratio of the circumference of a circle to its diameter, specified by the constant, π.
Tau	Represents the number of radians in one turn, specified by the constant, τ.

Methods

Expand table

Abs(Decimal)	Returns the absolute value of a Decimal number.
Abs(Double)	Returns the absolute value of a double-precision floating-point number.
Abs(Int16)	Returns the absolute value of a 16-bit signed integer.
Abs(Int32)	Returns the absolute value of a 32-bit signed integer.
Abs(Int64)	Returns the absolute value of a 64-bit signed integer.
Abs(IntPtr)	Returns the absolute value of a native signed integer.
Abs(SByte)	Returns the absolute value of an 8-bit signed integer.
Abs(Single)	Returns the absolute value of a single-precision floating-point number.

Acos(Double)	Returns the angle whose cosine is the specified number.
Acosh(Double)	Returns the angle whose hyperbolic cosine is the specified number.
Asin(Double)	Returns the angle whose sine is the specified number.
Asinh(Double)	Returns the angle whose hyperbolic sine is the specified number.
Atan(Double)	Returns the angle whose tangent is the specified number.
Atan2(Double, Double)	Returns the angle whose tangent is the quotient of two specified numbers.
Atanh(Double)	Returns the angle whose hyperbolic tangent is the specified number.
BigMul(Int32, Int32)	Produces the full product of two 32-bit numbers.
BigMul(Int64, Int64, Int64)	Produces the full product of two 64-bit numbers.
BigMul(UInt64, UInt64, UInt64)	Produces the full product of two unsigned 64-bit numbers.
BitDecrement(Double)	Returns the largest value that compares less than a specified value.
BitIncrement(Double)	Returns the smallest value that compares greater than a specified value.
Cbrt(Double)	Returns the cube root of a specified number.
Ceiling(Decimal)	Returns the smallest integral value that is greater than or equal to the specified decimal number.
Ceiling(Double)	Returns the smallest integral value that is greater than or equal to the specified double-precision floating-point number.
Clamp(Byte, Byte, Byte)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Decimal, Decimal, Decimal)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Double, Double, Double)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Int16, Int16, Int16)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Int32, Int32, Int32)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Int64, Int64, Int64)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(IntPtr, IntPtr, IntPtr)	Returns `value` clamped to the inclusive range of `min` and `max`.

Clamp(SByte, SByte, SByte)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Single, Single, Single)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UInt16, UInt16, UInt16)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UInt32, UInt32, UInt32)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UInt64, UInt64, UInt64)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UIntPtr, UIntPtr, UIntPtr)	Returns `value` clamped to the inclusive range of `min` and `max`.
CopySign(Double, Double)	Returns a value with the magnitude of `x` and the sign of `y`.
Cos(Double)	Returns the cosine of the specified angle.
Cosh(Double)	Returns the hyperbolic cosine of the specified angle.
DivRem(Byte, Byte)	Produces the quotient and the remainder of two unsigned 8-bit numbers.
DivRem(Int16, Int16)	Produces the quotient and the remainder of two signed 16-bit numbers.
DivRem(Int32, Int32)	Produces the quotient and the remainder of two signed 32-bit numbers.
DivRem(Int32, Int32, Int32)	Calculates the quotient of two 32-bit signed integers and also returns the remainder in an output parameter.
DivRem(Int64, Int64)	Produces the quotient and the remainder of two signed 64-bit numbers.
DivRem(Int64, Int64, Int64)	Calculates the quotient of two 64-bit signed integers and also returns the remainder in an output parameter.
DivRem(IntPtr, IntPtr)	Produces the quotient and the remainder of two signed native-size numbers.
DivRem(SByte, SByte)	Produces the quotient and the remainder of two signed 8-bit numbers.
DivRem(UInt16, UInt16)	Produces the quotient and the remainder of two unsigned 16-bit numbers.
DivRem(UInt32, UInt32)	Produces the quotient and the remainder of two unsigned 32-bit numbers.
DivRem(UInt64, UInt64)	Produces the quotient and the remainder of two unsigned 64-bit numbers.
DivRem(UIntPtr, UIntPtr)	Produces the quotient and the remainder of two unsigned

	native-size numbers.
Exp(Double)	Returns `e` raised to the specified power.
Floor(Decimal)	Returns the largest integral value less than or equal to the specified decimal number.
Floor(Double)	Returns the largest integral value less than or equal to the specified double-precision floating-point number.
FusedMultiplyAdd(Double, Double, Double)	Returns (x * y) + z, rounded as one ternary operation.
IEEERemainder(Double, Double)	Returns the remainder resulting from the division of a specified number by another specified number.
ILogB(Double)	Returns the base 2 integer logarithm of a specified number.
Log(Double)	Returns the natural (base `e`) logarithm of a specified number.
Log(Double, Double)	Returns the logarithm of a specified number in a specified base.
Log10(Double)	Returns the base 10 logarithm of a specified number.
Log2(Double)	Returns the base 2 logarithm of a specified number.
Max(Byte, Byte)	Returns the larger of two 8-bit unsigned integers.
Max(Decimal, Decimal)	Returns the larger of two decimal numbers.
Max(Double, Double)	Returns the larger of two double-precision floating-point numbers.
Max(Int16, Int16)	Returns the larger of two 16-bit signed integers.
Max(Int32, Int32)	Returns the larger of two 32-bit signed integers.
Max(Int64, Int64)	Returns the larger of two 64-bit signed integers.
Max(IntPtr, IntPtr)	Returns the larger of two native signed integers.
Max(SByte, SByte)	Returns the larger of two 8-bit signed integers.
Max(Single, Single)	Returns the larger of two single-precision floating-point numbers.
Max(UInt16, UInt16)	Returns the larger of two 16-bit unsigned integers.
Max(UInt32, UInt32)	Returns the larger of two 32-bit unsigned integers.
Max(UInt64, UInt64)	Returns the larger of two 64-bit unsigned integers.
Max(UIntPtr, UIntPtr)	Returns the larger of two native unsigned integers.

MaxMagnitude(Double, Double)	Returns the larger magnitude of two double-precision floating-point numbers.
Min(Byte, Byte)	Returns the smaller of two 8-bit unsigned integers.
Min(Decimal, Decimal)	Returns the smaller of two decimal numbers.
Min(Double, Double)	Returns the smaller of two double-precision floating-point numbers.
Min(Int16, Int16)	Returns the smaller of two 16-bit signed integers.
Min(Int32, Int32)	Returns the smaller of two 32-bit signed integers.
Min(Int64, Int64)	Returns the smaller of two 64-bit signed integers.
Min(IntPtr, IntPtr)	Returns the smaller of two native signed integers.
Min(SByte, SByte)	Returns the smaller of two 8-bit signed integers.
Min(Single, Single)	Returns the smaller of two single-precision floating-point numbers.
Min(UInt16, UInt16)	Returns the smaller of two 16-bit unsigned integers.
Min(UInt32, UInt32)	Returns the smaller of two 32-bit unsigned integers.
Min(UInt64, UInt64)	Returns the smaller of two 64-bit unsigned integers.
Min(UIntPtr, UIntPtr)	Returns the smaller of two native unsigned integers.
MinMagnitude(Double, Double)	Returns the smaller magnitude of two double-precision floating-point numbers.
Pow(Double, Double)	Returns a specified number raised to the specified power.
ReciprocalEstimate(Double)	Returns an estimate of the reciprocal of a specified number.
ReciprocalSqrtEstimate(Double)	Returns an estimate of the reciprocal square root of a specified number.
Round(Decimal)	Rounds a decimal value to the nearest integral value, and rounds midpoint values to the nearest even number.
Round(Decimal, Int32)	Rounds a decimal value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.
Round(Decimal, Int32, MidpointRounding)	Rounds a decimal value to a specified number of fractional digits using the specified rounding convention.
Round(Decimal, MidpointRounding)	Rounds a decimal value an integer using the specified rounding convention.

Round(Double)	Rounds a double-precision floating-point value to the nearest integral value, and rounds midpoint values to the nearest even number.
Round(Double, Int32)	Rounds a double-precision floating-point value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.
Round(Double, Int32, MidpointRounding)	Rounds a double-precision floating-point value to a specified number of fractional digits using the specified rounding convention.
Round(Double, MidpointRounding)	Rounds a double-precision floating-point value to an integer using the specified rounding convention.
ScaleB(Double, Int32)	Returns x * 2^n computed efficiently.
Sign(Decimal)	Returns an integer that indicates the sign of a decimal number.
Sign(Double)	Returns an integer that indicates the sign of a double-precision floating-point number.
Sign(Int16)	Returns an integer that indicates the sign of a 16-bit signed integer.
Sign(Int32)	Returns an integer that indicates the sign of a 32-bit signed integer.
Sign(Int64)	Returns an integer that indicates the sign of a 64-bit signed integer.
Sign(IntPtr)	Returns an integer that indicates the sign of a native sized signed integer.
Sign(SByte)	Returns an integer that indicates the sign of an 8-bit signed integer.
Sign(Single)	Returns an integer that indicates the sign of a single-precision floating-point number.
Sin(Double)	Returns the sine of the specified angle.
SinCos(Double)	Returns the sine and cosine of the specified angle.
Sinh(Double)	Returns the hyperbolic sine of the specified angle.
Sqrt(Double)	Returns the square root of a specified number.
Tan(Double)	Returns the tangent of the specified angle.
Tanh(Double)	Returns the hyperbolic tangent of the specified angle.

Truncate(Decimal)	Calculates the integral part of a specified decimal number.
Truncate(Double)	Calculates the integral part of a specified double-precision floating-point number.

Math.E Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the natural logarithmic base, specified by the constant, `e`.

C#

```
public const double E = 2.7182818284590451;
```

Field Value

Value = 2.7182818284590451

Double

Examples

The following example compares E with the value calculated from a power series.

C#

```
// Example for the Math.E field.
using System;

class EField
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of Math.E == {0:E16}\n" +
            "generates the following output.\n",
            Math.E );
        Console.WriteLine(
            "Define the power series PS(n) = Sum(k->0,n)[1/k!]" );
        Console.WriteLine( " (limit n->infinity)PS(n) == e" );
        Console.WriteLine(
            "Display PS(n) and Math.E - PS(n), " +
            "and stop when delta < 1.0E-15\n" );

        CalcPowerSeries();
    }
```

```
    // Approximate E with a power series.
    static void CalcPowerSeries()
    {
        double factorial = 1.0;
        double PS = 0.0;

        // Stop iterating when the series converges,
        // and prevent a runaway process.
        for( int n = 0; n < 999 && Math.Abs( Math.E - PS ) > 1.0E-15; n++ )
        {
            // Calculate a running factorial.
            if( n > 0 )
                factorial *= (double)n;

            // Calculate and display the power series.
            PS += 1.0 / factorial;
            Console.WriteLine(
                "PS({0:D2}) == {1:E16},  Math.E - PS({0:D2}) == {2:E16}",
                n, PS, Math.E - PS );
        }
    }
}

/*
This example of Math.E == 2.7182818284590451E+000
generates the following output.

Define the power series PS(n) = Sum(k->0,n)[1/k!]
 (limit n->infinity)PS(n) == e
Display PS(n) and Math.E - PS(n), and stop when delta < 1.0E-15

Math.PI Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the ratio of the circumference of a circle to its diameter, specified by the constant, π.

C#

```
public const double PI = 3.1415926535897931;
```

Field Value

Value = 3.1415926535897931

Double

Examples

The following example uses PI to assist in the computation of the inner angles of a given trapezoid.

C#

```
/// <summary>
/// The following class represents simple functionality of the trapezoid.
/// </summary>
using System;

namespace MathClassCS
{
    class MathTrapezoidSample
    {
        private double m_longBase;
        private double m_shortBase;
        private double m_leftLeg;
        private double m_rightLeg;

        public MathTrapezoidSample(double longbase, double shortbase, double
leftLeg, double rightLeg)
        {
```

```
            m_longBase = Math.Abs(longbase);
            m_shortBase = Math.Abs(shortbase);
            m_leftLeg = Math.Abs(leftLeg);
            m_rightLeg = Math.Abs(rightLeg);
        }

        private double GetRightSmallBase()
        {
            return (Math.Pow(m_rightLeg,2.0) - Math.Pow(m_leftLeg,2.0) +
Math.Pow(m_longBase,2.0) + Math.Pow(m_shortBase,2.0) - 2* m_shortBase *
m_longBase)/ (2*(m_longBase - m_shortBase));
        }

        public double GetHeight()
        {
            double x = GetRightSmallBase();

Math.Abs Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the absolute value of a specified number.

Overloads

Expand table

Abs(Decimal)	Returns the absolute value of a Decimal number.
Abs(Double)	Returns the absolute value of a double-precision floating-point number.
Abs(Int16)	Returns the absolute value of a 16-bit signed integer.
Abs(Int32)	Returns the absolute value of a 32-bit signed integer.
Abs(Int64)	Returns the absolute value of a 64-bit signed integer.
Abs(IntPtr)	Returns the absolute value of a native signed integer.
Abs(SByte)	Returns the absolute value of an 8-bit signed integer.
Abs(Single)	Returns the absolute value of a single-precision floating-point number.

Abs(Decimal)

Returns the absolute value of a Decimal number.

C#

```
public static decimal Abs (decimal value);
```

Parameters

`value` Decimal

A number that is greater than or equal to Decimal.MinValue, but less than or equal to Decimal.MaxValue.

Returns

Decimal

A decimal number, x, such that 0 ≤ x ≤ Decimal.MaxValue.

Examples

The following example uses the Abs(Decimal) method to get the absolute value of a number of Decimal values.

C#

```
decimal[] decimals = { Decimal.MaxValue, 12.45M, 0M, -19.69M,
                       Decimal.MinValue };
foreach (decimal value in decimals)
   Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");

// The example displays the following output:
//       Abs(79228162514264337593543950335) =
79228162514264337593543950335
//       Abs(12.45) = 12.45
//       Abs(0) = 0
//       Abs(-19.69) = 19.69
//       Abs(-79228162514264337593543950335) =
79228162514264337593543950335
```

Remarks

The absolute value of a Decimal is its numeric value without its sign. For example, the absolute value of both 1.2 and -1.2 is 1.2.

Applies to

Abs(Double)

Returns the absolute value of a double-precision floating-point number.

C#

```
public static double Abs (double value);
```

Parameters

`value` Double

A number that is greater than or equal to Double.MinValue, but less than or equal to Double.MaxValue.

Returns

Double

A double-precision floating-point number, x, such that 0 ≤ x ≤ Double.MaxValue.

Examples

The following example uses the Abs(Double) method to get the absolute value of a number of Double values.

C#

```
double[] doubles = { Double.MaxValue, 16.354e-17, 15.098123, 0,
                     -19.069713, -15.058e18, Double.MinValue };
foreach (double value in doubles)
   Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");

// The example displays the following output:
//       Abs(1.79769313486232E+308) = 1.79769313486232E+308
//       Abs(1.6354E-16) = 1.6354E-16
//       Abs(15.098123) = 15.098123
//       Abs(0) = 0
```

```
//       Abs(-19.069713) = 19.069713
//       Abs(-1.5058E+19) = 1.5058E+19
//       Abs(-1.79769313486232E+308) = 1.79769313486232E+308
```

Remarks

The absolute value of a Double is its numeric value without its sign. For example, the absolute value of both 1.2e03 and -1.2e03 is 1.2e03.

If `value` is equal to NegativeInfinity or PositiveInfinity, the return value is PositiveInfinity. If `value` is equal to NaN, the return value is NaN.

UWP	10.0

Abs(Int16)

Returns the absolute value of a 16-bit signed integer.

C#

```
public static short Abs (short value);
```

Parameters

`value` Int16

A number that is greater than Int16.MinValue, but less than or equal to Int16.MaxValue.

Returns

Int16

A 16-bit signed integer, x, such that 0 ≤ x ≤ Int16.MaxValue.

Exceptions

OverflowException

`value` equals Int16.MinValue.

Examples

The following example uses the Abs(Int16) method to get the absolute value of a number of Int16 values.

C#

```
short[] values = { Int16.MaxValue, 10328, 0, -1476, Int16.MinValue };
foreach (short value in values)
{
   try {
      Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to calculate the absolute value of {0}.",
                        value);
   }
}

// The example displays the following output:
//       Abs(32767) = 32767
//       Abs(10328) = 10328
//       Abs(0) = 0
//       Abs(-1476) = 1476
//       Unable to calculate the absolute value of -32768.
```

Remarks

The absolute value of an Int16 is its numeric value without its sign. For example, the absolute value of both 123 and -123 is 123.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Abs(Int32)

Returns the absolute value of a 32-bit signed integer.

C#

```
public static int Abs (int value);
```

Parameters

`value` Int32

A number that is greater than Int32.MinValue, but less than or equal to Int32.MaxValue.

Returns

Int32

A 32-bit signed integer, x, such that 0 ≤ x ≤ Int32.MaxValue.

Exceptions

OverflowException

`value` equals Int32.MinValue.

Examples

The following example uses the Abs(Int32) method to get the absolute value of a number of Int32 values.

C#

```
int[] values = { Int32.MaxValue, 16921, 0, -804128, Int32.MinValue };
foreach (int value in values)
{
   try {
      Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to calculate the absolute value of {0}.",
                        value);
   }
}

// The example displays the following output:
//       Abs(2147483647) = 2147483647
//       Abs(16921) = 16921
//       Abs(0) = 0
//       Abs(-804128) = 804128
//       Unable to calculate the absolute value of -2147483648.
```

Remarks

The absolute value of an Int32 is its numeric value without its sign. For example, the absolute value of both 123 and -123 is 123.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Abs(Int64)

Returns the absolute value of a 64-bit signed integer.

```
C#
```

```
public static long Abs (long value);
```

Parameters

value Int64

A number that is greater than Int64.MinValue, but less than or equal to Int64.MaxValue.

Returns

Int64

A 64-bit signed integer, x, such that 0 ≤ x ≤ Int64.MaxValue.

Exceptions

OverflowException

`value` equals Int64.MinValue.

Examples

The following example uses the Abs(Int64) method to get the absolute value of a number of Int64 values.

C#

```
long[] values = { Int64.MaxValue, 109013, 0, -6871982, Int64.MinValue };
foreach (long value in values)
{
   try {
      Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to calculate the absolute value of {0}.",
                        value);
   }
}

// The example displays the following output:
//       Abs(9223372036854775807) = 9223372036854775807
//       Abs(109013) = 109013
//       Abs(0) = 0
//       Abs(-6871982) = 6871982
//       Unable to calculate the absolute value of -9223372036854775808.
```

Remarks

The absolute value of an Int64 is its numeric value without its sign. For example, the absolute value of both 123 and -123 is 123.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Abs(IntPtr)

Returns the absolute value of a native signed integer.

C#

```
public static IntPtr Abs (IntPtr value);
```

Parameters

`value` nint

A number that is greater than MinValue, but less than or equal to MaxValue.

Returns

nint

A native signed integer, x, such that 0 ≤ x ≤ MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Abs(SByte)

> Important
>
> This API is not CLS-compliant.

Returns the absolute value of an 8-bit signed integer.

```
C#

[System.CLSCompliant(false)]
public static sbyte Abs (sbyte value);
```

Parameters

`value` SByte

A number that is greater than SByte.MinValue, but less than or equal to SByte.MaxValue.

Returns

SByte

An 8-bit signed integer, x, such that 0 ≤ x ≤ SByte.MaxValue.

Attributes CLSCompliantAttribute

Exceptions

OverflowException

`value` equals SByte.MinValue.

Examples

The following example uses the Abs(SByte) method to get the absolute value of a number of SByte values.

C#

```
sbyte[] values = { SByte.MaxValue, 98, 0, -32, SByte.MinValue };
foreach (sbyte value in values)
{
   try {
      Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");
   }
   catch (OverflowException) {
      Console.WriteLine("Unable to calculate the absolute value of {0}.",
                        value);
   }
}

// The example displays the following output:
//       Abs(127) = 127
//       Abs(98) = 98
//       Abs(0) = 0
//       Abs(-32) = 32
//       Unable to calculate the absolute value of -128.
```

Remarks

The absolute value of a signed byte is its numeric value without its sign. For example, the absolute value of both 12 and -12 is 12.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Abs(Single)

Returns the absolute value of a single-precision floating-point number.

```C#
public static float Abs (float value);
```

Parameters

`value` Single

A number that is greater than or equal to Single.MinValue, but less than or equal to Single.MaxValue.

Returns

Single

A single-precision floating-point number, x, such that 0 ≤ x ≤ Single.MaxValue.

Examples

The following example uses the Abs(Single) method to get the absolute value of a number of Single values.

```C#
float[] values= { Single.MaxValue, 16.354e-12F, 15.098123F, 0F,
                  -19.069713F, -15.058e17F, Single.MinValue };
foreach (float value in values)
   Console.WriteLine($"Abs({value}) = {Math.Abs(value)}");

// The example displays the following output:
//       Abs(3.402823E+38) = 3.402823E+38
//       Abs(1.6354E-11) = 1.6354E-11
//       Abs(15.09812) = 15.09812
//       Abs(0) = 0
//       Abs(-19.06971) = 19.06971
//       Abs(-1.5058E+18) = 1.5058E+18
//       Abs(-3.402823E+38) = 3.402823E+38
```

Remarks

The absolute value of a Single is its numeric value without its sign. For example, the absolute value of both 1.2e-03 and -1.2e03 is 1.2e03.

If `value` is equal to NegativeInfinity or PositiveInfinity, the return value is PositiveInfinity. If `value` is equal to NaN, the return value is NaN.

Math.Acos(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose cosine is the specified number.

```
C#

public static double Acos (double d);
```

Parameters

d Double

A number representing a cosine, where `d` must be greater than or equal to -1, but less than or equal to 1.

Returns

Double

An angle, θ, measured in radians, such that 0 ≤ θ ≤ π.

-or-

NaN if `d` < -1 or `d` > 1 or `d` equals NaN.

Examples

The following example uses the Acos method to assist in the computation of the inner angles of a given trapezoid.

```
C#

/// <summary>
/// The following class represents simple functionality of the trapezoid.
/// </summary>
using System;
```

```
namespace MathClassCS
{
    class MathTrapezoidSample
    {
        private double m_longBase;
        private double m_shortBase;
        private double m_leftLeg;
        private double m_rightLeg;

        public MathTrapezoidSample(double longbase, double shortbase, double
leftLeg, double rightLeg)
        {
            m_longBase = Math.Abs(longbase);
            m_shortBase = Math.Abs(shortbase);
            m_leftLeg = Math.Abs(leftLeg);
            m_rightLeg = Math.Abs(rightLeg);
        }

        private double GetRightSmallBase()
        {
            return (Math.Pow(m_rightLeg,2.0) - Math.Pow(m_leftLeg,2.0) +
Math.Pow(m_longBase,2.0) + Math.Pow(m_shortBase,2.0) - 2* m_shortBase *
m_longBase)/ (2*(m_longBase - m_shortBase));
        }

        public double GetHeight()
        {
            double x = GetRightSmallBase();
            return Math.Sqrt(Math.Pow(m_rightLeg,2.0) - Math.Pow(x,2.0));
        }

        public double GetSquare()
        {
            return GetHeight() * m_longBase / 2.0;
        }

        public double GetLeftBaseRadianAngle()
        {
            double sinX = GetHeight()/m_leftLeg;
            return Math.Round(Math.Asin(sinX),2);
        }

        public double GetRightBaseRadianAngle()
        {
            double x = GetRightSmallBase();
            double cosX = (Math.Pow(m_rightLeg,2.0) + Math.Pow(x,2.0) -
Math.Pow(GetHeight(),2.0))/(2*x*m_rightLeg);
            return Math.Round(Math.Acos(cosX),2);
        }

        public double GetLeftBaseDegreeAngle()
        {
            double x = GetLeftBaseRadianAngle() * 180/ Math.PI;
            return Math.Round(x,2);
        }
```

```
        public double GetRightBaseDegreeAngle()
        {
            double x = GetRightBaseRadianAngle() * 180/ Math.PI;
            return Math.Round(x,2);
        }

        static void Main(string[] args)
        {
            MathTrapezoidSample trpz = new MathTrapezoidSample(20.0, 10.0,
8.0, 6.0);
            Console.WriteLine("The trapezoid's bases are 20.0 and 10.0, the
trapezoid's legs are 8.0 and 6.0");
            double h = trpz.GetHeight();
            Console.WriteLine("Trapezoid height is: " + h.ToString());
            double dxR = trpz.GetLeftBaseRadianAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dxR.ToString() + " Radians");
            double dyR = trpz.GetRightBaseRadianAngle();
            Console.WriteLine("Trapezoid right base angle is: " +
dyR.ToString() + " Radians");
            double dxD = trpz.GetLeftBaseDegreeAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dxD.ToString() + " Degrees");
            double dyD = trpz.GetRightBaseDegreeAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dyD.ToString() + " Degrees");
        }
    }
}
```

Remarks

Multiply the return value by 180/Math.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions

Math.Acosh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose hyperbolic cosine is the specified number.

```C#
public static double Acosh (double d);
```

Parameters

d Double

A number representing a hyperbolic cosine, where `d` must be greater than or equal to 1, but less than or equal to PositiveInfinity.

Returns

Double

An angle, θ, measured in radians, such that 0 ≤ θ ≤ ∞.

-or-

NaN if `d` < 1 or `d` equals NaN.

Remarks

Multiply the return value by 180/Math.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Math.Asin(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose sine is the specified number.

```
C#

public static double Asin (double d);
```

Parameters

d Double

A number representing a sine, where `d` must be greater than or equal to -1, but less than or equal to 1.

Returns

Double

An angle, θ, measured in radians, such that -π/2 ≤ θ ≤ π/2.

-or-

NaN if `d` < -1 or `d` > 1 or `d` equals NaN.

Examples

The following example uses Asin to assist in the computation of the inner angles of a given trapezoid.

```
C#

/// <summary>
/// The following class represents simple functionality of the trapezoid.
/// </summary>
using System;
```

```
namespace MathClassCS
{
    class MathTrapezoidSample
    {
        private double m_longBase;
        private double m_shortBase;
        private double m_leftLeg;
        private double m_rightLeg;

        public MathTrapezoidSample(double longbase, double shortbase, double
leftLeg, double rightLeg)
        {
            m_longBase = Math.Abs(longbase);
            m_shortBase = Math.Abs(shortbase);
            m_leftLeg = Math.Abs(leftLeg);
            m_rightLeg = Math.Abs(rightLeg);
        }

        private double GetRightSmallBase()
        {
            return (Math.Pow(m_rightLeg,2.0) - Math.Pow(m_leftLeg,2.0) +
Math.Pow(m_longBase,2.0) + Math.Pow(m_shortBase,2.0) - 2* m_shortBase *
m_longBase)/ (2*(m_longBase - m_shortBase));
        }

        public double GetHeight()
        {
            double x = GetRightSmallBase();
            return Math.Sqrt(Math.Pow(m_rightLeg,2.0) - Math.Pow(x,2.0));
        }

        public double GetSquare()
        {
            return GetHeight() * m_longBase / 2.0;
        }

        public double GetLeftBaseRadianAngle()
        {
            double sinX = GetHeight()/m_leftLeg;
            return Math.Round(Math.Asin(sinX),2);
        }

        public double GetRightBaseRadianAngle()
        {
            double x = GetRightSmallBase();
            double cosX = (Math.Pow(m_rightLeg,2.0) + Math.Pow(x,2.0) -
Math.Pow(GetHeight(),2.0))/(2*x*m_rightLeg);
            return Math.Round(Math.Acos(cosX),2);
        }

        public double GetLeftBaseDegreeAngle()
        {
            double x = GetLeftBaseRadianAngle() * 180/ Math.PI;
            return Math.Round(x,2);
        }
```

```
        public double GetRightBaseDegreeAngle()
        {
            double x = GetRightBaseRadianAngle() * 180/ Math.PI;
            return Math.Round(x,2);
        }

        static void Main(string[] args)
        {
            MathTrapezoidSample trpz = new MathTrapezoidSample(20.0, 10.0,
8.0, 6.0);
            Console.WriteLine("The trapezoid's bases are 20.0 and 10.0, the
trapezoid's legs are 8.0 and 6.0");
            double h = trpz.GetHeight();
            Console.WriteLine("Trapezoid height is: " + h.ToString());
            double dxR = trpz.GetLeftBaseRadianAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dxR.ToString() + " Radians");
            double dyR = trpz.GetRightBaseRadianAngle();
            Console.WriteLine("Trapezoid right base angle is: " +
dyR.ToString() + " Radians");
            double dxD = trpz.GetLeftBaseDegreeAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dxD.ToString() + " Degrees");
            double dyD = trpz.GetRightBaseDegreeAngle();
            Console.WriteLine("Trapezoid left base angle is: " +
dyD.ToString() + " Degrees");
        }
    }
}
```

Remarks

A positive return value represents a counterclockwise angle from the x-axis; a negative return value represents a clockwise angle.

Multiply the return value by 180/Math.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Math.Asinh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose hyperbolic sine is the specified number.

```
C#
public static double Asinh (double d);
```

Parameters

d Double

A number representing a hyperbolic sine, where `d` must be greater than or equal to NegativeInfinity, but less than or equal to PositiveInfinity.

Returns

Double

An angle, θ, measured in radians.

-or-

NaN if `d` equals NaN.

Remarks

Multiply the return value by 180/Math.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Math.Atan(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose tangent is the specified number.

```
C#

public static double Atan (double d);
```

Parameters

d Double

A number representing a tangent.

Returns

Double

An angle, θ, measured in radians, such that -π/2 ≤ θ ≤ π/2.

-or-

NaN if `d` equals NaN, -π/2 rounded to double precision (-1.5707963267949) if `d` equals NegativeInfinity, or π/2 rounded to double precision (1.5707963267949) if `d` equals PositiveInfinity.

Examples

The following example demonstrates how to calculate the arctangent of a value and display it to the console.

```
C#

// This example demonstrates Math.Atan()
//                           Math.Atan2()
//                           Math.Tan()
using System;
```

```
class Sample
{
    public static void Main()
    {
    double x = 1.0;
    double y = 2.0;
    double angle;
    double radians;
    double result;

// Calculate the tangent of 30 degrees.
    angle = 30;
    radians = angle * (Math.PI/180);
    result = Math.Tan(radians);
    Console.WriteLine("The tangent of 30 degrees is {0}.", result);

// Calculate the arctangent of the previous tangent.
    radians = Math.Atan(result);
    angle = radians * (180/Math.PI);
    Console.WriteLine("The previous tangent is equivalent to {0} degrees.",
angle);

// Calculate the arctangent of an angle.
    String line1 = "{0}The arctangent of the angle formed by the x-axis and
";
    String line2 = "a vector to point ({0},{1}) is {2}, ";
    String line3 = "which is equivalent to {0} degrees.";

    radians = Math.Atan2(y, x);
    angle = radians * (180/Math.PI);

    Console.WriteLine(line1, Environment.NewLine);
    Console.WriteLine(line2, x, y, radians);
    Console.WriteLine(line3, angle);
    }
}
/*
This example produces the following results:

The tangent of 30 degrees is 0.577350269189626.
The previous tangent is equivalent to 30 degrees.

The arctangent of the angle formed by the x-axis and
a vector to point (1,2) is 1.10714871779409,
which is equivalent to 63.434948822922 degrees.
*/
```

Remarks

A positive return value represents a counterclockwise angle from the x-axis; a negative return value represents a clockwise angle.

Multiply the return value by 180/Math.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.Atan2(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose tangent is the quotient of two specified numbers.

```
C#
public static double Atan2 (double y, double x);
```

Parameters

y Double

The y coordinate of a point.

x Double

The x coordinate of a point.

Returns

Double

An angle, θ, measured in radians, such that tan(θ) = `y` / `x`, where (`x`, `y`) is a point in the Cartesian plane. Observe the following:

- For (`x`, `y`) in quadrant 1, 0 < θ < π/2.
- For (`x`, `y`) in quadrant 2, π/2 < θ ≤ π.
- For (`x`, `y`) in quadrant 3, -π ≤ θ < -π/2.
- For (`x`, `y`) in quadrant 4, -π/2 < θ < 0.

For points on the boundaries of the quadrants, the return value is the following:

- If y is 0 and x is not negative, θ = 0.
- If y is 0 and x is negative, θ = π.

- If y is positive and x is 0, θ = π/2.
- If y is negative and x is 0, θ = -π/2.
- If y is 0 and x is 0, θ = 0.

If `x` or `y` is NaN, or if `x` and `y` are either PositiveInfinity or NegativeInfinity, the method returns NaN.

Examples

The following example demonstrates how to calculate the arctangent of an angle and a vector. The resulting value is displayed in the console.

C#

```
// This example demonstrates Math.Atan()
//                           Math.Atan2()
//                           Math.Tan()
using System;

class Sample
{
    public static void Main()
    {
    double x = 1.0;
    double y = 2.0;
    double angle;
    double radians;
    double result;

// Calculate the tangent of 30 degrees.
    angle = 30;
    radians = angle * (Math.PI/180);
    result = Math.Tan(radians);
    Console.WriteLine("The tangent of 30 degrees is {0}.", result);

// Calculate the arctangent of the previous tangent.
    radians = Math.Atan(result);
    angle = radians * (180/Math.PI);
    Console.WriteLine("The previous tangent is equivalent to {0} degrees.",
angle);

// Calculate the arctangent of an angle.
    String line1 = "{0}The arctangent of the angle formed by the x-axis and
";
    String line2 = "a vector to point ({0},{1}) is {2}, ";
    String line3 = "which is equivalent to {0} degrees.";

    radians = Math.Atan2(y, x);
    angle = radians * (180/Math.PI);
```

```
    Console.WriteLine(line1, Environment.NewLine);
    Console.WriteLine(line2, x, y, radians);
    Console.WriteLine(line3, angle);
    }
}
/*
This example produces the following results:

The tangent of 30 degrees is 0.577350269189626.
The previous tangent is equivalent to 30 degrees.

The arctangent of the angle formed by the x-axis and
a vector to point (1,2) is 1.10714871779409,
which is equivalent to 63.434948822922 degrees.
*/
```

Remarks

The return value is the angle in the Cartesian plane formed by the x-axis, and a vector starting from the origin, (0,0), and terminating at the point, (x,y).

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Math.Atanh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose hyperbolic tangent is the specified number.

```
C#
public static double Atanh (double d);
```

Parameters

d Double

A number representing a hyperbolic tangent, where `d` must be greater than or equal to -1, but less than or equal to 1.

Returns

Double

An angle, θ, measured in radians, such that -∞ < θ < -1, or 1 < θ < ∞.

-or-

NaN if `d` < -1 or `d` > 1 or `d` equals NaN.

Remarks

Multiply the return value by 180/Math.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Math.BigMul Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

BigMul(Int32, Int32)	Produces the full product of two 32-bit numbers.
BigMul(Int64, Int64, Int64)	Produces the full product of two 64-bit numbers.
BigMul(UInt64, UInt64, UInt64)	Produces the full product of two unsigned 64-bit numbers.

BigMul(Int32, Int32)

Produces the full product of two 32-bit numbers.

C#

```
public static long BigMul (int a, int b);
```

Parameters

a Int32

The first number to multiply.

b Int32

The second number to multiply.

Returns

Int64

The number containing the product of the specified numbers.

Examples

The following example demonstrates the use of the BigMul method to calculate the product of two integer values.

C#

```
// This example demonstrates Math.BigMul()
using System;

class Sample
{
    public static void Main()
    {
    int int1 = Int32.MaxValue;
    int int2 = Int32.MaxValue;
    long longResult;
//
    longResult = Math.BigMul(int1, int2);
    Console.WriteLine("Calculate the product of two Int32 values:");
    Console.WriteLine("{0} * {1} = {2}", int1, int2, longResult);
    }
}
/*
This example produces the following results:
Calculate the product of two Int32 values:
2147483647 * 2147483647 = 4611686014132420609
*/
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

BigMul(Int64, Int64, Int64)

Produces the full product of two 64-bit numbers.

C#

```
public static long BigMul (long a, long b, out long low);
```

Parameters

a Int64

The first number to multiply.

b Int64

The second number to multiply.

low Int64

When this method returns, contains the low 64-bit of the product of the specified numbers.

Returns

Int64

The high 64-bit of the product of the specified numbers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

BigMul(UInt64, UInt64, UInt64)

> Important
>
> This API is not CLS-compliant.

Produces the full product of two unsigned 64-bit numbers.

C#

```
[System.CLSCompliant(false)]
```

```
public static ulong BigMul (ulong a, ulong b, out ulong low);
```

Parameters

a UInt64

The first number to multiply.

b UInt64

The second number to multiply.

low UInt64

When this method returns, contains the low 64-bit of the product of the specified numbers.

Returns

UInt64

The high 64-bit of the product of the specified numbers.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Math.BitDecrement(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the largest value that compares less than a specified value.

C#

```
public static double BitDecrement (double x);
```

Parameters

x Double

The value to decrement.

Returns

Double

The largest value that compares less than `x`.

-or-

NegativeInfinity if `x` equals NegativeInfinity.

-or-

NaN if `x` equals NaN.

Applies to

Math.BitIncrement(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smallest value that compares greater than a specified value.

C#

```
public static double BitIncrement (double x);
```

Parameters

x Double

The value to increment.

Returns

Double

The smallest value that compares greater than `x`.

-or-

PositiveInfinity if `x` equals PositiveInfinity.

-or-

NaN if `x` equals NaN.

Applies to

Math.Cbrt(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the cube root of a specified number.

```
C#
public static double Cbrt (double d);
```

Parameters

d Double

The number whose cube root is to be found.

Returns

Double

The cube root of `d`.

-or-

NaN if `x` equals NaN.

Remarks

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Math.Ceiling Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smallest integral value greater than or equal to the specified number.

Overloads

Expand table

Ceiling(Decimal)	Returns the smallest integral value that is greater than or equal to the specified decimal number.
Ceiling(Double)	Returns the smallest integral value that is greater than or equal to the specified double-precision floating-point number.

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward positive infinity.

Ceiling(Decimal)

Returns the smallest integral value that is greater than or equal to the specified decimal number.

C#

```
public static decimal Ceiling (decimal d);
```

Parameters

d Decimal

A decimal number.

Returns

Decimal

The smallest integral value that is greater than or equal to `d`. Note that this method returns a Decimal instead of an integral type.

Examples

The following example illustrates the Math.Ceiling(Decimal) method and contrasts it with the Floor(Decimal) method.

C#

```
decimal[] values = {7.03m, 7.64m, 0.12m, -0.12m, -7.1m, -7.6m};
Console.WriteLine("  Value          Ceiling          Floor\n");
foreach (decimal value in values)
   Console.WriteLine("{0,7} {1,16} {2,14}",
                     value, Math.Ceiling(value), Math.Floor(value));
// The example displays the following output to the console:
//         Value          Ceiling          Floor
//
//          7.03                8              7
//          7.64                8              7
//          0.12                1              0
//         -0.12                0             -1
//          -7.1               -7             -8
//          -7.6               -7             -8
```

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward positive infinity. In other words, if `d` is positive, the presence of any fractional component causes `d` to be rounded to the next highest integer. If `d` is negative, the rounding operation causes any fractional component of `d` to be discarded. The operation of this method differs from the Floor(Decimal) method, which supports rounding toward negative infinity.

UWP	10.0

Ceiling(Double)

Returns the smallest integral value that is greater than or equal to the specified double-precision floating-point number.

C#

```
public static double Ceiling (double a);
```

Parameters

a Double

A double-precision floating-point number.

Returns

Double

The smallest integral value that is greater than or equal to `a`. If `a` is equal to NaN, NegativeInfinity, or PositiveInfinity, that value is returned. Note that this method returns a Double instead of an integral type.

Examples

The following example illustrates the Math.Ceiling(Double) method and contrasts it with the Floor(Double) method.

C#

```
double[] values = {7.03, 7.64, 0.12, -0.12, -7.1, -7.6};
Console.WriteLine("  Value          Ceiling          Floor\n");
foreach (double value in values)
   Console.WriteLine("{0,7} {1,16} {2,14}",
                     value, Math.Ceiling(value), Math.Floor(value));
// The example displays the following output to the console:
//         Value          Ceiling          Floor
//
//          7.03                8              7
//          7.64                8              7
//          0.12                1              0
//         -0.12                0             -1
//          -7.1               -7             -8
//          -7.6               -7             -8
```

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward positive infinity. In other words, if `a` is positive, the presence of any fractional component causes `a` to be rounded to the next highest integer. If `a` is negative, the rounding operation causes any fractional component of `a` to be discarded. The operation of this method differs from the Floor(Double) method, which supports rounding toward negative infinity.

Starting with Visual Basic 15.8, the performance of Double-to-integer conversion is optimized if you pass the value returned by the `Ceiling` method to the any of the integral conversion functions, or if the Double value returned by `Ceiling` is automatically converted to an integer with Option Strict set to Off. This optimization allows code to run faster -- up to twice as fast for code that does a large number of conversions to integer types. The following example illustrates such optimized conversions:

VB

```
Dim d1 As Double = 1043.75133
Dim i1 As Integer = CInt(Math.Ceiling(d1))        ' Result: 1044

Dim d2 As Double = 7968.4136
Dim i2 As Integer = CInt(Math.Ceiling(d2))        ' Result: 7969
```

Math.Clamp Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Clamp(UIntPtr, UIntPtr, UIntPtr)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UInt64, UInt64, UInt64)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UInt32, UInt32, UInt32)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(UInt16, UInt16, UInt16)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Single, Single, Single)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(SByte, SByte, SByte)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Int64, Int64, Int64)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Int32, Int32, Int32)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Int16, Int16, Int16)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Double, Double, Double)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(Decimal, Decimal, Decimal)	Returns `value` clamped to the inclusive range of `min` and `max`.

Clamp(Byte, Byte, Byte)	Returns `value` clamped to the inclusive range of `min` and `max`.
Clamp(IntPtr, IntPtr, IntPtr)	Returns `value` clamped to the inclusive range of `min` and `max`.

Clamp(UIntPtr, UIntPtr, UIntPtr)

> Important
>
> This API is not CLS-compliant.

Returns `value` clamped to the inclusive range of `min` and `max`.

C#

```
[System.CLSCompliant(false)]
public static UIntPtr Clamp (UIntPtr value, UIntPtr min, UIntPtr max);
```

Parameters

`value` nuint

The value to be clamped.

`min` nuint

The lower bound of the result.

`max` nuint

The upper bound of the result.

Returns

nuint

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Clamp(UInt64, UInt64, UInt64)

> Important
>
> This API is not CLS-compliant.

Returns `value` clamped to the inclusive range of `min` and `max`.

C#

```
[System.CLSCompliant(false)]
public static ulong Clamp (ulong value, ulong min, ulong max);
```

Parameters

`value` UInt64

The value to be clamped.

`min` UInt64

The lower bound of the result.

`max` UInt64

The upper bound of the result.

Returns

UInt64

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(UInt32, UInt32, UInt32)

> Important
>
> This API is not CLS-compliant.

Returns `value` clamped to the inclusive range of `min` and `max`.

C#

```
[System.CLSCompliant(false)]
public static uint Clamp (uint value, uint min, uint max);
```

Parameters

`value` UInt32

The value to be clamped.

`min` UInt32

The lower bound of the result.

`max` UInt32

The upper bound of the result.

Returns

UInt32

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(UInt16, UInt16, UInt16)

> Important
>
> This API is not CLS-compliant.

Returns `value` clamped to the inclusive range of `min` and `max`.

C#

```
[System.CLSCompliant(false)]
```

```
public static ushort Clamp (ushort value, ushort min, ushort max);
```

Parameters

`value` UInt16

The value to be clamped.

`min` UInt16

The lower bound of the result.

`max` UInt16

The upper bound of the result.

Returns

UInt16

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Single, Single, Single)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
public static float Clamp (float value, float min, float max);
```

Parameters

`value` Single

The value to be clamped.

`min` Single

The lower bound of the result.

`max` Single

The upper bound of the result.

Returns

Single

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

-or-

NaN if `value` equals NaN.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(SByte, SByte, SByte)

> Important
>
> This API is not CLS-compliant.

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
[System.CLSCompliant(false)]
public static sbyte Clamp (sbyte value, sbyte min, sbyte max);
```

Parameters

`value` SByte

The value to be clamped.

`min` SByte

The lower bound of the result.

`max` SByte

The upper bound of the result.

Returns

SByte

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Int64, Int64, Int64)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
public static long Clamp (long value, long min, long max);
```

Parameters

`value` Int64

The value to be clamped.

`min` Int64

The lower bound of the result.

`max` Int64

The upper bound of the result.

Returns

Int64

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Int32, Int32, Int32)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
public static int Clamp (int value, int min, int max);
```

Parameters

`value` Int32

The value to be clamped.

`min` Int32

The lower bound of the result.

`max` Int32

The upper bound of the result.

Returns

Int32

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Int16, Int16, Int16)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
public static short Clamp (short value, short min, short max);
```

Parameters

`value` Int16

The value to be clamped.

`min` Int16

The lower bound of the result.

`max` Int16

The upper bound of the result.

Returns

Int16

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Double, Double, Double)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
public static double Clamp (double value, double min, double max);
```

Parameters

`value` Double

The value to be clamped.

`min` Double

The lower bound of the result.

`max` Double

The upper bound of the result.

Returns

Double

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

-or-

NaN if `value` equals NaN.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Decimal, Decimal, Decimal)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#
public static decimal Clamp (decimal value, decimal min, decimal max);
```

Parameters

`value` Decimal

The value to be clamped.

`min` Decimal

The lower bound of the result.

`max` Decimal

The upper bound of the result.

Returns

Decimal

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(Byte, Byte, Byte)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#

public static byte Clamp (byte value, byte min, byte max);
```

Parameters

`value` Byte

The value to be clamped.

`min` Byte

The lower bound of the result.

`max` Byte

The upper bound of the result.

Returns

Byte

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Clamp(IntPtr, IntPtr, IntPtr)

Returns `value` clamped to the inclusive range of `min` and `max`.

```
C#

public static IntPtr Clamp (IntPtr value, IntPtr min, IntPtr max);
```

Parameters

`value` nint

The value to be clamped.

`min` nint

The lower bound of the result.

`max` nint

The upper bound of the result.

Returns

nint

`value` if `min` ≤ `value` ≤ `max`.

-or-

`min` if `value` < `min`.

-or-

`max` if `max` < `value`.

Applies to

Math.CopySign(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value with the magnitude of `x` and the sign of `y`.

C#

```
public static double CopySign (double x, double y);
```

Parameters

x Double

A number whose magnitude is used in the result.

y Double

A number whose sign is the used in the result.

Returns

Double

A value with the magnitude of `x` and the sign of `y`.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.Cos(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the cosine of the specified angle.

C#

```
public static double Cos (double d);
```

Parameters

d Double

An angle, measured in radians.

Returns

Double

The cosine of `d`. If `d` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Examples

The following example uses Cos to evaluate certain trigonometric identities for selected angles.

C#

```
// Example for the trigonometric Math.Sin( double )
// and Math.Cos( double ) methods.
using System;

class SinCos
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of trigonometric " +
```

```
            "Math.Sin( double ), Math.Cos( double ), and Math.SinCos( double
)\n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Convert selected values for X to radians \n" +
            "and evaluate these trigonometric identities:" );
        Console.WriteLine( "   sin^2(X) + cos^2(X) == 1\n" +
                           "   sin(2 * X) == 2 * sin(X) * cos(X)" );
        Console.WriteLine( "   cos(2 * X) == cos^2(X) - sin^2(X)" );
        Console.WriteLine( "   cos(2 * X) == cos^2(X) - sin^2(X)" );

        UseSineCosine(15.0);
        UseSineCosine(30.0);
        UseSineCosine(45.0);

        Console.WriteLine(
            "\nConvert selected values for X and Y to radians \n" +
            "and evaluate these trigonometric identities:" );
        Console.WriteLine( "   sin(X + Y) == sin(X) * cos(Y) + cos(X) *
sin(Y)" );
        Console.WriteLine( "   cos(X + Y) == cos(X) * cos(Y) - sin(X) *
sin(Y)" );

        UseTwoAngles(15.0, 30.0);
        UseTwoAngles(30.0, 45.0);

        Console.WriteLine(
            "\nWhen you have calls to sin(X) and cos(X) they \n" +
            "can be replaced with a single call to sincos(x):" );

        UseCombinedSineCosine(15.0);
        UseCombinedSineCosine(30.0);
        UseCombinedSineCosine(45.0);
    }

    // Evaluate trigonometric identities with a given angle.
    static void UseCombinedSineCosine(double degrees)
    {
        double angle = Math.PI * degrees / 180.0;
        (double sinAngle, double cosAngle) = Math.SinCos(angle);

        // Evaluate sin^2(X) + cos^2(X) == 1.
        Console.WriteLine(
            "\n                           Math.SinCos({0} deg) == ({1:E16},
{2:E16})",
            degrees, sinAngle, cosAngle);
        Console.WriteLine(
            "(double sin, double cos) = Math.SinCos({0} deg)",
            degrees );
        Console.WriteLine(
            "sin^2 + cos^2 == {0:E16}",
            sinAngle * sinAngle + cosAngle * cosAngle );
    }

    // Evaluate trigonometric identities with a given angle.
```

```
    static void UseSineCosine(double degrees)
    {
        double angle    = Math.PI * degrees / 180.0;
        double sinAngle = Math.Sin(angle);
        double cosAngle = Math.Cos(angle);

        // Evaluate sin^2(X) + cos^2(X) == 1.
        Console.WriteLine(
            "\n                            Math.Sin({0} deg) == {1:E16}\n" +
            "                            Math.Cos({0} deg) == {2:E16}",
            degrees, Math.Sin(angle), Math.Cos(angle) );
        Console.WriteLine(
            "(Math.Sin({0} deg))^2 + (Math.Cos({0} deg))^2 == {1:E16}",
            degrees, sinAngle * sinAngle + cosAngle * cosAngle );

        // Evaluate sin(2 * X) == 2 * sin(X) * cos(X).
        Console.WriteLine(
            "                            Math.Sin({0} deg) == {1:E16}",
            2.0 * degrees, Math.Sin(2.0 * angle) );
        Console.WriteLine(
            "    2 * Math.Sin({0} deg) * Math.Cos({0} deg) == {1:E16}",
            degrees, 2.0 * sinAngle * cosAngle );

        // Evaluate cos(2 * X) == cos^2(X) - sin^2(X).
        Console.WriteLine(
            "                            Math.Cos({0} deg) == {1:E16}",
            2.0 * degrees, Math.Cos(2.0 * angle) );
        Console.WriteLine(
            "(Math.Cos({0} deg))^2 - (Math.Sin({0} deg))^2 == {1:E16}",
            degrees, cosAngle * cosAngle - sinAngle * sinAngle );
    }

    // Evaluate trigonometric identities that are functions of two angles.
    static void UseTwoAngles(double degreesX, double degreesY)
    {
        double  angleX  = Math.PI * degreesX / 180.0;
        double  angleY  = Math.PI * degreesY / 180.0;

Math.Cosh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hyperbolic cosine of the specified angle.

C#

```
public static double Cosh (double value);
```

Parameters

`value` Double

An angle, measured in radians.

Returns

Double

The hyperbolic cosine of `value`. If `value` is equal to NegativeInfinity or PositiveInfinity, PositiveInfinity is returned. If `value` is equal to NaN, NaN is returned.

Examples

The following example uses Cosh to evaluate certain hyperbolic identities for selected values.

C#

```
// Example for the hyperbolic Math.Sinh( double )
// and Math.Cosh( double ) methods.
using System;

class SinhCosh
{
    public static void Main()
    {
        Console.WriteLine(
```

```
            "This example of hyperbolic Math.Sinh( double ) " +
            "and Math.Cosh( double )\n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Evaluate these hyperbolic identities " +
            "with selected values for X:" );
        Console.WriteLine(
            "   cosh^2(X) - sinh^2(X) == 1\n" +
            "   sinh(2 * X) == 2 * sinh(X) * cosh(X)" );
        Console.WriteLine( "   cosh(2 * X) == cosh^2(X) + sinh^2(X)" );

        UseSinhCosh(0.1);
        UseSinhCosh(1.2);
        UseSinhCosh(4.9);

        Console.WriteLine(
            "\nEvaluate these hyperbolic identities " +
            "with selected values for X and Y:" );
        Console.WriteLine(
            "   sinh(X + Y) == sinh(X) * cosh(Y) + cosh(X) * sinh(Y)" );
        Console.WriteLine(
            "   cosh(X + Y) == cosh(X) * cosh(Y) + sinh(X) * sinh(Y)" );

        UseTwoArgs(0.1, 1.2);
        UseTwoArgs(1.2, 4.9);
    }

    // Evaluate hyperbolic identities with a given argument.
    static void UseSinhCosh(double arg)
    {
        double sinhArg = Math.Sinh(arg);
        double coshArg = Math.Cosh(arg);

        // Evaluate cosh^2(X) - sinh^2(X) == 1.
        Console.WriteLine(
            "\n                        Math.Sinh({0}) == {1:E16}\n" +

Math.DivRem Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the quotient of two numbers and also returns the remainder in an output parameter.

Overloads

Expand table

DivRem(IntPtr, IntPtr)	Produces the quotient and the remainder of two signed native-size numbers.
DivRem(Int64, Int64, Int64)	Calculates the quotient of two 64-bit signed integers and also returns the remainder in an output parameter.
DivRem(Int32, Int32, Int32)	Calculates the quotient of two 32-bit signed integers and also returns the remainder in an output parameter.
DivRem(UIntPtr, UIntPtr)	Produces the quotient and the remainder of two unsigned native-size numbers.
DivRem(UInt64, UInt64)	Produces the quotient and the remainder of two unsigned 64-bit numbers.
DivRem(UInt32, UInt32)	Produces the quotient and the remainder of two unsigned 32-bit numbers.
DivRem(Int64, Int64)	Produces the quotient and the remainder of two signed 64-bit numbers.
DivRem(SByte, SByte)	Produces the quotient and the remainder of two signed 8-bit numbers.
DivRem(Int32, Int32)	Produces the quotient and the remainder of two signed 32-bit numbers.
DivRem(Int16, Int16)	Produces the quotient and the remainder of two signed 16-bit numbers.
DivRem(Byte, Byte)	Produces the quotient and the remainder of two unsigned 8-bit numbers.
DivRem(UInt16,	Produces the quotient and the remainder of two unsigned 16-bit

UInt16)	numbers.

DivRem(IntPtr, IntPtr)

Produces the quotient and the remainder of two signed native-size numbers.

C#

```
public static (IntPtr Quotient, IntPtr Remainder) DivRem (IntPtr left,
IntPtr right);
```

Parameters

`left` nint

The dividend.

`right` nint

The divisor.

Returns

ValueTuple<nint,nint>

The quotient and the remainder of the specified numbers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(Int64, Int64, Int64)

Calculates the quotient of two 64-bit signed integers and also returns the remainder in an output parameter.

C#

```
public static long DivRem (long a, long b, out long result);
```

Parameters

`a` Int64

The dividend.

`b` Int64

The divisor.

`result` Int64

When this method returns, contains the remainder.

Returns

Int64

The quotient of the specified numbers.

Exceptions

DivideByZeroException

`b` is zero.

Examples

The following example demonstrates the DivRem(Int64, Int64, Int64) method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define several positive and negative dividends.
      long[] dividends = { Int64.MaxValue, 13952, 0, -14032,
                           Int64.MinValue };
      // Define one positive and one negative divisor.
      long[] divisors = { 2000, -2000 };

      foreach (long divisor in divisors)
      {
```

```
            foreach (long dividend in dividends)
            {
               long remainder;
               long quotient = Math.DivRem(dividend, divisor, out
remainder);
               Console.WriteLine(@"{0:N0} \ {1:N0} = {2:N0}, remainder
{3:N0}",
                                 dividend, divisor, quotient, remainder);
            }
         }
      }
   }
// The example displays the following output:
//    9,223,372,036,854,775,807 \ 2,000 = 4,611,686,018,427,387,
remainder 1,807
//    13,952 \ 2,000 = 6, remainder 1,952
//    0 \ 2,000 = 0, remainder 0
//    -14,032 \ 2,000 = -7, remainder -32
//    -9,223,372,036,854,775,808 \ 2,000 = -4,611,686,018,427,387,
remainder -1,808
//    9,223,372,036,854,775,807 \ -2,000 = -4,611,686,018,427,387,
remainder 1,807
//    13,952 \ -2,000 = -6, remainder 1,952
//    0 \ -2,000 = 0, remainder 0
//    -14,032 \ -2,000 = 7, remainder -32
//    -9,223,372,036,854,775,808 \ -2,000 = 4,611,686,018,427,387,
remainder -1,808
```

Remarks

The remainder value equals the result of the remainder operator.

.NET Standard	2.0, 2.1

DivRem(Int32, Int32, Int32)

Calculates the quotient of two 32-bit signed integers and also returns the remainder in an output parameter.

```
C#

public static int DivRem (int a, int b, out int result);
```

Parameters

a Int32

The dividend.

b Int32

The divisor.

result Int32

When this method returns, contains the remainder.

Returns

Int32

The quotient of the specified numbers.

Exceptions

DivideByZeroException

`b` is zero.

Examples

The following example demonstrates the DivRem(Int32, Int32, Int32) method.

```
C#

using System;

public class Example
{
   public static void Main()
   {
```

```
        // Define several positive and negative dividends.
        int[] dividends = { Int32.MaxValue, 13952, 0, -14032,
                                        Int32.MinValue };
        // Define one positive and one negative divisor.
        int[] divisors = { 2000, -2000 };

        foreach (int divisor in divisors)
        {
           foreach (int dividend in dividends)
           {
              int remainder;
              int quotient = Math.DivRem(dividend, divisor, out remainder);
              Console.WriteLine(@"{0:N0} \ {1:N0} = {2:N0}, remainder
{3:N0}",
                                dividend, divisor, quotient, remainder);
           }
        }
    }
}
// The example displays the following output:
//       2,147,483,647 \ 2,000 = 1,073,741, remainder 1,647
//       13,952 \ 2,000 = 6, remainder 1,952
//       0 \ 2,000 = 0, remainder 0
//       -14,032 \ 2,000 = -7, remainder -32
//       -2,147,483,648 \ 2,000 = -1,073,741, remainder -1,648
//       2,147,483,647 \ -2,000 = -1,073,741, remainder 1,647
//       13,952 \ -2,000 = -6, remainder 1,952
//       0 \ -2,000 = 0, remainder 0
//       -14,032 \ -2,000 = 7, remainder -32
//       -2,147,483,648 \ -2,000 = 1,073,741, remainder -1,648
```

Remarks

The remainder value equals the result of the remainder operator.

Framework	4.8.1
.NET Standard	2.0, 2.1

DivRem(UIntPtr, UIntPtr)

> Important
>
> This API is not CLS-compliant.

Produces the quotient and the remainder of two unsigned native-size numbers.

C#

```
[System.CLSCompliant(false)]
public static (UIntPtr Quotient, UIntPtr Remainder) DivRem (UIntPtr left,
UIntPtr right);
```

Parameters

`left` nuint

The dividend.

`right` nuint

The divisor.

Returns

ValueTuple<nuint,nuint>

The quotient and the remainder of the specified numbers.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(UInt64, UInt64)

> Important
>
> This API is not CLS-compliant.

Produces the quotient and the remainder of two unsigned 64-bit numbers.

C#

```
[System.CLSCompliant(false)]
public static (ulong Quotient, ulong Remainder) DivRem (ulong left, ulong
right);
```

Parameters

`left` UInt64

The dividend.

`right` UInt64

The divisor.

Returns

ValueTuple<UInt64,UInt64>

The quotient and the remainder of the specified numbers.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(UInt32, UInt32)

> Important
>
> This API is not CLS-compliant.

Produces the quotient and the remainder of two unsigned 32-bit numbers.

C#

```
[System.CLSCompliant(false)]
public static (uint Quotient, uint Remainder) DivRem (uint left, uint
right);
```

Parameters

`left` UInt32

The dividend.

`right` UInt32

The divisor.

Returns

ValueTuple<UInt32,UInt32>

The quotient and the remainder of the specified numbers.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(Int64, Int64)

Produces the quotient and the remainder of two signed 64-bit numbers.

```
C#

public static (long Quotient, long Remainder) DivRem (long left, long
right);
```

Parameters

`left` Int64

The dividend.

`right` Int64

The divisor.

Returns

ValueTuple<Int64,Int64>

The quotient and the remainder of the specified numbers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(SByte, SByte)

> Important
>
> This API is not CLS-compliant.

Produces the quotient and the remainder of two signed 8-bit numbers.

```
C#

[System.CLSCompliant(false)]
public static (sbyte Quotient, sbyte Remainder) DivRem (sbyte left, sbyte
```

```
right);
```

Parameters

left SByte

The dividend.

right SByte

The divisor.

Returns

ValueTuple<SByte,SByte>

The quotient and the remainder of the specified numbers.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(Int32, Int32)

Produces the quotient and the remainder of two signed 32-bit numbers.

C#

```
public static (int Quotient, int Remainder) DivRem (int left, int right);
```

Parameters

left Int32

The dividend.

right Int32

The divisor.

Returns

ValueTuple<Int32,Int32>

The quotient and the remainder of the specified numbers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(Int16, Int16)

Produces the quotient and the remainder of two signed 16-bit numbers.

```
C#

public static (short Quotient, short Remainder) DivRem (short left, short
right);
```

Parameters

`left` Int16

The dividend.

`right` Int16

The divisor.

Returns

ValueTuple<Int16,Int16>

The quotient and the remainder of the specified numbers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(Byte, Byte)

Produces the quotient and the remainder of two unsigned 8-bit numbers.

```
C#

public static (byte Quotient, byte Remainder) DivRem (byte left, byte
right);
```

Parameters

`left` Byte

The dividend.

`right` Byte

The divisor.

Returns

ValueTuple<Byte,Byte>

The quotient and the remainder of the specified numbers.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

DivRem(UInt16, UInt16)

> Important
>
> This API is not CLS-compliant.

Produces the quotient and the remainder of two unsigned 16-bit numbers.

```
C#

[System.CLSCompliant(false)]
public static (ushort Quotient, ushort Remainder) DivRem (ushort left,
ushort right);
```

Parameters

`left` UInt16

The dividend.

`right` UInt16

The divisor.

Returns

ValueTuple<UInt16,UInt16>

The quotient and the remainder of the specified numbers.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Math.Exp(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns `e` raised to the specified power.

C#

```
public static double Exp (double d);
```

Parameters

d Double

A number specifying a power.

Returns

Double

The number `e` raised to the power `d`. If `d` equals NaN or PositiveInfinity, that value is returned. If `d` equals NegativeInfinity, 0 is returned.

Examples

The following example uses Exp to evaluate certain exponential and logarithmic identities for selected values.

C#

```
// Example for the Math.Exp( double ) method.
using System;

class ExpDemo
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of Math.Exp( double ) " +
```

```
            "generates the following output.\n" );
        Console.WriteLine(
            "Evaluate [e ^ ln(X) == ln(e ^ X) == X] " +
            "with selected values for X:" );

        UseLnExp(0.1);
        UseLnExp(1.2);
        UseLnExp(4.9);
        UseLnExp(9.9);

        Console.WriteLine(
            "\nEvaluate these identities with " +
            "selected values for X and Y:" );
        Console.WriteLine( "   (e ^ X) * (e ^ Y) == e ^ (X + Y)" );
        Console.WriteLine( "   (e ^ X) ^ Y == e ^ (X * Y)" );
        Console.WriteLine( "   X ^ Y == e ^ (Y * ln(X))" );

        UseTwoArgs(0.1, 1.2);
        UseTwoArgs(1.2, 4.9);
        UseTwoArgs(4.9, 9.9);
    }

    // Evaluate logarithmic/exponential identity with a given argument.
    static void UseLnExp(double arg)
    {
        // Evaluate e ^ ln(X) == ln(e ^ X) == X.
        Console.WriteLine(
            "\n      Math.Exp(Math.Log({0})) == {1:E16}\n" +
            "      Math.Log(Math.Exp({0})) == {2:E16}",
            arg, Math.Exp(Math.Log(arg)), Math.Log(Math.Exp(arg)) );
    }

    // Evaluate exponential identities that are functions of two arguments.
    static void UseTwoArgs(double argX, double argY)
    {
        // Evaluate (e ^ X) * (e ^ Y) == e ^ (X + Y).
        Console.WriteLine(
            "\nMath.Exp({0}) * Math.Exp({1}) == {2:E16}" +
            "\n          Math.Exp({0} + {1}) == {3:E16}",
            argX, argY, Math.Exp(argX) * Math.Exp(argY),
            Math.Exp(argX + argY) );

        // Evaluate (e ^ X) ^ Y == e ^ (X * Y).
        Console.WriteLine(
            " Math.Pow(Math.Exp({0}), {1}) == {2:E16}" +
            "\n          Math.Exp({0} * {1}) == {3:E16}",
            argX, argY, Math.Pow(Math.Exp(argX), argY),
            Math.Exp(argX * argY) );

        // Evaluate X ^ Y == e ^ (Y * ln(X)).
        Console.WriteLine(
            "           Math.Pow({0}, {1}) == {2:E16}" +
            "\nMath.Exp({1} * Math.Log({0})) == {3:E16}",
            argX, argY, Math.Pow(argX, argY),
            Math.Exp(argY * Math.Log(argX)) );
```

```
    }
}

/*
This example of Math.Exp( double ) generates the following output.

Evaluate [e ^ ln(X) == ln(e ^ X) == X] with selected values for X:

      Math.Exp(Math.Log(0.1)) == 1.0000000000000001E-001
      Math.Log(Math.Exp(0.1)) == 1.0000000000000008E-001

      Math.Exp(Math.Log(1.2)) == 1.2000000000000000E+000
      Math.Log(Math.Exp(1.2)) == 1.2000000000000000E+000

      Math.Exp(Math.Log(4.9)) == 4.9000000000000012E+000
      Math.Log(Math.Exp(4.9)) == 4.9000000000000004E+000

      Math.Exp(Math.Log(9.9)) == 9.9000000000000004E+000
      Math.Log(Math.Exp(9.9)) == 9.9000000000000004E+000

Evaluate these identities with selected values for X and Y:
   (e ^ X) * (e ^ Y) == e ^ (X + Y)
   (e ^ X) ^ Y == e ^ (X * Y)
   X ^ Y == e ^ (Y * ln(X))

Math.Exp(0.1) * Math.Exp(1.2) == 3.6692966676192444E+000
          Math.Exp(0.1 + 1.2) == 3.6692966676192444E+000
 Math.Pow(Math.Exp(0.1), 1.2) == 1.1274968515793757E+000
          Math.Exp(0.1 * 1.2) == 1.1274968515793757E+000
           Math.Pow(0.1, 1.2) == 6.3095734448019331E-002
Math.Exp(1.2 * Math.Log(0.1)) == 6.3095734448019344E-002

Math.Exp(1.2) * Math.Exp(4.9) == 4.4585777008251705E+002
          Math.Exp(1.2 + 4.9) == 4.4585777008251716E+002
 Math.Pow(Math.Exp(1.2), 4.9) == 3.5780924170885260E+002
          Math.Exp(1.2 * 4.9) == 3.5780924170885277E+002
           Math.Pow(1.2, 4.9) == 2.4433636334442981E+000
Math.Exp(4.9 * Math.Log(1.2)) == 2.4433636334442981E+000

Math.Exp(4.9) * Math.Exp(9.9) == 2.6764450551890982E+006
          Math.Exp(4.9 + 9.9) == 2.6764450551891015E+006
 Math.Pow(Math.Exp(4.9), 9.9) == 1.1684908531676833E+021
          Math.Exp(4.9 * 9.9) == 1.1684908531676829E+021
           Math.Pow(4.9, 9.9) == 6.8067718210957060E+006
Math.Exp(9.9 * Math.Log(4.9)) == 6.8067718210956985E+006
*/
```

Remarks

`e` is a mathematical constant whose value is approximately 2.71828.

Use the Pow method to calculate powers of other bases.

Exp is the inverse of Log.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Math.Floor Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the largest integral value less than or equal to the specified number.

Overloads

Expand table

Floor(Double)	Returns the largest integral value less than or equal to the specified double-precision floating-point number.
Floor(Decimal)	Returns the largest integral value less than or equal to the specified decimal number.

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward negative infinity.

Floor(Double)

Returns the largest integral value less than or equal to the specified double-precision floating-point number.

C#

```
public static double Floor (double d);
```

Parameters

d Double

A double-precision floating-point number.

Returns

Double

The largest integral value less than or equal to `d`. If `d` is equal to NaN, NegativeInfinity, or PositiveInfinity, that value is returned.

Examples

The following example illustrates the Math.Floor(Double) method and contrasts it with the Ceiling(Double) method.

C#

```
double[] values = {7.03, 7.64, 0.12, -0.12, -7.1, -7.6};
Console.WriteLine("  Value          Ceiling          Floor\n");
foreach (double value in values)
   Console.WriteLine("{0,7} {1,16} {2,14}",
                     value, Math.Ceiling(value), Math.Floor(value));
// The example displays the following output to the console:
//         Value          Ceiling          Floor
//
//          7.03                8              7
//          7.64                8              7
//          0.12                1              0
//         -0.12                0             -1
//          -7.1               -7             -8
//          -7.6               -7             -8
```

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward negative infinity. In other words, if `d` is positive, any fractional component is truncated. If `d` is negative, the presence of any fractional component causes it to be rounded to the smaller integer. The operation of this method differs from the Ceiling method, which supports rounding toward positive infinity.

Starting with Visual Basic 15.8, the performance of Double-to-integer conversion is optimized if you pass the value returned by the `Floor` method to the any of the integral conversion functions, or if the Double value returned by `Floor` is automatically converted to an integer with Option Strict set to Off. This optimization allows code to run faster -- up to twice as fast for code that does a large number of conversions to integer types. The following example illustrates such optimized conversions:

VB

```
Dim d1 As Double = 1043.75133
Dim i1 As Integer = CInt(Math.Floor(d1))        ' Result: 1043

Dim d2 As Double = 7968.4136
Dim i2 As Integer = CInt(Math.Floor(d2))        ' Result: 7968
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Floor(Decimal)

Returns the largest integral value less than or equal to the specified decimal number.

C#

```
public static decimal Floor (decimal d);
```

Parameters

d Decimal

A decimal number.

Returns

Decimal

The largest integral value less than or equal to `d`. Note that the method returns an integral value of type Decimal.

Examples

The following example illustrates the Math.Floor(Decimal) method and contrasts it with the Ceiling(Decimal) method.

C#

```
decimal[] values = {7.03m, 7.64m, 0.12m, -0.12m, -7.1m, -7.6m};
Console.WriteLine("  Value          Ceiling          Floor\n");
foreach (decimal value in values)
   Console.WriteLine("{0,7} {1,16} {2,14}",
                     value, Math.Ceiling(value), Math.Floor(value));
// The example displays the following output to the console:
//         Value          Ceiling          Floor
//
//          7.03                8              7
//          7.64                8              7
//          0.12                1              0
//         -0.12                0             -1
//          -7.1               -7             -8
//          -7.6               -7             -8
```

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward negative infinity. In other words, if `d` is positive, any fractional component is truncated. If `d` is negative, the presence of any fractional component causes it to be rounded to the smaller integer. The operation of this method differs from the Ceiling method, which supports rounding toward positive infinity.

Math.FusedMultiplyAdd(Double, Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns (x * y) + z, rounded as one ternary operation.

C#

```
public static double FusedMultiplyAdd (double x, double y, double z);
```

Parameters

x Double

The number to be multiplied with `y`.

y Double

The number to be multiplied with `x`.

z Double

The number to be added to the result of `x` multiplied by `y`.

Returns

Double

(x * y) + z, rounded as one ternary operation.

Remarks

This computes `(x * y)` as if to infinite precision, adds `z` to that result as if to infinite precision, and finally rounds to the nearest representable value.

This differs from the non-fused sequence which would compute `(x * y)` as if to infinite precision, round the result to the nearest representable value, add `z` to the rounded

result as if to infinite precision, and finally round to the nearest representable value.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.IEEERemainder(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the remainder resulting from the division of a specified number by another specified number.

C#

```
public static double IEEERemainder (double x, double y);
```

Parameters

x Double

A dividend.

y Double

A divisor.

Returns

Double

A number equal to `x` - (`y` Q), where Q is the quotient of `x` / `y` rounded to the nearest integer (if `x` / `y` falls halfway between two integers, the even integer is returned).

If `x` - (`y` Q) is zero, the value +0 is returned if `x` is positive, or -0 if `x` is negative.

If `y` = 0, NaN is returned.

Examples

The following example contrasts the remainder returned by the IEEERemainder method with the remainder returned by the remainder operator.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Console.WriteLine($"{"IEEERemainder",35} {"Remainder operator",20}");
      ShowRemainders(3, 2);
      ShowRemainders(4, 2);
      ShowRemainders(10, 3);
      ShowRemainders(11, 3);
      ShowRemainders(27, 4);
      ShowRemainders(28, 5);
      ShowRemainders(17.8, 4);
      ShowRemainders(17.8, 4.1);
      ShowRemainders(-16.3, 4.1);
      ShowRemainders(17.8, -4.1);
      ShowRemainders(-17.8, -4.1);
   }

   private static void ShowRemainders(double number1, double number2)
   {
      var formula = $"{number1} / {number2} = ";
      var ieeeRemainder = Math.IEEERemainder(number1, number2);
      var remainder = number1 % number2;
      Console.WriteLine($"{formula,-16} {ieeeRemainder,18} {remainder,20}");
   }
}
// The example displays the following output:
//
//
//                        IEEERemainder   Remainder operator
// 3 / 2 =                           -1                    1
// 4 / 2 =                            0                    0
// 10 / 3 =                           1                    1
// 11 / 3 =                          -1                    2
// 27 / 4 =                          -1                    3
// 28 / 5 =                          -2                    3
// 17.8 / 4 =                       1.8                  1.8
// 17.8 / 4.1 =                     1.4                  1.4
// -16.3 / 4.1 =    0.0999999999999979                   -4
// 17.8 / -4.1 =                    1.4                  1.4
// -17.8 / -4.1 =                  -1.4                 -1.4
```

Remarks

This operation complies with the remainder operation defined in Section 5.1 of ANSI/IEEE Std 754-1985; IEEE Standard for Binary Floating-Point Arithmetic; Institute of Electrical and Electronics Engineers, Inc; 1985.

The IEEERemainder method is not the same as the remainder operator. Although both return the remainder after division, the formulas they use are different. The formula for the IEEERemainder method is:

```
IEEERemainder = dividend - (divisor * Math.Round(dividend / divisor))
```

In contrast, the formula for the remainder operator is:

```
Remainder = (Math.Abs(dividend) - (Math.Abs(divisor) *
            (Math.Floor(Math.Abs(dividend) / Math.Abs(divisor))))) *
            Math.Sign(dividend)
```

Math.ILogB(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the base 2 integer logarithm of a specified number.

C#

```
public static int ILogB (double x);
```

Parameters

x Double

The number whose logarithm is to be found.

Returns

Int32

One of the values in the following table.

Expand table

`x` parameter	Return value
Default	The base 2 integer log of `x`; that is, (int)log2(`x`).
Zero	Int32.MinValue
Equal to NaN or PositiveInfinity or NegativeInfinity	Int32.MaxValue

Remarks

Parameter `x` is specified as a base 10 number.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

Math.Log Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the logarithm of a specified number.

Overloads

Expand table

Log(Double, Double)	Returns the logarithm of a specified number in a specified base.
Log(Double)	Returns the natural (base `e`) logarithm of a specified number.

Log(Double, Double)

Returns the logarithm of a specified number in a specified base.

C#

```
public static double Log (double a, double newBase);
```

Parameters

a Double

The number whose logarithm is to be found.

newBase Double

The base of the logarithm.

Returns

Double

One of the values in the following table. (+Infinity denotes PositiveInfinity, -Infinity denotes NegativeInfinity, and NaN denotes NaN.)

Expand table

a	newBase	Return value
a > 0	(0 < newBase < 1) -or- (newBase > 1)	lognewBase(a)
a < 0	(any value)	NaN
(any value)	newBase < 0	NaN
a != 1	newBase = 0	NaN
a != 1	newBase = +Infinity	NaN
a = NaN	(any value)	NaN
(any value)	newBase = NaN	NaN
(any value)	newBase = 1	NaN
a = 0	0 < newBase < 1	+Infinity
a = 0	newBase > 1	-Infinity
a = +Infinity	0 < newBase < 1	-Infinity
a = +Infinity	newBase > 1	+Infinity
a = 1	newBase = 0	0
a = 1	newBase = +Infinity	0

Examples

The following example uses Log to evaluate certain logarithmic identities for selected values.

C#

```
// Example for the Math.Log( double ) and Math.Log( double, double )
methods.
using System;

class LogDLogDD
{
    public static void Main()
    {
```

```
        Console.WriteLine(
            "This example of Math.Log( double ) and " +
            "Math.Log( double, double )\n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Evaluate these identities with " +
            "selected values for X and B (base):" );
        Console.WriteLine( "   log(B)[X] == 1 / log(X)[B]" );
        Console.WriteLine( "   log(B)[X] == ln[X] / ln[B]" );
        Console.WriteLine( "   log(B)[X] == log(B)[e] * ln[X]" );

        UseBaseAndArg(0.1, 1.2);
        UseBaseAndArg(1.2, 4.9);
        UseBaseAndArg(4.9, 9.9);
        UseBaseAndArg(9.9, 0.1);
    }

    // Evaluate logarithmic identities that are functions of two
arguments.
    static void UseBaseAndArg(double argB, double argX)
    {
        // Evaluate log(B)[X] == 1 / log(X)[B].
        Console.WriteLine(
            "\n                   Math.Log({1}, {0}) == {2:E16}" +
            "\n             1.0 / Math.Log({0}, {1}) == {3:E16}",
            argB, argX, Math.Log(argX, argB),
            1.0 / Math.Log(argB, argX) );

        // Evaluate log(B)[X] == ln[X] / ln[B].
        Console.WriteLine(
            "        Math.Log({1}) / Math.Log({0}) == {2:E16}",
            argB, argX, Math.Log(argX) / Math.Log(argB) );

        // Evaluate log(B)[X] == log(B)[e] * ln[X].
        Console.WriteLine(
            "Math.Log(Math.E, {0}) * Math.Log({1}) == {2:E16}",
            argB, argX, Math.Log(Math.E, argB) * Math.Log(argX) );
    }
}

/*
This example of Math.Log( double ) and Math.Log( double, double )
generates the following output.

Evaluate these identities with selected values for X and B (base):
   log(B)[X] == 1 / log(X)[B]
   log(B)[X] == ln[X] / ln[B]
   log(B)[X] == log(B)[e] * ln[X]

                   Math.Log(1.2, 0.1) == -7.9181246047624818E-002
             1.0 / Math.Log(0.1, 1.2) == -7.9181246047624818E-002
        Math.Log(1.2) / Math.Log(0.1) == -7.9181246047624818E-002
Math.Log(Math.E, 0.1) * Math.Log(1.2) == -7.9181246047624804E-002

                   Math.Log(4.9, 1.2) == 8.7166610085093179E+000
```

```
             1.0 / Math.Log(1.2, 4.9) == 8.7166610085093161E+000
        Math.Log(4.9) / Math.Log(1.2) == 8.7166610085093179E+000
Math.Log(Math.E, 1.2) * Math.Log(4.9) == 8.7166610085093179E+000

Log(Double)

Returns the natural (base `e`) logarithm of a specified number.

C#

```
public static double Log (double d);
```

Parameters

`d` Double

The number whose logarithm is to be found.

Returns

Double

One of the values in the following table.

Expand table

`d` parameter	Return value
Positive	The natural logarithm of `d`; that is, ln `d`, or log e `d`
Zero	NegativeInfinity
Negative	NaN
Equal to NaN	NaN
Equal to PositiveInfinity	PositiveInfinity

Examples

The following example illustrates the Log method.

C#

```
using System;
public class Example
{
   public static void Main()
   {
      Console.WriteLine("  Evaluate this identity with selected values
for X:");
      Console.WriteLine("                              ln(x) = 1 / log[X]
(B)");
      Console.WriteLine();

      double[] XArgs = { 1.2, 4.9, 9.9, 0.1 };

      foreach (double argX in XArgs)
      {
         // Find natural log of argX.
         Console.WriteLine("                      Math.Log({0}) =
{1:E16}",
                           argX, Math.Log(argX));
```

```
        // Evaluate 1 / log[X](e).
        Console.WriteLine("            1.0 / Math.Log(e, {0}) =
{1:E16}",
                          argX, 1.0 / Math.Log(Math.E, argX));
        Console.WriteLine();
      }
   }
}
// This example displays the following output:
//         Evaluate this identity with selected values for X:
//                                   ln(x) = 1 / log[X](B)
//
//                            Math.Log(1.2) = 1.8232155679395459E-001
//                    1.0 / Math.Log(e, 1.2) = 1.8232155679395459E-001
//
//                            Math.Log(4.9) = 1.5892352051165810E+000
//                    1.0 / Math.Log(e, 4.9) = 1.5892352051165810E+000
//
//                            Math.Log(9.9) = 2.2925347571405443E+000
//                    1.0 / Math.Log(e, 9.9) = 2.2925347571405443E+000
//
//                            Math.Log(0.1) = -2.3025850929940455E+000
//                    1.0 / Math.Log(e, 0.1) = -2.3025850929940455E+000
```

Remarks

Parameter `d` is specified as a base 10 number.

Math.Log10(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the base 10 logarithm of a specified number.

C#

```
public static double Log10 (double d);
```

Parameters

d Double

A number whose logarithm is to be found.

Returns

Double

One of the values in the following table.

Expand table

`d` parameter	Return value
Positive	The base 10 log of `d`; that is, log 10`d`.
Zero	NegativeInfinity
Negative	NaN
Equal to NaN	NaN
Equal to PositiveInfinity	PositiveInfinity

Examples

The following example uses the Log10 method to return the base 10 logarithm for selected values.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double[] numbers = {-1, 0, .105, .5, .798, 1, 4, 6.9, 10, 50,
                          100, 500, 1000, Double.MaxValue};

      foreach (double number in numbers)
         Console.WriteLine("The base 10 log of {0} is {1}.",
                           number, Math.Log10(number));
   }
}
// The example dislays the following output:
//       The base 10 log of -1 is NaN.
//       The base 10 log of 0 is -Infinity.
//       The base 10 log of 0.105 is -0.978810700930062.
//       The base 10 log of 0.5 is -0.301029995663981.
//       The base 10 log of 0.798 is -0.0979971086492706.
//       The base 10 log of 1 is 0.
//       The base 10 log of 4 is 0.602059991327962.
//       The base 10 log of 6.9 is 0.838849090737255.
//       The base 10 log of 10 is 1.
//       The base 10 log of 50 is 1.69897000433602.
//       The base 10 log of 100 is 2.
//       The base 10 log of 500 is 2.69897000433602.
//       The base 10 log of 1000 is 3.
//       The base 10 log of 1.79769313486232E+308 is 308.254715559917.
```

Remarks

Parameter `d` is specified as a base 10 number.

Math.Log2(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the base 2 logarithm of a specified number.

C#

```
public static double Log2 (double x);
```

Parameters

x Double

A number whose logarithm is to be found.

Returns

Double

One of the values in the following table.

Expand table

`x` parameter	Return value
Positive	The base 2 log of `x`; that is, log 2`x`.
Zero	NegativeInfinity
Negative	NaN
Equal to NaN	NaN
Equal to PositiveInfinity	PositiveInfinity

Remarks

Parameter `x` is specified as a base 10 number.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.Max Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the larger of two specified numbers.

Overloads

Expand table

Max(UIntPtr, UIntPtr)	Returns the larger of two native unsigned integers.
Max(UInt32, UInt32)	Returns the larger of two 32-bit unsigned integers.
Max(UInt16, UInt16)	Returns the larger of two 16-bit unsigned integers.
Max(Single, Single)	Returns the larger of two single-precision floating-point numbers.
Max(SByte, SByte)	Returns the larger of two 8-bit signed integers.
Max(IntPtr, IntPtr)	Returns the larger of two native signed integers.
Max(UInt64, UInt64)	Returns the larger of two 64-bit unsigned integers.
Max(Int32, Int32)	Returns the larger of two 32-bit signed integers.
Max(Int16, Int16)	Returns the larger of two 16-bit signed integers.
Max(Double, Double)	Returns the larger of two double-precision floating-point numbers.
Max(Decimal, Decimal)	Returns the larger of two decimal numbers.
Max(Byte, Byte)	Returns the larger of two 8-bit unsigned integers.
Max(Int64, Int64)	Returns the larger of two 64-bit signed integers.

Examples

The following example demonstrates how to use the Max method to return and display the greater of two variables:

C#

```
string str = "{0}: The greater of {1,3} and {2,3} is {3}.";

byte     xByte1    = 1,    xByte2    = 51;
short    xShort1   = -2,   xShort2   = 52;
int      xInt1     = -3,   xInt2     = 53;
long     xLong1    = -4,   xLong2    = 54;
float    xSingle1  = 5.0f, xSingle2  = 55.0f;
double   xDouble1  = 6.0,  xDouble2  = 56.0;
Decimal  xDecimal1 = 7m,   xDecimal2 = 57m;

// The following types are not CLS-compliant.
sbyte    xSbyte1   = 101, xSbyte2  = 111;
ushort   xUshort1  = 102, xUshort2 = 112;
uint     xUint1    = 103, xUint2   = 113;
ulong    xUlong1   = 104, xUlong2  = 114;

Console.WriteLine("Display the greater of two values:\n");
Console.WriteLine(str, "Byte   ", xByte1, xByte2, Math.Max(xByte1, xByte2));
Console.WriteLine(str, "Int16  ", xShort1, xShort2, Math.Max(xShort1,
xShort2));
Console.WriteLine(str, "Int32  ", xInt1, xInt2, Math.Max(xInt1, xInt2));
Console.WriteLine(str, "Int64  ", xLong1, xLong2, Math.Max(xLong1, xLong2));
Console.WriteLine(str, "Single ", xSingle1, xSingle2, Math.Max(xSingle1,
xSingle2));
Console.WriteLine(str, "Double ", xDouble1, xDouble2, Math.Max(xDouble1,
xDouble2));
Console.WriteLine(str, "Decimal", xDecimal1, xDecimal2, Math.Max(xDecimal1,
xDecimal2));

Console.WriteLine("\nThe following types are not CLS-compliant.\n");
Console.WriteLine(str, "SByte  ", xSbyte1, xSbyte2, Math.Max(xSbyte1,
xSbyte2));
Console.WriteLine(str, "UInt16 ", xUshort1, xUshort2, Math.Max(xUshort1,
xUshort2));
Console.WriteLine(str, "UInt32 ", xUint1, xUint2, Math.Max(xUint1, xUint2));
Console.WriteLine(str, "UInt64 ", xUlong1, xUlong2, Math.Max(xUlong1,
xUlong2));

/*
This example produces the following results:

Display the greater of two values:

Byte   : The greater of   1 and  51 is 51.
Int16  : The greater of  -2 and  52 is 52.
Int32  : The greater of  -3 and  53 is 53.
Int64  : The greater of  -4 and  54 is 54.
Single : The greater of   5 and  55 is 55.
Double : The greater of   6 and  56 is 56.
Decimal: The greater of   7 and  57 is 57.

(The following types are not CLS-compliant.)
```

```
SByte  : The greater of 101 and 111 is 111.
UInt16 : The greater of 102 and 112 is 112.
UInt32 : The greater of 103 and 113 is 113.
UInt64 : The greater of 104 and 114 is 114.
*/
```

Max(UIntPtr, UIntPtr)

> Important
>
> This API is not CLS-compliant.

Returns the larger of two native unsigned integers.

C#

```
[System.CLSCompliant(false)]
public static UIntPtr Max (UIntPtr val1, UIntPtr val2);
```

Parameters

`val1` nuint

The first of two native unsigned integers to compare.

`val2` nuint

The second of two native unsigned integers to compare.

Returns

nuint

Parameter `val1` or `val2`, whichever is larger.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Max(UInt32, UInt32)

> Important
>
> This API is not CLS-compliant.

Returns the larger of two 32-bit unsigned integers.

```
C#

[System.CLSCompliant(false)]
public static uint Max (uint val1, uint val2);
```

Parameters

`val1` UInt32

The first of two 32-bit unsigned integers to compare.

`val2` UInt32

The second of two 32-bit unsigned integers to compare.

Returns

UInt32

Parameter `val1` or `val2`, whichever is larger.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(UInt16, UInt16)

> Important
>
> This API is not CLS-compliant.

Returns the larger of two 16-bit unsigned integers.

C#

```
[System.CLSCompliant(false)]
public static ushort Max (ushort val1, ushort val2);
```

Parameters

`val1` UInt16

The first of two 16-bit unsigned integers to compare.

`val2` UInt16

The second of two 16-bit unsigned integers to compare.

Returns

UInt16

Parameter `val1` or `val2`, whichever is larger.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(Single, Single)

Returns the larger of two single-precision floating-point numbers.

C#

```
public static float Max (float val1, float val2);
```

Parameters

`val1` Single

The first of two single-precision floating-point numbers to compare.

`val2` Single

The second of two single-precision floating-point numbers to compare.

Returns

Single

Parameter `val1` or `val2`, whichever is larger. If `val1`, or `val2`, or both `val1` and `val2` are equal to NaN, NaN is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(SByte, SByte)

> Important
>
> This API is not CLS-compliant.

Returns the larger of two 8-bit signed integers.

C#

```
[System.CLSCompliant(false)]
public static sbyte Max (sbyte val1, sbyte val2);
```

Parameters

`val1` SByte

The first of two 8-bit signed integers to compare.

`val2` SByte

The second of two 8-bit signed integers to compare.

Returns

SByte

Parameter `val1` or `val2`, whichever is larger.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(IntPtr, IntPtr)

Returns the larger of two native signed integers.

C#

```
public static IntPtr Max (IntPtr val1, IntPtr val2);
```

Parameters

`val1` nint

The first of two native signed integers to compare.

`val2` nint

The second of two native signed integers to compare.

Returns

nint

Parameter `val1` or `val2`, whichever is larger.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Max(UInt64, UInt64)

> Important
>
> This API is not CLS-compliant.

Returns the larger of two 64-bit unsigned integers.

C#

```
[System.CLSCompliant(false)]
public static ulong Max (ulong val1, ulong val2);
```

Parameters

`val1` UInt64

The first of two 64-bit unsigned integers to compare.

`val2` UInt64

The second of two 64-bit unsigned integers to compare.

Returns

UInt64

Parameter `val1` or `val2`, whichever is larger.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Max(Int32, Int32)

Returns the larger of two 32-bit signed integers.

```
C#
public static int Max (int val1, int val2);
```

Parameters

`val1` Int32

The first of two 32-bit signed integers to compare.

`val2` Int32

The second of two 32-bit signed integers to compare.

Returns

Int32

Parameter `val1` or `val2`, whichever is larger.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(Int16, Int16)

Returns the larger of two 16-bit signed integers.

C#

```
public static short Max (short val1, short val2);
```

Parameters

`val1` Int16

The first of two 16-bit signed integers to compare.

`val2` Int16

The second of two 16-bit signed integers to compare.

Returns

Int16

Parameter `val1` or `val2`, whichever is larger.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(Double, Double)

Returns the larger of two double-precision floating-point numbers.

C#

```
public static double Max (double val1, double val2);
```

Parameters

`val1` Double

The first of two double-precision floating-point numbers to compare.

`val2` Double

The second of two double-precision floating-point numbers to compare.

Returns

Double

Parameter `val1` or `val2`, whichever is larger. If `val1`, `val2`, or both `val1` and `val2` are equal to NaN, NaN is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(Decimal, Decimal)

Returns the larger of two decimal numbers.

C#

```
public static decimal Max (decimal val1, decimal val2);
```

Parameters

`val1` Decimal

The first of two decimal numbers to compare.

`val2` Decimal

The second of two decimal numbers to compare.

Returns

Decimal

Parameter `val1` or `val2`, whichever is larger.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Max(Byte, Byte)

Returns the larger of two 8-bit unsigned integers.

C#

```
public static byte Max (byte val1, byte val2);
```

Parameters

`val1` Byte

The first of two 8-bit unsigned integers to compare.

`val2` Byte

The second of two 8-bit unsigned integers to compare.

Returns

Byte

Parameter `val1` or `val2`, whichever is larger.

Applies to

▼ .NET 9 and other versions

Product	Versions

UWP	10.0

Max(Int64, Int64)

Returns the larger of two 64-bit signed integers.

C#

```
public static long Max (long val1, long val2);
```

Parameters

`val1` Int64

The first of two 64-bit signed integers to compare.

`val2` Int64

The second of two 64-bit signed integers to compare.

Returns

Int64

Parameter `val1` or `val2`, whichever is larger.

Applies to

Math.MaxMagnitude(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the larger magnitude of two double-precision floating-point numbers.

C#

```
public static double MaxMagnitude (double x, double y);
```

Parameters

x Double

The first of two double-precision floating-point numbers to compare.

y Double

The second of two double-precision floating-point numbers to compare.

Returns

Double

Parameter `x` or `y`, whichever has the larger magnitude. If `x`, or `y`, or both `x` and `y` are equal to NaN, NaN is returned.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.Min Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smaller of two numbers.

Overloads

Expand table

Min(UInt32, UInt32)	Returns the smaller of two 32-bit unsigned integers.
Min(UInt16, UInt16)	Returns the smaller of two 16-bit unsigned integers.
Min(Single, Single)	Returns the smaller of two single-precision floating-point numbers.
Min(SByte, SByte)	Returns the smaller of two 8-bit signed integers.
Min(IntPtr, IntPtr)	Returns the smaller of two native signed integers.
Min(Double, Double)	Returns the smaller of two double-precision floating-point numbers.
Min(Int32, Int32)	Returns the smaller of two 32-bit signed integers.
Min(Int16, Int16)	Returns the smaller of two 16-bit signed integers.
Min(Decimal, Decimal)	Returns the smaller of two decimal numbers.
Min(Byte, Byte)	Returns the smaller of two 8-bit unsigned integers.
Min(UInt64, UInt64)	Returns the smaller of two 64-bit unsigned integers.
Min(Int64, Int64)	Returns the smaller of two 64-bit signed integers.
Min(UIntPtr, UIntPtr)	Returns the smaller of two native unsigned integers.

Examples

The following example demonstrates how to use the Min method to return and display the smaller of two variables:

C#

```
string str = "{0}: The lesser of {1,3} and {2,3} is {3}.";

byte     xByte1    = 1,    xByte2    = 51;
short    xShort1   = -2,   xShort2   = 52;
int      xInt1     = -3,   xInt2     = 53;
long     xLong1    = -4,   xLong2    = 54;
float    xSingle1  = 5.0f, xSingle2  = 55.0f;
double   xDouble1  = 6.0,  xDouble2  = 56.0;
Decimal  xDecimal1 = 7m,   xDecimal2 = 57m;

// The following types are not CLS-compliant.
sbyte    xSbyte1   = 101, xSbyte2  = 111;
ushort   xUshort1  = 102, xUshort2 = 112;
uint     xUint1    = 103, xUint2   = 113;
ulong    xUlong1   = 104, xUlong2  = 114;

Console.WriteLine("Display the lesser of two values:\n");
Console.WriteLine(str, "Byte   ", xByte1, xByte2, Math.Min(xByte1, xByte2));
Console.WriteLine(str, "Int16  ", xShort1, xShort2, Math.Min(xShort1,
xShort2));
Console.WriteLine(str, "Int32  ", xInt1, xInt2, Math.Min(xInt1, xInt2));
Console.WriteLine(str, "Int64  ", xLong1, xLong2, Math.Min(xLong1, xLong2));
Console.WriteLine(str, "Single ", xSingle1, xSingle2, Math.Min(xSingle1,
xSingle2));
Console.WriteLine(str, "Double ", xDouble1, xDouble2, Math.Min(xDouble1,
xDouble2));
Console.WriteLine(str, "Decimal", xDecimal1, xDecimal2, Math.Min(xDecimal1,
xDecimal2));

Console.WriteLine("\nThe following types are not CLS-compliant:\n");
Console.WriteLine(str, "SByte  ", xSbyte1, xSbyte2, Math.Min(xSbyte1,
xSbyte2));
Console.WriteLine(str, "UInt16 ", xUshort1, xUshort2, Math.Min(xUshort1,
xUshort2));
Console.WriteLine(str, "UInt32 ", xUint1, xUint2, Math.Min(xUint1, xUint2));
Console.WriteLine(str, "UInt64 ", xUlong1, xUlong2, Math.Min(xUlong1,
xUlong2));

/*
This example produces the following results:

Display the lesser of two values:

Byte   : The lesser of   1 and  51 is 1.
Int16  : The lesser of  -2 and  52 is -2.
Int32  : The lesser of  -3 and  53 is -3.
Int64  : The lesser of  -4 and  54 is -4.
Single : The lesser of   5 and  55 is 5.
Double : The lesser of   6 and  56 is 6.
Decimal: The lesser of   7 and  57 is 7.

The following types are not CLS-compliant:
```

```
SByte  : The lesser of 101 and 111 is 101.
UInt16 : The lesser of 102 and 112 is 102.
UInt32 : The lesser of 103 and 113 is 103.
UInt64 : The lesser of 104 and 114 is 104.
*/
```

Min(UInt32, UInt32)

> Important
>
> This API is not CLS-compliant.

Returns the smaller of two 32-bit unsigned integers.

C#

```
[System.CLSCompliant(false)]
public static uint Min (uint val1, uint val2);
```

Parameters

`val1` UInt32

The first of two 32-bit unsigned integers to compare.

`val2` UInt32

The second of two 32-bit unsigned integers to compare.

Returns

UInt32

Parameter `val1` or `val2`, whichever is smaller.

UWP	10.0

Min(UInt16, UInt16)

> Important
>
> This API is not CLS-compliant.

Returns the smaller of two 16-bit unsigned integers.

C#

```
[System.CLSCompliant(false)]
public static ushort Min (ushort val1, ushort val2);
```

Parameters

`val1` UInt16

The first of two 16-bit unsigned integers to compare.

`val2` UInt16

The second of two 16-bit unsigned integers to compare.

Returns

UInt16

Parameter `val1` or `val2`, whichever is smaller.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Min(Single, Single)

Returns the smaller of two single-precision floating-point numbers.

C#

```
public static float Min (float val1, float val2);
```

Parameters

`val1` Single

The first of two single-precision floating-point numbers to compare.

`val2` Single

The second of two single-precision floating-point numbers to compare.

Returns

Single

Parameter `val1` or `val2`, whichever is smaller. If `val1`, `val2`, or both `val1` and `val2` are equal to NaN, NaN is returned.

UWP	10.0

Min(SByte, SByte)

> Important
>
> This API is not CLS-compliant.

Returns the smaller of two 8-bit signed integers.

C#

```
[System.CLSCompliant(false)]
public static sbyte Min (sbyte val1, sbyte val2);
```

Parameters

`val1` SByte

The first of two 8-bit signed integers to compare.

`val2` SByte

The second of two 8-bit signed integers to compare.

Returns

SByte

Parameter `val1` or `val2`, whichever is smaller.

UWP	10.0

Min(IntPtr, IntPtr)

Returns the smaller of two native signed integers.

C#

```
public static IntPtr Min (IntPtr val1, IntPtr val2);
```

Parameters

`val1` nint

The first of two native signed integers to compare.

`val2` nint

The second of two native signed integers to compare.

Returns

nint

Parameter `val1` or `val2`, whichever is smaller.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Min(Double, Double)

Returns the smaller of two double-precision floating-point numbers.

```
C#
public static double Min (double val1, double val2);
```

Parameters

`val1` Double

The first of two double-precision floating-point numbers to compare.

`val2` Double

The second of two double-precision floating-point numbers to compare.

Returns

Double

Parameter `val1` or `val2`, whichever is smaller. If `val1`, `val2`, or both `val1` and `val2` are equal to NaN, NaN is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions

UWP	10.0

Min(Int32, Int32)

Returns the smaller of two 32-bit signed integers.

```
C#
public static int Min (int val1, int val2);
```

Parameters

`val1` Int32

The first of two 32-bit signed integers to compare.

`val2` Int32

The second of two 32-bit signed integers to compare.

Returns

Int32

Parameter `val1` or `val2`, whichever is smaller.

Applies to

UWP	10.0

Min(Decimal, Decimal)

Returns the smaller of two decimal numbers.

C#

```
public static decimal Min (decimal val1, decimal val2);
```

Parameters

`val1` Decimal

The first of two decimal numbers to compare.

`val2` Decimal

The second of two decimal numbers to compare.

Returns

Decimal

Parameter `val1` or `val2`, whichever is smaller.

Applies to

▼ .NET 9 and other versions

Product	Versions

UWP	10.0

Min(Byte, Byte)

Returns the smaller of two 8-bit unsigned integers.

C#

```
public static byte Min (byte val1, byte val2);
```

Parameters

`val1` Byte

The first of two 8-bit unsigned integers to compare.

`val2` Byte

The second of two 8-bit unsigned integers to compare.

Returns

Byte

Parameter `val1` or `val2`, whichever is smaller.

Applies to

UWP	10.0

Min(UInt64, UInt64)

> Important
>
> This API is not CLS-compliant.

Returns the smaller of two 64-bit unsigned integers.

C#

```
[System.CLSCompliant(false)]
public static ulong Min (ulong val1, ulong val2);
```

Parameters

`val1` UInt64

The first of two 64-bit unsigned integers to compare.

`val2` UInt64

The second of two 64-bit unsigned integers to compare.

Returns

UInt64

Parameter `val1` or `val2`, whichever is smaller.

Attributes CLSCompliantAttribute

Applies to

Math.MinMagnitude(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smaller magnitude of two double-precision floating-point numbers.

C#

```
public static double MinMagnitude (double x, double y);
```

Parameters

x Double

The first of two double-precision floating-point numbers to compare.

y Double

The second of two double-precision floating-point numbers to compare.

Returns

Double

Parameter `x` or `y`, whichever has the smaller magnitude. If `x`, or `y`, or both `x` and `y` are equal to NaN, NaN is returned.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.Pow(Double, Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a specified number raised to the specified power.

C#

```
public static double Pow (double x, double y);
```

Parameters

x Double

A double-precision floating-point number to be raised to a power.

y Double

A double-precision floating-point number that specifies a power.

Returns

Double

The number `x` raised to the power `y`.

Examples

The following example uses the Pow method to calculate the value that results from raising 2 to a power ranging from 0 to 32.

C#

```
int value = 2;
for (int power = 0; power <= 32; power++)
   Console.WriteLine($"{value}^{power} = {(long)Math.Pow(value, power):N0}
(0x{(long)Math.Pow(value, power):X})");

// The example displays the following output:
//     2^0 = 1 (0x1)
```

```
//      2^1 = 2 (0x2)
//      2^2 = 4 (0x4)
//      2^3 = 8 (0x8)
//      2^4 = 16 (0x10)
//      2^5 = 32 (0x20)
//      2^6 = 64 (0x40)
//      2^7 = 128 (0x80)
//      2^8 = 256 (0x100)
//      2^9 = 512 (0x200)
//      2^10 = 1,024 (0x400)
//      2^11 = 2,048 (0x800)
//      2^12 = 4,096 (0x1000)
//      2^13 = 8,192 (0x2000)
//      2^14 = 16,384 (0x4000)
//      2^15 = 32,768 (0x8000)
//      2^16 = 65,536 (0x10000)
//      2^17 = 131,072 (0x20000)
//      2^18 = 262,144 (0x40000)
//      2^19 = 524,288 (0x80000)
//      2^20 = 1,048,576 (0x100000)
//      2^21 = 2,097,152 (0x200000)
//      2^22 = 4,194,304 (0x400000)
//      2^23 = 8,388,608 (0x800000)
//      2^24 = 16,777,216 (0x1000000)
//      2^25 = 33,554,432 (0x2000000)
//      2^26 = 67,108,864 (0x4000000)
//      2^27 = 134,217,728 (0x8000000)
//      2^28 = 268,435,456 (0x10000000)
//      2^29 = 536,870,912 (0x20000000)
//      2^30 = 1,073,741,824 (0x40000000)
//      2^31 = 2,147,483,648 (0x80000000)
//      2^32 = 4,294,967,296 (0x100000000)
```

Remarks

The following table indicates the return value when various values or ranges of values are specified for the `x` and `y` parameters. For more information, see Double.PositiveInfinity, Double.NegativeInfinity, and Double.NaN.

Expand table

x	y	Return value
`NaN`	Any value except 0	`NaN`
`NaN`	0	1 (`NaN` on .NET Framework)
Any value except `NaN`	0	1

x	y	Return value
1	Any value except `NaN`	1
1	`NaN`	1 (`NaN` on .NET Framework)
Any value except 1	`NaN`	`NaN`
`NegativeInfinity`	< 0	0
`NegativeInfinity`	Positive odd integer	`NegativeInfinity`
`NegativeInfinity`	Positive but not an odd integer	`PositiveInfinity`
< 0 but not `NegativeInfinity`	Not an integer, `NegativeInfinity`, or `PositiveInfinity`	`NaN`
-1	= `NegativeInfinity` or `PositiveInfinity`	`NaN`
-1 < x < 1	`NegativeInfinity`	`PositiveInfinity`
-1 < x < 1	`PositiveInfinity`	0
< -1 or > 1	`NegativeInfinity`	0
< -1 or > 1	`PositiveInfinity`	`PositiveInfinity`
0	< 0	`PositiveInfinity`
0	> 0	0
`PositiveInfinity`	< 0	0
`PositiveInfinity`	> 0	`PositiveInfinity`

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Math.ReciprocalEstimate(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an estimate of the reciprocal of a specified number.

```
C#
public static double ReciprocalEstimate (double d);
```

Parameters

d Double

The number whose reciprocal is to be estimated.

Returns

Double

An estimate of the reciprocal of `d`.

Remarks

On ARM64 hardware this may use the `FRECPE` instruction which performs a single Newton-Raphson iteration.

On hardware without specialized support, this may just return `1.0 / d`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Math.ReciprocalSqrtEstimate(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an estimate of the reciprocal square root of a specified number.

C#

```
public static double ReciprocalSqrtEstimate (double d);
```

Parameters

d Double

The number whose reciprocal square root is to be estimated.

Returns

Double

An estimate of the reciprocal square root `d`.

Remarks

On ARM64 hardware this may use the `FRSQRTE` instruction which performs a single Newton-Raphson iteration.

On hardware without specialized support, this may just return `1.0 / Sqrt(d)`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Math.Round Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rounds a value to the nearest integer or to the specified number of fractional digits.

Overloads

Expand table

Round(Double, Int32, MidpointRounding)	Rounds a double-precision floating-point value to a specified number of fractional digits using the specified rounding convention.
Round(Decimal, Int32, MidpointRounding)	Rounds a decimal value to a specified number of fractional digits using the specified rounding convention.
Round(Double, MidpointRounding)	Rounds a double-precision floating-point value to an integer using the specified rounding convention.
Round(Double, Int32)	Rounds a double-precision floating-point value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.
Round(Decimal, Int32)	Rounds a decimal value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.
Round(Double)	Rounds a double-precision floating-point value to the nearest integral value, and rounds midpoint values to the nearest even number.
Round(Decimal)	Rounds a decimal value to the nearest integral value, and rounds midpoint values to the nearest even number.
Round(Decimal, MidpointRounding)	Rounds a decimal value an integer using the specified rounding convention.

Examples

In addition to the examples in the Remarks section, this article includes examples that illustrate the following overloads of the `Math.Round` method:

Math.Round(Decimal)
Math.Round(Double)
Math.Round(Decimal, Int32)
Math.Round(Decimal, MidpointRounding)
Math.Round(Double, Int32)
Math.Round(Double, MidpointRounding)
Math.Round(Decimal, Int32, MidpointRounding)
Math.Round(Double, Int32, MidpointRounding)

Remarks

In this section:

- Which method do I call?
- Midpoint values and rounding conventions
- Rounding and precision
- Rounding and single-precision floating point values
- Examples of individual overloads

Which method do I call?

You can use the following table to select an appropriate rounding method. In addition to the `Math.Round` methods, it also includes Math.Ceiling and Math.Floor.

Expand table

To	Call
Round a number to an integer by using the rounding-to-nearest convention.	Round(Decimal) -or- Round(Double)
Round a number to an integer by using a specified rounding convention.	Round(Decimal, MidpointRounding) -or- Round(Double, MidpointRounding)
Round a number to a specified number of fractional digits by using the rounding to nearest convention.	Round(Decimal, Int32) -or- Round(Double, Int32)

To	Call
Round a number to a specified number of fractional digits by using a specified rounding convention.	Round(Decimal, Int32, MidpointRounding) -or- Round(Double, Int32, MidpointRounding)
Round a Single value to a specified number of fractional digits by using a specified rounding convention and minimizing the loss of precision.	Convert the Single to a Decimal and call Round(Decimal, Int32, MidpointRounding).
Round a number to a specified number of fractional digits while minimizing problems of precision in rounding midpoint values.	Call a rounding method that implements a "greater than or approximately equal to" comparison. See Rounding and precision.
Round a fractional value to an integer that is greater than the fractional value. For example, round 3.1 to 4.	Ceiling
Round a fractional value to an integer that is less than the fractional value. For example, round 3.9 to 3.	Floor

Midpoint values and rounding conventions

Rounding involves converting a numeric value with a specified precision to a value with less precision. For example, you can use the Round(Double) method to round a value of 3.4 to 3.0, and the Round(Double, Int32) method to round a value of 3.579 to 3.58.

In a midpoint value, the value after the least significant digit in the result is precisely half way between two numbers. For example, 3.47500 is a midpoint value if it is to be rounded to two decimal places, and 7.500 is a midpoint value if it is to be rounded to an integer. In these cases, if the round-to-nearest strategy is used, the nearest value can't be easily identified without a rounding convention.

The Round method supports two rounding conventions for handling midpoint values:

- **Rounding away from zero**

  Midpoint values are rounded to the next number away from zero. For example, 3.75 rounds to 3.8, 3.85 rounds to 3.9, -3.75 rounds to -3.8, and -3.85 rounds to -3.9. This form of rounding is represented by the MidpointRounding.AwayFromZero enumeration member.

- **Rounding to nearest even, or banker's rounding**

Midpoint values are rounded to the nearest even number. For example, both 3.75 and 3.85 round to 3.8, and both -3.75 and -3.85 round to -3.8. This form of rounding is represented by the MidpointRounding.ToEven enumeration member.

> **Note**
>
> In .NET Core 3.0 and later versions, three additional rounding strategies are available through the **MidpointRounding** enumeration. These strategies are used in all cases, not just for midpoint values as **MidpointRounding.ToEven** and **MidpointRounding.AwayFromZero** are.

Rounding away from zero is the most widely known form of rounding, while rounding to nearest even is the standard in financial and statistical operations. It conforms to IEEE Standard 754, section 4. When used in multiple rounding operations, rounding to nearest even reduces the rounding error that is caused by consistently rounding midpoint values in a single direction. In some cases, this rounding error can be significant.

The following example illustrates the bias that can result from consistently rounding midpoint values in a single direction. The example computes the true mean of an array of Decimal values, and then computes the mean when the values in the array are rounded by using the two conventions. In this example, the true mean and the mean that results when rounding to nearest are the same. However, the mean that results when rounding away from zero differs by .05 (or by 3.6%) from the true mean.

C#

```
decimal[] values = { 1.15m, 1.25m, 1.35m, 1.45m, 1.55m, 1.65m };
decimal sum = 0;

// Calculate true mean.
foreach (var value in values)
    sum += value;

Console.WriteLine("True mean:     {0:N2}", sum / values.Length);

// Calculate mean with rounding away from zero.
sum = 0;
foreach (var value in values)
    sum += Math.Round(value, 1, MidpointRounding.AwayFromZero);

Console.WriteLine("AwayFromZero:  {0:N2}", sum / values.Length);

// Calculate mean with rounding to nearest.
sum = 0;
foreach (var value in values)
```

```
    sum += Math.Round(value, 1, MidpointRounding.ToEven);

Console.WriteLine("ToEven:        {0:N2}", sum / values.Length);

// The example displays the following output:
//       True mean:     1.40
//       AwayFromZero:  1.45
//       ToEven:        1.40
```

By default, the Round method uses the round to nearest even convention. The following table lists the overloads of the Round method and the rounding convention that each uses.

Expand table

Overload	Rounding convention
Round(Decimal)	ToEven
Round(Double)	ToEven
Round(Decimal, Int32)	ToEven
Round(Double, Int32)	ToEven
Round(Decimal, MidpointRounding)	Determined by `mode` parameter.
Round(Double, MidpointRounding)	Determined by `mode` parameter
Round(Decimal, Int32, MidpointRounding)	Determined by `mode` parameter
Round(Double, Int32, MidpointRounding)	Determined by `mode` parameter

Rounding and precision

In order to determine whether a rounding operation involves a midpoint value, the Round method multiplies the original value to be rounded by 10^n, where *n* is the desired number of fractional digits in the return value, and then determines whether the remaining fractional portion of the value is greater than or equal to .5. This is a slight variation on a test for equality, and as discussed in the "Testing for Equality" section of the Double reference topic, tests for equality with floating-point values are problematic because of the floating-point format's issues with binary representation and precision. This means that any fractional portion of a number that is slightly less than .5 (because of a loss of precision) will not be rounded upward.

The following example illustrates the problem. It repeatedly adds .1 to 11.0 and rounds the result to the nearest integer. 11.5 should round to 12 using either of the midpoint-rounding conventions (`ToEven` or `AwayFromZero`). However, as the output from the example shows, it does not. The example uses the "R" standard numeric format string to display the floating point value's full precision, and shows that the value to be rounded has lost precision during repeated additions, and its value is actually 11.499999999999998. Because .499999999999998 is less than .5, the midpoint-rounding conventions don't come into play and the value is rounded down. As the example also shows, this problem does not occur if you assign the constant value 11.5 to a Double variable.

C#

```
public static void Example()
{
    Console.WriteLine("{0,5} {1,20:R}  {2,12} {3,15}\n",
                      "Value", "Full Precision", "ToEven",
                      "AwayFromZero");
    double value = 11.1;
    for (int ctr = 0; ctr <= 5; ctr++)
        value = RoundValueAndAdd(value);

    Console.WriteLine();

    value = 11.5;
    RoundValueAndAdd(value);
}

private static double RoundValueAndAdd(double value)
{
    Console.WriteLine("{0,5:N1} {0,20:R}  {1,12} {2,15}",
                      value, Math.Round(value, MidpointRounding.ToEven),
                      Math.Round(value, MidpointRounding.AwayFromZero));
    return value + .1;
}

// The example displays the following output:
//       Value       Full Precision        ToEven    AwayFromZero
//
//        11.1                 11.1            11              11
//        11.2                 11.2            11              11
//        11.3   11.299999999999999            11              11
//        11.4   11.399999999999999            11              11
//        11.5   11.499999999999998            11              11
//        11.6   11.599999999999998            12              12
//
//        11.5                 11.5            12              12
```

Problems of precision in rounding midpoint values are most likely to arise in the following conditions:

- When a fractional value cannot be expressed precisely in the floating-point type's binary format.
- When the value to be rounded is calculated from one or more floating-point operations.
- When the value to be rounded is a Single rather than a Double or Decimal. For more information, see the next section, Rounding and single-precision floating-point values.

In cases where the lack of precision in rounding operations is problematic, you can do the following:

- If the rounding operation calls an overload that rounds a Double value, you can change the Double to a Decimal value and call an overload that rounds a Decimal value instead. Although the Decimal data type also has problems of representation and loss of precision, these issues are far less common.
- Define a custom rounding algorithm that performs a "nearly equal" test to determine whether the value to be rounded is acceptably close to a midpoint value. The following example defines a `RoundApproximate` method that examines whether a fractional value is sufficiently near to a midpoint value to be subject to midpoint rounding. As the output from the example shows, it corrects the rounding problem shown in the previous example.

C#

```
public static void Example()
{
    Console.WriteLine("{0,5} {1,20:R}  {2,12} {3,15}\n",
                      "Value", "Full Precision", "ToEven",
                      "AwayFromZero");
    double value = 11.1;
    for (int ctr = 0; ctr <= 5; ctr++)
        value = RoundValueAndAdd(value);

    Console.WriteLine();

    value = 11.5;
    RoundValueAndAdd(value);
}

private static double RoundValueAndAdd(double value)
{
    const double tolerance = 8e-14;
```

```
    Console.WriteLine("{0,5:N1} {0,20:R}  {1,12} {2,15}",
                      value,
                      RoundApproximate(value, 0, tolerance,
MidpointRounding.ToEven),
                      RoundApproximate(value, 0, tolerance,
MidpointRounding.AwayFromZero));
    return value + .1;
}

private static double RoundApproximate(double dbl, int digits, double
margin,
                                   MidpointRounding mode)
{
    double fraction = dbl * Math.Pow(10, digits);
    double value = Math.Truncate(fraction);
    fraction = fraction - value;
    if (fraction == 0)
        return dbl;

    double tolerance = margin * dbl;
    // Determine whether this is a midpoint value.
    if ((fraction >= .5 - tolerance) & (fraction <= .5 + tolerance))
    {
        if (mode == MidpointRounding.AwayFromZero)
            return (value + 1) / Math.Pow(10, digits);
        else
           if (value % 2 != 0)
            return (value + 1) / Math.Pow(10, digits);
        else
            return value / Math.Pow(10, digits);
    }
    // Any remaining fractional value greater than .5 is not a midpoint
value.
    if (fraction > .5)
        return (value + 1) / Math.Pow(10, digits);
    else
        return value / Math.Pow(10, digits);
}

// The example displays the following output:
//       Value       Full Precision        ToEven    AwayFromZero
//
//        11.1                 11.1            11              11
//        11.2                 11.2            11              11
//        11.3   11.299999999999999            11              11
//        11.4   11.399999999999999            11              11
//        11.5   11.499999999999998            12              12
//        11.6   11.599999999999998            12              12
//
//        11.5                 11.5            12              12
```

Rounding and single-precision floating-point values

The Round method includes overloads that accept arguments of type Decimal and Double. There are no methods that round values of type Single. If you pass a Single value to one of the overloads of the Round method, it is cast (in C#) or converted (in Visual Basic) to a Double, and the corresponding Round overload with a Double parameter is called. Although this is a widening conversion, it often involves a loss of precision, as the following example illustrates. When a Single value of 16.325 is passed to the Round method and rounded to two decimal places using the rounding to nearest convention, the result is 16.33 and not the expected result of 16.32.

C#

```
Single value = 16.325f;
Console.WriteLine("Widening Conversion of {0:R} (type {1}) to {2:R} (type
{3}): ",
                  value, value.GetType().Name, (double)value,
                  ((double)(value)).GetType().Name);
Console.WriteLine(Math.Round(value, 2));
Console.WriteLine(Math.Round(value, 2, MidpointRounding.AwayFromZero));
Console.WriteLine();

Decimal decValue = (decimal)value;
Console.WriteLine("Cast of {0:R} (type {1}) to {2} (type {3}): ",
                  value, value.GetType().Name, decValue,
                  decValue.GetType().Name);
Console.WriteLine(Math.Round(decValue, 2));
Console.WriteLine(Math.Round(decValue, 2, MidpointRounding.AwayFromZero));

// The example displays the following output:
//    Widening Conversion of 16.325 (type Single) to 16.325000762939453
(type Double):
//    16.33
//    16.33
//
//    Cast of 16.325 (type Single) to 16.325 (type Decimal):
//    16.32
//    16.33
```

This unexpected result is due to a loss of precision in the conversion of the Single value to a Double. Because the resulting Double value of 16.325000762939453 is not a midpoint value and is greater than 16.325, it is always rounded upward.

In many cases, as the example illustrates, the loss of precision can be minimized or eliminated by casting or converting the Single value to a Decimal. Note that, because this is a narrowing conversion, it requires using a cast operator or calling a conversion method.

Round(Double, Int32, MidpointRounding)

Rounds a double-precision floating-point value to a specified number of fractional digits using the specified rounding convention.

```
C#

public static double Round (double value, int digits, MidpointRounding
mode);
```

Parameters

`value` Double

A double-precision floating-point number to be rounded.

`digits` Int32

The number of fractional digits in the return value.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Double

The number that has `digits` fractional digits that `value` is rounded to. If `value` has fewer fractional digits than `digits`, `value` is returned unchanged.

Exceptions

ArgumentOutOfRangeException

`digits` is less than 0 or greater than 15.

ArgumentException

`mode` is not a valid value of MidpointRounding.

Remarks

The value of the `digits` argument can range from 0 to 15. The maximum number of integral and fractional digits supported by the Double type is 15.

See Midpoint values and rounding conventions for information about rounding numbers with midpoint values.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `value` argument is Double.NaN, the method returns Double.NaN. If `value` is Double.PositiveInfinity or Double.NegativeInfinity, the method returns Double.PositiveInfinity or Double.NegativeInfinity, respectively.

Example

The following example demonstrates how to use the Round(Double, Int32, MidpointRounding) method with the MidpointRounding enumeration.

C#

```
// Round a positive and a negative value using the default.
double result = Math.Round(3.45, 1);
Console.WriteLine($"{result,4} = Math.Round({3.45,5}, 1)");
result = Math.Round(-3.45, 1);
Console.WriteLine($"{result,4} = Math.Round({-3.45,5}, 1)\n");

// Round a positive value using a MidpointRounding value.
result = Math.Round(3.45, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result,4} = Math.Round({3.45,5}, 1,
MidpointRounding.ToEven)");
result = Math.Round(3.45, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result,4} = Math.Round({3.45,5}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(3.47, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result,4} = Math.Round({3.47,5}, 1,
MidpointRounding.ToZero)\n");

// Round a negative value using a MidpointRounding value.
result = Math.Round(-3.45, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result,4} = Math.Round({-3.45,5}, 1,
MidpointRounding.ToEven)");
result = Math.Round(-3.45, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result,4} = Math.Round({-3.45,5}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(-3.47, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result,4} = Math.Round({-3.47,5}, 1,
MidpointRounding.ToZero)\n");

// The example displays the following output:
```

```
//          3.4 = Math.Round( 3.45, 1)
//         -3.4 = Math.Round(-3.45, 1)

//          3.4 = Math.Round(3.45, 1, MidpointRounding.ToEven)
//          3.5 = Math.Round(3.45, 1, MidpointRounding.AwayFromZero)
//          3.4 = Math.Round(3.47, 1, MidpointRounding.ToZero)

//         -3.4 = Math.Round(-3.45, 1, MidpointRounding.ToEven)
//         -3.5 = Math.Round(-3.45, 1, MidpointRounding.AwayFromZero)
//         -3.4 = Math.Round(-3.47, 1, MidpointRounding.ToZero)
```

Notes to Callers

Because of the loss of precision that can result from representing decimal values as floating-point numbers or performing arithmetic operations on floating-point values, in some cases the Round(Double, Int32, MidpointRounding) method may not appear to round midpoint values as specified by the `mode` parameter. This is illustrated in the following example, where 2.135 is rounded to 2.13 instead of 2.14. This occurs because internally the method multiplies `value` by 10^{digits}, and the multiplication operation in this case suffers from a loss of precision.

C#

```
double[] values = { 2.125, 2.135, 2.145, 3.125, 3.135, 3.145 };
foreach (double value in values)
   Console.WriteLine("{0} --> {1}", value,
                     Math.Round(value, 2,
MidpointRounding.AwayFromZero));

// The example displays the following output:
//       2.125 --> 2.13
//       2.135 --> 2.13
//       2.145 --> 2.15
//       3.125 --> 3.13
//       3.135 --> 3.14
//       3.145 --> 3.15
```

Round(Decimal, Int32, MidpointRounding)

Rounds a decimal value to a specified number of fractional digits using the specified rounding convention.

C#

```
public static decimal Round (decimal d, int decimals, MidpointRounding
mode);
```

Parameters

`d` Decimal

A decimal number to be rounded.

`decimals` Int32

The number of decimal places in the return value.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Decimal

The number with `decimals` fractional digits that `d` is rounded to. If `d` has fewer fractional digits than `decimals`, `d` is returned unchanged.

Exceptions

ArgumentOutOfRangeException

`decimals` is less than 0 or greater than 28.

ArgumentException

`mode` is not a valid value of MidpointRounding.

OverflowException

The result is outside the range of a Decimal.

Remarks

See Midpoint values and rounding conventions for information about rounding numbers with midpoint values.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

The value of the `decimals` argument can range from 0 to 28.

Example

The following example demonstrates how to use the Round method with the MidpointRounding enumeration.

C#

```
decimal result;

// Round a positive value using different strategies.
// The precision of the result is 1 decimal place.

result = Math.Round(3.45m, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result} = Math.Round({3.45m}, 1,
MidpointRounding.ToEven)");
result = Math.Round(3.45m, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result} = Math.Round({3.45m}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(3.47m, 1, MidpointRounding.ToZero);
```

```
Console.WriteLine($"{result} = Math.Round({3.47m}, 1,
MidpointRounding.ToZero)\n");

// Round a negative value using different strategies.
// The precision of the result is 1 decimal place.

result = Math.Round(-3.45m, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result} = Math.Round({-3.45m}, 1,
MidpointRounding.ToEven)");
result = Math.Round(-3.45m, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result} = Math.Round({-3.45m}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(-3.47m, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result} = Math.Round({-3.47m}, 1,
MidpointRounding.ToZero)\n");

/*
This code example produces the following results:

3.4 = Math.Round(3.45, 1, MidpointRounding.ToEven)
3.5 = Math.Round(3.45, 1, MidpointRounding.AwayFromZero)
3.4 = Math.Round(3.47, 1, MidpointRounding.ToZero)

-3.4 = Math.Round(-3.45, 1, MidpointRounding.ToEven)
-3.5 = Math.Round(-3.45, 1, MidpointRounding.AwayFromZero)
-3.4 = Math.Round(-3.47, 1, MidpointRounding.ToZero)
*/
```

Round(Double, MidpointRounding)

Rounds a double-precision floating-point value to an integer using the specified rounding convention.

```
C#

public static double Round (double value, MidpointRounding mode);
```

Parameters

`value` Double

A double-precision floating-point number to be rounded.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Double

The integer that `value` is rounded to. This method returns a Double instead of an integral type.

Exceptions

ArgumentException

`mode` is not a valid value of MidpointRounding.

Remarks

See Midpoint values and rounding conventions for information about rounding numbers with midpoint values.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `value` argument is Double.NaN, the method returns Double.NaN. If `value` is Double.PositiveInfinity or Double.NegativeInfinity, the method returns Double.PositiveInfinity or Double.NegativeInfinity, respectively.

Example

The following example displays values returned by the Round(Double, MidpointRounding) method with different `mode` values.

C#

```
Double[] values = { 12.0, 12.1, 12.2, 12.3, 12.4, 12.5, 12.6,
                    12.7, 12.8, 12.9, 13.0 };
Console.WriteLine($"{"Value",-10} {"Default",-10} {"ToEven",-10}
{"AwayFromZero",-15} {"ToZero",-15}");

foreach (var value in values)
    Console.WriteLine($"{value,-10:R} {Math.Round(value),-10} " +
        $"{Math.Round(value, MidpointRounding.ToEven),-10} " +
        $"{Math.Round(value, MidpointRounding.AwayFromZero),-15} " +
        $"{Math.Round(value, MidpointRounding.ToZero),-15}");

// The example displays the following output:
//       Value      Default    ToEven     AwayFromZero    ToZero
//       12         12         12         12              12
//       12.1       12         12         12              12
//       12.2       12         12         12              12
//       12.3       12         12         12              12
//       12.4       12         12         12              12
//       12.5       12         12         13              12
//       12.6       13         13         13              12
//       12.7       13         13         13              12
//       12.8       13         13         13              12
//       12.9       13         13         13              12
//       13         13         13         13              13
```

Notes to Callers

Because of the loss of precision that can result from representing decimal values as floating-point numbers or performing arithmetic operations on floating-point values, in some cases the Round(Double, MidpointRounding) method may not appear to round midpoint values to the nearest even integer. In the following example, because the floating-point value .1 has no finite binary representation, the first call to the Round(Double) method with a value of 11.5 returns 11 instead of 12.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double value = 11.1;
      for (int ctr = 0; ctr <= 5; ctr++)
         value = RoundValueAndAdd(value);

      Console.WriteLine();

      value = 11.5;
      RoundValueAndAdd(value);
   }

   private static double RoundValueAndAdd(double value)
   {
      Console.WriteLine("{0} --> {1}", value, Math.Round(value,
                        MidpointRounding.AwayFromZero));
      return value + .1;
   }
}
// The example displays the following output:
//       11.1 --> 11
//       11.2 --> 11
//       11.3 --> 11
//       11.4 --> 11
//       11.5 --> 11
//       11.6 --> 12
//
//       11.5 --> 12
```

UWP	10.0

Round(Double, Int32)

Rounds a double-precision floating-point value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.

```
C#
public static double Round (double value, int digits);
```

Parameters

`value` Double

A double-precision floating-point number to be rounded.

`digits` Int32

The number of fractional digits in the return value.

Returns

Double

The number nearest to `value` that contains a number of fractional digits equal to `digits`.

Exceptions

ArgumentOutOfRangeException

`digits` is less than 0 or greater than 15.

Remarks

The value of the `digits` argument can range from 0 to 15. The maximum number of integral and fractional digits supported by the Double type is 15.

This method uses the default rounding convention of MidpointRounding.ToEven. See Midpoint values and rounding conventions for information about rounding numbers with midpoint values.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `value` argument is Double.NaN, the method returns Double.NaN. If `value` is Double.PositiveInfinity or Double.NegativeInfinity, the method returns Double.PositiveInfinity or Double.NegativeInfinity, respectively.

Example

The following example rounds double values with two fractional digits to doubles that have a single fractional digit.

C#

```
Math.Round(3.44, 1); //Returns 3.4.
Math.Round(3.45, 1); //Returns 3.4.
Math.Round(3.46, 1); //Returns 3.5.

Math.Round(4.34, 1); // Returns 4.3
Math.Round(4.35, 1); // Returns 4.4
Math.Round(4.36, 1); // Returns 4.4
```

Notes to Callers

Because of the loss of precision that can result from representing decimal values as floating-point numbers or performing arithmetic operations on floating-point values, in some cases the Round(Double, Int32) method may not appear to round midpoint values to the nearest even value in the `digits` decimal position. This is illustrated in the following example, where 2.135 is rounded to 2.13 instead of 2.14. This occurs because internally the method multiplies `value` by 10^{digits}, and the multiplication operation in this case suffers from a loss of precision.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double[] values = { 2.125, 2.135, 2.145, 3.125, 3.135, 3.145 };
      foreach (double value in values)
         Console.WriteLine("{0} --> {1}", value, Math.Round(value, 2));
   }
}
// The example displays the following output:
//       2.125 --> 2.12
//       2.135 --> 2.13
//       2.145 --> 2.14
//       3.125 --> 3.12
//       3.135 --> 3.14
//       3.145 --> 3.14
```

Round(Decimal, Int32)

Rounds a decimal value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.

```
C#
public static decimal Round (decimal d, int decimals);
```

Parameters

d Decimal

A decimal number to be rounded.

decimals Int32

The number of decimal places in the return value.

Returns

Decimal

The number nearest to `d` that contains a number of fractional digits equal to `decimals`.

Exceptions

ArgumentOutOfRangeException

`decimals` is less than 0 or greater than 28.

OverflowException

The result is outside the range of a Decimal.

Remarks

The value of the `decimals` argument can range from 0 to 28.

This method uses the default rounding convention of MidpointRounding.ToEven. For information about rounding numbers with midpoint values, see Midpoint values and rounding conventions.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

Example

The following example rounds decimal values with two fractional digits to values that have a single fractional digit.

C#

```
Console.WriteLine(Math.Round(3.44m, 1));
Console.WriteLine(Math.Round(3.45m, 1));
Console.WriteLine(Math.Round(3.46m, 1));
Console.WriteLine();

Console.WriteLine(Math.Round(4.34m, 1));
Console.WriteLine(Math.Round(4.35m, 1));
Console.WriteLine(Math.Round(4.36m, 1));

// The example displays the following output:
//       3.4
//       3.4
//       3.5
//
//       4.3
//       4.4
//       4.4
```

.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Round(Double)

Rounds a double-precision floating-point value to the nearest integral value, and rounds midpoint values to the nearest even number.

```
C#

public static double Round (double a);
```

Parameters

a Double

A double-precision floating-point number to be rounded.

Returns

Double

The integer nearest `a`. If the fractional component of `a` is halfway between two integers, one of which is even and the other odd, then the even number is returned. Note that this method returns a Double instead of an integral type.

Remarks

This method uses the default rounding convention of MidpointRounding.ToEven. For information about rounding numbers with midpoint values, see Midpoint values and rounding conventions.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `a` argument is Double.NaN, the method returns Double.NaN. If `a` is Double.PositiveInfinity or Double.NegativeInfinity, the method returns Double.PositiveInfinity or Double.NegativeInfinity, respectively.

Starting with Visual Basic 15.8, the performance of Double-to-integer conversion is optimized if you pass the value returned by the `Round` method to the any of the

integral conversion functions, or if the Double value returned by `Round` is automatically converted to an integer with Option Strict set to Off. This optimization allows code to run faster -- up to twice as fast for code that does a large number of conversions to integer types. The following example illustrates such optimized conversions:

VB

```
Dim d1 As Double = 1043.75133
Dim i1 As Integer = CInt(Math.Ceiling(d1))        ' Result: 1044

Dim d2 As Double = 7968.4136
Dim i2 As Integer = CInt(Math.Ceiling(d2))        ' Result: 7968
```

Example

The following example demonstrates rounding to the nearest integer value.

C#

```
Console.WriteLine("Classic Math.Round in CSharp");
Console.WriteLine(Math.Round(4.4)); // 4
Console.WriteLine(Math.Round(4.5)); // 4
Console.WriteLine(Math.Round(4.6)); // 5
Console.WriteLine(Math.Round(5.5)); // 6
```

Notes to Callers

Because of the loss of precision that can result from representing decimal values as floating-point numbers or performing arithmetic operations on floating-point values, in some cases the Round(Double) method may not appear to round midpoint values to the nearest even integer. In the following example, because the floating-point value .1 has no finite binary representation, the first call to the Round(Double) method with a value of 11.5 returns 11 instead of 12.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      double value = 11.1;
      for (int ctr = 0; ctr <= 5; ctr++)
```

```
            value = RoundValueAndAdd(value);

        Console.WriteLine();

        value = 11.5;
        RoundValueAndAdd(value);
    }

    private static double RoundValueAndAdd(double value)
    {
        Console.WriteLine("{0} --> {1}", value, Math.Round(value));
        return value + .1;
    }
}
// The example displays the following output:
//       11.1 --> 11
//       11.2 --> 11
//       11.3 --> 11
//       11.4 --> 11
//       11.5 --> 11
//       11.6 --> 12
//
//       11.5 --> 12
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Round(Decimal)

Rounds a decimal value to the nearest integral value, and rounds midpoint values to the nearest even number.

C#

```
public static decimal Round (decimal d);
```

Parameters

d Decimal

A decimal number to be rounded.

Returns

Decimal

The integer nearest the `d` parameter. If the fractional component of `d` is halfway between two integers, one of which is even and the other odd, the even number is returned. Note that this method returns a Decimal instead of an integral type.

Exceptions

OverflowException

The result is outside the range of a Decimal.

Examples

The following example demonstrates the Round(Decimal) method. The Decimal value of 4.5 rounds to 4 rather than 5, because this overload uses the default ToEven convention.

C#

```
for (decimal value = 4.2m; value <= 4.8m; value+=.1m )
   Console.WriteLine("{0} --> {1}", value, Math.Round(value));
// The example displays the following output:
//       4.2 --> 4
//       4.3 --> 4
//       4.4 --> 4
//       4.5 --> 4
//       4.6 --> 5
//       4.7 --> 5
//       4.8 --> 5
```

Remarks

This method uses the default rounding convention of MidpointRounding.ToEven. For information about rounding numbers with midpoint values, see Midpoint values and rounding conventions.

> ⓘ **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

Round(Decimal, MidpointRounding)

Rounds a decimal value an integer using the specified rounding convention.

```
C#
```

```
public static decimal Round (decimal d, MidpointRounding mode);
```

Parameters

`d` Decimal

A decimal number to be rounded.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Decimal

The integer that `d` is rounded to. This method returns a Decimal instead of an integral type.

Exceptions

ArgumentException

`mode` is not a valid value of MidpointRounding.

OverflowException

The result is outside the range of a Decimal.

Remarks

For information about rounding numbers with midpoint values, see Midpoint values and rounding conventions.

> ⓘ **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

Example

The following example displays values returned by the Round(Decimal, MidpointRounding) method with different `mode` values.

C#

```
Console.WriteLine($"{"Value",-10} {"Default",-10} {"ToEven",-10}
{"AwayFromZero",-15} {"ToZero",-15}");
for (decimal value = 12.0m; value <= 13.0m; value += 0.1m)
    Console.WriteLine($"{value,-10} {Math.Round(value),-10} " +
        $"{Math.Round(value, MidpointRounding.ToEven),-10} " +
        $"{Math.Round(value, MidpointRounding.AwayFromZero),-15} " +
        $"{Math.Round(value, MidpointRounding.ToZero),-15}");

// The example displays the following output:
//       Value      Default    ToEven     AwayFromZero    ToZero
//       12.0       12         12         12              12
//       12.1       12         12         12              12
//       12.2       12         12         12              12
//       12.3       12         12         12              12
//       12.4       12         12         12              12
//       12.5       12         12         13              12
//       12.6       13         13         13              12
//       12.7       13         13         13              12
//       12.8       13         13         13              12
//       12.9       13         13         13              12
//       13.0       13         13         13              13
```

Math.ScaleB(Double, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns x * 2^n computed efficiently.

```
C#
public static double ScaleB (double x, int n);
```

Parameters

x Double

A double-precision floating-point number that specifies the base value.

n Int32

A 32-bit integer that specifies the power.

Returns

Double

x * 2^n computed efficiently.

Remarks

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Math.Sign Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an integer that indicates the sign of a number.

Overloads

Expand table

Sign(IntPtr)	Returns an integer that indicates the sign of a native sized signed integer.
Sign(Single)	Returns an integer that indicates the sign of a single-precision floating-point number.
Sign(SByte)	Returns an integer that indicates the sign of an 8-bit signed integer.
Sign(Int64)	Returns an integer that indicates the sign of a 64-bit signed integer.
Sign(Decimal)	Returns an integer that indicates the sign of a decimal number.
Sign(Int16)	Returns an integer that indicates the sign of a 16-bit signed integer.
Sign(Double)	Returns an integer that indicates the sign of a double-precision floating-point number.
Sign(Int32)	Returns an integer that indicates the sign of a 32-bit signed integer.

Sign(IntPtr)

Returns an integer that indicates the sign of a native sized signed integer.

C#

```
public static int Sign (IntPtr value);
```

Parameters

`value` nint

A signed number.

Returns

Int32

A number that indicates the sign of `value`, as shown in the following table.

Expand table

Return value	Meaning
-1	`value` is less than zero.
0	`value` is equal to zero.
1	`value` is greater than zero.

Examples

The following example demonstrates how to use the Sign(IntPtr) method to determine the sign of an IntPtr value and display it to the console.

C#

```
// This example demonstrates Math.Sign()
using System;

class Sample
{
    public static void Main()
    {
        string str = "{0}: {1,3} is {2} zero.";
        string nl = Environment.NewLine;
        byte     xByte1    = 0;
        short    xShort1   = -2;
        int      xInt1     = -3;
        long     xLong1    = -4;
        float    xSingle1  = 0.0f;
        double   xDouble1  = 6.0;
        Decimal  xDecimal1 = -7m;

Sign(Single)

Returns an integer that indicates the sign of a single-precision floating-point number.

```
C#
public static int Sign (float value);
```

Parameters

`value` Single

A signed number.

Returns

Int32

A number that indicates the sign of `value`, as shown in the following table.

Expand table

Return value	Meaning
-1	`value` is less than zero.
0	`value` is equal to zero.
1	`value` is greater than zero.

Exceptions

ArithmeticException

`value` is equal to NaN.

Examples

The following example demonstrates how to use the Sign(Single) method to determine the sign of a Single value and display it to the console.

C#

```
// This example demonstrates Math.Sign()
using System;

class Sample
{
    public static void Main()
    {
        string str = "{0}: {1,3} is {2} zero.";
        string nl = Environment.NewLine;
        byte     xByte1    = 0;
        short    xShort1   = -2;
        int      xInt1     = -3;
        long     xLong1    = -4;
        float    xSingle1  = 0.0f;
        double   xDouble1  = 6.0;
        Decimal  xDecimal1 = -7m;
        nint     xIntPtr1  = 8;

        // The following type is not CLS-compliant.

Sign(SByte)

> Important
>
> This API is not CLS-compliant.

Returns an integer that indicates the sign of an 8-bit signed integer.

C#

```
[System.CLSCompliant(false)]
public static int Sign (sbyte value);
```

Parameters

`value` SByte

A signed number.

Returns

Int32

A number that indicates the sign of `value`, as shown in the following table.

Expand table

Return value	Meaning
-1	`value` is less than zero.
0	`value` is equal to zero.
1	`value` is greater than zero.

Attributes CLSCompliantAttribute

Examples

The following example demonstrates how to use the Sign(SByte) method to determine the sign of an SByte value and display it to the console.

C#

```
// This example demonstrates Math.Sign()
using System;
