public static int Sign (short value);
```

Parameters

`value` Int16

A signed number.

Returns

Int32

A number that indicates the sign of `value`, as shown in the following table.

Expand table

Return value	Meaning
-1	`value` is less than zero.
0	`value` is equal to zero.
1	`value` is greater than zero.

Examples

The following example demonstrates how to use the Sign(Int16) method to determine the sign of an Int16 value and display it to the console.

C#

```
// This example demonstrates Math.Sign()
using System;

class Sample
{
    public static void Main()
    {
        string str = "{0}: {1,3} is {2} zero.";
        string nl = Environment.NewLine;
        byte     xByte1    = 0;
        short    xShort1   = -2;
        int      xInt1     = -3;
        long     xLong1    = -4;
        float    xSingle1  = 0.0f;
        double   xDouble1  = 6.0;
        Decimal  xDecimal1 = -7m;
        nint     xIntPtr1  = 8;

        // The following type is not CLS-compliant.
        sbyte    xSbyte1   = -101;

        Console.WriteLine($"{nl}Test the sign of the following types of
values:");
        Console.WriteLine(str, "Byte   ", xByte1,
Test(Math.Sign(xByte1)));
        Console.WriteLine(str, "Int16  ", xShort1,
Test(Math.Sign(xShort1)));
        Console.WriteLine(str, "Int32  ", xInt1, Test(Math.Sign(xInt1)));
        Console.WriteLine(str, "Int64  ", xLong1,
Test(Math.Sign(xLong1)));
        Console.WriteLine(str, "Single ", xSingle1,
Test(Math.Sign(xSingle1)));
        Console.WriteLine(str, "Double ", xDouble1,
Test(Math.Sign(xDouble1)));
```

```
        Console.WriteLine(str, "Decimal", xDecimal1,
Test(Math.Sign(xDecimal1)));
        Console.WriteLine(str, "IntPtr", xIntPtr1,
Test(Math.Sign(xIntPtr1)));

        Console.WriteLine($"{nl}The following type is not CLS-
compliant.");
        Console.WriteLine(str, "SByte  ", xSbyte1,
Test(Math.Sign(xSbyte1)));
    }

    public static string Test(int compare)
    {
        if (compare == 0)
            return "equal to";
        else if (compare < 0)
            return "less than";
        else
            return "greater than";
    }
}
/*
This example produces the following results:

Test the sign of the following types of values:
Byte   :   0 is equal to zero.
Int16  :  -2 is less than zero.
Int32  :  -3 is less than zero.
Int64  :  -4 is less than zero.
Single :   0 is equal to zero.

Sign(Double)

Returns an integer that indicates the sign of a double-precision floating-point number.

```
C#
public static int Sign (double value);
```

Parameters

`value` Double

A signed number.

Returns

Int32

A number that indicates the sign of `value`, as shown in the following table.

Expand table

Return value	Meaning
-1	`value` is less than zero.
0	`value` is equal to zero.
1	`value` is greater than zero.

Exceptions

ArithmeticException

`value` is equal to NaN.

Examples

The following example demonstrates how to use the Sign(Double) method to determine the sign of a Double value and display it to the console.

C#

```
// This example demonstrates Math.Sign()
using System;

Math.Sin(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the sine of the specified angle.

C#

```
public static double Sin (double a);
```

Parameters

a Double

An angle, measured in radians.

Returns

Double

The sine of `a`. If `a` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Examples

The following example uses Sin to evaluate certain trigonometric identities for selected angles.

C#

```
// Example for the trigonometric Math.Sin( double )
// and Math.Cos( double ) methods.
using System;

class SinCos
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of trigonometric " +
```

```
            "Math.Sin( double ), Math.Cos( double ), and Math.SinCos( double
)\n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Convert selected values for X to radians \n" +
            "and evaluate these trigonometric identities:" );
        Console.WriteLine( "   sin^2(X) + cos^2(X) == 1\n" +
                           "   sin(2 * X) == 2 * sin(X) * cos(X)" );
        Console.WriteLine( "   cos(2 * X) == cos^2(X) - sin^2(X)" );
        Console.WriteLine( "   cos(2 * X) == cos^2(X) - sin^2(X)" );

        UseSineCosine(15.0);
        UseSineCosine(30.0);
        UseSineCosine(45.0);

        Console.WriteLine(
            "\nConvert selected values for X and Y to radians \n" +
            "and evaluate these trigonometric identities:" );
        Console.WriteLine( "   sin(X + Y) == sin(X) * cos(Y) + cos(X) *
sin(Y)" );
        Console.WriteLine( "   cos(X + Y) == cos(X) * cos(Y) - sin(X) *
sin(Y)" );

        UseTwoAngles(15.0, 30.0);
        UseTwoAngles(30.0, 45.0);

        Console.WriteLine(
            "\nWhen you have calls to sin(X) and cos(X) they \n" +
            "can be replaced with a single call to sincos(x):" );

        UseCombinedSineCosine(15.0);
        UseCombinedSineCosine(30.0);
        UseCombinedSineCosine(45.0);
    }

        Math.Cos(30 deg) * Math.Cos(45 deg) -
```

```
        Math.Sin(30 deg) * Math.Sin(45 deg) == 2.5881904510252085E-001
                           Math.Cos(75 deg) == 2.5881904510252096E-001
*/
```

Remarks

The angle, `a`, must be in radians. Multiply by Math.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Math.SinCos(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the sine and cosine of the specified angle.

C#

```
public static (double Sin, double Cos) SinCos (double x);
```

Parameters

x Double

An angle, measured in radians.

Returns

ValueTuple<Double,Double>

The sine and cosine of `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Examples

The following example uses SinCos to evaluate certain trigonometric identities for selected angles.

C#

```
// Example for the trigonometric Math.Sin( double )
// and Math.Cos( double ) methods.
using System;

class SinCos
{
    public static void Main()
    {
        Console.WriteLine(
            "This example of trigonometric " +
```

```
            "Math.Sin( double ), Math.Cos( double ), and Math.SinCos( double
)\n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Convert selected values for X to radians \n" +
            "and evaluate these trigonometric identities:" );
        Console.WriteLine( "   sin^2(X) + cos^2(X) == 1\n" +
                           "   sin(2 * X) == 2 * sin(X) * cos(X)" );
        Console.WriteLine( "   cos(2 * X) == cos^2(X) - sin^2(X)" );
        Console.WriteLine( "   cos(2 * X) == cos^2(X) - sin^2(X)" );

        UseSineCosine(15.0);
        UseSineCosine(30.0);
        UseSineCosine(45.0);

        Console.WriteLine(
            "\nConvert selected values for X and Y to radians \n" +
            "and evaluate these trigonometric identities:" );
        Console.WriteLine( "   sin(X + Y) == sin(X) * cos(Y) + cos(X) *
sin(Y)" );
        Console.WriteLine( "   cos(X + Y) == cos(X) * cos(Y) - sin(X) *
sin(Y)" );

        UseTwoAngles(15.0, 30.0);
        UseTwoAngles(30.0, 45.0);

        Console.WriteLine(
            "\nWhen you have calls to sin(X) and cos(X) they \n" +
            "can be replaced with a single call to sincos(x):" );

        UseCombinedSineCosine(15.0);

Math.Sinh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hyperbolic sine of the specified angle.

C#

```
public static double Sinh (double value);
```

Parameters

`value` Double

An angle, measured in radians.

Returns

Double

The hyperbolic sine of `value`. If `value` is equal to NegativeInfinity, PositiveInfinity, or NaN, this method returns a Double equal to `value`.

Examples

The following example uses Sinh to evaluate certain hyperbolic identities for selected values.

C#

```
// Example for the hyperbolic Math.Sinh( double )
// and Math.Cosh( double ) methods.
using System;

class SinhCosh
{
    public static void Main()
    {
        Console.WriteLine(
```

```
            "This example of hyperbolic Math.Sinh( double ) " +
            "and Math.Cosh( double )\n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Evaluate these hyperbolic identities " +
            "with selected values for X:" );
        Console.WriteLine(
            "   cosh^2(X) - sinh^2(X) == 1\n" +
            "   sinh(2 * X) == 2 * sinh(X) * cosh(X)" );
        Console.WriteLine( "   cosh(2 * X) == cosh^2(X) + sinh^2(X)" );

        UseSinhCosh(0.1);
        UseSinhCosh(1.2);
        UseSinhCosh(4.9);

        Console.WriteLine(
            "\nEvaluate these hyperbolic identities " +
            "with selected values for X and Y:" );
        Console.WriteLine(
            "   sinh(X + Y) == sinh(X) * cosh(Y) + cosh(X) * sinh(Y)" );
        Console.WriteLine(
            "   cosh(X + Y) == cosh(X) * cosh(Y) + sinh(X) * sinh(Y)" );

        UseTwoArgs(0.1, 1.2);
        UseTwoArgs(1.2, 4.9);
    }

    // Evaluate hyperbolic identities with a given argument.
    static void UseSinhCosh(double arg)
    {

*/
```

Remarks

The angle, `value`, must be in radians. Multiply by Math.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Math.Sqrt(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the square root of a specified number.

C#

```
public static double Sqrt (double d);
```

Parameters

`d` Double

The number whose square root is to be found.

Returns

Double

One of the values in the following table.

Expand table

`d` parameter	Return value
Zero or positive	The positive square root of `d`.
Negative	NaN
Equals NaN	NaN
Equals PositiveInfinity	PositiveInfinity

Examples

The square root of the area of a square represents the length of any side of the square. The following example displays the area of some cities in the United States and gives an impression of each city's size if it were represented by a square.

C#

```
// Create an array containing the area of some squares.
Tuple<string, double>[] areas =
               { Tuple.Create("Sitka, Alaska", 2870.3),
                 Tuple.Create("New York City", 302.6),
                 Tuple.Create("Los Angeles", 468.7),
                 Tuple.Create("Detroit", 138.8),
                 Tuple.Create("Chicago", 227.1),
                 Tuple.Create("San Diego", 325.2) };

Console.WriteLine("{0,-18} {1,14:N1} {2,30}\n", "City", "Area (mi.)",
                  "Equivalent to a square with:");

foreach (var area in areas)
  Console.WriteLine("{0,-18} {1,14:N1} {2,14:N2} miles per side",
                    area.Item1, area.Item2,
Math.Round(Math.Sqrt(area.Item2), 2));

// The example displays the following output:
//    City                   Area (mi.)   Equivalent to a square with:
//
//    Sitka, Alaska             2,870.3          53.58 miles per side
//    New York City               302.6          17.40 miles per side
//    Los Angeles                 468.7          21.65 miles per side
//    Detroit                     138.8          11.78 miles per side
//    Chicago                     227.1          15.07 miles per side
//    San Diego                   325.2          18.03 miles per side
```

Math.Tan(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the tangent of the specified angle.

C#

```
public static double Tan (double a);
```

Parameters

a Double

An angle, measured in radians.

Returns

Double

The tangent of `a`. If `a` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Examples

The following example demonstrates how to calculate the tangent of an angle and display it to the console.

C#

```
// This example demonstrates Math.Atan()
//                           Math.Atan2()
//                           Math.Tan()
using System;

class Sample
{
    public static void Main()
    {
    double x = 1.0;
```

```
    double y = 2.0;
    double angle;
    double radians;
    double result;

// Calculate the tangent of 30 degrees.
    angle = 30;
    radians = angle * (Math.PI/180);
    result = Math.Tan(radians);
    Console.WriteLine("The tangent of 30 degrees is {0}.", result);

// Calculate the arctangent of the previous tangent.
    radians = Math.Atan(result);
    angle = radians * (180/Math.PI);
    Console.WriteLine("The previous tangent is equivalent to {0} degrees.",
angle);

// Calculate the arctangent of an angle.
    String line1 = "{0}The arctangent of the angle formed by the x-axis and
";
    String line2 = "a vector to point ({0},{1}) is {2}, ";
    String line3 = "which is equivalent to {0} degrees.";

    radians = Math.Atan2(y, x);
    angle = radians * (180/Math.PI);

    Console.WriteLine(line1, Environment.NewLine);
    Console.WriteLine(line2, x, y, radians);
    Console.WriteLine(line3, angle);
    }
}
/*
This example produces the following results:

The tangent of 30 degrees is 0.577350269189626.
The previous tangent is equivalent to 30 degrees.

The arctangent of the angle formed by the x-axis and
a vector to point (1,2) is 1.10714871779409,
which is equivalent to 63.434948822922 degrees.
*/
```

Remarks

The angle, `a`, must be in radians. Multiply by Math.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Math.Tanh(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hyperbolic tangent of the specified angle.

C#

```
public static double Tanh (double value);
```

Parameters

`value` Double

An angle, measured in radians.

Returns

Double

The hyperbolic tangent of `value`. If `value` is equal to NegativeInfinity, this method returns -1. If value is equal to PositiveInfinity, this method returns 1. If `value` is equal to NaN, this method returns NaN.

Examples

The following example uses Tanh to evaluate certain hyperbolic tangent identities for selected values.

C#

```
// Example for the hyperbolic Math.Tanh( double ) method.
using System;

class DemoTanh
{
    public static void Main()
    {
        Console.WriteLine(
```

```
            "This example of hyperbolic Math.Tanh( double )\n" +
            "generates the following output." );
        Console.WriteLine(
            "\nEvaluate these hyperbolic identities " +
            "with selected values for X:" );
        Console.WriteLine( "   tanh(X) == sinh(X) / cosh(X)" );
        Console.WriteLine(
            "   tanh(2 * X) == 2 * tanh(X) / (1 + tanh^2(X))" );

        UseTanh(0.1);
        UseTanh(1.2);
        UseTanh(4.9);

        Console.WriteLine(
            "\nEvaluate [tanh(X + Y) == (tanh(X) + tanh(Y)) " +
            "/ (1 + tanh(X) * tanh(Y))]" +
            "\nwith selected values for X and Y:" );

        UseTwoArgs(0.1, 1.2);
        UseTwoArgs(1.2, 4.9);
    }

    // Evaluate hyperbolic identities with a given argument.
    static void UseTanh(double arg)
    {
        double tanhArg = Math.Tanh(arg);

        // Evaluate tanh(X) == sinh(X) / cosh(X).
        Console.WriteLine(
            "\n                        Math.Tanh({0}) == {1:E16}\n" +
            "      Math.Sinh({0}) / Math.Cosh({0}) == {2:E16}",
            arg, tanhArg, (Math.Sinh(arg) / Math.Cosh(arg)) );

        // Evaluate tanh(2 * X) == 2 * tanh(X) / (1 + tanh^2(X)).
        Console.WriteLine(
            "                    2 * Math.Tanh({0}) /",
            arg, 2.0 * tanhArg );
        Console.WriteLine(
            "             (1 + (Math.Tanh({0}))^2) == {1:E16}",
            arg, 2.0 * tanhArg / (1.0 + tanhArg * tanhArg ) );
        Console.WriteLine(
            "                       Math.Tanh({0}) == {1:E16}",
            2.0 * arg, Math.Tanh(2.0 * arg) );
    }

Math.Truncate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the integral part of a number.

Overloads

Expand table

Truncate(Decimal)	Calculates the integral part of a specified decimal number.
Truncate(Double)	Calculates the integral part of a specified double-precision floating-point number.

Remarks

The number is rounded to the nearest integer towards zero.

Truncate(Decimal)

Calculates the integral part of a specified decimal number.

C#

```
public static decimal Truncate (decimal d);
```

Parameters

d Decimal

A number to truncate.

Returns

Decimal

The integral part of `d`; that is, the number that remains after any fractional digits have been discarded.

Examples

The following example calls the Truncate(Decimal) method to truncate both a positive and a negative Decimal value.

C#

```
decimal decimalNumber;

decimalNumber = 32.7865m;
// Displays 32
Console.WriteLine(Math.Truncate(decimalNumber));

decimalNumber = -32.9012m;
// Displays -32
Console.WriteLine(Math.Truncate(decimalNumber));
```

Remarks

Truncate rounds `d` to the nearest integer towards zero.

- Floor(Decimal)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Truncate(Double)

Calculates the integral part of a specified double-precision floating-point number.

C#

```
public static double Truncate (double d);
```

Parameters

d Double

A number to truncate.

Returns

Double

The integral part of `d`; that is, the number that remains after any fractional digits have been discarded, or one of the values listed in the following table.

Expand table

`d`	**Return value**
NaN	NaN
NegativeInfinity	NegativeInfinity
PositiveInfinity	PositiveInfinity

Examples

The following example calls the Truncate(Double) method to truncate both a positive and a negative Double value.

C#

```
double floatNumber;
```

```
floatNumber = 32.7865;
// Displays 32
Console.WriteLine(Math.Truncate(floatNumber));

floatNumber = -32.9012;
// Displays -32
Console.WriteLine(Math.Truncate(floatNumber));
```

Remarks

Truncate rounds `d` to the nearest integer towards zero.

Starting with Visual Basic 15.8, the performance of Double-to-integer conversion is optimized if you pass the value returned by the `Truncate` method to the any of the integral conversion functions, or if the Double value returned by `Truncate` is automatically converted to an integer with Option Strict set to Off. This optimization allows code to run faster -- up to twice as fast for code that does a large number of conversions to integer types. The following example illustrates such an optimized conversion:

VB

```
Dim d As Double = 164.7194
Dim i As Integer = CInt(Math.Truncate(d))     ' Result: 164
```

MathF Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides constants and static methods for trigonometric, logarithmic, and other common mathematical functions.

C#

```
public static class MathF
```

Inheritance Object → MathF

Remarks

The static fields and methods of the `MathF` class correspond to those of the Math class, except that their parameters are of type Single rather than Double, and they return Single rather than Double values.

Fields

Expand table

E	Represents the natural logarithmic base, specified by the constant, `e`.
PI	Represents the ratio of the circumference of a circle to its diameter, specified by the constant, p.
Tau	Represents the number of radians in one turn, specified by the constant, τ.

Methods

Expand table

Abs(Single)	Returns the absolute value of a single-precision floating-point number.
Acos(Single)	Returns the angle whose cosine is the specified number.
Acosh(Single)	Returns the angle whose hyperbolic cosine is the specified number.
Asin(Single)	Returns the angle whose sine is the specified number.
Asinh(Single)	Returns the angle whose hyperbolic sine is the specified number.
Atan(Single)	Returns the angle whose tangent is the specified number.
Atan2(Single, Single)	Returns the angle whose tangent is the quotient of two specified numbers.
Atanh(Single)	Returns the angle whose hyperbolic tangent is the specified number.
BitDecrement(Single)	Returns the largest value that compares less than a specified value.
BitIncrement(Single)	Returns the smallest value that compares greater than a specified value.
Cbrt(Single)	Returns the cube root of a specified number.
Ceiling(Single)	Returns the smallest integral value that is greater than or equal to the specified single-precision floating-point number.
CopySign(Single, Single)	Returns a value with the magnitude of `x` and the sign of `y`.
Cos(Single)	Returns the cosine of the specified angle.
Cosh(Single)	Returns the hyperbolic cosine of the specified angle.
Exp(Single)	Returns `e` raised to the specified power.
Floor(Single)	Returns the largest integral value less than or equal to the specified single-precision floating-point number.
FusedMultiplyAdd(Single, Single, Single)	Returns (x * y) + z, rounded as one ternary operation.
IEEERemainder(Single, Single)	Returns the remainder resulting from the division of a specified number by another specified number.
ILogB(Single)	Returns the base 2 integer logarithm of a specified number.
Log(Single)	Returns the natural (base `e`) logarithm of a specified number.

Log(Single, Single)	Returns the logarithm of a specified number in a specified base.
Log10(Single)	Returns the base 10 logarithm of a specified number.
Log2(Single)	Returns the base 2 logarithm of a specified number.
Max(Single, Single)	Returns the larger of two single-precision floating-point numbers.
MaxMagnitude(Single, Single)	Returns the larger magnitude of two single-precision floating-point numbers.
Min(Single, Single)	Returns the smaller of two single-precision floating-point numbers.
MinMagnitude(Single, Single)	Returns the smaller magnitude of two single-precision floating-point numbers.
Pow(Single, Single)	Returns a specified number raised to the specified power.
ReciprocalEstimate(Single)	Returns an estimate of the reciprocal of a specified number.
ReciprocalSqrt Estimate(Single)	Returns an estimate of the reciprocal square root of a specified number.
Round(Single)	Rounds a single-precision floating-point value to the nearest integral value, and rounds midpoint values to the nearest even number.
Round(Single, Int32)	Rounds a single-precision floating-point value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.
Round(Single, Int32, Midpoint Rounding)	Rounds a single-precision floating-point value to a specified number of fractional digits using the specified rounding convention.
Round(Single, Midpoint Rounding)	Rounds a single-precision floating-point value to an integer using the specified rounding convention.
ScaleB(Single, Int32)	Returns x * 2^n computed efficiently.
Sign(Single)	Returns an integer that indicates the sign of a single-precision floating-point number.
Sin(Single)	Returns the sine of the specified angle.
SinCos(Single)	Returns the sine and cosine of the specified angle.
Sinh(Single)	Returns the hyperbolic sine of the specified angle.
Sqrt(Single)	Returns the square root of a specified number.

Tan(Single)	Returns the tangent of the specified angle.
Tanh(Single)	Returns the hyperbolic tangent of the specified angle.
Truncate(Single)	Calculates the integral part of a specified single-precision floating-point number.

Applies to

Product	Versions

MathF.Abs(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the absolute value of a single-precision floating-point number.

C#

```
public static float Abs (float x);
```

Parameters

x Single

A number that is greater than or equal to Single.MinValue, but less than or equal to Single.MaxValue.

Returns

Single

A single-precision floating-point number, x, such that 0 ≤ x ≤ Single.MaxValue.

Remarks

The absolute value of a Single is its numeric value without its sign. For example, the absolute value of both 1.2e-03 and -1.2e03 is 1.2e03.

If `x` is equal to NegativeInfinity or PositiveInfinity, the return value is PositiveInfinity. If `x` is equal to NaN, the return value is NaN.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

MathF.Acos(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose cosine is the specified number.

C#

```
public static float Acos (float x);
```

Parameters

x Single

A number representing a cosine, where `x` must be greater than or equal to -1, but less than or equal to 1.

Returns

Single

An angle, θ, measured in radians, such that 0 ≤ θ ≤ π.

-or-

NaN if `x` < -1 or `x` > 1 or `x` equals NaN.

Remarks

Multiply the return value by 180/MathF.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

MathF.Acosh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose hyperbolic cosine is the specified number.

```
C#
public static float Acosh (float x);
```

Parameters

x Single

A number representing a hyperbolic cosine, where `x` must be greater than or equal to 1, but less than or equal to PositiveInfinity.

Returns

Single

An angle, θ, measured in radians, such that 0 ≤ θ ≤ ∞.

-or-

NaN if `x` < 1 or `x` equals NaN.

Remarks

Multiply the return value by 180/MathF.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

MathF.Asin(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose sine is the specified number.

C#

```
public static float Asin (float x);
```

Parameters

x Single

A number representing a sine, where `x` must be greater than or equal to -1, but less than or equal to 1.

Returns

Single

An angle, θ, measured in radians, such that -π/2 ≤ θ ≤ π/2.

-or-

NaN if `x` < -1 or `x` > 1 or `x` equals NaN.

Remarks

A positive return value represents a counterclockwise angle from the x-axis; a negative return value represents a clockwise angle.

Multiply the return value by 180/MathF.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Asinh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose hyperbolic sine is the specified number.

C#

```
public static float Asinh (float x);
```

Parameters

x Single

A number representing a hyperbolic sine, where `x` must be greater than or equal to NegativeInfinity, but less than or equal to PositiveInfinity.

Returns

Single

An angle, θ, measured in radians.

-or-

NaN if `x` equals NaN.

Remarks

Multiply the return value by 180/MathF.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

MathF.Atan(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose tangent is the specified number.

```
C#
public static float Atan (float x);
```

Parameters

x Single

A number representing a tangent.

Returns

Single

An angle, θ, measured in radians, such that -π/2 ≤ θ ≤ π/2.

-or-

NaN if `x` equals NaN, -π/2 rounded to double precision (-1.5707963267949) if `x` equals NegativeInfinity, or π/2 rounded to double precision (1.5707963267949) if `x` equals PositiveInfinity.

Remarks

A positive return value represents a counterclockwise angle from the x-axis; a negative return value represents a clockwise angle.

Multiply the return value by 180/MathF.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Atan2(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose tangent is the quotient of two specified numbers.

```
C#
public static float Atan2 (float y, float x);
```

Parameters

y Single

The y coordinate of a point.

x Single

The x coordinate of a point.

Returns

Single

An angle, θ, measured in radians, such that -π ≤ θ ≤ π, and tan(θ) = `y` / `x`, where (`x`, `y`) is a point in the Cartesian plane. Observe the following:

- For (`x`, `y`) in quadrant 1, 0 < θ < π/2.
- For (`x`, `y`) in quadrant 2, π/2 < θ ≤ π.
- For (`x`, `y`) in quadrant 3, -π < θ < -π/2.
- For (`x`, `y`) in quadrant 4, -π/2 < θ < 0.

For points on the boundaries of the quadrants, the return value is the following:

- If y is 0 and x is not negative, θ = 0.
- If y is 0 and x is negative, θ = π.

- If y is positive and x is 0, θ = π/2.
- If y is negative and x is 0, θ = -π/2.
- If y is 0 and x is 0, θ = 0.

If `x` or `y` is NaN, or if `x` and `y` are either PositiveInfinity or NegativeInfinity, the method returns NaN.

Remarks

The return value is the angle in the Cartesian plane formed by the x-axis, and a vector starting from the origin, (0,0), and terminating at the point, (x,y).

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Atanh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the angle whose hyperbolic tangent is the specified number.

```
C#
public static float Atanh (float x);
```

Parameters

x Single

A number representing a hyperbolic tangent, where `x` must be greater than or equal to -1, but less than or equal to 1.

Returns

Single

An angle, θ, measured in radians, such that -∞ < θ <-1, or 1 < θ < ∞.

-or-

NaN if `x` < -1 or `x` > 1 or `x` equals NaN.

Remarks

Multiply the return value by 180/MathF.PI to convert from radians to degrees.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.BitDecrement(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the largest value that compares less than a specified value.

```
C#
public static float BitDecrement (float x);
```

Parameters

x Single

The value to decrement.

Returns

Single

The largest value that compares less than `x`.

-or-

NegativeInfinity if `x` is equals NegativeInfinity.

-or-

NaN if `x` equals NaN.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

MathF.BitIncrement(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smallest value that compares greater than a specified value.

```
C#
public static float BitIncrement (float x);
```

Parameters

x Single

The value to increment.

Returns

Single

The smallest value that compares greater than `x`.

-or-

PositiveInfinity if `x` equals PositiveInfinity.

-or-

NaN if `x` is equals NaN.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

MathF.Cbrt(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the cube root of a specified number.

```
C#
public static float Cbrt (float x);
```

Parameters

x Single

The number whose cube root is to be found.

Returns

Single

The cube root of `x`.

-or-

NaN if `x` is equals NaN.

Remarks

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

MathF.Ceiling(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smallest integral value that is greater than or equal to the specified single-precision floating-point number.

```C#
public static float Ceiling (float x);
```

Parameters

x Single

A single-precision floating-point number.

Returns

Single

The smallest integral value that is greater than or equal to `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, that value is returned. Note that this method returns a Single instead of an integral type.

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward positive infinity. In other words, if `x` is positive, the presence of any fractional component causes `x` to be rounded to the next highest integer. If `x` is negative, the rounding operation causes any fractional component of `x` to be discarded. The operation of this method differs from the Floor(Single) method, which supports rounding toward negative infinity.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Cos(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the cosine of the specified angle.

```
C#
public static float Cos (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

Single

The cosine of `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Remarks

The angle, `x`, must be in radians. Multiply by MathF.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

MathF.Cosh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hyperbolic cosine of the specified angle.

C#

```
public static float Cosh (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

Single

The hyperbolic cosine of `x`. If `x` is equal to NegativeInfinity or PositiveInfinity, PositiveInfinity is returned. If `x` is equal to NaN, NaN is returned.

Remarks

The angle, `x`, must be in radians. Multiply by MathF.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

MathF.Exp(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns `e` raised to the specified power.

```
C#
public static float Exp (float x);
```

Parameters

x Single

A number specifying a power.

Returns

Single

The number `e` raised to the power `x`. If `x` equals NaN or PositiveInfinity, that value is returned. If `x` equals NegativeInfinity, 0 is returned.

Remarks

`e` is a mathematical constant whose value is approximately 2.71828.

Use the Pow method to calculate powers of other bases.

Exp is the inverse of Log.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Floor(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the largest integral value less than or equal to the specified single-precision floating-point number.

```
C#
public static float Floor (float x);
```

Parameters

x Single

A single-precision floating-point number.

Returns

Single

The largest integral value less than or equal to `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, that value is returned.

Remarks

The behavior of this method follows IEEE Standard 754, section 4. This kind of rounding is sometimes called rounding toward negative infinity. In other words, if `x` is positive, any fractional component is truncated. If `x` is negative, the presence of any fractional component causes it to be rounded to the smaller integer. The operation of this method differs from the Ceiling method, which supports rounding toward positive infinity.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.FusedMultiplyAdd(Single, Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns (x * y) + z, rounded as one ternary operation.

```
C#
public static float FusedMultiplyAdd (float x, float y, float z);
```

Parameters

x Single

The number to be multiplied with `y`.

y Single

The number to be multiplied with `x`.

z Single

The number to be added to the result of `x` multiplied by `y`.

Returns

Single

(x * y) + z, rounded as one ternary operation.

Remarks

This computes `(x * y)` as if to infinite precision, adds `z` to that result as if to infinite precision, and finally rounds to the nearest representable value.

This differs from the non-fused sequence which would compute `(x * y)` as if to infinite preicision, round the result to the nearest representable value, add 'z' to the rounded

result as if to infinite precision, and finally round to the nearest representable value.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.IEEERemainder(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the remainder resulting from the division of a specified number by another specified number.

```
C#
public static float IEEERemainder (float x, float y);
```

Parameters

x Single

A dividend.

y Single

A divisor.

Returns

Single

A number equal to `x` - (`y` Q), where Q is the quotient of `x` / `y` rounded to the nearest integer (if `x` / `y` falls halfway between two integers, the even integer is returned).

If `x` - (`y` Q) is zero, the value +0 is returned if `x` is positive, or -0 if `x` is negative.

If `y` = 0, NaN is returned.

Remarks

This operation complies with the remainder operation defined in Section 5.1 of ANSI/IEEE Std 754-1985; IEEE Standard for Binary Floating-Point Arithmetic; Institute of

Electrical and Electronics Engineers, Inc; 1985.

The IEEERemainder method is not the same as the remainder operator. Although both return the remainder after division, the formulas they use are different. The formula for the IEEERemainder method is:

```
IEEERemainder = dividend - (divisor * MathF.Round(dividend / divisor))
```

In contrast, the formula for the remainder operator is:

```
Remainder = (MathF.Abs(dividend) - (MathF.Abs(divisor) *
            (MathF.Floor(MathF.Abs(dividend) / MathF.Abs(divisor))))) *
            MathF.Sign(dividend)
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.ILogB(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the base 2 integer logarithm of a specified number.

C#

```
public static int ILogB (float x);
```

Parameters

x Single

The number whose logarithm is to be found.

Returns

Int32

One of the values in the following table.

Expand table

`x` parameter	Return value
Default	The base 2 integer log of `x`; that is, (int)log2(`x`).
Zero	Int32.MinValue
Equal to NaN or PositiveInfinity or NegativeInfinity	Int32.MaxValue

Remarks

Parameter `x` is specified as a base 10 number.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.Log Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Log(Single)	Returns the natural (base `e`) logarithm of a specified number.
Log(Single, Single)	Returns the logarithm of a specified number in a specified base.

Log(Single)

Returns the natural (base `e`) logarithm of a specified number.

C#

```
public static float Log (float x);
```

Parameters

x Single

The number whose logarithm is to be found.

Returns

Single

One of the values in the following table.

Expand table

`x` parameter	Return value
Positive	The natural logarithm of `x`; that is, ln `x`, or log e `x`

`x` parameter	Return value
Zero	NegativeInfinity
Negative	NaN
Equal to NaN	NaN
Equal to PositiveInfinity	PositiveInfinity

Remarks

Parameter `x` is specified as a base 10 number.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Log(Single, Single)

Returns the logarithm of a specified number in a specified base.

C#

```
public static float Log (float x, float y);
```

Parameters

x Single

The number whose logarithm is to be found.

y Single

The base.

Returns

Single

One of the values in the following table. (+Infinity denotes PositiveInfinity, -Infinity denotes NegativeInfinity, and NaN denotes NaN.)

Expand table

x	newBase	Return value
x > 0	(0 < newBase < 1) -or-(newBase > 1)	lognewBase(a)
x < 0	(any value)	NaN
(any value)	newBase < 0	NaN
x != 1	newBase = 0	NaN
x != 1	newBase = +Infinity	NaN
x = NaN	(any value)	NaN
(any value)	newBase = NaN	NaN
(any value)	newBase = 1	NaN
x = 0	0 < newBase < 1	+Infinity
x = 0	newBase > 1	-Infinity
x = +Infinity	0 < newBase < 1	-Infinity
x = +Infinity	newBase > 1	+Infinity
x = 1	newBase = 0	0
x = 1	newBase = +Infinity	0

Remarks

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

MathF.Log10(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the base 10 logarithm of a specified number.

C#

```
public static float Log10 (float x);
```

Parameters

x Single

A number whose logarithm is to be found.

Returns

Single

One of the values in the following table.

Expand table

`x` parameter	Return value
Positive	The base 10 log of `x`; that is, log 10`x`.
Zero	NegativeInfinity
Negative	NaN
Equal to NaN	NaN
Equal to PositiveInfinity	PositiveInfinity

Remarks

Parameter `x` is specified as a base 10 number.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions

MathF.Log2(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the base 2 logarithm of a specified number.

C#

```
public static float Log2 (float x);
```

Parameters

x Single

A number whose logarithm is to be found.

Returns

Single

One of the values in the following table.

Expand table

`x` parameter	Return value
Positive	The base 2 log of `x`; that is, log 2`x`.
Zero	NegativeInfinity
Negative	NaN
Equal to NaN	NaN
Equal to PositiveInfinity	PositiveInfinity

Remarks

Parameter `x` is specified as a base 10 number.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

MathF.Max(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the larger of two single-precision floating-point numbers.

C#

```
public static float Max (float x, float y);
```

Parameters

x Single

The first of two single-precision floating-point numbers to compare.

y Single

The second of two single-precision floating-point numbers to compare.

Returns

Single

Parameter `x` or `y`, whichever is larger. If `x`, or `y`, or both `x` and `y` are equal to NaN, NaN is returned.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.MaxMagnitude(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the larger magnitude of two single-precision floating-point numbers.

C#

```
public static float MaxMagnitude (float x, float y);
```

Parameters

x Single

The first of two single-precision floating-point numbers to compare.

y Single

The second of two single-precision floating-point numbers to compare.

Returns

Single

Parameter `x` or `y`, whichever has the larger magnitude. If `x`, or `y`, or both `x` and `y` are equal to NaN, NaN is returned.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.Min(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the smaller of two single-precision floating-point numbers.

C#

```
public static float Min (float x, float y);
```

Parameters

x Single

The first of two single-precision floating-point numbers to compare.

y Single

The second of two single-precision floating-point numbers to compare.

Returns

Single

Parameter `x` or `y`, whichever is smaller. If `x`, `y`, or both `x` and `y` are equal to NaN, NaN is returned.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Pow(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a specified number raised to the specified power.

C#

```
public static float Pow (float x, float y);
```

Parameters

x Single

A single-precision floating-point number to be raised to a power.

y Single

A single-precision floating-point number that specifies a power.

Returns

Single

The number `x` raised to the power `y`.

Remarks

The following table indicates the return value when various values or ranges of values are specified for the `x` and `y` parameters. For more information, see Single.PositiveInfinity, Single.NegativeInfinity, and Single.NaN.

Expand table

Parameters	Return value
`x` is any value; `y` = 0.	1
`x` = 1; `y` is any value.	1

Parameters	Return value
`x` or `y` = `NaN` (except if `y` = 0 or `x` = 1).	`NaN`
`x` = `NegativeInfinity`; `y` < 0.	0
`x` = `NegativeInfinity`; `y` is a positive odd integer.	`NegativeInfinity`
`x` = `NegativeInfinity`; `y` is positive but not an odd integer.	`PositiveInfinity`
`x` < 0 but not `NegativeInfinity`; `y` is not an integer, `NegativeInfinity`, or `PositiveInfinity`.	`NaN`
`x` = -1; `y` = `NegativeInfinity` or `PositiveInfinity`.	`NaN`
-1 < `x` < 1; `y` = `NegativeInfinity`.	`PositiveInfinity`
-1 < `x` < 1; `y` = `PositiveInfinity`.	0
`x` < -1 or `x` > 1; `y` = `NegativeInfinity`.	0
`x` < -1 or `x` > 1; `y` = `PositiveInfinity`.	`PositiveInfinity`
`x` = 0; `y` < 0.	`PositiveInfinity`
`x` = 0; `y` > 0.	0
`x` = `PositiveInfinity`; `y` < 0.	0
`x` = `PositiveInfinity`; `y` > 0.	`PositiveInfinity`

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.ReciprocalEstimate(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an estimate of the reciprocal of a specified number.

```
C#
public static float ReciprocalEstimate (float x);
```

Parameters

x Single

The number whose reciprocal is to be estimated.

Returns

Single

An estimate of the reciprocal of `x`.

Remarks

On x86/x64 hardware this may use the `RCPSS` instruction which has a maximum relative error of `1.5 * 2^-12`.

On ARM64 hardware this may use the `FRECPE` instruction which performs a single Newton-Raphson iteration.

On hardware without specialized support, this may just return `1.0 / x`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

MathF.ReciprocalSqrtEstimate(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an estimate of the reciprocal square root of a specified number.

```
C#
public static float ReciprocalSqrtEstimate (float x);
```

Parameters

x Single

The number whose reciprocal square root is to be estimated.

Returns

Single

An estimate of the reciprocal square root `x`.

Remarks

On x86/x64 hardware this may use the `RSQRTSS` instruction which has a maximum relative error of `1.5 * 2^-12`.

On ARM64 hardware this may use the `FRSQRTE` instruction which performs a single Newton-Raphson iteration.

On hardware without specialized support, this may just return `1.0 / Sqrt(x)`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

MathF.Round Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Round(Single, Int32, MidpointRounding)	Rounds a single-precision floating-point value to a specified number of fractional digits using the specified rounding convention.
Round(Single, MidpointRounding)	Rounds a single-precision floating-point value to an integer using the specified rounding convention.
Round(Single)	Rounds a single-precision floating-point value to the nearest integral value, and rounds midpoint values to the nearest even number.
Round(Single, Int32)	Rounds a single-precision floating-point value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.

Round(Single, Int32, MidpointRounding)

Rounds a single-precision floating-point value to a specified number of fractional digits using the specified rounding convention.

C#

```
public static float Round (float x, int digits, MidpointRounding mode);
```

Parameters

x Single

A single-precision floating-point number to be rounded.

`digits` Int32

The number of fractional digits in the return value.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Single

The number that `x` is rounded to that has `digits` fractional digits. If `x` has fewer fractional digits than `digits`, `x` is returned unchanged.

Exceptions

ArgumentOutOfRangeException

`digits` is less than 0 or greater than 6.

ArgumentException

`mode` is not a valid value of MidpointRounding.

Remarks

The value of the `digits` argument can range from 0 to 6. The maximum number of integral and fractional digits supported by the Single type is 6.

> ⓘ **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `x` argument is Single.NaN, the method returns Single.NaN. If `x` is Single.PositiveInfinity or Single.NegativeInfinity, the method returns Single.PositiveInfinity or Single.NegativeInfinity, respectively.

See also

- Ceiling(Single)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Round(Single, MidpointRounding)

Rounds a single-precision floating-point value to an integer using the specified rounding convention.

C#

```
public static float Round (float x, MidpointRounding mode);
```

Parameters

`x` Single

A single-precision floating-point number to be rounded.

`mode` MidpointRounding

One of the enumeration values that specifies which rounding strategy to use.

Returns

Single

The integer that `x` is rounded to using the `mode` rounding convention. This method returns a Single instead of an integral type.

Exceptions

ArgumentException

`mode` is not a valid value of MidpointRounding.

Remarks

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `x` argument is Single.NaN, the method returns Single.NaN. If `x` is Single.PositiveInfinity or Single.NegativeInfinity, the method returns Single.PositiveInfinity or Single.NegativeInfinity, respectively.

- Ceiling(Single)
- Floor(Single)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Round(Single)

Rounds a single-precision floating-point value to the nearest integral value, and rounds midpoint values to the nearest even number.

C#

```
public static float Round (float x);
```

Parameters

x Single

A single-precision floating-point number to be rounded.

Returns

Single

The integer nearest `x`. If the fractional component of `x` is halfway between two integers, one of which is even and the other odd, then the even number is returned. Note that this method returns a Single instead of an integral type.

Remarks

This method uses the default rounding convention of MidpointRounding.ToEven.

> ⓘ **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `x` argument is Single.NaN, the method returns Single.NaN. If `x` is Single.PositiveInfinity or Single.NegativeInfinity, the method returns Single.PositiveInfinity or Single.NegativeInfinity, respectively.

Notes to Callers

Because of the loss of precision that can result from representing decimal values as floating-point numbers or performing arithmetic operations on floating-point values, in some cases the Round(Single) method may not appear to round midpoint values to the nearest even integer.

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Round(Single, Int32)

Rounds a single-precision floating-point value to a specified number of fractional digits, and rounds midpoint values to the nearest even number.

C#

```
public static float Round (float x, int digits);
```

Parameters

`x` Single

A single-precision floating-point number to be rounded.

`digits` Int32

The number of fractional digits in the return value.

Returns

Single

The number nearest to `x` that contains a number of fractional digits equal to `digits`.

Exceptions

ArgumentOutOfRangeException

`digits` is less than 0 or greater than 6.

Remarks

The value of the `digits` argument can range from 0 to 6. Note that 6 is the maximum number of integral and fractional digits supported by the Single type.

This method uses the default rounding convention of MidpointRounding.ToEven.

> **Important**
>
> When rounding midpoint values, the rounding algorithm performs an equality test. Because of problems of binary representation and precision in the floating-point format, the value returned by the method can be unexpected. For more information, see **Rounding and precision**.

If the value of the `x` argument is Single.NaN, the method returns Single.NaN. If `x` is Single.PositiveInfinity or Single.NegativeInfinity, the method returns Single.PositiveInfinity or Single.NegativeInfinity, respectively.

MathF.ScaleB(Single, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns x * 2^n computed efficiently.

C#

```
public static float ScaleB (float x, int n);
```

Parameters

x Single

A single-precision floating-point number that specifies the base value.

n Int32

A single-precision floating-point number that specifies the power.

Returns

Single

x * 2^n computed efficiently.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.Sign(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an integer that indicates the sign of a single-precision floating-point number.

C#

```
public static int Sign (float x);
```

Parameters

x Single

A signed number.

Returns

Int32

A number that indicates the sign of `x`, as shown in the following table.

Expand table

Return value	Meaning
-1	`x` is less than zero.
0	`x` is equal to zero.
1	`x` is greater than zero.

Exceptions

ArithmeticException

`x` is equal to NaN.

Remarks

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MathF.Sin(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the sine of the specified angle.

C#

```
public static float Sin (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

Single

The sine of `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Remarks

The angle, `x`, must be in radians. Multiply by MathF.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

MathF.SinCos(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the sine and cosine of the specified angle.

```
C#
public static (float Sin, float Cos) SinCos (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

ValueTuple<Single,Single>

The sine and cosine of `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Remarks

The angle, `x`, must be in radians. Multiply by Math.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	6, 7, 8, 9

MathF.Sinh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hyperbolic sine of the specified angle.

C#

```
public static float Sinh (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

Single

The hyperbolic sine of `x`. If `x` is equal to NegativeInfinity, PositiveInfinity, or NaN, this method returns a Single equal to `x`.

Remarks

The angle, `x`, must be in radians. Multiply by MathF.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.Sqrt(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the square root of a specified number.

C#

```
public static float Sqrt (float x);
```

Parameters

x Single

The number whose square root is to be found.

Returns

Single

One of the values in the following table.

Expand table

`x` parameter	Return value
Zero or positive	The positive square root of `x`.
Negative	NaN
Equals NaN	NaN
Equals PositiveInfinity	PositiveInfinity

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

MathF.Tan(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the tangent of the specified angle.

```
C#
public static float Tan (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

Single

The tangent of `x`. If `x` is equal to NaN, NegativeInfinity, or PositiveInfinity, this method returns NaN.

Remarks

The angle, `x`, must be in radians. Multiply by MathF.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MathF.Tanh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hyperbolic tangent of the specified angle.

```
C#
public static float Tanh (float x);
```

Parameters

x Single

An angle, measured in radians.

Returns

Single

The hyperbolic tangent of `x`. If `x` is equal to NegativeInfinity, this method returns -1. If value is equal to PositiveInfinity, this method returns 1. If `x` is equal to NaN, this method returns NaN.

Remarks

The angle, `x`, must be in radians. Multiply by MathF.PI/180 to convert degrees to radians.

This method calls into the underlying C runtime, and the exact result or valid input range may differ between different operating systems or architectures.

Applies to

Product	Versions

MathF.Truncate(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the integral part of a specified single-precision floating-point number.

C#

```
public static float Truncate (float x);
```

Parameters

x Single

A number to truncate.

Returns

Single

The integral part of `x`; that is, the number that remains after any fractional digits have been discarded, or one of the values listed in the following table.

Expand table

x	Return value
NaN	NaN
NegativeInfinity	NegativeInfinity
PositiveInfinity	PositiveInfinity

Remarks

Truncate rounds `x` to the nearest integer towards zero.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemberAccessException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an attempt to access a class member fails.

```
C#
public class MemberAccessException : SystemException
```

Inheritance Object → Exception → SystemException → MemberAccessException

Derived System.FieldAccessException
System.MethodAccessException
System.MissingMemberException

Remarks

MemberAccessException is the base class for FieldAccessException, MethodAccessException, MissingMemberException, MissingMethodException, and MissingFieldException, and (.NET Native only). These exceptions are thrown when a class member is not found or access to the member is not permitted.

MemberAccessException is thrown by the following methods:

Invoke of the System.Reflection classes, GetValue of the FieldInfo class, and DynamicInvoke of the Delegate class.

Apps compiled by using the .NET Native tool chain may throw a MissingRuntimeArtifactException exception at run time. `MissingRuntimeArtifactException` is an internal-only exception type derived from MemberAccessException. The exception indicates that metadata needed for the successful execution of an app is not present at run time. You should not use a `try`/`catch` block to handle the exception. Instead, you should determine what metadata is missing and modify your app's runtime directives file to ensure that it is present at run time.

MemberAccessException uses the HRESULT COR_E_MEMBERACCESS, that has the value 0x8013151A.

For a list of initial property values for an instance of MemberAccessException, see the MemberAccessException constructors.

Constructors

Expand table

MemberAccessException()	Initializes a new instance of the MemberAccessException class.
MemberAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MemberAccessException class with serialized data.
MemberAccessException(String)	Initializes a new instance of the MemberAccessException class with a specified error message.
MemberAccessException(String, Exception)	Initializes a new instance of the MemberAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error.

	(Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception.

(Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MemberAccessException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MemberAccessException class.

Overloads

Expand table

MemberAccessException()	Initializes a new instance of the MemberAccessException class.
MemberAccessException(String)	Initializes a new instance of the MemberAccessException class with a specified error message.
MemberAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MemberAccessException class with serialized data.
MemberAccessException(String, Exception)	Initializes a new instance of the MemberAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

MemberAccessException()

Initializes a new instance of the MemberAccessException class.

C#

```
public MemberAccessException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Cannot access member." This message takes into account the current system culture.

The following table shows the initial property values for an instance of MemberAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MemberAccessException(String)

Initializes a new instance of the MemberAccessException class with a specified error message.

C#

```
public MemberAccessException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of `message` should be understood by the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of MemberAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MemberAccessException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the MemberAccessException class with serialized data.

```C#
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected MemberAccessException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MemberAccessException(String, Exception)

Initializes a new instance of the MemberAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public MemberAccessException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of MemberAccessException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

See also

- Exception

- Handling and Throwing Exceptions

Memory<T> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a contiguous region of memory.

```
C#
public readonly struct Memory<T> : IEquatable<Memory<T>>
```

Type Parameters

T

The type of items in the Memory<T>.

Inheritance Object → ValueType → Memory<T>

Implements IEquatable<Memory<T>>

Remarks

Like Span<T>, `Memory<T>` represents a contiguous region of memory. Unlike Span<T>, however, `Memory<T>` is not a ref struct. This means that `Memory<T>` can be placed on the managed heap, whereas Span<T> cannot. As a result, the `Memory<T>` structure does not have the same restrictions as a Span<T> instance. In particular:

- It can be used as a field in a class.
- It can be used across `await` and `yield` boundaries.

In addition to `Memory<T>`, you can use System.ReadOnlyMemory<T> to represent immutable or read-only memory.

Constructors

Expand table

Memory<T>(T[])	Creates a new Memory<T> object over the entirety of a specified array.
Memory<T>(T[], Int32, Int32)	Creates a new Memory<T> object that includes a specified number of elements of an array beginning at a specified index.

Properties

Expand table

Empty	Returns an empty Memory<T> object.
IsEmpty	Indicates whether the current instance is empty.
Length	Gets the number of items in the current instance.
Span	Returns a span from the current instance.

Methods

Expand table

CopyTo(Memory<T>)	Copies the contents of a Memory<T> object into a destination Memory<T> object.
Equals(Memory<T>)	Determines whether the specified Memory<T> object is equal to the current object.
Equals(Object)	Determines whether the specified object is equal to the current object.
GetHashCode()	Returns the hash code for this instance.
Pin()	Creates a handle for the Memory<T> object.
Slice(Int32)	Forms a slice out of the current memory that begins at a specified index.
Slice(Int32, Int32)	Forms a slice out of the current memory starting at a specified index for a specified length.
ToArray()	Copies the contents from the memory into a new array.
ToString()	Returns the string representation of this Memory<T> object.
TryCopy To(Memory<T>)	Copies the contents of the memory into a destination Memory<T> instance.

Operators

Expand table

Implicit(ArraySegment<T> to Memory<T>)	Defines an implicit conversion of an ArraySegment<T> object to a Memory<T> object.
Implicit(Memory<T> to ReadOnlyMemory<T>)	Defines an implicit conversion of a Memory<T> object to a ReadOnlyMemory<T> object.
Implicit(T[] to Memory<T>)	Defines an implicit conversion of an array to a Memory<T> object.

Extension Methods

Expand table

Trim<T>(Memory<T>, T)	Removes all leading and trailing occurrences of a specified element from a memory region.
Trim<T>(Memory<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a memory region.
TrimEnd<T>(Memory<T>, T)	Removes all trailing occurrences of a specified element from a character memory region.
TrimEnd<T>(Memory<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a memory region.
TrimStart<T>(Memory<T>, T)	Removes all leading occurrences of a specified element from a memory region.
TrimStart<T>(Memory<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Memory<T>(T[])	Creates a new Memory<T> object over the entirety of a specified array.
Memory<T>(T[], Int32, Int32)	Creates a new Memory<T> object that includes a specified number of elements of an array beginning at a specified index.

Memory<T>(T[])

Creates a new Memory<T> object over the entirety of a specified array.

C#

```
public Memory (T[]? array);
```

Parameters

array T[]

The array from which to create the Memory<T> object.

Exceptions

ArrayTypeMismatchException

`T` is a reference type, and `array` is not an array of type `T`.

-or-

The array is covariant.

Remarks

If `array` is `null`, this constructor returns a Memory<T> object with a `default<T>` value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T>(T[], Int32, Int32)

Creates a new Memory<T> object that includes a specified number of elements of an array beginning at a specified index.

```
C#

public Memory (T[]? array, int start, int length);
```

Parameters

`array` T[]

The source array.

`start` Int32

The index of the first element to include in the new Memory<T>.

`length` Int32

The number of elements to include in the new Memory<T>.

Exceptions

ArgumentOutOfRangeException

`array` is `null`, but `start` or `length` is non-zero.

-or-

`start` is outside the bounds of the array.

-or-

`start` and `length` exceeds the number of elements in the array.

ArrayTypeMismatchException

`T` is a reference type, and `array` is not an array of type `T`.

Remarks

If `array` is `null`, this constructor returns a Memory<T> object with a `default<T>` value.

Applies to

▼ .NET 9 and other versions

Memory<T>.Empty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an empty Memory<T> object.

C#

```
public static Memory<T> Empty { get; }
```

Property Value

Memory<T>

An empty object.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T>.IsEmpty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the current instance is empty.

C#

```
public bool IsEmpty { get; }
```

Property Value

Boolean

`true` if the current instance is empty; otherwise, `false`.

Remarks

A Memory<T> object is empty if its length is 0.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of items in the current instance.

C#

```
public int Length { get; }
```

Property Value

Int32

The number of items in the current instance.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.Span Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a span from the current instance.

```
C#
public Span<T> Span { get; }
```

Property Value

Span<T>

A span created from the current Memory<T> object.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.CopyTo(Memory<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of a Memory<T> object into a destination Memory<T> object.

```
C#
public void CopyTo (Memory<T> destination);
```

Parameters

destination Memory<T>

The destination Memory<T> object.

Exceptions

ArgumentException

The length of `destination` is less than the length of the current instance.

Remarks

This method copies all of the contents of the current Memory<T> instance to `destination` even if the contents of the current instance and `destination` overlap.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Memory<T>)	Determines whether the specified Memory<T> object is equal to the current object.
Equals(Object)	Determines whether the specified object is equal to the current object.

Equals(Memory<T>)

Determines whether the specified Memory<T> object is equal to the current object.

C#

```
public bool Equals (Memory<T> other);
```

Parameters

`other` Memory<T>

The object to compare with the current instance.

Returns

Boolean

`true` if the current instance and `other` are equal; otherwise, `false`.

Implements

Equals(T)

Remarks

The two objects are equal if:

- `other` is a Memory<T> or ReadOnlyMemory<T> object.
- Both objects point to the same array and have the same length.

The `Equals(Memory<T>)` method performs a test for reference equality; it does not compare the elements of Memory<T> for equality.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Equals(Object)

Determines whether the specified object is equal to the current object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare with the current instance.

Returns

Boolean

`true` if the current instance and `obj` are equal; otherwise, `false`.

Remarks

Two Memory<T> objects are equal if both objects point to the same array and have the same length. Note that the test for equality does not check whether the contents are equal.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.Pin Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a handle for the Memory<T> object.

```
C#
public System.Buffers.MemoryHandle Pin ();
```

Returns

MemoryHandle

A handle for the Memory<T> object.

Exceptions

ArgumentException

An instance with non-primitive (non-blittable) members cannot be pinned.

Remarks

The garbage collector will not move the memory until the returned MemoryHandle object is disposed. This enables you to retrieve and use the memory's address.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T>.Slice Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Slice(Int32)	Forms a slice out of the current memory that begins at a specified index.
Slice(Int32, Int32)	Forms a slice out of the current memory starting at a specified index for a specified length.

Slice(Int32)

Forms a slice out of the current memory that begins at a specified index.

C#

```
public Memory<T> Slice (int start);
```

Parameters

`start` Int32

The index at which to begin the slice.

Returns

Memory<T>

An object that contains all elements of the current instance from `start` to the end of the instance.

Exceptions

ArgumentOutOfRangeException

`start` is less than zero or greater than Length.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Slice(Int32, Int32)

Forms a slice out of the current memory starting at a specified index for a specified length.

```
C#
public Memory<T> Slice (int start, int length);
```

Parameters

`start` Int32

The index at which to begin the slice.

`length` Int32

The number of elements to include in the slice.

Returns

Memory<T>

An object that contains `length` elements from the current instance starting at `start`.

Exceptions

ArgumentOutOfRangeException

`start` is less than zero or greater than Length.

-or-

`length` is greater than Length - `start`

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T>.ToArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents from the memory into a new array.

C#

```
public T[] ToArray ();
```

Returns

T[]

An array containing the elements in the current memory.

Remarks

Because a call to the `ToArray` method performs a heap allocation, it should generally be avoided. However, it is sometimes necessary to take advantage of functionality that is only available for arrays.

Each call to the `ToArray` method returns a new array.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of this Memory<T> object.

C#

```
public override string ToString ();
```

Returns

String

the string representation of this Memory<T> object.

Remarks

For a `Memory<Char>`, the `ToString` method returns a String that contains the characters pointed to by the Memory<T>. Otherwise, it returns a String with the name of the type and the number of elements that the Memory<T> contains.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Memory<T>.TryCopyTo(Memory<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of the memory into a destination Memory<T> instance.

C#

```
public bool TryCopyTo (Memory<T> destination);
```

Parameters

destination Memory<T>

The destination Memory<T> object.

Returns

Boolean

`true` if the copy operation succeeds; otherwise, `false`.

Remarks

This method copies all of the contents of the current Memory<T> instance to `destination` even if the contents of the current instance and `destination` overlap.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Memory<T>.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(T[] to Memory<T>)	Defines an implicit conversion of an array to a Memory<T> object.
Implicit(ArraySegment<T> to Memory<T>)	Defines an implicit conversion of an ArraySegment<T> object to a Memory<T> object.
Implicit(Memory<T> to ReadOnlyMemory<T>)	Defines an implicit conversion of a Memory<T> object to a ReadOnlyMemory<T> object.

Implicit(T[] to Memory<T>)

Defines an implicit conversion of an array to a Memory<T> object.

C#

```
public static implicit operator Memory<T> (T[]? array);
```

Parameters

`array` T[]

The array to convert.

Returns

Memory<T>

The converted object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Implicit(ArraySegment<T> to Memory<T>)

Defines an implicit conversion of an ArraySegment<T> object to a Memory<T> object.

```
C#

public static implicit operator Memory<T> (ArraySegment<T> segment);
```

Parameters

`segment` ArraySegment<T>

The object to convert.

Returns

Memory<T>

The converted ArraySegment<T> object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Implicit(Memory<T> to ReadOnlyMemory<T>)

Defines an implicit conversion of a Memory<T> object to a ReadOnlyMemory<T> object.

```
C#

public static implicit operator ReadOnlyMemory<T> (Memory<T> memory);
```

Parameters

`memory` Memory<T>

The object to convert.

Returns

ReadOnlyMemory<T>

The converted object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

MemoryExtensions Class

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Provides extension methods for the memory-related and span-related types, such as Memory<T>, ReadOnlyMemory<T>, Span<T>, and ReadOnlySpan<T>.

C#

```
public static class MemoryExtensions
```

Inheritance Object → MemoryExtensions

Methods

Expand table

AsMemory(String)	Creates a new `ReadOnlyMemory<Char>` over the portion of the target string.
AsMemory(String, Index)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified index.
AsMemory(String, Int32)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified character position.
AsMemory(String, Int32, Int32)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string beginning at a specified position with a length.
AsMemory(String, Range)	Creates a new `ReadOnlyMemory<Char>` over a specified range of the target string.
AsMemory<T>(ArraySegment<T>)	Creates a new memory region over the portion of the target array segment.

AsMemory<T>(ArraySegment<T>, Int32)	Creates a new memory region over the portion of the target array segment starting at a specified position to the end of the segment.
AsMemory<T>(ArraySegment<T>, Int32, Int32)	Creates a new memory region over the portion of the target array segment beginning at a specified position with a specified length.
AsMemory<T>(T[])	Creates a new memory region over the target array.
AsMemory<T>(T[], Index)	Creates a new memory region over the portion of the target array starting at a specified index to the end of the array.
AsMemory<T>(T[], Int32)	Creates a new memory region over the portion of the target array starting at a specified position to the end of the array.
AsMemory<T>(T[], Int32, Int32)	Creates a new memory region over the portion of the target array beginning at a specified position with a specified length.
AsMemory<T>(T[], Range)	Creates a new memory region over the portion of the target array beginning at inclusive start index of the range and ending at the exclusive end index of the range.
AsSpan(String)	Creates a new read-only span over a string.
AsSpan(String, Index)	Creates a new ReadOnlySpan<T> over a portion of the target string from a specified position to the end of the string.
AsSpan(String, Int32)	Creates a new read-only span over a portion of the target string from a specified position to the end of the string.
AsSpan(String, Int32, Int32)	Creates a new read-only span over a portion of the target string from a specified position for a specified number of characters.
AsSpan(String, Range)	Creates a new ReadOnlySpan<T> over a portion of a target string using the range start and end indexes.
AsSpan<T>(ArraySegment<T>)	Creates a new span over a target array segment.
AsSpan<T>(ArraySegment<T>, Index)	Creates a new span over a portion of the target array segment beginning at a specified

	index and ending at the end of the segment.
AsSpan<T>(ArraySegment<T>, Int32)	Creates a new span over a portion of a target array segment from a specified position to the end of the segment.
AsSpan<T>(ArraySegment<T>, Int32, Int32)	Creates a new span over a portion of a target array segment from a specified position for a specified length.
AsSpan<T>(ArraySegment<T>, Range)	Creates a new span over a portion of a target array segment using the range start and end indexes.
AsSpan<T>(T[])	Creates a new span over a target array.
AsSpan<T>(T[], Index)	Creates a new span over the portion of the target array defined by an Index value.
AsSpan<T>(T[], Int32)	Creates a new span over a portion of the target array starting at a specified position to the end of the array.
AsSpan<T>(T[], Int32, Int32)	Creates a new span over the portion of the target array beginning at a specified position for a specified length.
AsSpan<T>(T[], Range)	Creates a new span over a portion of a target array defined by a Range value.
BinarySearch<T,TComparable>(ReadOnlySpan<T>, TComparable)	Searches an entire sorted ReadOnlySpan<T> for a value using the specified `TComparable` generic type.
BinarySearch<T,TComparable>(Span<T>, TComparable)	Searches an entire sorted Span<T> for a value using the specified `TComparable` generic type.
BinarySearch<T,TComparer>(ReadOnlySpan<T>, T, TComparer)	Searches an entire sorted ReadOnlySpan<T> for a specified value using the specified `TComparer` generic type.
BinarySearch<T,TComparer>(Span<T>, T, TComparer)	Searches an entire sorted Span<T> for a specified value using the specified `TComparer` generic type.
BinarySearch<T>(ReadOnlySpan<T>, IComparable<T>)	Searches an entire sorted ReadOnlySpan<T> for a value using the specified IComparable<T> generic interface.
BinarySearch<T>(Span<T>, IComparable<T>)	Searches an entire sorted Span<T> for a value using the specified IComparable<T> generic interface.

CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Finds the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>)	Finds the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Finds the length of any common prefix shared between `span` and `other`.
CompareTo(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Compares one character span with another using a specified string comparison, and returns an integer that indicates their relative position in the sort order.
Contains(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Indicates whether a specified value occurs within a read-only character span.
Contains<T>(ReadOnlySpan<T>, T)	Indicates whether a specified value is found in a read-only span. Values are compared using IEquatable{T}.Equals(T).
Contains<T>(Span<T>, T)	Indicates whether a specified value is found in a span. Values are compared using IEquatable{T}.Equals(T).
ContainsAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, T, T)	Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, SearchValues<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If

	not found, returns `false`.
ContainsAny<T>(Span<T>, T, T)	Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, T, T, T)	Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for any value other than the specified `value`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for any value other than `value0` or `value1`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for any value other than `value0`, `value1`, or `value2`.
ContainsAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(Span<T>, T)	Searches for any value other than the specified `value`.
ContainsAnyExcept<T>(Span<T>, T, T)	Searches for any value other than `value0` or `value1`.
ContainsAnyExcept<T>(Span<T>, T, T, T)	Searches for any value other than `value0`, `value1`, or `value2`.
ContainsAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
ContainsAnyExceptInRange<T>(Span<T>, T, T)	Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
ContainsAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for any value in the range between `lowInclusive` and `highInclusive`, inclusive,

	and returns `true` if found. If not found, returns `false`.
ContainsAnyInRange<T>(Span<T>, T, T)	Searches for any value in the range between `lowInclusive` and `highInclusive`, inclusive, and returns `true` if found. If not found, returns `false`.
CopyTo<T>(T[], Memory<T>)	Copies the contents of the array into a memory region.
CopyTo<T>(T[], Span<T>)	Copies the contents of the array into the span.
Count<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Counts the number of times `value` occurs in `span`.
Count<T>(ReadOnlySpan<T>, T)	Counts the number of times the specified `value` occurs in the `span`.
Count<T>(Span<T>, ReadOnlySpan<T>)	Counts the number of times the specified `value` occurs in the `span`.
Count<T>(Span<T>, T)	Counts the number of times the specified `value` occurs in the `span`.
EndsWith(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Determines whether the end of the `span` matches the specified `value` when compared using the specified `comparisonType` option.
EndsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether the specified sequence appears at the end of a read-only span.
EndsWith<T>(Span<T>, ReadOnlySpan<T>)	Determines whether the specified sequence appears at the end of a span.
EnumerateLines(ReadOnlySpan<Char>)	Returns an enumeration of lines over the provided span.
EnumerateLines(Span<Char>)	Returns an enumeration of lines over the provided span.
EnumerateRunes(ReadOnlySpan<Char>)	Returns an enumeration of Rune from the provided read-only span.
EnumerateRunes(Span<Char>)	Returns an enumeration of Rune from the provided span.
Equals(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Determines whether this `span` and the specified `other` span have the same characters when compared using the specified `comparisonType` option.

IndexOf(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Reports the zero-based index of the first occurrence of the specified `value` in the current `span`.
IndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(ReadOnlySpan<T>, T)	Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(Span<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(Span<T>, T)	Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the first index of any of the specified values.
IndexOfAny<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, SearchValues<T>)	Searches for the first index of any of the specified values.
IndexOfAny<T>(Span<T>, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, T, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

IndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for the first index of any value other than the specified `value`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value other than the specified `value0` or `value1`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.
IndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(Span<T>, T)	Searches for the first index of any value other than the specified `value`.
IndexOfAnyExcept<T>(Span<T>, T, T)	Searches for the first index of any value other than the specified `value0` or `value1`.
IndexOfAnyExcept<T>(Span<T>, T, T, T)	Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.
IndexOfAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
IndexOfAnyExceptInRange<T>(Span<T>, T, T)	Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
IndexOfAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
IndexOfAnyInRange<T>(Span<T>, T, T)	Searches for the first index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
IsWhiteSpace(ReadOnlySpan<Char>)	Indicates whether the specified span contains only whitespace characters.
LastIndexOf(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Reports the zero-based index of the last occurrence of the specified `value` in the

	current `span`.
LastIndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(ReadOnlySpan<T>, T)	Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(Span<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(Span<T>, T)	Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the last index of any of the specified values.
LastIndexOfAny<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, SearchValues<T>)	Searches for the last index of any of the specified values.
LastIndexOfAny<T>(Span<T>, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, T, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the last index of any value other than the specified `values`.

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for the last index of any value other than the specified `value`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value other than the specified `value0` or `value1`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.
LastIndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(Span<T>, T)	Searches for the last index of any value other than the specified `value`.
LastIndexOfAnyExcept<T>(Span<T>, T, T)	Searches for the last index of any value other than the specified `value0` or `value1`.
LastIndexOfAnyExcept<T>(Span<T>, T, T, T)	Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.
LastIndexOfAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyExceptInRange<T>(Span<T>, T, T)	Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyInRange<T>(Span<T>, T, T)	Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether two read-only sequences overlap in memory.
Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, Int32)	Determines whether two read-only sequences overlap in memory and outputs the element offset.

Overlaps<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a span and a read-only span overlap in memory.
Overlaps<T>(Span<T>, ReadOnlySpan<T>, Int32)	Determines whether a span and a read-only span overlap in memory and outputs the element offset.
Replace<T>(ReadOnlySpan<T>, Span<T>, T, T)	Copies `source` to `destination`, replacing all occurrences of `oldValue` with `newValue`.
Replace<T>(Span<T>, T, T)	Replaces all occurrences of `oldValue` with `newValue`.
Reverse<T>(Span<T>)	Reverses the sequence of the elements in the entire span.
SequenceCompareTo<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines the relative order of two read-only sequences by comparing their elements using IComparable{T}.CompareTo(T).
SequenceCompareTo<T>(Span<T>, ReadOnlySpan<T>)	Determines the relative order of a span and a read-only span by comparing the elements using IComparable{T}.CompareTo(T).
SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether two read-only sequences are equal by comparing the elements using IEquatable{T}.Equals(T).
SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.
SequenceEqual<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a span and a read-only span are equal by comparing the elements using IEquatable{T}.Equals(T).
SequenceEqual<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.
Sort<T,TComparer>(Span<T>, TComparer)	Sorts the elements in the entire Span<T> using the `TComparer`.
Sort<T>(Span<T>)	Sorts the elements in the entire Span<T> using the IComparable<T> implementation of each element of the Span<T>.
Sort<T>(Span<T>, Comparison<T>)	Sorts the elements in the entire Span<T> using the specified Comparison<T>.
Sort<TKey,TValue,TComparer>(Span<TKey>, Span<TValue>, TComparer)	Sorts a pair of spans (one containing the keys and the other containing the corresponding

	items) based on the keys in the first Span<T> using the specified comparer.
Sort<TKey,TValue>(Span<TKey>, Span<TValue>)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the IComparable<T> implementation of each key.
Sort<TKey,TValue>(Span<TKey>, Span<TValue>, Comparison<TKey>)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparison.
Split(ReadOnlySpan<Char>, Span<Range>, Char, StringSplitOptions)	Parses the source ReadOnlySpan<T> for the specified `separator`, populating the `destination` span with Range instances representing the regions between the separators.
Split(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<Char>, StringSplitOptions)	Parses the source ReadOnlySpan<T> for the specified `separator`, populating the `destination` span with Range instances representing the regions between the separators.
SplitAny(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<Char>, StringSplitOptions)	Parses the source ReadOnlySpan<T> for one of the specified `separators`, populating the `destination` span with Range instances representing the regions between the separators.
SplitAny(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<String>, StringSplitOptions)	Parses the source ReadOnlySpan<T> for one of the specified `separators`, populating the `destination` span with Range instances representing the regions between the separators.
StartsWith(ReadOnlySpan<Char>, ReadOnly Span<Char>, StringComparison)	Determines whether a read-only character span begins with a specified value when compared using a specified StringComparison value.
StartsWith<T>(ReadOnlySpan<T>, ReadOnly Span<T>)	Determines whether a specified sequence appears at the start of a read-only span.
StartsWith<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a specified sequence appears at the start of a span.
ToLower(ReadOnlySpan<Char>, Span<Char>, CultureInfo)	Copies the characters from the source span into the destination, converting each character

	to lowercase, using the casing rules of the specified culture.
ToLowerInvariant(ReadOnlySpan<Char>, Span<Char>)	Copies the characters from the source span into the destination, converting each character to lowercase, using the casing rules of the invariant culture.
ToUpper(ReadOnlySpan<Char>, Span<Char>, CultureInfo)	Copies the characters from the source span into the destination, converting each character to uppercase, using the casing rules of the specified culture.
ToUpperInvariant(ReadOnlySpan<Char>, Span<Char>)	Copies the characters from the source span into the destination, converting each character to uppercase using the casing rules of the invariant culture.
Trim(Memory<Char>)	Removes all leading and trailing whitespace characters from a character memory region.
Trim(ReadOnlyMemory<Char>)	Removes all leading and trailing whitespace characters from a read-only character memory region.
Trim(ReadOnlySpan<Char>)	Removes all leading and trailing whitespace characters from a read-only character span.
Trim(ReadOnlySpan<Char>, Char)	Removes all leading and trailing occurrences of a specified character from a read-only character span.
Trim(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Removes all leading and trailing occurrences of a set of characters specified in a read-only span from a read-only character span.
Trim(Span<Char>)	Removes all leading and trailing whitespace characters from a character span.
Trim<T>(Memory<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a memory region.
Trim<T>(Memory<T>, T)	Removes all leading and trailing occurrences of a specified element from a memory region.
Trim<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.
Trim<T>(ReadOnlyMemory<T>, T)	Removes all leading and trailing occurrences of a specified element from a read-only

	memory region.
Trim<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only span.
Trim<T>(ReadOnlySpan<T>, T)	Removes all leading and trailing occurrences of a specified element from a read-only span.
Trim<T>(Span<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a span.
Trim<T>(Span<T>, T)	Removes all leading and trailing occurrences of a specified element from a span.
TrimEnd(Memory<Char>)	Removes all trailing whitespace characters from a character memory region.
TrimEnd(ReadOnlyMemory<Char>)	Removes all trailing whitespace characters from a read-only character memory region.
TrimEnd(ReadOnlySpan<Char>)	Removes all trailing whitespace characters from a read-only character span.
TrimEnd(ReadOnlySpan<Char>, Char)	Removes all trailing occurrences of a specified character from a read-only span.
TrimEnd(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Removes all trailing occurrences of a set of characters specified in a read-only span from a read-only character span.
TrimEnd(Span<Char>)	Removes all trailing whitespace characters from a character span.
TrimEnd<T>(Memory<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a memory region.
TrimEnd<T>(Memory<T>, T)	Removes all trailing occurrences of a specified element from a character memory region.
TrimEnd<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.
TrimEnd<T>(ReadOnlyMemory<T>, T)	Removes all trailing occurrences of a specified element from a read-only memory region.
TrimEnd<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only span.

TrimEnd<T>(ReadOnlySpan<T>, T)	Removes all trailing occurrences of a specified element from a read-only span.
TrimEnd<T>(Span<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a span.
TrimEnd<T>(Span<T>, T)	Removes all trailing occurrences of a specified element from a span.
TrimStart(Memory<Char>)	Removes all leading whitespace characters from a memory region.
TrimStart(ReadOnlyMemory<Char>)	Removes all leading whitespace characters from a read-only memory region.
TrimStart(ReadOnlySpan<Char>)	Removes all leading whitespace characters from a read-only span.
TrimStart(ReadOnlySpan<Char>, Char)	Removes all leading occurrences of a specified character from the span.
TrimStart(ReadOnlySpan<Char>, ReadOnly Span<Char>)	Removes all leading occurrences of a set of characters specified in a read-only span from the span.
TrimStart(Span<Char>)	Removes all leading whitespace characters from a span.
TrimStart<T>(Memory<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.
TrimStart<T>(Memory<T>, T)	Removes all leading occurrences of a specified element from a memory region.
TrimStart<T>(ReadOnlyMemory<T>, ReadOnly Span<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.
TrimStart<T>(ReadOnlyMemory<T>, T)	Removes all leading occurrences of a specified element from a memory region.
TrimStart<T>(ReadOnlySpan<T>, ReadOnly Span<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from the span.
TrimStart<T>(ReadOnlySpan<T>, T)	Removes all leading occurrences of a specified element from the span.
TrimStart<T>(Span<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from

	the span.
TrimStart<T>(Span<T>, T)	Removes all leading occurrences of a specified element from the span.
TryWrite(Span<Char>, IFormatProvider, CompositeFormat, Int32, Object[])	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite(Span<Char>, IFormatProvider, CompositeFormat, Int32, ReadOnlySpan<Object>)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite(Span<Char>, IFormatProvider, MemoryExtensions+TryWriteInterpolatedStringHandler, Int32)	Writes the specified interpolated string to the character span.
TryWrite(Span<Char>, MemoryExtensions+TryWriteInterpolatedStringHandler, Int32)	Writes the specified interpolated string to the character span.
TryWrite<TArg0,TArg1,TArg2>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0, TArg1, TArg2)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite<TArg0,TArg1>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0, TArg1)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite<TArg0>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.AsMemory Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

AsMemory(String)	Creates a new `ReadOnlyMemory<Char>` over the portion of the target string.
AsMemory(String, Index)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified index.
AsMemory(String, Int32)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified character position.
AsMemory(String, Range)	Creates a new `ReadOnlyMemory<Char>` over a specified range of the target string.
AsMemory(String, Int32, Int32)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string beginning at a specified position with a length.
AsMemory<T>(ArraySegment<T>)	Creates a new memory region over the portion of the target array segment.
AsMemory<T>(T[])	Creates a new memory region over the target array.
AsMemory<T>(ArraySegment<T>, Int32)	Creates a new memory region over the portion of the target array segment starting at a specified position to the end of the segment.
AsMemory<T>(T[], Index)	Creates a new memory region over the portion of the target array starting at a specified index to the end of the array.
AsMemory<T>(T[], Int32)	Creates a new memory region over the portion of the target array starting at a specified position to the end of the array.
AsMemory<T>(T[], Range)	Creates a new memory region over the portion of the target array beginning at inclusive start index of the range and ending at the exclusive end index of the range.

AsMemory<T> (ArraySegment<T>, Int32, Int32)	Creates a new memory region over the portion of the target array segment beginning at a specified position with a specified length.
AsMemory<T>(T[], Int32, Int32)	Creates a new memory region over the portion of the target array beginning at a specified position with a specified length.

AsMemory(String)

Creates a new `ReadOnlyMemory<Char>` over the portion of the target string.

```
C#
public static ReadOnlyMemory<char> AsMemory (this string? text);
```

Parameters

`text` String

The target string.

Returns

ReadOnlyMemory<Char>

The read-only character memory representation of the string, or `default` if `text` is `null`.

Remarks

Returns default when `text` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory(String, Index)

Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified index.

C#

```
public static ReadOnlyMemory<char> AsMemory (this string? text, Index
startIndex);
```

Parameters

`text` String

The target string.

`startIndex` Index

The index at which to begin this slice.

Returns

ReadOnlyMemory<Char>

The read-only character memory representation of the string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory(String, Int32)

Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified character position.

C#

```
public static ReadOnlyMemory<char> AsMemory (this string? text, int
start);
```

Parameters

`text` String

The target string.

`start` Int32

The index at which to begin this slice.

Returns

ReadOnlyMemory<Char>

The read-only character memory representation of the string, or `default` if `text` is `null`.

Exceptions

ArgumentOutOfRangeException

`start` is not in the range of `text` (`start` is < 0 or > `text.Length`).

Remarks

Returns default when `text` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory(String, Range)

Creates a new `ReadOnlyMemory<Char>` over a specified range of the target string.

```
C#

public static ReadOnlyMemory<char> AsMemory (this string? text, Range
range);
```

Parameters

`text` String

The target string.

`range` Range

The range that indicates the start and length of the sliced string.

Returns

ReadOnlyMemory<Char>

The read-only character memory representation of the string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory(String, Int32, Int32)

Creates a new `ReadOnlyMemory<Char>` over a portion of the target string beginning at a specified position with a length.

```
C#

public static ReadOnlyMemory<char> AsMemory (this string? text, int
start, int length);
```

Parameters

`text` String

The target string.

`start` Int32

The index at which to begin this slice.

`length` Int32

The desired length for the slice.

Returns

ReadOnlyMemory<Char>

The read-only character memory representation of the string, or `default` if `text` is `null`.

Exceptions

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` is not in the range of `text`.

Remarks

Returns default when `text` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(ArraySegment<T>)

Creates a new memory region over the portion of the target array segment.

C#

```
public static Memory<T> AsMemory<T> (this ArraySegment<T> segment);
```

Type Parameters

`T`

The type of the segment.

Parameters

`segment` ArraySegment<T>

The segment to convert.

Returns

Memory<T>

The memory representation of the segment.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(T[])

Creates a new memory region over the target array.

C#

```
public static Memory<T> AsMemory<T> (this T[]? array);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The array to convert.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(ArraySegment<T>, Int32)

Creates a new memory region over the portion of the target array segment starting at a specified position to the end of the segment.

C#

```
public static Memory<T> AsMemory<T> (this ArraySegment<T> segment, int
start);
```

Type Parameters

`T`

The type of the array.

Parameters

`segment` ArraySegment<T>

The target array segment.

`start` Int32

The index at which to begin the memory.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Exceptions

ArrayTypeMismatchException

`segment` is covariant, and the type of `segment` is not exactly `T[]`.

ArgumentOutOfRangeException

`start` is less than 0 or greater than `segment.Count`.

Remarks

Returns `default` when `segment` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(T[], Index)

Creates a new memory region over the portion of the target array starting at a specified index to the end of the array.

C#

```
public static Memory<T> AsMemory<T> (this T[]? array, Index startIndex);
```

Type Parameters

T

The type of the array.

Parameters

`array` T[]

The array to convert.

`startIndex` Index

The first position of the array.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(T[], Int32)

Creates a new memory region over the portion of the target array starting at a specified position to the end of the array.

C#

```
public static Memory<T> AsMemory<T> (this T[]? array, int start);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The target array.

`start` Int32

The index at which to begin the memory.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Exceptions

ArrayTypeMismatchException

`array` is covariant, and the array's type is not exactly `T[]`.

ArgumentOutOfRangeException

`start` index less than 0 or greater than `array.Length`.

Remarks

Returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(T[], Range)

Creates a new memory region over the portion of the target array beginning at inclusive start index of the range and ending at the exclusive end index of the range.

```
C#
public static Memory<T> AsMemory<T> (this T[]? array, Range range);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The array to convert.

`range` Range

The range to convert from the array.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(ArraySegment<T>, Int32, Int32)

Creates a new memory region over the portion of the target array segment beginning at a specified position with a specified length.

C#

```
public static Memory<T> AsMemory<T> (this ArraySegment<T> segment, int
start, int length);
```

Type Parameters

`T`

The type of the array.

Parameters

`segment` ArraySegment<T>

The target array segment.

`start` Int32

The index at which to begin the memory.

`length` Int32

The number of items in the memory.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Exceptions

ArrayTypeMismatchException

`segment` is covariant, and the array's type is not exactly `T[]`.

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` is not in the range of `segment`.

Remarks

Returns `default` when `segment` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsMemory<T>(T[], Int32, Int32)

Creates a new memory region over the portion of the target array beginning at a specified position with a specified length.

```
C#

public static Memory<T> AsMemory<T> (this T[]? array, int start, int
length);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The target array.

`start` Int32

The index at which to begin the memory region.

`length` Int32

The number of items in the memory region.

Returns

Memory<T>

The memory representation of the whole or part of the array.

Exceptions

ArrayTypeMismatchException

`array` is covariant, and the array's type is not exactly `T[]`.

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` is not in the range of `array`.

Remarks

Returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.AsSpan Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

AsSpan(String, Int32, Int32)	Creates a new read-only span over a portion of the target string from a specified position for a specified number of characters.
AsSpan(String, Range)	Creates a new ReadOnlySpan<T> over a portion of a target string using the range start and end indexes.
AsSpan(String, Int32)	Creates a new read-only span over a portion of the target string from a specified position to the end of the string.
AsSpan(String, Index)	Creates a new ReadOnlySpan<T> over a portion of the target string from a specified position to the end of the string.
AsSpan(String)	Creates a new read-only span over a string.
AsSpan<T> (ArraySegment<T>)	Creates a new span over a target array segment.
AsSpan<T>(T[])	Creates a new span over a target array.
AsSpan<T> (ArraySegment<T>, Index)	Creates a new span over a portion of the target array segment beginning at a specified index and ending at the end of the segment.
AsSpan<T> (ArraySegment<T>, Int32)	Creates a new span over a portion of a target array segment from a specified position to the end of the segment.
AsSpan<T> (ArraySegment<T>, Range)	Creates a new span over a portion of a target array segment using the range start and end indexes.
AsSpan<T>(T[], Index)	Creates a new span over the portion of the target array defined by an Index value.
AsSpan<T>(T[], Int32)	Creates a new span over a portion of the target array starting at a specified position to the end of the array.

AsSpan<T>(T[], Range)	Creates a new span over a portion of a target array defined by a Range value.
AsSpan<T>(ArraySegment<T>, Int32, Int32)	Creates a new span over a portion of a target array segment from a specified position for a specified length.
AsSpan<T>(T[], Int32, Int32)	Creates a new span over the portion of the target array beginning at a specified position for a specified length.

AsSpan(String, Int32, Int32)

Creates a new read-only span over a portion of the target string from a specified position for a specified number of characters.

C#

```
public static ReadOnlySpan<char> AsSpan (this string? text, int start,
int length);
```

Parameters

`text` String

The target string.

`start` Int32

The index at which to begin this slice.

`length` Int32

The desired length for the slice.

Returns

ReadOnlySpan<Char>

The read-only span representation of the string.

Exceptions

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` is not in the range of `text`.

Remarks

Returns `default` when `text` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan(String, Range)

Creates a new ReadOnlySpan<T> over a portion of a target string using the range start and end indexes.

C#

```
public static ReadOnlySpan<char> AsSpan (this string? text, Range range);
```

Parameters

`text` String

The target string.

`range` Range

The range that has start and end indexes to use for slicing the string.

Returns

ReadOnlySpan<Char>

Exceptions

ArgumentNullException

`text` is `null`.

ArgumentOutOfRangeException

`range`'s start or end index is not within the bounds of the string.

ArgumentOutOfRangeException

`range`'s start index is greater than its end index.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

AsSpan(String, Int32)

Creates a new read-only span over a portion of the target string from a specified position to the end of the string.

```
C#

public static ReadOnlySpan<char> AsSpan (this string? text, int start);
```

Parameters

`text` String

The target string.

`start` Int32

The index at which to begin this slice.

Returns

ReadOnlySpan<Char>

The read-only span representation of the string.

Exceptions

ArgumentOutOfRangeException

`start` is less than 0 or greater than `text.Length`.

ArgumentNullException

Thrown when `text` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan(String, Index)

Creates a new ReadOnlySpan<T> over a portion of the target string from a specified position to the end of the string.

```
C#

public static ReadOnlySpan<char> AsSpan (this string? text, Index
startIndex);
```

Parameters

`text` String

The target string.

`startIndex` Index

The index at which to begin this slice.

Returns

ReadOnlySpan<Char>

Exceptions

ArgumentOutOfRangeException

`startIndex` is less than 0 or greater than `text`.Length.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

AsSpan(String)

Creates a new read-only span over a string.

```
C#
public static ReadOnlySpan<char> AsSpan (this string? text);
```

Parameters

`text` String

The target string.

Returns

ReadOnlySpan<Char>

The read-only span representation of the string.

Remarks

Returns `default` when `text` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(ArraySegment<T>)

Creates a new span over a target array segment.

```
C#
public static Span<T> AsSpan<T> (this ArraySegment<T> segment);
```

Type Parameters

`T`

The type of the array segment.

Parameters

`segment` ArraySegment<T>

The array segment to convert.

Returns

Span<T>

The span representation of the array segment.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(T[])

Creates a new span over a target array.

```
C#
public static Span<T> AsSpan<T> (this T[]? array);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The array to convert.

Returns

Span<T>

The span representation of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(ArraySegment<T>, Index)

Creates a new span over a portion of the target array segment beginning at a specified index and ending at the end of the segment.

C#

```
public static Span<T> AsSpan<T> (this ArraySegment<T> segment, Index
startIndex);
```

Type Parameters

`T`

The type of the array segment.

Parameters

`segment` ArraySegment<T>

The target array segment.

`startIndex` Index

The index at which to begin the Span.

Returns

Span<T>

The span representation of the array segment.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(ArraySegment<T>, Int32)

Creates a new span over a portion of a target array segment from a specified position to the end of the segment.

C#

```
public static Span<T> AsSpan<T> (this ArraySegment<T> segment, int
start);
```

Type Parameters

`T`

The type of the array segment.

Parameters

`segment` ArraySegment<T>

The target array segment.

`start` Int32

The index at which to begin the san.

Returns

Span<T>

The span representation of the array segment.

Exceptions

ArrayTypeMismatchException

`segment` is covariant, and the array's type is not exactly `T[]`.

ArgumentOutOfRangeException

`start` is less than 0 or greater than `segment.Count`.

Remarks

Returns `default` when `segment` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(ArraySegment<T>, Range)

Creates a new span over a portion of a target array segment using the range start and end indexes.

C#

```
public static Span<T> AsSpan<T> (this ArraySegment<T> segment, Range
range);
```

Type Parameters

`T`

The type of the array segment.

Parameters

`segment` ArraySegment<T>

The target array segment.

`range` Range

The range which has start and end indexes to use for slicing the array.

Returns

Span<T>

The span representation of the array segment.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(T[], Index)

Creates a new span over the portion of the target array defined by an Index value.

C#

```
public static Span<T> AsSpan<T> (this T[]? array, Index startIndex);
```

Type Parameters

`T`

The array type.

Parameters

`array` T[]

The array to convert.

`startIndex` Index

The starting index.

Returns

Span<T>

The span representation of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(T[], Int32)

Creates a new span over a portion of the target array starting at a specified position to the end of the array.

```
C#

public static Span<T> AsSpan<T> (this T[]? array, int start);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The array to convert.

`start` Int32

The initial index from which the array will be converted.

Returns

Span<T>

The span representation of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(T[], Range)

Creates a new span over a portion of a target array defined by a Range value.

```
C#

public static Span<T> AsSpan<T> (this T[]? array, Range range);
```

Type Parameters

`T`

The type of the array.

Parameters

`array` T[]

The array to convert.

`range` Range

The range of the array to convert.

Returns

Span<T>

The span representation of the array.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(ArraySegment<T>, Int32, Int32)

Creates a new span over a portion of a target array segment from a specified position for a specified length.

C#

```
public static Span<T> AsSpan<T> (this ArraySegment<T> segment, int start,
int length);
```

Type Parameters

`T`

The type of the array segment.

Parameters

`segment` ArraySegment<T>

The target array segment.

`start` Int32

The index at which to begin the span.

`length` Int32

The number of items in the span.

Returns

Span<T>

The span representation of the array.

Exceptions

ArrayTypeMismatchException

`segment` is covariant, and the array's type is not exactly `T[]`.

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` is not in the range of `segment`.

Remarks

Returns `default` when `segment` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

AsSpan<T>(T[], Int32, Int32)

Creates a new span over the portion of the target array beginning at a specified position for a specified length.

C#

```
public static Span<T> AsSpan<T> (this T[]? array, int start, int length);
```

Type Parameters

T

The type of the array.

Parameters

`array` T[]

The target array.

`start` Int32

The index at which to begin the span.

`length` Int32

The number of items in the span.

Returns

Span<T>

The span representation of the array.

Exceptions

ArrayTypeMismatchException

`array` is covariant, and the array's type is not exactly `T[]`".

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` is not in the range of `array`.

Remarks

Returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.BinarySearch Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

BinarySearch<T,TComparable> (ReadOnlySpan<T>, TComparable)	Searches an entire sorted ReadOnlySpan<T> for a value using the specified `TComparable` generic type.
BinarySearch<T,TComparable>(Span<T>, TComparable)	Searches an entire sorted Span<T> for a value using the specified `TComparable` generic type.
BinarySearch<T,TComparer>(Span<T>, T, TComparer)	Searches an entire sorted Span<T> for a specified value using the specified `TComparer` generic type.
BinarySearch<T,TComparer> (ReadOnlySpan<T>, T, TComparer)	Searches an entire sorted ReadOnlySpan<T> for a specified value using the specified `TComparer` generic type.
BinarySearch<T>(ReadOnlySpan<T>, IComparable<T>)	Searches an entire sorted ReadOnlySpan<T> for a value using the specified IComparable<T> generic interface.
BinarySearch<T>(Span<T>, IComparable<T>)	Searches an entire sorted Span<T> for a value using the specified IComparable<T> generic interface.

BinarySearch<T,TComparable> (ReadOnlySpan<T>, TComparable)

Searches an entire sorted ReadOnlySpan<T> for a value using the specified `TComparable` generic type.

```
C#
```

```
public static int BinarySearch<T,TComparable> (this ReadOnlySpan<T> span,
TComparable comparable) where TComparable : IComparable<T>;
```

Type Parameters

`T`

The element type of the span.

`TComparable`

The specific type of IComparable<T>.

Parameters

`span` ReadOnlySpan<T>

The sorted ReadOnlySpan<T> to search.

`comparable` TComparable

The `TComparable` to use when comparing.

Returns

Int32

The zero-based index of `comparable` in the sorted `span`, if `comparable` is found; otherwise, a negative number that is the bitwise complement of the index of the next element that is larger than `comparable` or, if there is no larger element, the bitwise complement of Length.

Exceptions

ArgumentNullException

`comparable` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

BinarySearch<T,TComparable>(Span<T>, TComparable)

Searches an entire sorted Span<T> for a value using the specified `TComparable` generic type.

C#

```
public static int BinarySearch<T,TComparable> (this Span<T> span,
TComparable comparable) where TComparable : IComparable<T>;
```

Type Parameters

`T`

The element type of the span.

`TComparable`

The specific type of IComparable<T>.

Parameters

`span` Span<T>

The sorted Span<T> to search.

`comparable` TComparable

The `TComparable` to use when comparing.

Returns

Int32

The zero-based index of `comparable` in the sorted `span`, if `comparable` is found; otherwise, a negative number that is the bitwise complement of the index of the next element that is larger than `comparable` or, if there is no larger element, the bitwise complement of Length.

Exceptions

ArgumentNullException

`comparable` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

BinarySearch<T,TComparer>(Span<T>, T, TComparer)

Searches an entire sorted Span<T> for a specified value using the specified `TComparer` generic type.

C#

```
public static int BinarySearch<T,TComparer> (this Span<T> span, T value,
TComparer comparer) where TComparer :
System.Collections.Generic.IComparer<T>;
```

Type Parameters

`T`

The element type of the span.

`TComparer`

The specific type of IComparer<T>.

Parameters

`span` Span<T>

The sorted Span<T> to search.

`value` T

The object to locate. The value can be `null` for reference types.

`comparer` TComparer

The `TComparer` to use when comparing.

Returns

Int32

The zero-based index of `value` in the sorted `span`, if `value` is found; otherwise, a negative number that is the bitwise complement of the index of the next element that is larger than `value` or, if there is no larger element, the bitwise complement of Length.

Exceptions

ArgumentNullException

`comparer` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

BinarySearch<T,TComparer> (ReadOnlySpan<T>, T, TComparer)

Searches an entire sorted ReadOnlySpan<T> for a specified value using the specified `TComparer` generic type.

C#

```
public static int BinarySearch<T,TComparer> (this ReadOnlySpan<T> span, T
value, TComparer comparer) where TComparer :
System.Collections.Generic.IComparer<T>;
```

Type Parameters

`T`

The element type of the span.

`TComparer`

The specific type of IComparer<T>.

Parameters

`span` ReadOnlySpan<T>

The sorted ReadOnlySpan<T> to search.

`value` T

The object to locate. The value can be `null` for reference types.

`comparer` TComparer

The `TComparer` to use when comparing.

Returns

Int32

The zero-based index of `value` in the sorted `span`, if `value` is found; otherwise, a negative number that is the bitwise complement of the index of the next element that is larger than `value` or, if there is no larger element, the bitwise complement of Length.

Exceptions

ArgumentNullException

`comparer` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

BinarySearch<T>(ReadOnlySpan<T>, IComparable<T>)

Searches an entire sorted ReadOnlySpan<T> for a value using the specified IComparable<T> generic interface.

```
C#

public static int BinarySearch<T> (this ReadOnlySpan<T> span,
IComparable<T> comparable);
```

Type Parameters

T

The element type of the span.

Parameters

span ReadOnlySpan<T>

The sorted ReadOnlySpan<T> to search.

comparable IComparable<T>

The IComparable<T> to use when comparing.

Returns

Int32

The zero-based index of `comparable` in the sorted `span`, if `comparable` is found; otherwise, a negative number that is the bitwise complement of the index of the next element that is larger than `comparable` or, if there is no larger element, the bitwise complement of Length.

Exceptions

ArgumentNullException

`comparable` is `null`.

BinarySearch<T>(Span<T>, IComparable<T>)

Searches an entire sorted Span<T> for a value using the specified IComparable<T> generic interface.

C#

```
public static int BinarySearch<T> (this Span<T> span, IComparable<T>
comparable);
```

Type Parameters

T

The element type of the span.

Parameters

span Span<T>

The sorted Span<T> to search.

comparable IComparable<T>

The IComparable<T> to use when comparing.

Returns

Int32

The zero-based index of `comparable` in the sorted `span`, if `comparable` is found; otherwise, a negative number that is the bitwise complement of the index of the next element that is larger than `comparable` or, if there is no larger element, the bitwise complement of Length.

MemoryExtensions.CommonPrefixLength Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Finds the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>)	Finds the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Finds the length of any common prefix shared between `span` and `other`.

CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Finds the length of any common prefix shared between `span` and `other`.

C#

```
public static int CommonPrefixLength<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other);
```

Type Parameters

T

The type of the elements in the spans.

Parameters

`span` ReadOnlySpan<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

Returns

Int32

The length of the common prefix shared by the two spans. If there's no shared prefix, 0 is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>)

Finds the length of any common prefix shared between `span` and `other`.

C#

```
public static int CommonPrefixLength<T> (this Span<T> span,
ReadOnlySpan<T> other);
```

Type Parameters

`T`

The type of the elements in the spans.

Parameters

`span` Span<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

Returns

Int32

The length of the common prefix shared by the two spans. If there's no shared prefix, 0 is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)

Determines the length of any common prefix shared between `span` and `other`.

C#

```
public static int CommonPrefixLength<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other, System.Collections.Generic.IEqualityComparer<T>?
comparer);
```

Type Parameters

`T`

The type of the elements in the sequences.

Parameters

`span` ReadOnlySpan<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

`comparer` IEqualityComparer<T>

The IEqualityComparer<T> implementation to use when comparing elements, or `null` to use the default IEqualityComparer<T> for the type of an element.

Returns

Int32

The length of the common prefix shared by the two spans. If there's no shared prefix, 0 is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)

Finds the length of any common prefix shared between `span` and `other`.

C#

```
public static int CommonPrefixLength<T> (this Span<T> span,
ReadOnlySpan<T> other, System.Collections.Generic.IEqualityComparer<T>?
comparer);
```

Type Parameters

`T`

The type of the elements in the spans.

Parameters

`span` Span<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

`comparer` IEqualityComparer<T>

The IEqualityComparer<T> implementation to use when comparing elements, or `null` to use the default IEqualityComparer<T> for the type of an element.

Returns

Int32

The length of the common prefix shared by the two spans. If there's no shared prefix, 0 is returned.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

MemoryExtensions.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Compares one character span with another using a specified string comparison, and returns an integer that indicates their relative position in the sort order.

C#

```
public static int CompareTo (this ReadOnlySpan<char> span,
ReadOnlySpan<char> other, StringComparison comparisonType);
```

Parameters

span ReadOnlySpan<Char>

The source span.

other ReadOnlySpan<Char>

The value to compare with the source span.

comparisonType StringComparison

An enumeration value that determines how `span` and `other` are compared.

Returns

Int32

A signed integer that indicates the relative order of `span` and `other`:
- If less than 0, `span` precedes than `other`.
- If 0, `span` equals `other`.
- If greater than 0, `span` follows `other`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

MemoryExtensions.Contains Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Contains(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Indicates whether a specified value occurs within a read-only character span.
Contains<T>(ReadOnlySpan<T>, T)	Indicates whether a specified value is found in a read-only span. Values are compared using IEquatable{T}.Equals(T).
Contains<T>(Span<T>, T)	Indicates whether a specified value is found in a span. Values are compared using IEquatable{T}.Equals(T).

Contains(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)

Indicates whether a specified value occurs within a read-only character span.

C#

```
public static bool Contains (this ReadOnlySpan<char> span,
ReadOnlySpan<char> value, StringComparison comparisonType);
```

Parameters

span ReadOnlySpan<Char>

The source span.

value ReadOnlySpan<Char>

The value to seek within the source span.

`comparisonType` StringComparison

An enumeration value that determines how the characters in `span` and `value` are compared.

Returns

Boolean

`true` if `value` occurs within the span, `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Contains<T>(ReadOnlySpan<T>, T)

Indicates whether a specified value is found in a read-only span. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static bool Contains<T> (this ReadOnlySpan<T> span, T value) where
T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` T

The value to search for.

Returns

Boolean

`true` if found, `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Contains<T>(Span<T>, T)

Indicates whether a specified value is found in a span. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static bool Contains<T> (this Span<T> span, T value) where T :
IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The span to search.

`value` T

The value to search for.

Returns

Boolean

`true` if found, `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.ContainsAny Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

ContainsAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, T, T)	Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, T, T)	Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, SearchValues<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, T, T, T)	Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.

ContainsAny<T>(ReadOnlySpan<T>, T, T, T)

Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.

```
C#
```

```
public static bool ContainsAny<T> (this ReadOnlySpan<T> span, T value0, T value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

`value2` T

One of the values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(Span<T>, T, T)

Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.

```
C#
```

```
public static bool ContainsAny<T> (this Span<T> span, T value0, T value1)
where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(ReadOnlySpan<T>, T, T)

Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.

C#

```
public static bool ContainsAny<T> (this ReadOnlySpan<T> span, T value0, T
value1) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(ReadOnlySpan<T>, SearchValues<T>)

Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.

C#

```
public static bool ContainsAny<T> (this ReadOnlySpan<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` SearchValues<T>

The set of values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(Span<T>, SearchValues<T>)

Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.

C#

```
public static bool ContainsAny<T> (this Span<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`values` SearchValues<T>

The set of values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.

C#

```
public static bool ContainsAny<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` ReadOnlySpan<T>

The set of values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(Span<T>, T, T, T)

Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.

```
C#

public static bool ContainsAny<T> (this Span<T> span, T value0, T value1,
T value2) where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span Span<T>

The span to search.

value0 T

One of the values to search for.

value1 T

One of the values to search for.

value2 T

One of the values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAny<T>(Span<T>, ReadOnlySpan<T>)

Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.

```
C#

public static bool ContainsAny<T> (this Span<T> span, ReadOnlySpan<T>
values) where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span Span<T>

The span to search.

values ReadOnlySpan<T>

The set of values to search for.

Returns

Boolean

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.ContainsAnyExcept Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

ContainsAnyExcept<T>(Span<T>, T, T)	Searches for any value other than `value0` or `value1`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for any value other than `value0` or `value1`.
ContainsAnyExcept<T>(Span<T>, T, T, T)	Searches for any value other than `value0`, `value1`, or `value2`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for any value other than `value0`, `value1`, or `value2`.
ContainsAnyExcept<T>(Span<T>, T)	Searches for any value other than the specified `value`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for any value other than the specified `value`.

ContainsAnyExcept<T>(Span<T>, T, T)

Searches for any value other than `value0` or `value1`.

```
C#

public static bool ContainsAnyExcept<T> (this Span<T> span, T value0, T
value1) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`value0` T

The value to exclude from the search.

`value1` T

The value to exclude from the search.

Returns

Boolean

`true` if any value other than `value0` or `value1` is present in the span. If all of the values are `value0` or `value1`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T)

Searches for any value other than `value0` or `value1`.

```
C#

public static bool ContainsAnyExcept<T> (this ReadOnlySpan<T> span, T
value0, T value1) where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span ReadOnlySpan<T>

The span to search.

value0 T

The value to exclude from the search.

value1 T

The value to exclude from the search.

Returns

Boolean

`true` if any value other than `value0` or `value1` is present in the span. If all of the values are `value0` or `value1`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(Span<T>, T, T, T)

Searches for any value other than `value0`, `value1`, or `value2`.

```
C#

public static bool ContainsAnyExcept<T> (this Span<T> span, T value0, T
value1, T value2) where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span Span<T>

The span to search.

value0 T

The value to exclude from the search.

value1 T

The value to exclude from the search.

value2 T

The value to exclude from the search.

Returns

Boolean

`true` if any value other than `value0`, `value1`, or `value2` is present in the span. If all of the values are `value0`, `value1`, or `value2`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T, T)

Searches for any value other than `value0`, `value1`, or `value2`.

```
C#

public static bool ContainsAnyExcept<T> (this ReadOnlySpan<T> span, T
value0, T value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

The value to exclude from the search.

`value1` T

The value to exclude from the search.

`value2` T

The value to exclude from the search.

Returns

Boolean

`true` if any value other than `value0`, `value1`, or `value2` is present in the span. If all of the values are `value0`, `value1`, or `value2`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(Span<T>, T)

Searches for any value other than the specified `value`.

```
C#

public static bool ContainsAnyExcept<T> (this Span<T> span, T value)
where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span Span<T>

The span to search.

value T

The value to exclude from the search.

Returns

Boolean

`true` if any value other than `value` is present in the span. If all of the values are `value`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for any value other than the specified `values`.

```
C#

public static bool ContainsAnyExcept<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span ReadOnlySpan<T>

The span to search.

values ReadOnlySpan<T>

The set of values to exclude from the search.

Returns

Boolean

`true` if any value other than those in `values` is present in the span. If all of the values are in `values`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(Span<T>, SearchValues<T>)

Searches for any value other than the specified `values`.

```
C#

public static bool ContainsAnyExcept<T> (this Span<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

T

Parameters

span Span<T>

The span to search.

values SearchValues<T>

The set of values to exclude from the search.

Returns

Boolean

`true` if any value other than those in `values` is present in the span. If all of the values are in `values`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)

Searches for any value other than the specified `values`.

```
C#
```

```
public static bool ContainsAnyExcept<T> (this ReadOnlySpan<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` SearchValues<T>

The set of values to exclude from the search.

Returns

Boolean

`true` if any value other than those in `values` is present in the span. If all of the values are in `values`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(Span<T>, ReadOnlySpan<T>)

Searches for any value other than the specified `values`.

C#

```
public static bool ContainsAnyExcept<T> (this Span<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`values` ReadOnlySpan<T>

The set of values to exclude from the search.

Returns

Boolean

`true` if any value other than those in `values` is present in the span. If all of the values are in `values`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExcept<T>(ReadOnlySpan<T>, T)

Searches for any value other than the specified `value`.

```
C#

public static bool ContainsAnyExcept<T> (this ReadOnlySpan<T> span, T
value) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` T

The value to exclude from the search.

Returns

Boolean

`true` if any value other than `value` is present in the span. If all of the values are `value`, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.ContainsAnyExceptInRange Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

ContainsAnyExceptInRange<T> (ReadOnlySpan<T>, T, T)	Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
ContainsAnyExceptInRange<T>(Span<T>, T, T)	Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

ContainsAnyExceptInRange<T> (ReadOnlySpan<T>, T, T)

Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static bool ContainsAnyExceptInRange<T> (this ReadOnlySpan<T>
span, T lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

T

Parameters

span ReadOnlySpan<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the excluded range.

`highInclusive` T

The upper bound, inclusive, of the excluded range.

Returns

Boolean

`true` if any value other than those in the specified range is present in the span. If all of the values are inside of the specified range, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

ContainsAnyExceptInRange<T>(Span<T>, T, T)

Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static bool ContainsAnyExceptInRange<T> (this Span<T> span, T
lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the excluded range.

`highInclusive` T

The upper bound, inclusive, of the excluded range.

Returns

Boolean

`true` if any value other than those in the specified range is present in the span. If all of the values are inside of the specified range, returns `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.CopyTo Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

CopyTo<T>(T[], Memory<T>)	Copies the contents of the array into a memory region.
CopyTo<T>(T[], Span<T>)	Copies the contents of the array into the span.

CopyTo<T>(T[], Memory<T>)

Copies the contents of the array into a memory region.

C#

```
public static void CopyTo<T> (this T[]? source, Memory<T> destination);
```

Type Parameters

`T`

The type of the array.

Parameters

`source` T[]

The array to copy items from.

`destination` Memory<T>

The memory to copy items into.

Exceptions

ArgumentException

The destination is shorter than the source array.

Remarks

If `source` and `destination` overlap, this method behaves as if the original values are in a temporary location before the destination is overwritten.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

CopyTo<T>(T[], Span<T>)

Copies the contents of the array into the span.

C#

```
public static void CopyTo<T> (this T[]? source, Span<T> destination);
```

Type Parameters

T

The type of the array.

Parameters

source T[]

The array to copy items from.

destination Span<T>

The span to copy items into.

Exceptions

ArgumentException

The destination Span is shorter than the source array.

Remarks

If `source` and `destination` overlap, this method behaves as if the original values are in a temporary location before the destination is overwritten.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.Count Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Count<T>(ReadOnlySpan<T>, T)	Counts the number of times the specified `value` occurs in the `span`.
Count<T>(Span<T>, T)	Counts the number of times the specified `value` occurs in the `span`.
Count<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Counts the number of times `value` occurs in `span`.
Count<T>(Span<T>, ReadOnlySpan<T>)	Counts the number of times the specified `value` occurs in the `span`.

Count<T>(ReadOnlySpan<T>, T)

Counts the number of times the specified `value` occurs in the `span`.

C#

```
public static int Count<T> (this ReadOnlySpan<T> span, T value) where T :
IEquatable<T>;
```

Type Parameters

T

The element type of the span.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` T

The value for which to search.

Returns

Int32

The number of times `value` was found in the `span`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Count<T>(Span<T>, T)

Counts the number of times the specified `value` occurs in the `span`.

C#

```
public static int Count<T> (this Span<T> span, T value) where T :
IEquatable<T>;
```

Type Parameters

`T`

The element type of the span.

Parameters

`span` Span<T>

The span to search.

`value` T

The value for which to search.

Returns

Int32

The number of times `value` was found in the `span`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Count<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Counts the number of times `value` occurs in `span`.

C#

```
public static int Count<T> (this ReadOnlySpan<T> span, ReadOnlySpan<T>
value) where T : IEquatable<T>;
```

Type Parameters

T

The element type of the span.

Parameters

span ReadOnlySpan<T>

The span to search.

value ReadOnlySpan<T>

The value for which to search.

Returns

Int32

The number of times `value` was found in `span`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Count<T>(Span<T>, ReadOnlySpan<T>)

Counts the number of times the specified `value` occurs in the `span`.

C#

```
public static int Count<T> (this Span<T> span, ReadOnlySpan<T> value)
where T : IEquatable<T>;
```

Type Parameters

`T`

The element type of the span.

Parameters

`span` Span<T>

The span to search.

`value` ReadOnlySpan<T>

The value for which to search.

Returns

Int32

The number of times `value` was found in the `span`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.EndsWith Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

EndsWith(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Determines whether the end of the `span` matches the specified `value` when compared using the specified `comparisonType` option.
EndsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether the specified sequence appears at the end of a read-only span.
EndsWith<T>(Span<T>, ReadOnlySpan<T>)	Determines whether the specified sequence appears at the end of a span.

EndsWith(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)

Determines whether the end of the `span` matches the specified `value` when compared using the specified `comparisonType` option.

C#

```
public static bool EndsWith (this ReadOnlySpan<char> span,
ReadOnlySpan<char> value, StringComparison comparisonType);
```

Parameters

span ReadOnlySpan<Char>

The source span.

value ReadOnlySpan<Char>

The sequence to compare to the end of the source span.

`comparisonType` StringComparison

An enumeration value that determines how `span` and `value` are compared.

Returns

Boolean

`true` if `value` matches the end of `span`; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

EndsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Determines whether the specified sequence appears at the end of a read-only span.

C#

```
public static bool EndsWith<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> value) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span.

Parameters

`span` ReadOnlySpan<T>

The source span.

`value` ReadOnlySpan<T>

The sequence to compare to the end of the source span.

Returns

Boolean

`true` if `value` matches the end of `span`; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

EndsWith<T>(Span<T>, ReadOnlySpan<T>)

Determines whether the specified sequence appears at the end of a span.

C#

```
public static bool EndsWith<T> (this Span<T> span, ReadOnlySpan<T> value)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span.

Parameters

`span` Span<T>

The source span.

`value` ReadOnlySpan<T>

The sequence to compare to the end of the source span.

Returns

Boolean

`true` if `value` matches the end of `span`; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.EnumerateLines Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

EnumerateLines(ReadOnlySpan<Char>)	Returns an enumeration of lines over the provided span.
EnumerateLines(Span<Char>)	Returns an enumeration of lines over the provided span.

EnumerateLines(ReadOnlySpan<Char>)

Returns an enumeration of lines over the provided span.

C#

```
public static System.Text.SpanLineEnumerator EnumerateLines (this
ReadOnlySpan<char> span);
```

Parameters

span ReadOnlySpan<Char>

A span containing the lines to enumerate.

Returns

SpanLineEnumerator

An enumeration of lines.

Remarks

It is recommended that protocol parsers not utilize this API. See the documentation for ReplaceLineEndings() for more information on how newline sequences are detected.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

EnumerateLines(Span<Char>)

Returns an enumeration of lines over the provided span.

C#

```
public static System.Text.SpanLineEnumerator EnumerateLines (this
Span<char> span);
```

Parameters

span Span<Char>

A span containing the lines to enumerate.

Returns

SpanLineEnumerator

An enumeration of lines.

Remarks

It is recommended that protocol parsers not utilize this API. See the documentation for ReplaceLineEndings() for more information on how newline sequences are detected.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

MemoryExtensions.EnumerateRunes Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

EnumerateRunes(ReadOnlySpan<Char>)	Returns an enumeration of Rune from the provided read-only span.
EnumerateRunes(Span<Char>)	Returns an enumeration of Rune from the provided span.

EnumerateRunes(ReadOnlySpan<Char>)

Returns an enumeration of Rune from the provided read-only span.

C#

```
public static System.Text.SpanRuneEnumerator EnumerateRunes (this
ReadOnlySpan<char> span);
```

Parameters

span ReadOnlySpan<Char>

The source span.

Returns

SpanRuneEnumerator

A rune enumerator.

Remarks

Invalid sequences will be represented in the enumeration by Rune.ReplacementChar.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

EnumerateRunes(Span<Char>)

Returns an enumeration of Rune from the provided span.

C#

```
public static System.Text.SpanRuneEnumerator EnumerateRunes (this
Span<char> span);
```

Parameters

span Span<Char>

The source span.

Returns

SpanRuneEnumerator

A rune enumerator.

Remarks

Invalid sequences will be represented in the enumeration by ReplacementChar.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Determines whether this `span` and the specified `other` span have the same characters when compared using the specified `comparisonType` option.

C#

```
public static bool Equals (this ReadOnlySpan<char> span, ReadOnlySpan<char>
other, StringComparison comparisonType);
```

Parameters

`span` ReadOnlySpan<Char>

The source span.

`other` ReadOnlySpan<Char>

The value to compare with the source span.

`comparisonType` StringComparison

An enumeration value that determines how `span` and `other` are compared.

Returns

Boolean

`true` if equal, `false` otherwise.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

MemoryExtensions.IndexOf Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

IndexOf(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Reports the zero-based index of the first occurrence of the specified `value` in the current `span`.
IndexOf<T>(Span<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(Span<T>, T)	Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(ReadOnlySpan<T>, T)	Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).

IndexOf(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)

Reports the zero-based index of the first occurrence of the specified `value` in the current `span`.

C#

```
public static int IndexOf (this ReadOnlySpan<char> span,
ReadOnlySpan<char> value, StringComparison comparisonType);
```

Parameters

`span` ReadOnlySpan<Char>

The source span.

`value` ReadOnlySpan<Char>

The value to seek within the source span.

`comparisonType` StringComparison

An enumeration value that determines how `span` and `value` are compared.

Returns

Int32

The index of the occurrence of the value in the span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOf<T>(Span<T>, ReadOnlySpan<T>)

Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int IndexOf<T> (this Span<T> span, ReadOnlySpan<T> value)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` Span<T>

The span to search.

`value` ReadOnlySpan<T>

The sequence to search for.

Returns

Int32

The index of the occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOf<T>(Span<T>, T)

Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int IndexOf<T> (this Span<T> span, T value) where T :
IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` Span<T>

The span to search.

`value` T

The value to search for.

Returns

Int32

The index of the occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOf<T>(ReadOnlySpan<T>, T)

Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int IndexOf<T> (this ReadOnlySpan<T> span, T value) where T
: IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` T

The value to search for.

Returns

Int32

The index of the occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int IndexOf<T> (this ReadOnlySpan<T> span, ReadOnlySpan<T>
value) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` ReadOnlySpan<T>

The sequence to search for.

Returns

Int32

The index of the occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.IndexOfAny Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

IndexOfAny<T>(Span<T>, T, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the first index of any of the specified values.
IndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, SearchValues<T>)	Searches for the first index of any of the specified values.
IndexOfAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

IndexOfAny<T>(Span<T>, T, T, T)

Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

```
C#

public static int IndexOfAny<T> (this Span<T> span, T value0, T value1, T
value2) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

value0 T

One of the values to search for.

value1 T

One of the values to search for.

value2 T

One of the values to search for.

Returns

Int32

The first index of the occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

IndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)

Searches for the first index of any of the specified values.

C#

```
public static int IndexOfAny<T> (this ReadOnlySpan<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` SearchValues<T>

The set of values to search for.

Returns

Int32

The first index of any of the specified values, or -1 if none are found.

Remarks

This method is similar to calling IndexOf several times with the logical OR operator.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

IndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

C#

```
public static int IndexOfAny<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

values ReadOnlySpan<T>

The set of values to search for.

Returns

Int32

The first index of the occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOfAny<T>(Span<T>, SearchValues<T>)

Searches for the first index of any of the specified values.

C#

```
public static int IndexOfAny<T> (this Span<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`values` SearchValues<T>

The set of values to search for.

Returns

Int32

The first index of any of the specified values, or -1 if none are found.

Remarks

This method is similar to calling IndexOf several times with the logical OR operator.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

IndexOfAny<T>(Span<T>, ReadOnlySpan<T>)

Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

```
C#

public static int IndexOfAny<T> (this Span<T> span, ReadOnlySpan<T>
values) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

values ReadOnlySpan<T>

The set of values to search for.

Returns

Int32

The first index of the occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

IndexOfAny<T>(ReadOnlySpan<T>, T, T)

Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

```
C#

public static int IndexOfAny<T> (this ReadOnlySpan<T> span, T value0, T
value1) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

value0 T

One of the values to search for.

value1 T

One of the values to search for.

Returns

Int32

The first index of the occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOfAny<T>(Span<T>, T, T)

Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

```
C#

public static int IndexOfAny<T> (this Span<T> span, T value0, T value1)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

Returns

Int32

The first index of the occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOfAny<T>(ReadOnlySpan<T>, T, T, T)

Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.

C#

```
public static int IndexOfAny<T> (this ReadOnlySpan<T> span, T value0, T
value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

`value2` T

One of the values to search for.

Returns

Int32

The first index of the occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.IndexOfAnyExcept Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

IndexOfAnyExcept<T>(Span<T>, T, T)	Searches for the first index of any value other than the specified `value0` or `value1`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value other than the specified `value0` or `value1`.
IndexOfAnyExcept<T>(Span<T>, T)	Searches for the first index of any value other than the specified `value`.
IndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for the first index of any value other than the specified `value`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.
IndexOfAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(Span<T>, T, T, T)	Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.

IndexOfAnyExcept<T>(Span<T>, T, T)

Searches for the first index of any value other than the specified `value0` or `value1`.

```
C#

public static int IndexOfAnyExcept<T> (this Span<T> span, T value0, T
value1) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

value0 T

A value to avoid.

value1 T

A value to avoid

Returns

Int32

The index in the span of the first occurrence of any value other than `value0` and `value1`. If all of the values are `value0` or `value1`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)

Searches for the first index of any value other than the specified `value0` or `value1`.

```
C#

public static int IndexOfAnyExcept<T> (this ReadOnlySpan<T> span, T
value0, T value1) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

value0 T

A value to avoid.

value1 T

A value to avoid

Returns

Int32

The index in the span of the first occurrence of any value other than `value0` and `value1`. If all of the values are `value0` or `value1`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(Span<T>, T)

Searches for the first index of any value other than the specified `value`.

```
C#

public static int IndexOfAnyExcept<T> (this Span<T> span, T value) where
T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

value T

A value to avoid.

Returns

Int32

The index in the span of the first occurrence of any value other than `value`. If all of the values are `value`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)

Searches for the first index of any value other than the specified `values`.

```
C#
```

```
public static int IndexOfAnyExcept<T> (this Span<T> span, ReadOnlySpan<T>
values) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

values ReadOnlySpan<T>

The values to avoid.

Returns

Int32

The index in the span of the first occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)

Searches for the first index of any value other than the specified `values`.

C#

```
public static int IndexOfAnyExcept<T> (this ReadOnlySpan<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` SearchValues<T>

The values to exclude from the search.

Returns

Int32

The index in the span of the first occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

IndexOfAnyExcept<T>(ReadOnlySpan<T>, T)

Searches for the first index of any value other than the specified `value`.

C#

```
public static int IndexOfAnyExcept<T> (this ReadOnlySpan<T> span, T
value) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` T

A value to avoid.

Returns

Int32

The index in the span of the first occurrence of any value other than `value`. If all of the values are `value`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for the first index of any value other than the specified `values`.

C#

```
public static int IndexOfAnyExcept<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` ReadOnlySpan<T>

The values to avoid.

Returns

Int32

The index in the span of the first occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)

Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.

C#

```
public static int IndexOfAnyExcept<T> (this ReadOnlySpan<T> span, T
value0, T value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

A value to avoid.

`value1` T

A value to avoid

`value2` T

A value to avoid

Returns

Int32

The index in the span of the first occurrence of any value other than `value0`, `value1`, and `value2`. If all of the values are `value0`, `value1`, and `value2`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

IndexOfAnyExcept<T>(Span<T>, SearchValues<T>)

Searches for the first index of any value other than the specified `values`.

C#

```
public static int IndexOfAnyExcept<T> (this Span<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`values` SearchValues<T>

The values to exclude from the search.

Returns

Int32

The index in the span of the first occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

IndexOfAnyExcept<T>(Span<T>, T, T, T)

Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.

```
C#

public static int IndexOfAnyExcept<T> (this Span<T> span, T value0, T
value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`value0` T

A value to avoid.

`value1` T

A value to avoid

`value2` T

A value to avoid

Returns

Int32

The index in the span of the first occurrence of any value other than `value0`, `value1`, and `value2`. If all of the values are `value0`, `value1`, and `value2`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

MemoryExtensions.IndexOfAnyExceptInRange Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

IndexOfAnyExceptInRange<T> (Span<T>, T, T)	Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
IndexOfAnyExceptInRange<T> (ReadOnlySpan<T>, T, T)	Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

IndexOfAnyExceptInRange<T>(Span<T>, T, T)

Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static int IndexOfAnyExceptInRange<T> (this Span<T> span, T
lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the excluded range.

`highInclusive` T

The upper bound, inclusive, of the excluded range.

Returns

Int32

The index in the span of the first occurrence of any value outside of the specified range. If all of the values are inside of the specified range, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

IndexOfAnyExceptInRange<T> (ReadOnlySpan<T>, T, T)

Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static int IndexOfAnyExceptInRange<T> (this ReadOnlySpan<T> span,
T lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the excluded range.

`highInclusive` T

The upper bound, inclusive, of the excluded range.

Returns

Int32

The index in the span of the first occurrence of any value outside of the specified range. If all of the values are inside of the specified range, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.IsWhiteSpace(ReadOnlySpan<Char>) Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Indicates whether the specified span contains only whitespace characters.

C#

```
public static bool IsWhiteSpace (this ReadOnlySpan<char> span);
```

Parameters

span ReadOnlySpan<Char>

The source span.

Returns

Boolean

`true` if the span contains only whitespace characters, `false` otherwise.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.LastIndexOf Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

LastIndexOf(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Reports the zero-based index of the last occurrence of the specified `value` in the current `span`.
LastIndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(ReadOnlySpan<T>, T)	Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(Span<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(Span<T>, T)	Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).

LastIndexOf(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)

Reports the zero-based index of the last occurrence of the specified `value` in the current `span`.

C#

```
public static int LastIndexOf (this ReadOnlySpan<char> span,
```

```
ReadOnlySpan<char> value, StringComparison comparisonType);
```

Parameters

span ReadOnlySpan<Char>

The source span.

value ReadOnlySpan<Char>

The value to seek within the source span.

comparisonType StringComparison

An enumeration value that determines how `span` and `value` are compared.

Returns

Int32

The index of the last occurrence of the value in the span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

LastIndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int LastIndexOf<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> value) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` ReadOnlySpan<T>

The sequence to search for.

Returns

Int32

The index of the last occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOf<T>(ReadOnlySpan<T>, T)

Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int LastIndexOf<T> (this ReadOnlySpan<T> span, T value)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value` T

The value to search for.

Returns

Int32

The index of the last occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOf<T>(Span<T>, ReadOnlySpan<T>)

Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int LastIndexOf<T> (this Span<T> span, ReadOnlySpan<T>
value) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` Span<T>

The span to search.

`value` ReadOnlySpan<T>

The sequence to search for.

Returns

Int32

The index of the last occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOf<T>(Span<T>, T)

Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).

C#

```
public static int LastIndexOf<T> (this Span<T> span, T value) where T :
IEquatable<T>;
```

Type Parameters

`T`

The type of the span and value.

Parameters

`span` Span<T>

The span to search.

`value` T

The value to search for.

Returns

Int32

The index of the last occurrence of the value in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.LastIndexOfAny Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

LastIndexOfAny<T>(Span<T>, T, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, SearchValues<T>)	Searches for the last index of any of the specified values.
LastIndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the last index of any of the specified values.
LastIndexOfAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

LastIndexOfAny<T>(Span<T>, T, T, T)

Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

```
C#

public static int LastIndexOfAny<T> (this Span<T> span, T value0, T
value1, T value2) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

value0 T

One of the values to search for.

value1 T

One of the values to search for.

value2 T

One of the values to search for.

Returns

Int32

The index of the last occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOfAny<T>(ReadOnlySpan<T>, T, T, T)

Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

```
C#

public static int LastIndexOfAny<T> (this ReadOnlySpan<T> span, T value0,
T value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

`value2` T

One of the values to search for.

Returns

Int32

The index of the last occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOfAny<T>(ReadOnlySpan<T>, T, T)

Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

C#

```
public static int LastIndexOfAny<T> (this ReadOnlySpan<T> span, T value0,
T value1) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

Returns

Int32

The index of the last occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOfAny<T>(Span<T>, T, T)

Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

C#

```
public static int LastIndexOfAny<T> (this Span<T> span, T value0, T
value1) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`value0` T

One of the values to search for.

`value1` T

One of the values to search for.

Returns

Int32

The index of the last occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOfAny<T>(Span<T>, SearchValues<T>)

Searches for the last index of any of the specified values.

```
C#

public static int LastIndexOfAny<T> (this Span<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` Span<T>

The span to search.

`values` SearchValues<T>

The set of values to search for.

Returns

Int32

The last index of any of the specified values, or -1 if none are found.

Remarks

This method is similar to calling LastIndexOf several times with the logical OR operator.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

LastIndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

C#

```
public static int LastIndexOfAny<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` ReadOnlySpan<T>

The set of values to search for.

Returns

Int32

The index of the last occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

LastIndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)

Searches for the last index of any of the specified values.

C#

```
public static int LastIndexOfAny<T> (this ReadOnlySpan<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

Parameters

`span` ReadOnlySpan<T>

The span to search.

`values` SearchValues<T>

The set of values to search for.

Returns

Int32

The last index of any of the specified values, or -1 if none are found.

Remarks

This method is similar to calling LastIndexOf several times with the logical OR operator.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

LastIndexOfAny<T>(Span<T>, ReadOnlySpan<T>)

Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.

C#

```
public static int LastIndexOfAny<T> (this Span<T> span, ReadOnlySpan<T>
values) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span Span<T>

The span to search.

values ReadOnlySpan<T>

The set of values to search for.

Returns

Int32

The index of the last occurrence of any of the values in the span. If not found, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.LastIndexOfAnyExcept Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for the last index of any value other than the specified `value`.
LastIndexOfAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(Span<T>, T)	Searches for the last index of any value other than the specified `value`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value other than the specified `value0` or `value1`.
LastIndexOfAnyExcept<T>(Span<T>, T, T)	Searches for the last index of any value other than the specified `value0` or `value1`.
LastIndexOfAnyExcept<T>(Span<T>, T, T, T)	Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)

Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.

```
C#

public static int LastIndexOfAnyExcept<T> (this ReadOnlySpan<T> span, T
value0, T value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

A value to avoid.

`value1` T

A value to avoid

`value2` T

A value to avoid

Returns

Int32

The index in the span of the last occurrence of any value other than `value0`, `value1`, and `value2`. If all of the values are `value0`, `value1`, and `value2`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)

Searches for the last index of any value other than the specified `values`.

```
C#

public static int LastIndexOfAnyExcept<T> (this ReadOnlySpan<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

values SearchValues<T>

The values to exclude from the search.

Returns

Int32

The index in the span of the last occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Searches for the last index of any value other than the specified `values`.

```
C#

public static int LastIndexOfAnyExcept<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

values ReadOnlySpan<T>

The values to avoid.

Returns

Int32

The index in the span of the first occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T)

Searches for the last index of any value other than the specified `value`.

```
C#

public static int LastIndexOfAnyExcept<T> (this ReadOnlySpan<T> span, T
value) where T : IEquatable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

value T

A value to avoid.

Returns

Int32

The index in the span of the last occurrence of any value other than `value`. If all of the values are `value`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(Span<T>, SearchValues<T>)

Searches for the last index of any value other than the specified `values`.

```
C#
```

```
public static int LastIndexOfAnyExcept<T> (this Span<T> span,
System.Buffers.SearchValues<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`values` SearchValues<T>

The values to exclude from the search.

Returns

Int32

The index in the span of the last occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

LastIndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)

Searches for the last index of any value other than the specified `values`.

C#

```
public static int LastIndexOfAnyExcept<T> (this Span<T> span,
ReadOnlySpan<T> values) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`values` ReadOnlySpan<T>

The values to avoid.

Returns

Int32

The index in the span of the last occurrence of any value other than those in `values`. If all of the values are in `values`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(Span<T>, T)

Searches for the last index of any value other than the specified `value`.

C#

```
public static int LastIndexOfAnyExcept<T> (this Span<T> span, T value)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`value` T

A value to avoid.

Returns

Int32

The index in the span of the last occurrence of any value other than `value`. If all of the values are `value`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)

Searches for the last index of any value other than the specified `value0` or `value1`.

C#

```
public static int LastIndexOfAnyExcept<T> (this ReadOnlySpan<T> span, T
value0, T value1) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`value0` T

A value to avoid.

`value1` T

A value to avoid

Returns

Int32

The index in the span of the last occurrence of any value other than `value0` and `value1`. If all of the values are `value0` or `value1`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(Span<T>, T, T)

Searches for the last index of any value other than the specified `value0` or `value1`.

C#

```
public static int LastIndexOfAnyExcept<T> (this Span<T> span, T value0, T
value1) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`value0` T

A value to avoid.

`value1` T

A value to avoid

Returns

Int32

The index in the span of the last occurrence of any value other than `value0` and `value1`. If all of the values are `value0` or `value1`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

LastIndexOfAnyExcept<T>(Span<T>, T, T, T)

Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.

C#

```
public static int LastIndexOfAnyExcept<T> (this Span<T> span, T value0, T value1, T value2) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`value0` T

A value to avoid.

`value1` T

A value to avoid

`value2` T

A value to avoid

Returns

Int32

The index in the span of the last occurrence of any value other than `value0`, `value1`, and `value2`. If all of the values are `value0`, `value1`, and `value2`, returns -1.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

MemoryExtensions.LastIndexOfAnyExceptInRange Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

LastIndexOfAnyExceptInRange<T>(Span<T>, T, T)	Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

LastIndexOfAnyExceptInRange<T>(Span<T>, T, T)

Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static int LastIndexOfAnyExceptInRange<T> (this Span<T> span, T
lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

`span` Span<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the excluded range.

`highInclusive` T

The upper bound, inclusive, of the excluded range.

Returns

Int32

The index in the span of the last occurrence of any value outside of the specified range. If all of the values are inside of the specified range, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

LastIndexOfAnyExceptInRange<T> (ReadOnlySpan<T>, T, T)

Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static int LastIndexOfAnyExceptInRange<T> (this ReadOnlySpan<T>
span, T lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

`T`

The type of the span and values.

Parameters

`span` ReadOnlySpan<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the excluded range.

`highInclusive` T

The upper bound, inclusive, of the excluded range.

Returns

Int32

The index in the span of the last occurrence of any value outside of the specified range. If all of the values are inside of the specified range, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

LastIndexOfAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyInRange<T>(Span<T>, T, T)	Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.

LastIndexOfAnyInRange<T>(ReadOnlySpan<T>, T, T)

Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.

C#

```
public static int LastIndexOfAnyInRange<T> (this ReadOnlySpan<T> span, T lowInclusive, T highInclusive) where T : IComparable<T>;
```

Type Parameters

T

The type of the span and values.

Parameters

span ReadOnlySpan<T>

The span to search.

`lowInclusive` T

The lower bound, inclusive, of the range for which to search.

`highInclusive` T

The upper bound, inclusive, of the range for which to search.

Returns

Int32

The index in the span of the last occurrence of any value in the specified range. If all of the values are outside of the specified range, returns -1.

Applies to

▼ .NET 9 and .NET 8

Product	Versions

MemoryExtensions.Overlaps Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether two read-only sequences overlap in memory.
Overlaps<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a span and a read-only span overlap in memory.
Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, Int32)	Determines whether two read-only sequences overlap in memory and outputs the element offset.
Overlaps<T>(Span<T>, ReadOnlySpan<T>, Int32)	Determines whether a span and a read-only span overlap in memory and outputs the element offset.

Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Determines whether two read-only sequences overlap in memory.

C#

```
public static bool Overlaps<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other);
```

Type Parameters

T

The type of elements in the read-only sequence.

Parameters

`span` ReadOnlySpan<T>

The first sequence.

`other` ReadOnlySpan<T>

The second sequence.

Returns

Boolean

`true` if the two sequences overlap; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Overlaps<T>(Span<T>, ReadOnlySpan<T>)

Determines whether a span and a read-only span overlap in memory.

C#

```
public static bool Overlaps<T> (this Span<T> span, ReadOnlySpan<T>
other);
```

Type Parameters

`T`

The type of elements in the span.

Parameters

`span` Span<T>

The span to compare.

`other` ReadOnlySpan<T>

The read-only span to compare.

Returns

Boolean

`true` if the two sequences overlap; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, Int32)

Determines whether two read-only sequences overlap in memory and outputs the element offset.

C#

```
public static bool Overlaps<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other, out int elementOffset);
```

Type Parameters

`T`

The type of elements in the span.

Parameters

`span` ReadOnlySpan<T>

The first sequence.

`other` ReadOnlySpan<T>

The second sequence.

`elementOffset` Int32

When the method returns, contains the offset between `span` and `other`.

Returns

Boolean

`true` if the two sequences overlap; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Overlaps<T>(Span<T>, ReadOnlySpan<T>, Int32)

Determines whether a span and a read-only span overlap in memory and outputs the element offset.

C#

```
public static bool Overlaps<T> (this Span<T> span, ReadOnlySpan<T> other,
out int elementOffset);
```

Type Parameters

`T`

The type of elements in the span.

Parameters

`span` Span<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

`elementOffset` Int32

When the method returns, contains the offset between `span` and `other`.

Returns

Boolean

`true` if the two sequences overlap; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.Replace Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Replace<T>(Span<T>, T, T)	Replaces all occurrences of `oldValue` with `newValue`.
Replace<T>(ReadOnlySpan<T>, Span<T>, T, T)	Copies `source` to `destination`, replacing all occurrences of `oldValue` with `newValue`.

Replace<T>(Span<T>, T, T)

Replaces all occurrences of `oldValue` with `newValue`.

C#

```
public static void Replace<T> (this Span<T> span, T oldValue, T newValue)
where T : IEquatable<T>;
```

Type Parameters

T

The type of the elements in the span.

Parameters

span Span<T>

The span in which the elements should be replaced.

oldValue T

The value to be replaced with `newValue`.

`newValue` T

The value to replace all occurrences of `oldValue`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Replace<T>(ReadOnlySpan<T>, Span<T>, T, T)

Copies `source` to `destination`, replacing all occurrences of `oldValue` with `newValue`.

```
C#

public static void Replace<T> (this ReadOnlySpan<T> source, Span<T>
destination, T oldValue, T newValue) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the spans.

Parameters

`source` ReadOnlySpan<T>

The span to copy.

`destination` Span<T>

The span into which the copied and replaced values should be written.

`oldValue` T

The value to be replaced with `newValue`.

`newValue` T

The value to replace all occurrences of `oldValue`.

Exceptions

ArgumentException

The `destination` span is shorter than the `source` span. -or- `source` and `destination` overlap but don't refer to the same starting location.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.Reverse<T> (Span<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Reverses the sequence of the elements in the entire span.

C#

```
public static void Reverse<T> (this Span<T> span);
```

Type Parameters

T

The type of elements in the span.

Parameters

span Span<T>

The span to reverse.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

MemoryExtensions.SequenceCompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

SequenceCompareTo<T>(Span<T>, ReadOnlySpan<T>)	Determines the relative order of a span and a read-only span by comparing the elements using IComparable{T}.CompareTo(T).
SequenceCompareTo<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines the relative order of two read-only sequences by comparing their elements using IComparable{T}.CompareTo(T).

SequenceCompareTo<T>(Span<T>, ReadOnlySpan<T>)

Determines the relative order of a span and a read-only span by comparing the elements using IComparable{T}.CompareTo(T).

C#

```
public static int SequenceCompareTo<T> (this Span<T> span,
ReadOnlySpan<T> other) where T : IComparable<T>;
```

Type Parameters

T

The type of elements in the span.

Parameters

`span` Span<T>

The span to compare.

`other` ReadOnlySpan<T>

The read-only span to compare.

Returns

Int32

A signed integer that indicates the relative order of `span` and `other`:
- If less than 0, `span` precedes than `other`.
- If 0, `span` equals `other`.
- If greater than 0, `span` follows `other`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

SequenceCompareTo<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Determines the relative order of two read-only sequences by comparing their elements using IComparable{T}.CompareTo(T).

C#

```
public static int SequenceCompareTo<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other) where T : IComparable<T>;
```

Type Parameters

`T`

The type of elements in the sequence.

Parameters

`span` ReadOnlySpan<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

Returns

Int32

A signed integer that indicates the relative order of `span` and `other`:
- If less than 0, `span` precedes than `other`.
- If 0, `span` equals `other`.
- If greater than 0, `span` follows `other`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.SequenceEqual Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

SequenceEqual<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.
SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.
SequenceEqual<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a span and a read-only span are equal by comparing the elements using IEquatable{T}.Equals(T).
SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether two read-only sequences are equal by comparing the elements using IEquatable{T}.Equals(T).

SequenceEqual<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)

Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.

C#

```
public static bool SequenceEqual<T> (this Span<T> span, ReadOnlySpan<T>
other, System.Collections.Generic.IEqualityComparer<T>? comparer =
default);
```

Type Parameters

`T`

The type of elements in the sequence.

Parameters

`span` Span<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

`comparer` IEqualityComparer<T>

The IEqualityComparer<T> implementation to use when comparing elements, or `null` to use the default IEqualityComparer<T> for the type of an element.

Returns

Boolean

`true` if the two sequences are equal; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)

Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.

C#

```
public static bool SequenceEqual<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other, System.Collections.Generic.IEqualityComparer<T>?
```

```
comparer = default);
```

Type Parameters

`T`

The type of elements in the sequence.

Parameters

`span` ReadOnlySpan<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

`comparer` IEqualityComparer<T>

The IEqualityComparer<T> implementation to use when comparing elements, or `null` to use the default IEqualityComparer<T> for the type of an element.

Returns

Boolean

`true` if the two sequences are equal; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

SequenceEqual<T>(Span<T>, ReadOnlySpan<T>)

Determines whether a span and a read-only span are equal by comparing the elements using IEquatable{T}.Equals(T).

```
C#
```

```
public static bool SequenceEqual<T> (this Span<T> span, ReadOnlySpan<T>
other) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of elements in the sequence.

Parameters

`span` Span<T>

The span to compare.

`other` ReadOnlySpan<T>

The read-only span to compare.

Returns

Boolean

`true` if the two sequences are equal; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Determines whether two read-only sequences are equal by comparing the elements using IEquatable{T}.Equals(T).

```
C#
```

```
public static bool SequenceEqual<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> other) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of elements in the sequence.

Parameters

`span` ReadOnlySpan<T>

The first sequence to compare.

`other` ReadOnlySpan<T>

The second sequence to compare.

Returns

Boolean

`true` if the two sequences are equal; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.Sort Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Sort<T,TComparer>(Span<T>, TComparer)	Sorts the elements in the entire Span<T> using the `TComparer`.
Sort<T>(Span<T>)	Sorts the elements in the entire Span<T> using the IComparable<T> implementation of each element of the Span<T>.
Sort<T>(Span<T>, Comparison<T>)	Sorts the elements in the entire Span<T> using the specified Comparison<T>.
Sort<TKey,TValue,TComparer>(Span<TKey>, Span<TValue>, TComparer)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparer.
Sort<TKey,TValue>(Span<TKey>, Span<TValue>)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the IComparable<T> implementation of each key.
Sort<TKey,TValue>(Span<TKey>, Span<TValue>, Comparison<TKey>)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparison.

Sort<T,TComparer>(Span<T>, TComparer)

Sorts the elements in the entire Span<T> using the `TComparer`.

```
C#
```

```
public static void Sort<T,TComparer> (this Span<T> span, TComparer
comparer) where TComparer : System.Collections.Generic.IComparer<T>;
```

Type Parameters

`T`

The type of the elements of the span.

`TComparer`

The type of the comparer to use to compare elements.

Parameters

`span` Span<T>

The span of memory to sort.

`comparer` TComparer

The method to use when comparing elements, or `null` to use each element's IComparable<T> interface implementation.

Exceptions

InvalidOperationException

`comparer` is `null`, and one or more elements in `span` do not implement the IComparable<T> interface.

ArgumentException

The implementation of `comparer` caused an error during the sort.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Sort<T>(Span<T>)

Sorts the elements in the entire Span<T> using the IComparable<T> implementation of each element of the Span<T>.

```
C#
public static void Sort<T> (this Span<T> span);
```

Type Parameters

T

The type of the elements of the span.

Parameters

span Span<T>

The span of memory to sort.

Exceptions

InvalidOperationException

One or more elements in `span` do not implement the IComparable<T> interface.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Sort<T>(Span<T>, Comparison<T>)

Sorts the elements in the entire Span<T> using the specified Comparison<T>.

```
C#
public static void Sort<T> (this Span<T> span, Comparison<T> comparison);
```

Type Parameters

T

The type of the elements of the span.

Parameters

`span` Span<T>

The span of memory to sort.

`comparison` Comparison<T>

The method to use when comparing elements.

Exceptions

ArgumentNullException

`comparison` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Sort<TKey,TValue,TComparer>(Span<TKey>, Span<TValue>, TComparer)

Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparer.

C#

```
public static void Sort<TKey,TValue,TComparer> (this Span<TKey> keys,
Span<TValue> items, TComparer comparer) where TComparer :
System.Collections.Generic.IComparer<TKey>;
```

Type Parameters

`TKey`

The type of the elements of the key span.

`TValue`

The type of the elements of the items span.

`TComparer`

The type of the comparer to use to compare elements.

Parameters

`keys` Span<TKey>

The span that contains the keys to sort.

`items` Span<TValue>

The span that contains the items that correspond to the keys in `keys`.

`comparer` TComparer

The IComparer<T> implementation to use when comparing elements, or `null` to use the IComparable<T> interface implementation of each element.

Exceptions

ArgumentException

The length of `keys` isn't equal to the length of `items`.

InvalidOperationException

`comparer` is `null`, and one or more elements in `keys` do not implement the IComparable<T> interface.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Sort<TKey,TValue>(Span<TKey>, Span<TValue>)

Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the IComparable<T> implementation of each key.

```
C#

public static void Sort<TKey,TValue> (this Span<TKey> keys, Span<TValue>
items);
```

Type Parameters

`TKey`

The type of the elements of the key span.

`TValue`

The type of the elements of the items span.

Parameters

`keys` Span<TKey>

The span that contains the keys to sort.

`items` Span<TValue>

The span that contains the items that correspond to the keys in `keys`.

Exceptions

ArgumentException

The length of `keys` isn't equal to the length of `items`.

InvalidOperationException

One or more elements in `keys` do not implement the IComparable<T> interface.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Sort<TKey,TValue>(Span<TKey>, Span<TValue>, Comparison<TKey>)

Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparison.

```
C#

public static void Sort<TKey,TValue> (this Span<TKey> keys, Span<TValue>
items, Comparison<TKey> comparison);
```

Type Parameters

`TKey`

The type of the elements of the key span.

`TValue`

The type of the elements of the items span.

Parameters

`keys` Span<TKey>

The span that contains the keys to sort.

`items` Span<TValue>

The span that contains the items that correspond to the keys in `keys`.

`comparison` Comparison<TKey>

The Comparison<T> to use when comparing elements.

Exceptions

ArgumentNullException

`comparison` is `null`.

ArgumentException

The length of `keys` isn't equal to the length of `items`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

MemoryExtensions.Split Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Split(ReadOnlySpan<Char>, Span<Range>, Char, StringSplitOptions)	Parses the source ReadOnlySpan<T> for the specified `separator`, populating the `destination` span with Range instances representing the regions between the separators.
Split(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<Char>, StringSplitOptions)	Parses the source ReadOnlySpan<T> for the specified `separator`, populating the `destination` span with Range instances representing the regions between the separators.

Split(ReadOnlySpan<Char>, Span<Range>, Char, StringSplitOptions)

Parses the source ReadOnlySpan<T> for the specified `separator`, populating the `destination` span with Range instances representing the regions between the separators.

C#

```
public static int Split (this ReadOnlySpan<char> source, Span<Range>
destination, char separator, StringSplitOptions options =
System.StringSplitOptions.None);
```

Parameters

source ReadOnlySpan<Char>

The source span to parse.

`destination` Span<Range>

The destination span into which the resulting ranges are written.

`separator` Char

A character that delimits the regions in this instance.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim whitespace and include empty ranges.

Returns

Int32

The number of ranges written into `destination`.

Remarks

Delimiter characters are not included in the elements of the returned array.

If the `destination` span is empty, or if the `options` specifies RemoveEmptyEntries and `source` is empty, or if `options` specifies both RemoveEmptyEntries and TrimEntries and the `source` is entirely whitespace, no ranges are written to the destination.

If the span does not contain `separator`, or if `destination`'s length is 1, a single range will be output containing the entire `source`, subject to the processing implied by `options`.

If there are more regions in `source` than will fit in `destination`, the first `destination` length minus 1 ranges are stored in `destination`, and a range for the remainder of `source` is stored in `destination`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Split(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<Char>, StringSplitOptions)

Parses the source ReadOnlySpan<T> for the specified `separator`, populating the `destination` span with Range instances representing the regions between the separators.

```
C#

public static int Split (this ReadOnlySpan<char> source, Span<Range>
destination, ReadOnlySpan<char> separator, StringSplitOptions options =
System.StringSplitOptions.None);
```

Parameters

`source` ReadOnlySpan<Char>

The source span to parse.

`destination` Span<Range>

The destination span into which the resulting ranges are written.

`separator` ReadOnlySpan<Char>

A character that delimits the regions in this instance.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim whitespace and include empty ranges.

Returns

Int32

The number of ranges written into `destination`.

Remarks

Delimiter characters are not included in the elements of the returned array.

If the `destination` span is empty, or if the `options` specifies RemoveEmptyEntries and `source` is empty, or if `options` specifies both RemoveEmptyEntries and

TrimEntries and the `source` is entirely whitespace, no ranges are written to the destination.

If the span does not contain `separator`, or if `destination`'s length is 1, a single range will be output containing the entire `source`, subject to the processing implied by `options`.

If there are more regions in `source` than will fit in `destination`, the first `destination` length minus 1 ranges are stored in `destination`, and a range for the remainder of `source` is stored in `destination`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.SplitAny Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

SplitAny(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<String>, StringSplitOptions)	Parses the source ReadOnlySpan<T> for one of the specified `separators`, populating the `destination` span with Range instances representing the regions between the separators.
SplitAny(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<Char>, StringSplitOptions)	Parses the source ReadOnlySpan<T> for one of the specified `separators`, populating the `destination` span with Range instances representing the regions between the separators.

SplitAny(ReadOnlySpan<Char>, Span<Range>, ReadOnlySpan<String>, StringSplitOptions)

Parses the source ReadOnlySpan<T> for one of the specified `separators`, populating the `destination` span with Range instances representing the regions between the separators.

C#

```
public static int SplitAny (this ReadOnlySpan<char> source, Span<Range>
destination, ReadOnlySpan<string> separators, StringSplitOptions options
= System.StringSplitOptions.None);
```

Parameters

`source` ReadOnlySpan<Char>

The source span to parse.

`destination` Span<Range>

The destination span into which the resulting ranges are written.

`separators` ReadOnlySpan<String>

Any number of strings that may delimit the regions in this instance. If empty, all Unicode whitespace characters are used as the separators.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim whitespace and include empty ranges.

Returns

Int32

The number of ranges written into `destination`.

Remarks

Delimiter characters are not included in the elements of the returned array.

If the `destination` span is empty, or if the `options` specifies RemoveEmptyEntries and `source` is empty, or if `options` specifies both RemoveEmptyEntries and TrimEntries and the `source` is entirely whitespace, no ranges are written to the destination.

If the span does not contain any of the `separators`, or if `destination`'s length is 1, a single range will be output containing the entire `source`, subject to the processing implied by `options`.

If there are more regions in `source` than will fit in `destination`, the first `destination` length minus 1 ranges are stored in `destination`, and a range for the remainder of `source` is stored in `destination`.

Applies to

MemoryExtensions.StartsWith Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

StartsWith(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)	Determines whether a read-only character span begins with a specified value when compared using a specified StringComparison value.
StartsWith<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a specified sequence appears at the start of a span.
StartsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether a specified sequence appears at the start of a read-only span.

StartsWith(ReadOnlySpan<Char>, ReadOnlySpan<Char>, StringComparison)

Determines whether a read-only character span begins with a specified value when compared using a specified StringComparison value.

C#

```
public static bool StartsWith (this ReadOnlySpan<char> span,
ReadOnlySpan<char> value, StringComparison comparisonType);
```

Parameters

span ReadOnlySpan<Char>

The source span.

value ReadOnlySpan<Char>

The sequence to compare to the beginning of the source span.

`comparisonType` StringComparison

An enumeration value that determines how `span` and `value` are compared.

Returns

Boolean

`true` if `value` matches the beginning of `span`; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

StartsWith<T>(Span<T>, ReadOnlySpan<T>)

Determines whether a specified sequence appears at the start of a span.

C#

```
public static bool StartsWith<T> (this Span<T> span, ReadOnlySpan<T>
value) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The span to search.

`value` ReadOnlySpan<T>

A sequence to search for at the start of `span`.

Returns

Boolean

`true` if `value` matches the beginning of `span`; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

StartsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Determines whether a specified sequence appears at the start of a read-only span.

C#

```
public static bool StartsWith<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> value) where T : IEquatable<T>;
```

Type Parameters

T

The type of elements in the span.

Parameters

span ReadOnlySpan<T>

The read-only character span to search.

value ReadOnlySpan<T>

A sequence to search for at the start of `span`.

Returns

Boolean

`true` if `value` matches the beginning of `span`; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.ToLower Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Copies the characters from the source span into the destination, converting each character to lowercase, using the casing rules of the specified culture.

C#

```
public static int ToLower (this ReadOnlySpan<char> source, Span<char>
destination, System.Globalization.CultureInfo? culture);
```

Parameters

source ReadOnlySpan<Char>

The source span.

destination Span<Char>

The destination span which contains the transformed characters.

culture CultureInfo

An object that supplies culture-specific casing rules.

Returns

Int32

The number of characters written into the destination span. If the destination is too small, returns -1.

Exceptions

InvalidOperationException

The source and destination buffers overlap.

Remarks

If `culture` is `null`, CultureInfo.CurrentCulture will be used.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

MemoryExtensions.ToLowerInvariant Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Copies the characters from the source span into the destination, converting each character to lowercase, using the casing rules of the invariant culture.

C#

```
public static int ToLowerInvariant (this ReadOnlySpan<char> source,
Span<char> destination);
```

Parameters

source ReadOnlySpan<Char>

The source span.

destination Span<Char>

The destination span which contains the transformed characters.

Returns

Int32

The number of characters written into the destination span. If the destination is too small, returns -1.

Exceptions

InvalidOperationException

The source and destination buffers overlap.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.ToUpper Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Copies the characters from the source span into the destination, converting each character to uppercase, using the casing rules of the specified culture.

C#

```
public static int ToUpper (this ReadOnlySpan<char> source, Span<char>
destination, System.Globalization.CultureInfo? culture);
```

Parameters

source ReadOnlySpan<Char>

The source span.

destination Span<Char>

The destination span which contains the transformed characters.

culture CultureInfo

An object that supplies culture-specific casing rules.

Returns

Int32

The number of characters written into the destination span. If the destination is too small, returns -1.

Exceptions

InvalidOperationException

The source and destination buffers overlap.

Remarks

If `culture` is `null`, CultureInfo.CurrentCulture will be used.

MemoryExtensions.Trim Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Trim(Memory<Char>)	Removes all leading and trailing whitespace characters from a character memory region.
Trim(ReadOnlyMemory<Char>)	Removes all leading and trailing whitespace characters from a read-only character memory region.
Trim(ReadOnlySpan<Char>)	Removes all leading and trailing whitespace characters from a read-only character span.
Trim(Span<Char>)	Removes all leading and trailing whitespace characters from a character span.
Trim(ReadOnlySpan<Char>, Char)	Removes all leading and trailing occurrences of a specified character from a read-only character span.
Trim(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Removes all leading and trailing occurrences of a set of characters specified in a read-only span from a read-only character span.
Trim<T>(ReadOnlyMemory<T>, T)	Removes all leading and trailing occurrences of a specified element from a read-only memory region.
Trim<T>(Span<T>, T)	Removes all leading and trailing occurrences of a specified element from a span.
Trim<T>(Span<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a span.
Trim<T>(ReadOnlySpan<T>, T)	Removes all leading and trailing occurrences of a specified element from a read-only span.
Trim<T>(Memory<T>, T)	Removes all leading and trailing occurrences of a specified element from a memory region.

Trim<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.
Trim<T>(Memory<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a memory region.
Trim<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only span.

Trim(Memory<Char>)

Removes all leading and trailing whitespace characters from a character memory region.

C#

```
public static Memory<char> Trim (this Memory<char> memory);
```

Parameters

`memory` Memory<Char>

The source memory from which the characters are removed.

Returns

Memory<Char>

The trimmed character memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim(ReadOnlyMemory<Char>)

Removes all leading and trailing whitespace characters from a read-only character memory region.

```
C#

public static ReadOnlyMemory<char> Trim (this ReadOnlyMemory<char>
memory);
```

Parameters

`memory` ReadOnlyMemory<Char>

The source memory from which the characters are removed.

Returns

ReadOnlyMemory<Char>

The trimmed character memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim(ReadOnlySpan<Char>)

Removes all leading and trailing whitespace characters from a read-only character span.

```
C#

public static ReadOnlySpan<char> Trim (this ReadOnlySpan<char> span);
```

Parameters

`span` ReadOnlySpan<Char>

The source span from which the characters are removed.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Trim(Span<Char>)

Removes all leading and trailing whitespace characters from a character span.

C#

```
public static Span<char> Trim (this Span<char> span);
```

Parameters

span Span<Char>

The source span from which the characters are removed.

Returns

Span<Char>

The trimmed character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim(ReadOnlySpan<Char>, Char)

Removes all leading and trailing occurrences of a specified character from a read-only character span.

```
C#

public static ReadOnlySpan<char> Trim (this ReadOnlySpan<char> span, char
trimChar);
```

Parameters

`span` ReadOnlySpan<Char>

The source span from which the character is removed.

`trimChar` Char

The specified character to look for and remove.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Trim(ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Removes all leading and trailing occurrences of a set of characters specified in a read-only span from a read-only character span.

```
C#
```

```
public static ReadOnlySpan<char> Trim (this ReadOnlySpan<char> span,
ReadOnlySpan<char> trimChars);
```

Parameters

`span` ReadOnlySpan<Char>

The source span from which the characters are removed.

`trimChars` ReadOnlySpan<Char>

The span which contains the set of characters to remove.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Remarks

If `trimChars` is empty, whitespace characters are removed instead.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Trim<T>(ReadOnlyMemory<T>, T)

Removes all leading and trailing occurrences of a specified element from a read-only memory region.

C#

```
public static ReadOnlyMemory<T> Trim<T> (this ReadOnlyMemory<T> memory, T
trimElement) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only memory region.

Parameters

`memory` ReadOnlyMemory<T>

The source memory from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

ReadOnlyMemory<T>

The trimmed read-only memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(Span<T>, T)

Removes all leading and trailing occurrences of a specified element from a span.

```
C#

public static Span<T> Trim<T> (this Span<T> span, T trimElement) where T
: IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The source span from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

Span<T>

The trimmed span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(Span<T>, ReadOnlySpan<T>)

Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a span.

C#

```
public static Span<T> Trim<T> (this Span<T> span, ReadOnlySpan<T>
trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The source span from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

Span<T>

The trimmed span.

Remarks

If `trimElements` is empty, the span is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(ReadOnlySpan<T>, T)

Removes all leading and trailing occurrences of a specified element from a read-only span.

C#

```
public static ReadOnlySpan<T> Trim<T> (this ReadOnlySpan<T> span, T
trimElement) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only span.

Parameters

`span` ReadOnlySpan<T>

The source span from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

ReadOnlySpan<T>

The trimmed read-only span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(Memory<T>, T)

Removes all leading and trailing occurrences of a specified element from a memory region.

C#

```
public static Memory<T> Trim<T> (this Memory<T> memory, T trimElement)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the memory region.

Parameters

`memory` Memory<T>

The source memory from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

Memory<T>

The trimmed memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)

Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.

C#

```
public static ReadOnlyMemory<T> Trim<T> (this ReadOnlyMemory<T> memory,
ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only memory region.

Parameters

`memory` ReadOnlyMemory<T>

The source memory from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

ReadOnlyMemory<T>

The trimmed read-only memory region.

Remarks

If `trimElements` is empty, the memory is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(Memory<T>, ReadOnlySpan<T>)

Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a memory region.

```
C#

public static Memory<T> Trim<T> (this Memory<T> memory, ReadOnlySpan<T>
trimElements) where T : IEquatable<T>;
```

Type Parameters

T

The type of the elements in the memory region.

Parameters

memory Memory<T>

The source memory from which the elements are removed.

trimElements ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

Memory<T>

The trimmed memory region.

Remarks

If `trimElements` is empty, the memory is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Trim<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only span.

C#

```
public static ReadOnlySpan<T> Trim<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

T

The type of the elements in the read-only span.

Parameters

span ReadOnlySpan<T>

The source span from which the elements are removed.

trimElements ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

ReadOnlySpan<T>

The trimmed read-only span.

Remarks

If `trimElements` is empty, the span is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.TrimEnd Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

TrimEnd(ReadOnlySpan<Char>, Char)	Removes all trailing occurrences of a specified character from a read-only span.
TrimEnd(Memory<Char>)	Removes all trailing whitespace characters from a character memory region.
TrimEnd(ReadOnlyMemory<Char>)	Removes all trailing whitespace characters from a read-only character memory region.
TrimEnd(ReadOnlySpan<Char>)	Removes all trailing whitespace characters from a read-only character span.
TrimEnd(Span<Char>)	Removes all trailing whitespace characters from a character span.
TrimEnd(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Removes all trailing occurrences of a set of characters specified in a read-only span from a read-only character span.
TrimEnd<T>(Memory<T>, T)	Removes all trailing occurrences of a specified element from a character memory region.
TrimEnd<T>(Span<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a span.
TrimEnd<T>(Span<T>, T)	Removes all trailing occurrences of a specified element from a span.
TrimEnd<T>(ReadOnlySpan<T>, T)	Removes all trailing occurrences of a specified element from a read-only span.
TrimEnd<T>(Memory<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a memory region.

TrimEnd<T>(ReadOnlyMemory<T>, T)	Removes all trailing occurrences of a specified element from a read-only memory region.
TrimEnd<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.
TrimEnd<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only span.

TrimEnd(ReadOnlySpan<Char>, Char)

Removes all trailing occurrences of a specified character from a read-only span.

C#

```
public static ReadOnlySpan<char> TrimEnd (this ReadOnlySpan<char> span,
char trimChar);
```

Parameters

`span` ReadOnlySpan<Char>

The source span from which the character is removed.

`trimChar` Char

The specified character to look for and remove.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimEnd(Memory<Char>)

Removes all trailing whitespace characters from a character memory region.

C#

```
public static Memory<char> TrimEnd (this Memory<char> memory);
```

Parameters

memory Memory<Char>

The source memory from which the characters are removed.

Returns

Memory<Char>

The trimmed character memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd(ReadOnlyMemory<Char>)

Removes all trailing whitespace characters from a read-only character memory region.

C#

```
public static ReadOnlyMemory<char> TrimEnd (this ReadOnlyMemory<char>
memory);
```

Parameters

memory ReadOnlyMemory<Char>

The source memory from which the characters are removed.

Returns

ReadOnlyMemory<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd(ReadOnlySpan<Char>)

Removes all trailing whitespace characters from a read-only character span.

C#

```
public static ReadOnlySpan<char> TrimEnd (this ReadOnlySpan<char> span);
```

Parameters

span ReadOnlySpan<Char>

The source span from which the characters are removed.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimEnd(Span<Char>)

Removes all trailing whitespace characters from a character span.

C#

```
public static Span<char> TrimEnd (this Span<char> span);
```

Parameters

span Span<Char>

The source span from which the characters are removed.

Returns

Span<Char>

The trimmed character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd(ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Removes all trailing occurrences of a set of characters specified in a read-only span from a read-only character span.

C#

```
public static ReadOnlySpan<char> TrimEnd (this ReadOnlySpan<char> span,
ReadOnlySpan<char> trimChars);
```

Parameters

span ReadOnlySpan<Char>

The source span from which the characters are removed.

`trimChars` ReadOnlySpan<Char>

The span which contains the set of characters to remove.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Remarks

If `trimChars` is empty, whitespace characters are removed instead.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimEnd<T>(Memory<T>, T)

Removes all trailing occurrences of a specified element from a character memory region.

```
C#

public static Memory<T> TrimEnd<T> (this Memory<T> memory, T trimElement)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the memory region.

Parameters

`memory` Memory<T>

The source memory from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

Memory<T>

The trimmed memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(Span<T>, ReadOnlySpan<T>)

Removes all trailing occurrences of a set of elements specified in a read-only span from a span.

C#

```
public static Span<T> TrimEnd<T> (this Span<T> span, ReadOnlySpan<T>
trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The source span from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

Span<T>

The trimmed span.

Remarks

If `trimElements` is empty, the span is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(Span<T>, T)

Removes all trailing occurrences of a specified element from a span.

C#

```
public static Span<T> TrimEnd<T> (this Span<T> span, T trimElement) where
T : IEquatable<T>;
```

Type Parameters

T

The type of the elements in the span.

Parameters

span Span<T>

The source span from which the element is removed.

trimElement T

The specified element to look for and remove.

Returns

Span<T>

The trimmed span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(ReadOnlySpan<T>, T)

Removes all trailing occurrences of a specified element from a read-only span.

C#

```
public static ReadOnlySpan<T> TrimEnd<T> (this ReadOnlySpan<T> span, T
trimElement) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only span.

Parameters

`span` ReadOnlySpan<T>

The source span from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

ReadOnlySpan<T>

The trimmed read-only span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(Memory<T>, ReadOnlySpan<T>)

Removes all trailing occurrences of a set of elements specified in a read-only span from a memory region.

C#

```
public static Memory<T> TrimEnd<T> (this Memory<T> memory,
ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the memory region.

Parameters

`memory` Memory<T>

The source memory from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

Memory<T>

The trimmed memory region.

Remarks

If `trimElements` is empty, the memory is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(ReadOnlyMemory<T>, T)

Removes all trailing occurrences of a specified element from a read-only memory region.

C#

```
public static ReadOnlyMemory<T> TrimEnd<T> (this ReadOnlyMemory<T>
memory, T trimElement) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only memory region.

Parameters

`memory` ReadOnlyMemory<T>

The source memory from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

ReadOnlyMemory<T>

The trimmed read-only memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)

Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.

C#

```
public static ReadOnlyMemory<T> TrimEnd<T> (this ReadOnlyMemory<T>
memory, ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only memory region.

Parameters

`memory` ReadOnlyMemory<T>

The source memory from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

ReadOnlyMemory<T>

The trimmed read-only memory region.

Remarks

If `trimElements` is empty, the memory is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimEnd<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only span.

C#

```
public static ReadOnlySpan<T> TrimEnd<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only span.

Parameters

`span` ReadOnlySpan<T>

The source span from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

ReadOnlySpan<T>

The trimmed read-only span.

Remarks

If `trimElements` is empty, the span is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.TrimStart Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

TrimStart(Memory<Char>)	Removes all leading whitespace characters from a memory region.
TrimStart(ReadOnlyMemory<Char>)	Removes all leading whitespace characters from a read-only memory region.
TrimStart(ReadOnlySpan<Char>)	Removes all leading whitespace characters from a read-only span.
TrimStart(Span<Char>)	Removes all leading whitespace characters from a span.
TrimStart(ReadOnlySpan<Char>, Char)	Removes all leading occurrences of a specified character from the span.
TrimStart(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Removes all leading occurrences of a set of characters specified in a read-only span from the span.
TrimStart<T>(Span<T>, T)	Removes all leading occurrences of a specified element from the span.
TrimStart<T>(Span<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from the span.
TrimStart<T>(ReadOnlySpan<T>, T)	Removes all leading occurrences of a specified element from the span.
TrimStart<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from the span.

TrimStart<T>(Memory<T>, T)	Removes all leading occurrences of a specified element from a memory region.
TrimStart<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.
TrimStart<T>(Memory<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.
TrimStart<T>(ReadOnlyMemory<T>, T)	Removes all leading occurrences of a specified element from a memory region.

TrimStart(Memory<Char>)

Removes all leading whitespace characters from a memory region.

```
C#

public static Memory<char> TrimStart (this Memory<char> memory);
```

Parameters

`memory` Memory<Char>

The source memory from which the characters are removed.

Returns

Memory<Char>

The trimmed character memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart(ReadOnlyMemory<Char>)

Removes all leading whitespace characters from a read-only memory region.

```
C#

public static ReadOnlyMemory<char> TrimStart (this ReadOnlyMemory<char>
memory);
```

Parameters

memory ReadOnlyMemory<Char>

The source memory from which the characters are removed.

Returns

ReadOnlyMemory<Char>

The trimmed read-only character memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart(ReadOnlySpan<Char>)

Removes all leading whitespace characters from a read-only span.

```
C#

public static ReadOnlySpan<char> TrimStart (this ReadOnlySpan<char>
span);
```

Parameters

span ReadOnlySpan<Char>

The source span from which the characters are removed.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimStart(Span<Char>)

Removes all leading whitespace characters from a span.

C#

```
public static Span<char> TrimStart (this Span<char> span);
```

Parameters

span Span<Char>

The source span from which the characters are removed.

Returns

Span<Char>

The trimmed character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart(ReadOnlySpan<Char>, Char)

Removes all leading occurrences of a specified character from the span.

C#

```
public static ReadOnlySpan<char> TrimStart (this ReadOnlySpan<char> span,
char trimChar);
```

Parameters

`span` ReadOnlySpan<Char>

The source span from which the character is removed.

`trimChar` Char

The specified character to look for and remove.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimStart(ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Removes all leading occurrences of a set of characters specified in a read-only span from the span.

C#

```
public static ReadOnlySpan<char> TrimStart (this ReadOnlySpan<char> span,
ReadOnlySpan<char> trimChars);
```

Parameters

`span` ReadOnlySpan<Char>

The source span from which the characters are removed.

`trimChars` ReadOnlySpan<Char>

The span which contains the set of characters to remove.

Returns

ReadOnlySpan<Char>

The trimmed read-only character span.

Remarks

If `trimChars` is empty, whitespace characters are removed instead.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimStart<T>(Span<T>, T)

Removes all leading occurrences of a specified element from the span.

C#

```
public static Span<T> TrimStart<T> (this Span<T> span, T trimElement)
where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The source span from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

Span<T>

The trimmed span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(Span<T>, ReadOnlySpan<T>)

Removes all leading occurrences of a set of elements specified in a read-only span from the span.

C#

```
public static Span<T> TrimStart<T> (this Span<T> span, ReadOnlySpan<T>
trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the span.

Parameters

`span` Span<T>

The source span from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

Span<T>

The trimmed span.

Remarks

If `trimElements` is empty, the span is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(ReadOnlySpan<T>, T)

Removes all leading occurrences of a specified element from the span.

```
C#

public static ReadOnlySpan<T> TrimStart<T> (this ReadOnlySpan<T> span, T
trimElement) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only span.

Parameters

`span` ReadOnlySpan<T>

The source span from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

ReadOnlySpan<T>

The trimmed read-only span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)

Removes all leading occurrences of a set of elements specified in a read-only span from the span.

C#

```
public static ReadOnlySpan<T> TrimStart<T> (this ReadOnlySpan<T> span,
ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only span.

Parameters

`span` ReadOnlySpan<T>

The source span from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

ReadOnlySpan<T>

The trimmed read-only span.

Remarks

If `trimElements` is empty, the span is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(Memory<T>, T)

Removes all leading occurrences of a specified element from a memory region.

```
C#

public static Memory<T> TrimStart<T> (this Memory<T> memory, T
trimElement) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the memory region.

Parameters

`memory` Memory<T>

The source memory region from which the element is removed.

`trimElement` T

The specified element to look for and remove.

Returns

Memory<T>

The trimmed memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)

Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.

C#

```
public static ReadOnlyMemory<T> TrimStart<T> (this ReadOnlyMemory<T>
memory, ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

`T`

The type of the elements in the read-only memory region.

Parameters

`memory` ReadOnlyMemory<T>

The source memory from which the elements are removed.

`trimElements` ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

ReadOnlyMemory<T>

The trimmed read-only memory region.

Remarks

If `trimElements` is empty, the memory is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(Memory<T>, ReadOnlySpan<T>)

Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.

C#

```
public static Memory<T> TrimStart<T> (this Memory<T> memory,
ReadOnlySpan<T> trimElements) where T : IEquatable<T>;
```

Type Parameters

T

The type of the elements in the memory region.

Parameters

memory Memory<T>

The source memory from which the elements are removed.

trimElements ReadOnlySpan<T>

The span which contains the set of elements to remove.

Returns

Memory<T>

The trimmed memory region.

Remarks

If `trimElements` is empty, the memory is returned unaltered.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TrimStart<T>(ReadOnlyMemory<T>, T)

Removes all leading occurrences of a specified element from a memory region.

C#

```
public static ReadOnlyMemory<T> TrimStart<T> (this ReadOnlyMemory<T>
memory, T trimElement) where T : IEquatable<T>;
```

Type Parameters

T

The type of the elements in the read-only memory region.

Parameters

memory ReadOnlyMemory<T>

The source memory from which the element is removed.

trimElement T

The specified element to look for and remove.

Returns

ReadOnlyMemory<T>

The trimmed read-only memory region.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MemoryExtensions.TryWrite Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

TryWrite(Span<Char>, IFormatProvider, CompositeFormat, Int32, Object[])	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite(Span<Char>, MemoryExtensions+TryWriteInterpolatedStringHandler, Int32)	Writes the specified interpolated string to the character span.
TryWrite(Span<Char>, IFormatProvider, MemoryExtensions+TryWriteInterpolatedStringHandler, Int32)	Writes the specified interpolated string to the character span.
TryWrite(Span<Char>, IFormatProvider, CompositeFormat, Int32, ReadOnlySpan<Object>)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite<TArg0,TArg1,TArg2>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0, TArg1, TArg2)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.
TryWrite<TArg0,TArg1>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0, TArg1)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string

	representation of the corresponding arguments.
TryWrite<TArg0>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0)	Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

TryWrite(Span<Char>, IFormatProvider, CompositeFormat, Int32, Object[])

Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

C#

```
public static bool TryWrite (this Span<char> destination,
IFormatProvider? provider, System.Text.CompositeFormat format, out int
charsWritten, params object?[] args);
```

Parameters

destination Span<Char>

The span to which the string should be formatted.

provider IFormatProvider

An object that supplies culture-specific formatting information.

format CompositeFormat

A CompositeFormat.

charsWritten Int32

When this method returns, contains the number of characters written to the span.

args Object[]

An array of objects to format.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Exceptions

ArgumentNullException

`format` or `args` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryWrite(Span<Char>, MemoryExtensions+TryWriteInterpolatedStringHandler, Int32)

Writes the specified interpolated string to the character span.

C#

```
public static bool TryWrite (this Span<char> destination, ref
MemoryExtensions.TryWriteInterpolatedStringHandler handler, out int
charsWritten);
```

Parameters

`destination` Span<Char>

The span to which the interpolated string should be formatted.

`handler` MemoryExtensions.TryWriteInterpolatedStringHandler

The interpolated string, passed by reference.

`charsWritten` Int32

When this method returns, contains the number of characters written to the span.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryWrite(Span<Char>, IFormatProvider, MemoryExtensions+TryWriteInterpolatedStringHandler, Int32)

Writes the specified interpolated string to the character span.

C#

```
public static bool TryWrite (this Span<char> destination,
IFormatProvider? provider, ref
MemoryExtensions.TryWriteInterpolatedStringHandler handler, out int
charsWritten);
```

Parameters

`destination` Span<Char>

The span to which the interpolated string should be formatted.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`handler` MemoryExtensions.TryWriteInterpolatedStringHandler

The interpolated string, passed by reference.

`charsWritten` Int32

When this method returns, contains the number of characters written to the span.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryWrite(Span<Char>, IFormatProvider, CompositeFormat, Int32, ReadOnlySpan<Object>)

Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

C#

```
public static bool TryWrite (this Span<char> destination,
IFormatProvider? provider, System.Text.CompositeFormat format, out int
charsWritten, ReadOnlySpan<object?> args);
```

Parameters

`destination` Span<Char>

The span to which the string should be formatted.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`charsWritten` Int32

When this method returns, contains the number of characters written to the span.

`args` ReadOnlySpan<Object>

A span of objects to format.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryWrite<TArg0,TArg1,TArg2>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0, TArg1, TArg2)

Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

C#

```
public static bool TryWrite<TArg0,TArg1,TArg2> (this Span<char>
destination, IFormatProvider? provider, System.Text.CompositeFormat
format, out int charsWritten, TArg0 arg0, TArg1 arg1, TArg2 arg2);
```

Type Parameters

TArg0

The type of the first object to format.

TArg1

The type of the second object to format.

TArg2

The type of the third object to format.

Parameters

destination Span<Char>

The span to which the string should be formatted.

provider IFormatProvider

An object that supplies culture-specific formatting information.

format CompositeFormat

A CompositeFormat.

charsWritten Int32

When this method returns, contains the number of characters written to the span.

arg0 TArg0

The first object to format.

arg1 TArg1

The second object to format.

arg2 TArg2

The third object to format.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryWrite<TArg0,TArg1>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0, TArg1)

Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

C#

```
public static bool TryWrite<TArg0,TArg1> (this Span<char> destination,
IFormatProvider? provider, System.Text.CompositeFormat format, out int
charsWritten, TArg0 arg0, TArg1 arg1);
```

Type Parameters

`TArg0`

The type of the first object to format.

`TArg1`

The type of the second object to format.

Parameters

`destination` Span<Char>

The span to which the string should be formatted.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`charsWritten` Int32

When this method returns, contains the number of characters written to the span.

`arg0` TArg0

The first object to format.

`arg1` TArg1

The second object to format.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryWrite<TArg0>(Span<Char>, IFormatProvider, CompositeFormat, Int32, TArg0)

Writes the CompositeFormat string to the character span, substituting the format item or items with the string representation of the corresponding arguments.

C#

```
public static bool TryWrite<TArg0> (this Span<char> destination,
IFormatProvider? provider, System.Text.CompositeFormat format, out int
charsWritten, TArg0 arg0);
```

Type Parameters

`TArg0`

The type of the object to format.

Parameters

`destination` Span<Char>

The span to which the string should be formatted.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`charsWritten` Int32

When this method returns, contains the number of characters written to the span.

`arg0` TArg0

The object to format.

Returns

Boolean

`true` if the entire interpolated string could be formatted successfully; otherwise, `false`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

MemoryExtensions.TryWriteInterpolatedStringHandler Struct

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Provides a handler used by the language compiler to format interpolated strings into character spans.

C#

```
public ref struct MemoryExtensions.TryWriteInterpolatedStringHandler
```

Inheritance Object → ValueType → MemoryExtensions.TryWriteInterpolatedStringHandler

Constructors

Expand table

MemoryExtensions.TryWriteInterpolatedStringHandler(Int32, Int32, Span<Char>, Boolean)	Creates a handler used to write an interpolated string into a span of characters.
MemoryExtensions.TryWriteInterpolatedStringHandler(Int32, Int32, Span<Char>, IFormatProvider, Boolean)	Creates a handler used to write an interpolated string into a span of characters.

Methods

Expand table

AppendFormatted(Object, Int32, String)	Writes the specified value to the handler.
AppendFormatted(ReadOnlySpan<Char>)	Writes the specified value to the handler.

AppendFormatted(ReadOnlySpan<Char>, Int32, String)	Writes the specified value to the handler.
AppendFormatted(String)	Writes the specified value to the handler.
AppendFormatted(String, Int32, String)	Writes a specified value to the handler using a specified format string.
AppendFormatted<T>(T)	Writes the specified value to the handler.
AppendFormatted<T>(T, Int32)	Writes the specified value to the handler.
AppendFormatted<T>(T, Int32, String)	Writes a specified value to the handler using a specified format string.
AppendFormatted<T>(T, String)	Writes a specified value to the handler using a specified format string.
AppendLiteral(String)	Writes the specified string to the handler.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

MemoryExtensions.TryWriteInterpolatedStringHandler Constructors

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

MemoryExtensions.TryWriteInterpolatedStringHandler(Int32, Int32, Span<Char>, Boolean)	Creates a handler used to write an interpolated string into a span of characters.
MemoryExtensions.TryWriteInterpolatedStringHandler(Int32, Int32, Span<Char>, IFormatProvider, Boolean)	Creates a handler used to write an interpolated string into a span of characters.

MemoryExtensions.TryWriteInterpolatedStringHandler(Int32, Int32, Span<Char>, Boolean)

Creates a handler used to write an interpolated string into a span of characters.

C#

```
public TryWriteInterpolatedStringHandler (int literalLength, int
formattedCount, Span<char> destination, out bool shouldAppend);
```

Parameters

`literalLength` Int32

The number of constant characters outside of interpolation expressions in the interpolated string.

`formattedCount` Int32

The number of interpolation expressions in the interpolated string.

`destination` Span<Char>

The destination buffer.

`shouldAppend` Boolean

When this method returns, contains `true` if the destination may be long enough to support the formatting, or `false` if it won't be.

Remarks

This is intended to be called only by compiler-generated code. Arguments are not validated as they'd otherwise be for members intended to be used directly.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

MemoryExtensions.TryWriteInterpolatedStringHandler(Int32, Int32, Span<Char>, IFormatProvider, Boolean)

Creates a handler used to write an interpolated string into a span of characters.

C#

```
public TryWriteInterpolatedStringHandler (int literalLength, int
formattedCount, Span<char> destination, IFormatProvider? provider, out
bool shouldAppend);
```

Parameters

`literalLength` Int32

The number of constant characters outside of interpolation expressions in the interpolated string.

`formattedCount` Int32

The number of interpolation expressions in the interpolated string.

`destination` Span<Char>

The destination buffer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`shouldAppend` Boolean

When this method returns, contains `true` if the destination may be long enough to support the formatting, or `false` if it won't be.

Remarks

This is intended to be called only by compiler-generated code. Arguments are not validated as they'd otherwise be for members intended to be used directly.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

MemoryExtensions.TryWriteInterpolatedStringHandler.AppendFormatted Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

AppendFormatted(ReadOnlySpan<Char>)	Writes the specified value to the handler.
AppendFormatted(String)	Writes the specified value to the handler.
AppendFormatted(Object, Int32, String)	Writes the specified value to the handler.
AppendFormatted(ReadOnlySpan<Char>, Int32, String)	Writes the specified value to the handler.
AppendFormatted(String, Int32, String)	Writes a specified value to the handler using a specified format string.
AppendFormatted<T>(T)	Writes the specified value to the handler.
AppendFormatted<T>(T, Int32)	Writes the specified value to the handler.
AppendFormatted<T>(T, String)	Writes a specified value to the handler using a specified format string.
AppendFormatted<T>(T, Int32, String)	Writes a specified value to the handler using a specified format string.

AppendFormatted(ReadOnlySpan<Char>)

Writes the specified value to the handler.

```
C#
```

```
public bool AppendFormatted (scoped ReadOnlySpan<char> value);
```

Parameters

`value` ReadOnlySpan<Char>

The value to write.

Returns

Boolean

`false` if the operation failed; `true` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted(String)

Writes the specified value to the handler.

C#

```
public bool AppendFormatted (string? value);
```

Parameters

`value` String

The value to write.

Returns

Boolean

`true` on success; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted(Object, Int32, String)

Writes the specified value to the handler.

```
C#

public bool AppendFormatted (object? value, int alignment = 0, string?
format = default);
```

Parameters

`value` Object

The value to write.

`alignment` Int32

The minimum number of characters that should be written for this value. A negative value indicates left-aligned, and the required minimum is the absolute value.

`format` String

The format string.

Returns

Boolean

`true` on success; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted(ReadOnlySpan<Char>, Int32, String)

Writes the specified value to the handler.

```
C#

public bool AppendFormatted (scoped ReadOnlySpan<char> value, int
alignment = 0, string? format = default);
```

Parameters

`value` ReadOnlySpan<Char>

The value to write.

`alignment` Int32

>The minimum number of characters that should be written for this value. If the value is negative, it indicates left-aligned and the required minimum is the absolute value.

`format` String

The format string.

Returns

Boolean

`false` if the operation failed; `true` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted(String, Int32, String)

Writes a specified value to the handler using a specified format string.

```
C#

public bool AppendFormatted (string? value, int alignment = 0, string?
format = default);
```

Parameters

`value` String

The value to write.

`alignment` Int32

The minimum number of characters that should be written for this value. A negative value indicates left-aligned, and the required minimum is the absolute value.

`format` String

The format string.

Returns

Boolean

`true` on success; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted<T>(T)

Writes the specified value to the handler.

```
C#
```

```
public bool AppendFormatted<T> (T value);
```

Type Parameters

T

The type of the value to write.

Parameters

value T

The value to write.

Returns

Boolean

`true` on success; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted<T>(T, Int32)

Writes the specified value to the handler.

C#

```
public bool AppendFormatted<T> (T value, int alignment);
```

Type Parameters

T

The type of the value to write.

Parameters

`value` T

The value to write.

`alignment` Int32

The minimum number of characters that should be written for this value.A negative value indicates left-aligned, and the required minimum is the absolute value.

Returns

Boolean

`false` if the operation failed; `true` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted<T>(T, String)

Writes a specified value to the handler using a specified format string.

```
C#
public bool AppendFormatted<T> (T value, string? format);
```

Type Parameters

`T`

The type of the value to write.

Parameters

`value` T

The value to write.

`format` String

The format string.

Returns

Boolean

`true` on success; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AppendFormatted<T>(T, Int32, String)

Writes a specified value to the handler using a specified format string.

```
C#
public bool AppendFormatted<T> (T value, int alignment, string? format);
```

Type Parameters

T

The type of the value to write.

Parameters

value T

The value to write.

alignment Int32

The minimum number of characters that should be written for this value. A negative value indicates left-aligned, and the required minimum is the absolute value.

format String

The format string.

Returns

Boolean

`true` on success; `false` otherwise.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

MemoryExtensions.TryWriteInterpolatedStringHandler.AppendLiteral Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Writes the specified string to the handler.

C#

```
public bool AppendLiteral (string value);
```

Parameters

`value` String

The string to write.

Returns

Boolean

`true` if the value could be formatted to the span; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

MethodAccessException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an invalid attempt to access a method, such as accessing a private method from partially trusted code.

C#

```
public class MethodAccessException : MemberAccessException
```

Inheritance Object → Exception → SystemException → MemberAccessException → MethodAccessException

Remarks

> **Note**
>
> This exception is not included in the **.NET for Windows Store apps** or the **Portable Class Library**, but it is thrown by some members that are. To catch the exception in that case, write a `catch` statement for **MemberAccessException** instead.

This exception is thrown in situations such as the following:

- A private, protected, or internal method that would not be accessible from normal compiled code is accessed from partially trusted code by using reflection.
- A security-critical method is accessed from transparent code.
- The access level of a method in a class library has changed, and one or more assemblies that reference the library have not been recompiled.

> **Note**

Beginning with the .NET Framework 4, the common language runtime treats application code as transparent when it is run with partial trust. See **Security Considerations for Reflection**.

MethodAccessException uses the HRESULT COR_E_METHODACCESS, that has the value 0x80131510.

For a list of initial property values for an instance of MethodAccessException, see the MethodAccessException constructors.

Constructors

Expand table

MethodAccessException()	Initializes a new instance of the MethodAccessException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "Attempt to access the method failed." This message takes into account the current system culture.
MethodAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MethodAccessException class with serialized data.
MethodAccessException(String)	Initializes a new instance of the MethodAccessException class with a specified error message.
MethodAccessException(String, Exception)	Initializes a new instance of the MethodAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

	(Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MethodAccessException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MethodAccessException class.

Overloads

Expand table

MethodAccessException()	Initializes a new instance of the MethodAccessException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "Attempt to access the method failed." This message takes into account the current system culture.
MethodAccessException(String)	Initializes a new instance of the MethodAccessException class with a specified error message.
MethodAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MethodAccessException class with serialized data.
MethodAccessException(String, Exception)	Initializes a new instance of the MethodAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

MethodAccessException()

Initializes a new instance of the MethodAccessException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "Attempt to access the method failed." This message takes into account the current system culture.

```
C#
public MethodAccessException ();
```

Remarks

The following table shows the initial property values for an instance of MethodAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MethodAccessException(String)

Initializes a new instance of the MethodAccessException class with a specified error message.

```
C#
public MethodAccessException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of `message` should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of MethodAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MethodAccessException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the MethodAccessException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected MethodAccessException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions *(Obsolete)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MethodAccessException(String, Exception)

Initializes a new instance of the MethodAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public MethodAccessException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of MethodAccessException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

MidpointRounding Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the strategy that mathematical rounding methods should use to round a number.

C#

```
public enum MidpointRounding
```

Inheritance Object → ValueType → Enum → MidpointRounding

Fields

Expand table

AwayFromZero	1	The strategy of rounding to the nearest number, and when a number is halfway between two others, it's rounded toward the nearest number that's away from zero.
ToEven	0	The strategy of rounding to the nearest number, and when a number is halfway between two others, it's rounded toward the nearest even number.
ToNegativeInfinity	3	The strategy of downwards-directed rounding, with the result closest to and no greater than the infinitely precise result.
ToPositiveInfinity	4	The strategy of upwards-directed rounding, with the result closest to and no less than the infinitely precise result.
ToZero	2	The strategy of directed rounding toward zero, with the result closest to and no greater in magnitude than the infinitely precise result.

Examples

The following example demonstrates the Math.Round method in conjunction with the `MidpointRounding` enumeration:

C#

```
decimal result;

// Round a positive value using different strategies.
// The precision of the result is 1 decimal place.

result = Math.Round(3.45m, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result} = Math.Round({3.45m}, 1,
MidpointRounding.ToEven)");
result = Math.Round(3.45m, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result} = Math.Round({3.45m}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(3.47m, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result} = Math.Round({3.47m}, 1,
MidpointRounding.ToZero)\n");

// Round a negative value using different strategies.
// The precision of the result is 1 decimal place.

result = Math.Round(-3.45m, 1, MidpointRounding.ToEven);
Console.WriteLine($"{result} = Math.Round({-3.45m}, 1,
MidpointRounding.ToEven)");
result = Math.Round(-3.45m, 1, MidpointRounding.AwayFromZero);
Console.WriteLine($"{result} = Math.Round({-3.45m}, 1,
MidpointRounding.AwayFromZero)");
result = Math.Round(-3.47m, 1, MidpointRounding.ToZero);
Console.WriteLine($"{result} = Math.Round({-3.47m}, 1,
MidpointRounding.ToZero)\n");

/*
This code example produces the following results:

3.4 = Math.Round(3.45, 1, MidpointRounding.ToEven)
3.5 = Math.Round(3.45, 1, MidpointRounding.AwayFromZero)
3.4 = Math.Round(3.47, 1, MidpointRounding.ToZero)

-3.4 = Math.Round(-3.45, 1, MidpointRounding.ToEven)
-3.5 = Math.Round(-3.45, 1, MidpointRounding.AwayFromZero)
-3.4 = Math.Round(-3.47, 1, MidpointRounding.ToZero)
*/
```

Remarks

For more information about this API, see Supplemental API remarks for MidpointRounding.

MissingFieldException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to dynamically access a field that does not exist. If a field in a class library has been removed or renamed, recompile any assemblies that reference that library.

C#

```
public class MissingFieldException : MissingMemberException
```

Inheritance Object → Exception → SystemException → MemberAccessException → MissingMemberException → MissingFieldException

Examples

This example shows what happens if you attempt to use reflection to call a method that does not exist and access a field that does not exist. The application recovers by catching the MissingMethodException, MissingFieldException, and MissingMemberException.

C#

```
using System;
using System.Reflection;

public class App
{
    public static void Main()
    {

        try
        {
            // Attempt to call a static DoSomething method defined in the
App class.
            // However, because the App class does not define this method,
            // a MissingMethodException is thrown.
            typeof(App).InvokeMember("DoSomething", BindingFlags.Static |
```

```
                BindingFlags.InvokeMethod, null, null, null);
        }
        catch (MissingMethodException e)
        {
            // Show the user that the DoSomething method cannot be called.
            Console.WriteLine("Unable to call the DoSomething method: {0}",
e.Message);
        }

        try
        {
            // Attempt to access a static AField field defined in the App
class.
            // However, because the App class does not define this field,
            // a MissingFieldException is thrown.
            typeof(App).InvokeMember("AField", BindingFlags.Static |
BindingFlags.SetField,
                null, null, new Object[] { 5 });
        }
        catch (MissingFieldException e)
        {
         // Show the user that the AField field cannot be accessed.
         Console.WriteLine("Unable to access the AField field: {0}",
e.Message);
        }

        try
        {
            // Attempt to access a static AnotherField field defined in the
App class.
            // However, because the App class does not define this field,
            // a MissingFieldException is thrown.
            typeof(App).InvokeMember("AnotherField", BindingFlags.Static |
                BindingFlags.GetField, null, null, null);
        }
        catch (MissingMemberException e)
        {
         // Notice that this code is catching MissingMemberException which
is the
         // base class of MissingMethodException and MissingFieldException.
         // Show the user that the AnotherField field cannot be accessed.
         Console.WriteLine("Unable to access the AnotherField field: {0}",
e.Message);
        }
    }
}
// This code example produces the following output:
//
// Unable to call the DoSomething method: Method 'App.DoSomething' not
found.
// Unable to access the AField field: Field 'App.AField' not found.
// Unable to access the AnotherField field: Field 'App.AnotherField' not
found.
```

Remarks

Normally a compilation error is generated if code attempts to access a nonexistent member of a class. MissingFieldException is designed to handle cases where an attempt is made to dynamically access a renamed or deleted field of an assembly that is not referenced by its strong name. The MissingFieldException is thrown when code in a dependent assembly attempts to access a missing field in an assembly that was modified.

MissingFieldException uses the HRESULT COR_E_MISSINGFIELD, that has the value 0x80131511.

For a list of initial property values for an instance of MissingFieldException, see the MissingFieldException constructors.

Constructors

Expand table

MissingFieldException()	Initializes a new instance of the MissingFieldException class.
MissingFieldException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MissingFieldException class with serialized data.
MissingFieldException(String)	Initializes a new instance of the MissingFieldException class with a specified error message.
MissingFieldException(String, Exception)	Initializes a new instance of the MissingFieldException class with a specified error message and a reference to the inner exception that is the cause of this exception.
MissingFieldException(String, String)	Initializes a new instance of the MissingFieldException class with the specified class name and field name.

Fields

Expand table

ClassName	Holds the class name of the missing member. (Inherited from MissingMemberException)
MemberName	Holds the name of the missing member.

	(Inherited from MissingMemberException)
Signature	Holds the signature of the missing member. (Inherited from MissingMemberException)

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the text string showing the signature of the missing field, the class name, and the field name. This property is read-only.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)

GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the class name, the member name, the signature of the missing member, and additional exception information. (Inherited from MissingMemberException)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

MissingFieldException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MissingFieldException class.

Overloads

Expand table

MissingFieldException()	Initializes a new instance of the MissingFieldException class.
MissingFieldException(String)	Initializes a new instance of the MissingFieldException class with a specified error message.
MissingFieldException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MissingFieldException class with serialized data.
MissingFieldException(String, Exception)	Initializes a new instance of the MissingFieldException class with a specified error message and a reference to the inner exception that is the cause of this exception.
MissingFieldException(String, String)	Initializes a new instance of the MissingFieldException class with the specified class name and field name.

MissingFieldException()

Initializes a new instance of the MissingFieldException class.

C#

```
public MissingFieldException ();
```

Remarks

This constructor initializes Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to access a non-existing field." This message takes into account the current system culture.

The following table shows the initial property values for an instance of MissingFieldException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MissingFieldException(String)

Initializes a new instance of the MissingFieldException class with a specified error message.

C#

```
public MissingFieldException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of `message` should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of MissingFieldException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MissingFieldException(SerializationInfo, StreamingContext)

⊗ Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the MissingFieldException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected MissingFieldException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions *(Obsolete)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MissingFieldException(String, Exception)

Initializes a new instance of the MissingFieldException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public MissingFieldException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of MissingFieldException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MissingFieldException(String, String)

Initializes a new instance of the MissingFieldException class with the specified class name and field name.

C#

```
public MissingFieldException (string? className, string? fieldName);
```

Parameters

`className` String

The name of the class in which access to a nonexistent field was attempted.

`fieldName` String

The name of the field that cannot be accessed.

Applies to

MissingFieldException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the text string showing the signature of the missing field, the class name, and the field name. This property is read-only.

C#

```
public override string Message { get; }
```

Property Value

String

The error message string.

Examples

The following example demonstrates the Message property. This code example is part of a larger example provided for the MissingFieldException class.

C#

```
try
{
    // Attempt to access a static AField field defined in the App class.
    // However, because the App class does not define this field,
    // a MissingFieldException is thrown.
    typeof(App).InvokeMember("AField", BindingFlags.Static |
BindingFlags.SetField,
        null, null, new Object[] { 5 });
}
catch (MissingFieldException e)
{
 // Show the user that the AField field cannot be accessed.
```

```
  Console.WriteLine("Unable to access the AField field: {0}", e.Message);
 }
```

Remarks

If the class name is not specified when the object is constructed, the default text string inherited from the base class is returned. This property overrides Message. The error message should be localized.

MissingMemberException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to dynamically access a class member that does not exist or that is not declared as public. If a member in a class library has been removed or renamed, recompile any assemblies that reference that library.

C#

```
public class MissingMemberException : MemberAccessException
```

Inheritance Object → Exception → SystemException → MemberAccessException → MissingMemberException

Derived System.MissingFieldException
System.MissingMethodException

Examples

This example shows what happens if you attempt to use reflection to call a method that does not exist and access a field that does not exist. The application recovers by catching the MissingMethodException, MissingFieldException, and MissingMemberException.

C#

```
using System;
using System.Reflection;

public class App
{
    public static void Main()
    {

        try
        {
```

```
            // Attempt to call a static DoSomething method defined in the
App class.
            // However, because the App class does not define this method,
            // a MissingMethodException is thrown.
            typeof(App).InvokeMember("DoSomething", BindingFlags.Static |
                BindingFlags.InvokeMethod, null, null, null);
        }
        catch (MissingMethodException e)
        {
            // Show the user that the DoSomething method cannot be called.
            Console.WriteLine("Unable to call the DoSomething method: {0}",
e.Message);
        }

        try
        {
            // Attempt to access a static AField field defined in the App
class.
            // However, because the App class does not define this field,
            // a MissingFieldException is thrown.
            typeof(App).InvokeMember("AField", BindingFlags.Static |
BindingFlags.SetField,
                null, null, new Object[] { 5 });
        }
        catch (MissingFieldException e)
        {
         // Show the user that the AField field cannot be accessed.
         Console.WriteLine("Unable to access the AField field: {0}",
e.Message);
        }

        try
        {
            // Attempt to access a static AnotherField field defined in the
App class.
            // However, because the App class does not define this field,
            // a MissingFieldException is thrown.
            typeof(App).InvokeMember("AnotherField", BindingFlags.Static |
                BindingFlags.GetField, null, null, null);
        }
        catch (MissingMemberException e)
        {
         // Notice that this code is catching MissingMemberException which
is the
         // base class of MissingMethodException and MissingFieldException.
         // Show the user that the AnotherField field cannot be accessed.
         Console.WriteLine("Unable to access the AnotherField field: {0}",
e.Message);
        }
    }
}
// This code example produces the following output:
//
// Unable to call the DoSomething method: Method 'App.DoSomething' not
found.
```

```
// Unable to access the AField field: Field 'App.AField' not found.
// Unable to access the AnotherField field: Field 'App.AnotherField' not
found.
```

Remarks

Normally a compilation error is generated if the code attempts to access a nonexistent member of a class. MissingMemberException is designed to handle cases where a field or a method is deleted or renamed in one assembly and the change is not reflected in a second assembly. At runtime, MissingMemberException will be thrown when the code in the second assembly attempts to access the missing member in the first assembly.

MissingMemberException is the base class for MissingFieldException and MissingMethodException. In general it is better to use one of the derived classes of MissingMemberException to more precisely indicate the exact nature of the error. Throw a MissingMemberException if you are only interested in capturing the general case of a missing member error.

MissingMemberException uses the HRESULT COR_E_MISSINGMEMBER, that has the value 0x80131512.

For a list of initial property values for an instance of MissingMemberException, see the MissingMemberException constructors.

Constructors

Expand table

MissingMemberException()	Initializes a new instance of the MissingMemberException class.
MissingMember Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MissingMemberException class with serialized data.
MissingMemberException(String)	Initializes a new instance of the MissingMemberException class with a specified error message.
MissingMemberException(String, Exception)	Initializes a new instance of the MissingMemberException class with a specified error message and a reference to the inner exception that is the root cause of this exception.
MissingMemberException(String,	Initializes a new instance of the MissingMemberException

String)	class with the specified class name and member name.

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the text string showing the class name, the member name, and the signature of the missing member.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the class name, the member name, the signature of the missing member, and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions

MissingMemberException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MissingMemberException class.

Overloads

Expand table

MissingMemberException()	Initializes a new instance of the MissingMemberException class.
MissingMemberException(String)	Initializes a new instance of the MissingMemberException class with a specified error message.
MissingMemberException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MissingMemberException class with serialized data.
MissingMemberException(String, Exception)	Initializes a new instance of the MissingMemberException class with a specified error message and a reference to the inner exception that is the root cause of this exception.
MissingMemberException(String, String)	Initializes a new instance of the MissingMemberException class with the specified class name and member name.

MissingMemberException()

Initializes a new instance of the MissingMemberException class.

```
C#
```

```
public MissingMemberException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to access a missing member." This message takes into account the current system culture.

The following table shows the initial property values for an instance of MissingMemberException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MissingMemberException(String)

Initializes a new instance of the MissingMemberException class with a specified error message.

C#

```
public MissingMemberException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter should be understandable by the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of MissingMemberException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MissingMemberException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the MissingMemberException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected MissingMemberException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MissingMemberException(String, Exception)

Initializes a new instance of the MissingMemberException class with a specified error message and a reference to the inner exception that is the root cause of this exception.

C#

```
public MissingMemberException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

An instance of Exception that is the cause of the current `Exception`. If `inner` is not a null reference (`Nothing` in Visual Basic), then the current `Exception` is raised in a catch block handling `inner`.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of MissingMemberException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

UWP	10.0

MissingMemberException(String, String)

Initializes a new instance of the MissingMemberException class with the specified class name and member name.

C#

```
public MissingMemberException (string? className, string? memberName);
```

Parameters

`className` String

The name of the class in which access to a nonexistent member was attempted.

`memberName` String

The name of the member that cannot be accessed.

Applies to

MissingMemberException.Signature Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Holds the signature of the missing member.

C#

```
protected byte[]? Signature;
```

Field Value

Byte[]

Remarks

Signature contains a Byte value that represents the signature of the missing member.

Format is used to format the signature. For additional information, see SignatureHelper, SignatureToken, and String.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

MissingMemberException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the text string showing the class name, the member name, and the signature of the missing member.

C#

```
public override string Message { get; }
```

Property Value

String

The error message string.

Examples

The following example demonstrates the Message property. This code example is part of a larger example provided for the MissingMemberException class.

C#

```
try
{
    // Attempt to access a static AnotherField field defined in the App
class.
    // However, because the App class does not define this field,
    // a MissingFieldException is thrown.
    typeof(App).InvokeMember("AnotherField", BindingFlags.Static |
        BindingFlags.GetField, null, null, null);
}
catch (MissingMemberException e)
{
 // Notice that this code is catching MissingMemberException which is the
 // base class of MissingMethodException and MissingFieldException.
 // Show the user that the AnotherField field cannot be accessed.
```

```
 Console.WriteLine("Unable to access the AnotherField field: {0}",
e.Message);
}
```

Remarks

If the class name is not specified when the object is constructed, the default text string inherited from the base class is returned.

This property overrides Message. The error message should be localized.

This property is read-only.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

MissingMemberException.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the class name, the member name, the signature of the missing member, and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` object is `null`.

Remarks

GetObjectData sets a SerializationInfo with all the exception object data targeted for serialization. During deserialization, the exception object is reconstituted from the SerializationInfo transmitted over the stream.

For more information, see SerializationInfo.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

MissingMethodException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to dynamically access a method that does not exist.

C#

```
public class MissingMethodException : MissingMemberException
```

Inheritance Object → Exception → SystemException → MemberAccessException → MissingMemberException → MissingMethodException

Examples

This example shows what happens if you attempt to use reflection to call a method that does not exist and access a field that does not exist. The application recovers by catching the MissingMethodException, MissingFieldException, and MissingMemberException.

C#

```
using System;
using System.Reflection;

public class App
{
    public static void Main()
    {

        try
        {
            // Attempt to call a static DoSomething method defined in the
App class.
            // However, because the App class does not define this method,
            // a MissingMethodException is thrown.
            typeof(App).InvokeMember("DoSomething", BindingFlags.Static |
                BindingFlags.InvokeMethod, null, null, null);
        }
```

```
        catch (MissingMethodException e)
        {
            // Show the user that the DoSomething method cannot be called.
            Console.WriteLine("Unable to call the DoSomething method: {0}",
e.Message);
        }

        try
        {
            // Attempt to access a static AField field defined in the App
class.
            // However, because the App class does not define this field,
            // a MissingFieldException is thrown.
            typeof(App).InvokeMember("AField", BindingFlags.Static |
BindingFlags.SetField,
                null, null, new Object[] { 5 });
        }
        catch (MissingFieldException e)
        {
         // Show the user that the AField field cannot be accessed.
         Console.WriteLine("Unable to access the AField field: {0}",
e.Message);
        }

        try
        {
            // Attempt to access a static AnotherField field defined in the
App class.
            // However, because the App class does not define this field,
            // a MissingFieldException is thrown.
            typeof(App).InvokeMember("AnotherField", BindingFlags.Static |
                BindingFlags.GetField, null, null, null);
        }
        catch (MissingMemberException e)
        {
         // Notice that this code is catching MissingMemberException which
is the
         // base class of MissingMethodException and MissingFieldException.
         // Show the user that the AnotherField field cannot be accessed.
         Console.WriteLine("Unable to access the AnotherField field: {0}",
e.Message);
        }
    }
}
// This code example produces the following output:
//
// Unable to call the DoSomething method: Method 'App.DoSomething' not
found.
// Unable to access the AField field: Field 'App.AField' not found.
// Unable to access the AnotherField field: Field 'App.AnotherField' not
found.
```

Remarks

Normally a compilation error is generated if code attempts to access a nonexistent method of a class. MissingMethodException is designed to handle cases where an attempt is made to dynamically access a renamed or deleted method of an assembly that is not referenced by its strong name. MissingMethodException is thrown when code in a dependent assembly attempts to access a missing method in an assembly that was modified.

MissingMethodException uses the HRESULT COR_E_MISSINGMETHOD, that has the value 0x80131513.

For a list of initial property values for an instance of MissingMethodException, see the MissingMethodException constructors.

The exact timing of when statically referenced methods are loaded is unspecified. This exception may be thrown before the method that references the missing method starts executing.

> **Note**
>
> This exception is not included in **.NET for Windows Store apps** or the **Portable Class Library**, but it is thrown by some members that are. To catch the exception in that case, write a `catch` statement for **MissingMemberException** instead.

Constructors

Expand table

MissingMethodException()	Initializes a new instance of the MissingMethodException class.
MissingMethodException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MissingMethodException class with serialized data.
MissingMethodException(String)	Initializes a new instance of the MissingMethodException class with a specified error message.
MissingMethodException(String, Exception)	Initializes a new instance of the MissingMethodException class with a specified error message and a reference to the inner exception that is the cause of this exception.

MissingMethodException(String, String)	Initializes a new instance of the MissingMethodException class with the specified class name and method name.

Fields

Expand table

ClassName	Holds the class name of the missing member. (Inherited from MissingMemberException)
MemberName	Holds the name of the missing member. (Inherited from MissingMemberException)
Signature	Holds the signature of the missing member. (Inherited from MissingMemberException)

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the text string showing the class name, the method name, and the signature of the missing method. This property is read-only.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the class name, the member name, the signature of the missing member, and additional exception information. (Inherited from MissingMemberException)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MissingMethodException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MissingMethodException class.

Overloads

Expand table

MissingMethodException()	Initializes a new instance of the MissingMethodException class.
MissingMethodException(String)	Initializes a new instance of the MissingMethodException class with a specified error message.
MissingMethodException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the MissingMethodException class with serialized data.
MissingMethodException(String, Exception)	Initializes a new instance of the MissingMethodException class with a specified error message and a reference to the inner exception that is the cause of this exception.
MissingMethodException(String, String)	Initializes a new instance of the MissingMethodException class with the specified class name and method name.

MissingMethodException()

Initializes a new instance of the MissingMethodException class.

```
C#
```

```
public MissingMethodException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to access a missing method." This message takes into account the current system culture.

The following table shows the initial property values for an instance of MissingMethodException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

UWP	10.0

MissingMethodException(String)

Initializes a new instance of the MissingMethodException class with a specified error message.

C#

```
public MissingMethodException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of the `message` parameter should be understandable by the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of MissingMethodException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MissingMethodException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the MissingMethodException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected MissingMethodException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MissingMethodException(String, Exception)

Initializes a new instance of the MissingMethodException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public MissingMethodException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of MissingMethodException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

UWP	10.0

MissingMethodException(String, String)

Initializes a new instance of the MissingMethodException class with the specified class name and method name.

C#

```
public MissingMethodException (string? className, string? methodName);
```

Parameters

`className` String

The name of the class in which access to a nonexistent method was attempted.

`methodName` String

The name of the method that cannot be accessed.

Applies to

MissingMethodException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the text string showing the class name, the method name, and the signature of the missing method. This property is read-only.

C#

```
public override string Message { get; }
```

Property Value

String

The error message string.

Examples

The following example demonstrates the Message property. This code example is part of a larger example provided for the MissingMethodException class.

C#

```
try
{
    // Attempt to call a static DoSomething method defined in the App class.
    // However, because the App class does not define this method,
    // a MissingMethodException is thrown.
    typeof(App).InvokeMember("DoSomething", BindingFlags.Static |
        BindingFlags.InvokeMethod, null, null, null);
}
catch (MissingMethodException e)
{
    // Show the user that the DoSomething method cannot be called.
    Console.WriteLine("Unable to call the DoSomething method: {0}",
```

```
e.Message);
}
```

Remarks

If the class name is not specified when the object is constructed, the default text string inherited from the base class is returned.

This property overrides Message. The error message should be localized.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ModuleHandle Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a runtime handle for a module.

C#

```
public struct ModuleHandle : IEquatable<ModuleHandle>
```

Inheritance Object → ValueType → ModuleHandle

Implements IEquatable<ModuleHandle>

Remarks

The ResolveFieldHandle, ResolveMethodHandle, and ResolveTypeHandle methods provide efficient resolution of metadata tokens to runtime handles for fields, methods, and types in the current module.

Fields

Expand table

EmptyHandle	Represents an empty module handle.

Properties

Expand table

MDStreamVersion	Gets the metadata stream version.

Methods

Expand table

Equals(ModuleHandle)	Returns a Boolean value indicating whether the specified ModuleHandle structure is equal to the current ModuleHandle.
Equals(Object)	Returns a Boolean value indicating whether the specified object is a ModuleHandle structure, and equal to the current ModuleHandle.
GetHashCode()	Returns the hash code for this instance.
GetRuntimeFieldHandleFromMetadataToken(Int32)	Returns a runtime handle for the field identified by the specified metadata token.
GetRuntimeMethodHandleFromMetadataToken(Int32)	Returns a runtime method handle for the method or constructor identified by the specified metadata token.
GetRuntimeTypeHandleFromMetadataToken(Int32)	Returns a runtime type handle for the type identified by the specified metadata token.
ResolveFieldHandle(Int32)	Returns a runtime handle for the field identified by the specified metadata token.
ResolveFieldHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])	Returns a runtime field handle for the field identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.
ResolveMethodHandle(Int32)	Returns a runtime method handle for the method or constructor identified by the specified metadata token.
ResolveMethodHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])	Returns a runtime method handle for the method or constructor identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.
ResolveTypeHandle(Int32)	Returns a runtime type handle for the type identified by the specified metadata token.
ResolveTypeHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])	Returns a runtime type handle for the type identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

Operators

Expand table

Equality(ModuleHandle, ModuleHandle)	Tests whether two ModuleHandle structures are equal.
Inequality(ModuleHandle, ModuleHandle)	Tests whether two ModuleHandle structures are unequal.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ModuleHandle.EmptyHandle Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an empty module handle.

C#

```
public static readonly ModuleHandle EmptyHandle;
```

Field Value

ModuleHandle

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ModuleHandle.MDStreamVersion Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the metadata stream version.

```
C#
public int MDStreamVersion { get; }
```

Property Value

Int32

A 32-bit integer representing the metadata stream version. The high-order two bytes represent the major version number, and the low-order two bytes represent the minor version number.

Remarks

> **Note**
>
> For more information on the metadata header, see the metadata specification in Partition II of **ECMA-335 Common Language Infrastructure (CLI)**.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ModuleHandle.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether a specified ModuleHandle structure is equal to the current ModuleHandle.

Overloads

Expand table

Equals(ModuleHandle)	Returns a Boolean value indicating whether the specified ModuleHandle structure is equal to the current ModuleHandle.
Equals(Object)	Returns a Boolean value indicating whether the specified object is a ModuleHandle structure, and equal to the current ModuleHandle.

Equals(ModuleHandle)

Returns a Boolean value indicating whether the specified ModuleHandle structure is equal to the current ModuleHandle.

C#

```
public bool Equals (ModuleHandle handle);
```

Parameters

`handle` ModuleHandle

The ModuleHandle structure to be compared with the current ModuleHandle.

Returns

Boolean

`true` if `handle` is equal to the current ModuleHandle structure; otherwise `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(Object)

Returns a Boolean value indicating whether the specified object is a ModuleHandle structure, and equal to the current ModuleHandle.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to be compared with the current ModuleHandle structure.

Returns

Boolean

`true` if `obj` is a ModuleHandle structure, and is equal to the current ModuleHandle structure; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ModuleHandle.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer that is the hash code for this instance.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ModuleHandle.GetRuntimeFieldHandleFromMetadataToken(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a runtime handle for the field identified by the specified metadata token.

C#

```
public RuntimeFieldHandle GetRuntimeFieldHandleFromMetadataToken (int
fieldToken);
```

Parameters

`fieldToken` Int32

A metadata token that identifies a field in the module.

Returns

RuntimeFieldHandle

A RuntimeFieldHandle for the field identified by `fieldToken`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ModuleHandle.GetRuntimeTypeHandleFromMetadataToken(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a runtime type handle for the type identified by the specified metadata token.

C#

```
public RuntimeTypeHandle GetRuntimeTypeHandleFromMetadataToken (int
typeToken);
```

Parameters

typeToken Int32

A metadata token that identifies a type in the module.

Returns

RuntimeTypeHandle

A RuntimeTypeHandle for the type identified by `typeToken`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ModuleHandle.ResolveFieldHandle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a runtime field handle for a field identified by a metadata token.

Overloads

Expand table

ResolveFieldHandle(Int32)	Returns a runtime handle for the field identified by the specified metadata token.
ResolveFieldHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])	Returns a runtime field handle for the field identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

ResolveFieldHandle(Int32)

Returns a runtime handle for the field identified by the specified metadata token.

C#

```
public RuntimeFieldHandle ResolveFieldHandle (int fieldToken);
```

Parameters

`fieldToken` Int32

A metadata token that identifies a field in the module.

Returns

RuntimeFieldHandle

A RuntimeFieldHandle for the field identified by `fieldToken`.

Exceptions

BadImageFormatException

`metadataToken` is not a valid token in the scope of the current module.

-or-

`metadataToken` is not a token for a field in the scope of the current module.

-or-

`metadataToken` identifies a field whose parent `TypeSpec` has a signature containing element type `var` or `mvar`.

InvalidOperationException

The method is called on an empty field handle.

Remarks

To resolve a metadata token that identifies a field whose parent `TypeSpec` has a signature containing element type `var` or `mvar`, use the ResolveFieldHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[]) method overload, which allows you to supply the necessary context.

> **Note**
>
> Information about metadata tokens can be found in the **Common Language Infrastructure (CLI) documentation**, especially "Partition II: Metadata Definition and Semantics".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.0, 2.1

ResolveFieldHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])

Returns a runtime field handle for the field identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

C#

```
public RuntimeFieldHandle ResolveFieldHandle (int fieldToken,
RuntimeTypeHandle[]? typeInstantiationContext, RuntimeTypeHandle[]?
methodInstantiationContext);
```

Parameters

`fieldToken` Int32

A metadata token that identifies a field in the module.

`typeInstantiationContext` RuntimeTypeHandle[]

An array of RuntimeTypeHandle structures representing the generic type arguments of the type where the token is in scope, or `null` if that type is not generic.

`methodInstantiationContext` RuntimeTypeHandle[]

An array of RuntimeTypeHandle structures representing the generic type arguments of the method where the token is in scope, or `null` if that method is not generic.

Returns

RuntimeFieldHandle

A RuntimeFieldHandle for the field identified by `fieldToken`.

Exceptions

BadImageFormatException

`metadataToken` is not a valid token in the scope of the current module.

-or-

`metadataToken` is not a token for a field in the scope of the current module.

-or-

`metadataToken` identifies a field whose parent `TypeSpec` has a signature containing element type `var` or `mvar`.

InvalidOperationException

The method is called on an empty field handle.

ArgumentOutOfRangeException

`fieldToken` is not a valid token.

Remarks

> **Note**
>
> Information about metadata tokens can be found in the **Common Language Infrastructure (CLI) documentation**, especially "Partition II: Metadata Definition and Semantics".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ModuleHandle.ResolveMethodHandle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a runtime method handle for a method or constructor identified by a metadata token.

Overloads

Expand table

ResolveMethodHandle(Int32)	Returns a runtime method handle for the method or constructor identified by the specified metadata token.
ResolveMethodHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])	Returns a runtime method handle for the method or constructor identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

ResolveMethodHandle(Int32)

Returns a runtime method handle for the method or constructor identified by the specified metadata token.

C#

```
public RuntimeMethodHandle ResolveMethodHandle (int methodToken);
```

Parameters

`methodToken` Int32

A metadata token that identifies a method or constructor in the module.

Returns

RuntimeMethodHandle

A RuntimeMethodHandle for the method or constructor identified by `methodToken`.

Exceptions

BadImageFormatException

`methodToken` is not a valid metadata token for a method in the current module.

-or-

`metadataToken` is not a token for a method or constructor in the scope of the current module.

-or-

`metadataToken` is a `MethodSpec` whose signature contains element type `var` or `mvar`.

InvalidOperationException

The method is called on an empty method handle.

Remarks

To resolve a metadata token for a `MethodSpec` whose signature contains element type `var` or `mvar`, use the ResolveMethodHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[]) method overload, which allows you to supply the necessary context.

> **Note**
>
> Information about metadata tokens can be found in the **Common Language Infrastructure (CLI) documentation**, especially "Partition II: Metadata Definition and Semantics".

Applies to

.NET Standard	2.0, 2.1

ResolveMethodHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])

Returns a runtime method handle for the method or constructor identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

C#

```
public RuntimeMethodHandle ResolveMethodHandle (int methodToken,
RuntimeTypeHandle[]? typeInstantiationContext, RuntimeTypeHandle[]?
methodInstantiationContext);
```

Parameters

`methodToken` Int32

A metadata token that identifies a method or constructor in the module.

`typeInstantiationContext` RuntimeTypeHandle[]

An array of RuntimeTypeHandle structures representing the generic type arguments of the type where the token is in scope, or `null` if that type is not generic.

`methodInstantiationContext` RuntimeTypeHandle[]

An array of RuntimeTypeHandle structures representing the generic type arguments of the method where the token is in scope, or `null` if that method is not generic.

Returns

RuntimeMethodHandle

A RuntimeMethodHandle for the method or constructor identified by `methodToken`.

Exceptions

BadImageFormatException

`methodToken` is not a valid metadata token for a method in the current module.

-or-

`metadataToken` is not a token for a method or constructor in the scope of the current module.

-or-

`metadataToken` is a `MethodSpec` whose signature contains element type `var` or `mvar`.

InvalidOperationException

The method is called on an empty method handle.

ArgumentOutOfRangeException

`methodToken` is not a valid token.

Remarks

> **Note**
>
> Information about metadata tokens can be found in the **Common Language Infrastructure (CLI) documentation**, especially "Partition II: Metadata Definition and Semantics".

Applies to

ModuleHandle.ResolveTypeHandle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a runtime type handle for a type identified by a metadata token.

Overloads

Expand table

ResolveTypeHandle(Int32)	Returns a runtime type handle for the type identified by the specified metadata token.
ResolveTypeHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])	Returns a runtime type handle for the type identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

ResolveTypeHandle(Int32)

Returns a runtime type handle for the type identified by the specified metadata token.

C#

```
public RuntimeTypeHandle ResolveTypeHandle (int typeToken);
```

Parameters

`typeToken` Int32

A metadata token that identifies a type in the module.

Returns

RuntimeTypeHandle

A RuntimeTypeHandle for the type identified by `typeToken`.

Exceptions

BadImageFormatException

`typeToken` is not a valid metadata token for a type in the current module.

-or-

`metadataToken` is not a token for a type in the scope of the current module.

-or-

`metadataToken` is a `TypeSpec` whose signature contains element type `var` or `mvar`.

InvalidOperationException

The method is called on an empty type handle.

Remarks

To resolve a metadata token for a `TypeSpec` whose signature contains element type `var` or `mvar`, use the ResolveTypeHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[]) method overload, which allows you to supply the necessary context.

> **Note**
>
> Information about metadata tokens can be found in the **Common Language Infrastructure (CLI) documentation**, especially "Partition II: Metadata Definition and Semantics".

Applies to

Product	Versions
.NET Standard	2.0, 2.1

ResolveTypeHandle(Int32, RuntimeTypeHandle[], RuntimeTypeHandle[])

Returns a runtime type handle for the type identified by the specified metadata token, specifying the generic type arguments of the type and method where the token is in scope.

C#

```
public RuntimeTypeHandle ResolveTypeHandle (int typeToken,
RuntimeTypeHandle[]? typeInstantiationContext, RuntimeTypeHandle[]?
methodInstantiationContext);
```

Parameters

`typeToken` Int32

A metadata token that identifies a type in the module.

`typeInstantiationContext` RuntimeTypeHandle[]

An array of RuntimeTypeHandle structures representing the generic type arguments of the type where the token is in scope, or `null` if that type is not generic.

`methodInstantiationContext` RuntimeTypeHandle[]

An array of RuntimeTypeHandle structures objects representing the generic type arguments of the method where the token is in scope, or `null` if that method is not generic.

Returns

RuntimeTypeHandle

A RuntimeTypeHandle for the type identified by `typeToken`.

Exceptions

BadImageFormatException

`typeToken` is not a valid metadata token for a type in the current module.

-or-

`metadataToken` is not a token for a type in the scope of the current module.

-or-

`metadataToken` is a `TypeSpec` whose signature contains element type `var` or `mvar`.

InvalidOperationException

The method is called on an empty type handle.

ArgumentOutOfRangeException

`typeToken` is not a valid token.

Remarks

> **Note**
>
> Information about metadata tokens can be found in the **Common Language Infrastructure (CLI) documentation**, especially "Partition II: Metadata Definition and Semantics".

ModuleHandle.Equality(ModuleHandle, ModuleHandle) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tests whether two ModuleHandle structures are equal.

```
C#
public static bool operator == (ModuleHandle left, ModuleHandle right);
```

Parameters

`left` ModuleHandle

The ModuleHandle structure to the left of the equality operator.

`right` ModuleHandle

The ModuleHandle structure to the right of the equality operator.

Returns

Boolean

`true` if the ModuleHandle structures are equal; otherwise, `false`.

Remarks

The equivalent method for this operator is ModuleHandle.Equals(ModuleHandle).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

ModuleHandle.Inequality(ModuleHandle, ModuleHandle) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tests whether two ModuleHandle structures are unequal.

```
C#
public static bool operator != (ModuleHandle left, ModuleHandle right);
```

Parameters

`left` ModuleHandle

The ModuleHandle structure to the left of the inequality operator.

`right` ModuleHandle

The ModuleHandle structure to the right of the inequality operator.

Returns

Boolean

`true` if the ModuleHandle structures are unequal; otherwise, `false`.

Remarks

The equivalent method for this operator is ModuleHandle.Equals(ModuleHandle).

Applies to

Product	Versions

MTAThreadAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that the COM threading model for an application is multithreaded apartment (MTA).

C#

```
[System.AttributeUsage(System.AttributeTargets.Method)]
public sealed class MTAThreadAttribute : Attribute
```

Inheritance Object → Attribute → MTAThreadAttribute

Attributes AttributeUsageAttribute

Remarks

Apply this attribute to the entry point method (the `Main()` method in C# and Visual Basic). It has no effect on other methods. To set the apartment state of threads you start in your code, use the Thread.SetApartmentState or Thread.TrySetApartmentState method before starting the thread.

> **Note**
>
> For an overview of COM threading models, see **Understanding and Using COM Threading Models**.

COM threading models only apply to applications that use COM interop. The COM threading model can be set to single-threaded apartment or multithreaded apartment. The application thread is only initialized for COM interop if the thread actually makes a call to a COM component. If COM interop is not used, then the thread is not initialized, and the MTAThreadAttribute attribute, if it is present, has no effect.

Starting with the .NET Framework version 2.0, the default threading model for COM interop depends on the language in which you are developing your application, as the following table shows.

Expand table

Language	COM apartment model
C#	Multithreaded apartment
C++	Multithreaded apartment
Visual Basic	Single-threaded apartment

To change these defaults, you use the MTAThreadAttribute attribute to set the threading model for the application, or call the Thread.SetApartmentState or Thread.TrySetApartmentState method before starting the thread to set the threading model for a particular thread. In C++, you can also use the /CLRTHREADATTRIBUTE (Set CLR Thread Attribute) linker option to specify the apartment model.

Some of the cases in which you want to use the MTAThreadAttribute attribute to explicitly set the threading model to multithreaded apartment include the following:

- You're developing a Visual Basic app that calls to a C# library that in turn relies on COM interop. Because the multithreaded apartment model is the default for C#, you should change your app's threading model to multithreaded by using the MTAThreadAttribute attribute.
- Your application makes calls to COM components that use the multithreaded apartment model.

Constructors

Expand table

MTAThreadAttribute()	Initializes a new instance of the MTAThreadAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute.

	(Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions

MulticastDelegate Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a multicast delegate; that is, a delegate that can have more than one element in its invocation list.

```
C#
public abstract class MulticastDelegate : Delegate
```

Inheritance Object → Delegate → MulticastDelegate

Examples

The following example defines a class, `StringContainer`, which includes a collection of strings. One of its members is the `CheckAndDisplayDelegate` delegate, which is used to display strings stored in a `StringContainer` object that satisfy particular criteria. The delegate takes a single string as a parameter and returns `void` (or, in Visual Basic, it's a `Sub` procedure). It also includes a method, `DisplayAllQualified`, that has a single parameter, a `CheckAndDisplayDelegate` delegate. This allows the method to be called and to display a set of strings that are filtered based on the methods that the delegate contains.

The example also defines a utility class, `StringExtensions`, that has two methods:

- `ConStart`, which displays strings that begin with a consonant.
- `VowelStart`, which displays strings that begin with a vowel.

Note that both methods include a single string parameter and return `void`. In other words, both methods can be assigned to the `CheckAndDisplayDelegate` delegate.

The `Test.Main` method is the application entry point. It instantiates a `StringContainer` object, populates it with strings, and creates two `CheckAndDisplayDelegate` delegates, `conStart` and `vowelStart`, that invoke a single method. It then calls the

Delegate.Combine method to create the `multipleDelegates` delegate, which initially contains the `ConStart` and `VowelStart` delegates. Note that when the `multipleDelegates` delegate is invoked, it displays all the strings in the collection in their original order. This is because each letter is passed separately to each delegate, and each letter meets the filtering criteria of only one of the two delegates. Finally, after calls to Delegate.Remove and Delegate.Combine, `multipleDelegates` contains two `conStart` delegates. When it is invoked, each string in the `StringContainer` object is displayed twice.

C#

```
using System;
using System.Collections.Generic;

class StringContainer
{
   // Define a delegate to handle string display.
   public delegate void CheckAndDisplayDelegate(string str);

   // A generic list object that holds the strings.
   private List<String> container = new List<String>();

   // A method that adds strings to the collection.
   public void AddString(string str)
   {
      container.Add(str);
   }

   // Iterate through the strings and invoke the method(s) that the delegate
points to.
   public void DisplayAllQualified(CheckAndDisplayDelegate displayDelegate)
   {
      foreach (var str in container) {
         displayDelegate(str);
      }
   }
 }

// This class defines some methods to display strings.
class StringExtensions
{
   // Display a string if it starts with a consonant.
   public static void ConStart(string str)
   {
      if (!
(str[0]=='a'||str[0]=='e'||str[0]=='i'||str[0]=='o'||str[0]=='u'))
          Console.WriteLine(str);
   }

   // Display a string if it starts with a vowel.
   public static void VowelStart(string str)
```

```
    {
        if ((str[0]=='a'||str[0]=='e'||str[0]=='i'||str[0]=='o'||str[0]=='u'))
            Console.WriteLine(str);
    }
}

// Demonstrate the use of delegates, including the Remove and
// Combine methods to create and modify delegate combinations.
class Test
{
    static public void Main()
    {
        // Declare the StringContainer class and add some strings
        StringContainer container = new StringContainer();
        container.AddString("This");
        container.AddString("is");
        container.AddString("a");
        container.AddString("multicast");
        container.AddString("delegate");
        container.AddString("example");

        // Create two delegates individually using different methods.
        StringContainer.CheckAndDisplayDelegate conStart =
StringExtensions.ConStart;
        StringContainer.CheckAndDisplayDelegate vowelStart =
StringExtensions.VowelStart;

        // Get the list of all delegates assigned to this MulticastDelegate
instance.
        Delegate[] delegateList = conStart.GetInvocationList();
        Console.WriteLine("conStart contains {0} delegate(s).",
delegateList.Length);
        delegateList = vowelStart.GetInvocationList();
        Console.WriteLine("vowelStart contains {0} delegate(s).\n",
delegateList.Length);

        // Determine whether the delegates are System.Multicast delegates.
        if (conStart is System.MulticastDelegate && vowelStart is
System.MulticastDelegate)
            Console.WriteLine("conStart and vowelStart are derived from
MulticastDelegate.\n");

        // Execute the two delegates.
        Console.WriteLine("Executing the conStart delegate:");
        container.DisplayAllQualified(conStart);
        Console.WriteLine();
        Console.WriteLine("Executing the vowelStart delegate:");
        container.DisplayAllQualified(vowelStart);
        Console.WriteLine();

        // Create a new MulticastDelegate and call Combine to add two
delegates.
        StringContainer.CheckAndDisplayDelegate multipleDelegates =
              (StringContainer.CheckAndDisplayDelegate)
Delegate.Combine(conStart, vowelStart);
```

```
      // How many delegates does multipleDelegates contain?
      delegateList = multipleDelegates.GetInvocationList();
      Console.WriteLine("\nmultipleDelegates contains {0} delegates.\n",
                        delegateList.Length);

      // Pass this multicast delegate to DisplayAllQualified.
      Console.WriteLine("Executing the multipleDelegate delegate.");
      container.DisplayAllQualified(multipleDelegates);

      // Call remove and combine to change the contained delegates.
      multipleDelegates = (StringContainer.CheckAndDisplayDelegate)
Delegate.Remove(multipleDelegates, vowelStart);
      multipleDelegates = (StringContainer.CheckAndDisplayDelegate)
Delegate.Combine(multipleDelegates, conStart);

      // Pass multipleDelegates to DisplayAllQualified again.
      Console.WriteLine("\nExecuting the multipleDelegate delegate with two
conStart delegates:");
      container.DisplayAllQualified(multipleDelegates);
   }
}
// The example displays the following output:
//    conStart contains 1 delegate(s).
//    vowelStart contains 1 delegate(s).
//
//    conStart and vowelStart are derived from MulticastDelegate.
//
//    Executing the conStart delegate:
//    This
//    multicast
//    delegate
//
//    Executing the vowelStart delegate:
//    is
//    a
//    example
//
//
//    multipleDelegates contains 2 delegates.
//
//    Executing the multipleDelegate delegate.
//    This
//    is
//    a
//    multicast
//    delegate
//    example
//
//    Executing the multipleDelegate delegate with two conStart delegates:
//    This
//    This
//    multicast
//    multicast
```

```
//    delegate
//    delegate
```

Remarks

MulticastDelegate is a special class. Compilers and other tools can derive from this class, but you cannot derive from it explicitly. The same is true of the Delegate class.

In addition to the methods that delegate types inherit from MulticastDelegate, the common language runtime provides two special methods: `BeginInvoke` and `EndInvoke`. For more information about these methods, see Calling Synchronous Methods Asynchronously.

A MulticastDelegate has a linked list of delegates, called an invocation list, consisting of one or more elements. When a multicast delegate is invoked, the delegates in the invocation list are called synchronously in the order in which they appear. If an error occurs during execution of the list then an exception is thrown.

Constructors

Expand table

MulticastDelegate(Object, String)	Initializes a new instance of the MulticastDelegate class.
MulticastDelegate(Type, String)	Initializes a new instance of the MulticastDelegate class.

Properties

Expand table

Method	Gets the method represented by the delegate. (Inherited from Delegate)
Target	Gets the class instance on which the current delegate invokes the instance method. (Inherited from Delegate)

Methods

Expand table

Clone()	Creates a shallow copy of the delegate. (Inherited from Delegate)
CombineImpl(Delegate)	Combines this Delegate with the specified Delegate to form a new delegate.
DynamicInvoke(Object[])	Dynamically invokes (late-bound) the method represented by the current delegate. (Inherited from Delegate)
DynamicInvokeImpl(Object[])	Dynamically invokes (late-bound) the method represented by the current delegate. (Inherited from Delegate)
Equals(Object)	Determines whether this multicast delegate and the specified object are equal.
GetHashCode()	Returns the hash code for this instance.
GetInvocationList()	Returns the invocation list of this multicast delegate, in invocation order.
GetMethodImpl()	Returns a method represented by the current MulticastDelegate.
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo object with all the data needed to serialize this instance.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
RemoveImpl(Delegate)	Removes an element from the invocation list of this MulticastDelegate that is equal to the specified delegate.
ToString()	Returns a string that represents the current object. (Inherited from Object)

Operators

Expand table

Equality(MulticastDelegate, MulticastDelegate)	Determines whether two MulticastDelegate objects are equal.

Inequality(MulticastDelegate, MulticastDelegate)	Determines whether two MulticastDelegate objects are not equal.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

MulticastDelegate Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MulticastDelegate class.

Overloads

Expand table

MulticastDelegate(Object, String)	Initializes a new instance of the MulticastDelegate class.
MulticastDelegate(Type, String)	Initializes a new instance of the MulticastDelegate class.

MulticastDelegate(Object, String)

Initializes a new instance of the MulticastDelegate class.

C#

```
protected MulticastDelegate (object target, string method);
```

Parameters

target Object

The object on which `method` is defined.

method String

The name of the method for which a delegate is created.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

This constructor cannot be used in application code. To create a delegate by specifying the name of an instance method, use an overload of the Delegate.CreateDelegate method that specifies a method name and a target object. For example, the Delegate.CreateDelegate(Type, Object, String) method overload creates a delegate for an instance method with a specified name.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MulticastDelegate(Type, String)

Initializes a new instance of the MulticastDelegate class.

C#

```
protected MulticastDelegate (Type target, string method);
```

Parameters

`target` Type

The type of object on which `method` is defined.

`method` String

The name of the static method for which a delegate is created.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

This constructor cannot be used in application code. To create a delegate by specifying the name of a static method, use an overload of the Delegate.CreateDelegate method that specifies a method name but does not specify a target object. For example, the Delegate.CreateDelegate(Type, Type, String) method overload creates a static delegate for a method with a specified name.

Applies to

▼ .NET 9 and other versions

Namespace: System

Assembly: System.Runtime.dll

Combines this Delegate with the specified Delegate to form a new delegate.

C#

```
protected override sealed Delegate CombineImpl (Delegate? follow);
```

Parameters

`follow` Delegate

The delegate to combine with this delegate.

Returns

Delegate

A delegate that is the new root of the MulticastDelegate invocation list.

Exceptions

ArgumentException

`follow` does not have the same type as this instance.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MulticastDelegate.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether this multicast delegate and the specified object are equal.

C#

```
public override sealed bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if `obj` and this instance have the same invocation lists; otherwise, `false`.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

Two delegates are equal if they are not `null` and are of exactly the same type, their invocation lists contain the same number of elements, and every element in the invocation list of the first delegate is equal to the corresponding element in the invocation list of the second delegate.

Two invocation list elements are equal if they invoke the same instance method on the same target instance, or they invoke the same static method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MulticastDelegate.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override sealed int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MulticastDelegate.GetInvocationList Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the invocation list of this multicast delegate, in invocation order.

C#

```
public override sealed Delegate[] GetInvocationList ();
```

Returns

Delegate[]

An array of delegates whose invocation lists collectively match the invocation list of this instance.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

The array contains a set of delegates, each with an invocation list of one entry. Invoking these delegates sequentially, in the order they appear in the array, produces the same results as invoking the current instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

MulticastDelegate.GetMethodImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a method represented by the current MulticastDelegate.

C#

```
protected override System.Reflection.MethodInfo GetMethodImpl ();
```

Returns

MethodInfo

A method represented by the current MulticastDelegate.

Remarks

If the MulticastDelegate represents multiple methods, only one method is returned.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MulticastDelegate.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo object with all the data needed to serialize this instance.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

An object that holds all the data needed to serialize or deserialize this instance.

`context` StreamingContext

(Reserved) The location where serialized data is stored and retrieved.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

SerializationException

A serialization error occurred.

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

This method stores all the information in `info` necessary to serialize this instance.

The `context` parameter is reserved and is not currently used in the execution of this method.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MulticastDelegate.RemoveImpl(Delegate) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Removes an element from the invocation list of this MulticastDelegate that is equal to the specified delegate.

C#

```
protected override sealed Delegate? RemoveImpl (Delegate value);
```

Parameters

`value` Delegate

The delegate to search for in the invocation list.

Returns

Delegate

If `value` is found in the invocation list for this instance, then a new Delegate without `value` in its invocation list; otherwise, this instance with its original invocation list.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

MulticastDelegate. Equality(MulticastDelegate, MulticastDelegate) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two MulticastDelegate objects are equal.

```
C#

public static bool operator == (MulticastDelegate? d1, MulticastDelegate?
d2);
```

Parameters

d1 MulticastDelegate

The left operand.

d2 MulticastDelegate

The right operand.

Returns

Boolean

`true` if `d1` and `d2` have the same invocation lists; otherwise, `false`.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

Two delegates are equal if they are not `null` and are of exactly the same type, their invocation lists contain the same number of elements, and every element in the invocation list of the first delegate is equal to the corresponding element in the invocation list of the second delegate.

Two invocation list elements are equal if they invoke the same instance method on the same target instance, or they invoke the same static method.

The equivalent method for this operator is MulticastDelegate.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MulticastDelegate.Inequality(MulticastDelegate, MulticastDelegate) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two MulticastDelegate objects are not equal.

```
C#

public static bool operator != (MulticastDelegate? d1, MulticastDelegate?
d2);
```

Parameters

d1 MulticastDelegate

The left operand.

d2 MulticastDelegate

The right operand.

Returns

Boolean

`true` if `d1` and `d2` do not have the same invocation lists; otherwise, `false`.

Exceptions

MemberAccessException

Cannot create an instance of an abstract class, or this member was invoked with a late-binding mechanism.

Remarks

Two delegates are equal if they are not `null` and are of exactly the same type, their invocation lists contain the same number of elements, and every element in the invocation list of the first delegate is equal to the corresponding element in the invocation list of the second delegate.

Two invocation list elements are equal if they invoke the same instance method on the same target instance, or they invoke the same static method.

The equivalent method for this operator is MulticastDelegate.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

MulticastNotSupportedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to combine two delegates based on the Delegate type instead of the MulticastDelegate type. This class cannot be inherited.

C#

```
public sealed class MulticastNotSupportedException : SystemException
```

Inheritance Object → Exception → SystemException → MulticastNotSupportedException

Remarks

Only delegates based on the MulticastDelegate type can be combined. Two multicast delegates can be combined using the CombineImpl method.

MulticastNotSupportedException uses the HRESULT COR_E_MULTICASTNOTSUPPORTED, which has the value 0x80131514.

For a list of initial property values for an instance of MulticastNotSupportedException, see the MulticastNotSupportedException constructors.

Constructors

Expand table

MulticastNotSupportedException()	Initializes a new instance of the MulticastNotSupportedException class.
MulticastNotSupportedException(String)	Initializes a new instance of the MulticastNotSupportedException class with a specified error message.

MulticastNotSupportedException(String, Exception)	Initializes a new instance of the MulticastNotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
InnerException	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)

GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

See also

- Exception
- MulticastDelegate

MulticastNotSupportedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the MulticastNotSupportedException class.

Overloads

Expand table

MulticastNotSupportedException()	Initializes a new instance of the MulticastNotSupportedException class.
MulticastNotSupportedException(String)	Initializes a new instance of the MulticastNotSupportedException class with a specified error message.
MulticastNotSupportedException(String, Exception)	Initializes a new instance of the MulticastNotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

MulticastNotSupportedException()

Initializes a new instance of the MulticastNotSupportedException class.

C#

```
public MulticastNotSupportedException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "This operation cannot be

performed with the specified delegates." This message takes into account the current system culture.

The following table shows the initial property values for an instance of MulticastNotSupportedException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MulticastNotSupportedException(String)

Initializes a new instance of the MulticastNotSupportedException class with a specified error message.

C#

```
public MulticastNotSupportedException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of MulticastNotSupportedException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

MulticastNotSupportedException(String, Exception)

Initializes a new instance of the MulticastNotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public MulticastNotSupportedException (string? message, Exception?
inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of MulticastNotSupportedException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

See also

- Exception
- Handling and throwing exceptions in .NET

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

NetPipeStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A parser based on the NetPipe scheme for the "Indigo" system.

C#

```
public class NetPipeStyleUriParser : UriParser
```

Inheritance Object → UriParser → NetPipeStyleUriParser

Remarks

This parser is for future use with the "Indigo" system.

Constructors

Expand table

NetPipeStyleUriParser()	Create a parser based on the NetPipe scheme for the "Indigo" system.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)

GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

NetTcpStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A parser based on the NetTcp scheme for the "Indigo" system.

C#

```
public class NetTcpStyleUriParser : UriParser
```

Inheritance Object → UriParser → NetTcpStyleUriParser

Remarks

This parser is for future use with the "Indigo" system.

Constructors

Expand table

NetTcpStyleUriParser()	Create a parser based on the NetTcp scheme for the "Indigo" system.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)

GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

NetTcpStyleUriParser Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Create a parser based on the NetTcp scheme for the "Indigo" system.

C#

```
public NetTcpStyleUriParser ();
```

Remarks

Use this constructor as an argument to UriParser.Register(UriParser, String, Int32).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NewsStyleUriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A customizable parser based on the news scheme using the Network News Transfer Protocol (NNTP).

C#

```
public class NewsStyleUriParser : UriParser
```

Inheritance Object → UriParser → NewsStyleUriParser

Constructors

Expand table

NewsStyleUriParser()	Create a customizable parser based on the news scheme using the Network News Transfer Protocol (NNTP).

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI. (Inherited from UriParser)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)

InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI. (Inherited from UriParser)
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`. (Inherited from UriParser)
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed. (Inherited from UriParser)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance. (Inherited from UriParser)
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered. (Inherited from UriParser)
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI. (Inherited from UriParser)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

NonSerializedAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that a field of a serializable class should not be serialized. This class cannot be inherited.

C#

```
[System.AttributeUsage(System.AttributeTargets.Field, Inherited=false)]
public sealed class NonSerializedAttribute : Attribute
```

Inheritance Object → Attribute → NonSerializedAttribute

Attributes AttributeUsageAttribute

Examples

The following example demonstrates SOAP serialization of an object marked with the SerializableAttribute attribute, and the behavior of a field marked with the NonSerializedAttribute in the serialized object.

> **Note**
>
> The code uses the **SoapFormatter** class to serialize the object. The class is found in the system.runtime.serialization.formatters.soap.dll file, which is not loaded by default into a project. To run the code, you must add a reference to the DLL to your project.

C#

```
using System;
using System.IO;
using System.Runtime.Serialization.Formatters.Soap;

public class Test {
```

```
    public static void Main()  {

      // Creates a new TestSimpleObject object.
      TestSimpleObject obj = new TestSimpleObject();

      Console.WriteLine("Before serialization the object contains: ");
      obj.Print();

      // Opens a file and serializes the object into it in binary format.
      Stream stream = File.Open("data.xml", FileMode.Create);
      SoapFormatter formatter = new SoapFormatter();

      formatter.Serialize(stream, obj);
      stream.Close();

      // Empties obj.
      obj = null;

      // Opens file "data.xml" and deserializes the object from it.
      stream = File.Open("data.xml", FileMode.Open);
      formatter = new SoapFormatter();

      obj = (TestSimpleObject)formatter.Deserialize(stream);
      stream.Close();

      Console.WriteLine("");
      Console.WriteLine("After deserialization the object contains: ");
      obj.Print();
    }
}

// A test object that needs to be serialized.
[Serializable()]
public class TestSimpleObject  {

    public int member1;
    public string member2;
    public string member3;
    public double member4;

    // A field that is not serialized.
    [NonSerialized()] public string member5;

    public TestSimpleObject() {

        member1 = 11;
        member2 = "hello";
        member3 = "hello";
        member4 = 3.14159265;
        member5 = "hello world!";
    }

    public void Print() {

        Console.WriteLine("member1 = '{0}'", member1);
```

```
        Console.WriteLine("member2 = '{0}'", member2);
        Console.WriteLine("member3 = '{0}'", member3);
        Console.WriteLine("member4 = '{0}'", member4);
        Console.WriteLine("member5 = '{0}'", member5);
    }
}
```

Remarks

When using the BinaryFormatter or SoapFormatter classes to serialize an object, use the NonSerializedAttribute attribute to prevent a field from being serialized. For example, you can use this attribute to prevent the serialization of sensitive data.

The target objects for the NonSerializedAttribute attribute are public and private fields of a serializable class. By default, classes are not serializable unless they are marked with SerializableAttribute. During the serialization process all the public and private fields of a class are serialized by default. Fields marked with NonSerializedAttribute are excluded during serialization. If you are using the XmlSerializer class to serialize an object, use the XmlIgnoreAttribute class to get the same functionality. Alternatively, implement the ISerializable interface to explicitly control the serialization process. Note that classes that implement ISerializable must still be marked with SerializableAttribute.

To apply the NonSerializedAttribute class to an event, set the attribute location to field, as shown in the following C# code.

C#

```
[field:NonSerializedAttribute()]
public event ChangedEventHandler Changed;
```

If a field is not serialized, but it still requires a default value that must be supplied after deserialization, you can create a method that supplies the field with a value, then apply the OnDeserializedAttribute to the method.

For more information about using attributes, see Attributes.

> **Note**
>
> This attribute does not apply to JSON serialization using **System.Text.Json**.

Constructors

Expand table

NonSerializedAttribute()	Initializes a new instance of the NonSerializedAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

NotFiniteNumberException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a floating-point value is positive infinity, negative infinity, or Not-a-Number (NaN).

C#

```
public class NotFiniteNumberException : ArithmeticException
```

Inheritance Object → Exception → SystemException → ArithmeticException → NotFiniteNumberException

Remarks

NotFiniteNumberException is available for programming languages that do not support the concepts of infinity and Not-a-Number in floating-point operations.

NotFiniteNumberException uses the HRESULT COR_E_NOTFINITENUMBER, which has the value 0x80131528.

For a list of initial property values for an instance of NotFiniteNumberException, see the NotFiniteNumberException constructors.

Constructors

Expand table

NotFiniteNumberException()	Initializes a new instance of the NotFiniteNumberException class.
NotFiniteNumber Exception(Double)	Initializes a new instance of the NotFiniteNumberException class with the invalid number.
NotFiniteNumber Exception(SerializationInfo,	**Obsolete.**

StreamingContext)	Initializes a new instance of the NotFiniteNumberException class with serialized data.
NotFiniteNumberException(String)	Initializes a new instance of the NotFiniteNumberException class with a specified error message.
NotFiniteNumberException(String, Double)	Initializes a new instance of the NotFiniteNumberException class with a specified error message and the invalid number.
NotFiniteNumberException(String, Double, Exception)	Initializes a new instance of the NotFiniteNumberException class with a specified error message, the invalid number, and a reference to the inner exception that is root cause of this exception.
NotFiniteNumberException(String, Exception)	Initializes a new instance of the NotFiniteNumberException class with a specified error message and a reference to the inner exception that is root cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
InnerException	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Offending Number	Gets the invalid number that is a positive infinity, a negative infinity, or Not-a-Number (NaN).
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception.

	(Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the invalid number and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotFiniteNumberException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the NotFiniteNumberException class.

Overloads

Expand table

NotFiniteNumberException()	Initializes a new instance of the NotFiniteNumberException class.
NotFiniteNumberException(Double)	Initializes a new instance of the NotFiniteNumberException class with the invalid number.
NotFiniteNumberException(String)	Initializes a new instance of the NotFiniteNumberException class with a specified error message.
NotFiniteNumberException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NotFiniteNumberException class with serialized data.
NotFiniteNumberException(String, Double)	Initializes a new instance of the NotFiniteNumberException class with a specified error message and the invalid number.
NotFiniteNumberException(String, Exception)	Initializes a new instance of the NotFiniteNumberException class with a specified error message and a reference to the inner exception that is root cause of this exception.
NotFiniteNumberException(String, Double, Exception)	Initializes a new instance of the NotFiniteNumberException class with a specified error message, the invalid number, and a

	reference to the inner exception that is root cause of this exception.

NotFiniteNumberException()

Initializes a new instance of the NotFiniteNumberException class.

```
C#

public NotFiniteNumberException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The number encountered was not a finite quantity." This message takes into account the current system culture.

The following table shows the initial property values for an instance of NotFiniteNumberException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotFiniteNumberException(Double)

Initializes a new instance of the NotFiniteNumberException class with the invalid number.

```
C#

public NotFiniteNumberException (double offendingNumber);
```

Parameters

`offendingNumber` Double

The value of the argument that caused the exception.

Remarks

The `offendingNumber` parameter must be both a Double and an invalid number.

The following table shows the initial property values for an instance of NotFiniteNumberException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
OffendingNumber	The invalid number.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotFiniteNumberException(String)

Initializes a new instance of the NotFiniteNumberException class with a specified error message.

```
C#

public NotFiniteNumberException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

Ensure that the `message` string is understandable to the user and that it is localized for the current culture.

The following table shows the initial property values for an instance of NotFiniteNumberException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotFiniteNumberException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the NotFiniteNumberException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected NotFiniteNumberException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotFiniteNumberException(String, Double)

Initializes a new instance of the NotFiniteNumberException class with a specified error message and the invalid number.

C#

```
public NotFiniteNumberException (string? message, double
offendingNumber);
```

Parameters

`message` String

The message that describes the error.

`offendingNumber` Double

The value of the argument that caused the exception.

Remarks

Ensure that the `message` string is understandable to the user and that it is localized for the current culture.

The following table shows the initial property values for an instance of NotFiniteNumberException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Property	Value
OffendingNumber	The invalid number.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotFiniteNumberException(String, Exception)

Initializes a new instance of the NotFiniteNumberException class with a specified error message and a reference to the inner exception that is root cause of this exception.

C#

```
public NotFiniteNumberException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of NotFiniteNumberException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions

NotFiniteNumberException.OffendingNumber Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the invalid number that is a positive infinity, a negative infinity, or Not-a-Number (NaN).

C#

```
public double OffendingNumber { get; }
```

Property Value

Double

The invalid number.

Remarks

The OffendingNumber property returns the same value as was passed into the constructor, or zero if no value was supplied. Override the OffendingNumber property to customize the content or format of the invalid value.

This property is read-only.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

NotFiniteNumberException.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the invalid number and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` object is `null`.

Remarks

GetObjectData sets a SerializationInfo with all the exception object data targeted for serialization. During deserialization, the exception object is reconstituted from the SerializationInfo transmitted over the stream.

For more information, see SerializationInfo.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotImplementedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a requested method or operation is not implemented.

C#

```
public class NotImplementedException : SystemException
```

Inheritance Object → Exception → SystemException → NotImplementedException

Examples

The following example throws this exception for a method that has not been developed.

C#

```
static void Main(string[] args)
{
    try
    {
        FutureFeature();
    }
    catch (NotImplementedException notImp)
    {
        Console.WriteLine(notImp.Message);
    }
}

static void FutureFeature()
{
    // Not developed yet.
    throw new NotImplementedException();
}
```

Remarks

For more information about this API, see Supplemental API remarks for NotImplementedException.

Constructors

Expand table

NotImplementedException()	Initializes a new instance of the NotImplementedException class with default properties.
NotImplemented Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NotImplementedException class with serialized data.
NotImplementedException(String)	Initializes a new instance of the NotImplementedException class with a specified error message.
NotImplementedException(String, Exception)	Initializes a new instance of the NotImplementedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack.

	(Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NotImplementedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the NotImplementedException class.

Overloads

Expand table

NotImplementedException()	Initializes a new instance of the NotImplementedException class with default properties.
NotImplementedException(String)	Initializes a new instance of the NotImplementedException class with a specified error message.
NotImplementedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NotImplementedException class with serialized data.
NotImplementedException(String, Exception)	Initializes a new instance of the NotImplementedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

NotImplementedException()

Initializes a new instance of the NotImplementedException class with default properties.

C#

```
public NotImplementedException ();
```

Remarks

The following table shows the initial property values for an instance of NotImplementedException.

Expand table

Property	Value
InnerException	`null`.
Message	The empty string ("").

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NotImplementedException(String)

Initializes a new instance of the NotImplementedException class with a specified error message.

C#

```
public NotImplementedException (string? message);
```

Parameters

`message` String

The error message that explains the reason for the exception.

Remarks

The following table shows the initial property values for an instance of NotImplementedException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NotImplementedException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the NotImplementedException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected NotImplementedException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotImplementedException(String, Exception)

Initializes a new instance of the NotImplementedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public NotImplementedException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of NotImplementedException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

NotSupportedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an invoked method is not supported, or when there is an attempt to read, seek, or write to a stream that does not support the invoked functionality.

C#

```
public class NotSupportedException : SystemException
```

Inheritance Object → Exception → SystemException → NotSupportedException

Derived System.PlatformNotSupportedException

Remarks

For more information about this API, see Supplemental API remarks for NotSupportedException.

Constructors

Expand table

NotSupportedException()	Initializes a new instance of the NotSupportedException class, setting the Message property of the new instance to a system-supplied message that describes the error. This message takes into account the current system culture.
NotSupportedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NotSupportedException class with serialized data.
NotSupportedException(String)	Initializes a new instance of the NotSupportedException class with a specified error message.

NotSupportedException(String, Exception)	Initializes a new instance of the NotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)

NotSupportedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the NotSupportedException class.

Overloads

Expand table

NotSupportedException()	Initializes a new instance of the NotSupportedException class, setting the Message property of the new instance to a system-supplied message that describes the error. This message takes into account the current system culture.
NotSupportedException(String)	Initializes a new instance of the NotSupportedException class with a specified error message.
NotSupportedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NotSupportedException class with serialized data.
NotSupportedException(String, Exception)	Initializes a new instance of the NotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

NotSupportedException()

Initializes a new instance of the NotSupportedException class, setting the Message property of the new instance to a system-supplied message that describes the error. This message takes into account the current system culture.

```
C#
```

```
public NotSupportedException ();
```

Remarks

The following table shows the initial property values for an instance of NotSupportedException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NotSupportedException(String)

Initializes a new instance of the NotSupportedException class with a specified error message.

C#

```
public NotSupportedException (string? message);
```

Parameters

`message` String

A String that describes the error. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of NotSupportedException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NotSupportedException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the NotSupportedException class with serialized data.

```
C#

[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected NotSupportedException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NotSupportedException(String, Exception)

Initializes a new instance of the NotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public NotSupportedException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of NotSupportedException.

Nullable Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Supports a value type that can be assigned `null`. This class cannot be inherited.

C#

```
public static class Nullable
```

Inheritance Object → Nullable

Remarks

For more information about this API, see Supplemental API remarks for Nullable.

Methods

Expand table

Compare<T>(Nullable<T>, Nullable<T>)	Compares the relative values of two Nullable<T> objects.
Equals<T>(Nullable<T>, Nullable<T>)	Indicates whether two specified Nullable<T> objects are equal.
GetUnderlyingType(Type)	Returns the underlying type argument of the specified nullable type.
GetValueRefOrDefaultRef<T>(Nullable<T>)	Retrieves a readonly reference to the location in the Nullable<T> instance where the value is stored.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Nullable.Compare<T>(Nullable<T>, Nullable<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the relative values of two Nullable<T> objects.

C#

```
public static int Compare<T> (T? n1, T? n2) where T : struct;
```

Type Parameters

T

The underlying value type of the `n1` and `n2` parameters.

Parameters

n1 Nullable<T>

A Nullable<T> object.

n2 Nullable<T>

A Nullable<T> object.

Returns

Int32

An integer that indicates the relative values of the `n1` and `n2` parameters.

Expand table

Return Value	Description
Less than zero	The HasValue property for `n1` is `false`, and the HasValue property for `n2` is `true`, or the HasValue properties for `n1` and `n2` are `true`, and the value of the Value property for `n1` is less than the value of the Value property for `n2`.
Zero	The HasValue properties for `n1` and `n2` are `false`, or the HasValue properties for `n1` and `n2` are `true`, and the value of the Value property for `n1` is equal to the value of the Value property for `n2`.
Greater than zero	The HasValue property for `n1` is `true`, and the HasValue property for `n2` is `false`, or the HasValue properties for `n1` and `n2` are `true`, and the value of the Value property for `n1` is greater than the value of the Value property for `n2`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Nullable.Equals<T>(Nullable<T>, Nullable<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two specified Nullable<T> objects are equal.

C#

```
public static bool Equals<T> (T? n1, T? n2) where T : struct;
```

Type Parameters

T

The underlying value type of the `n1` and `n2` parameters.

Parameters

n1 Nullable<T>

A Nullable<T> object.

n2 Nullable<T>

A Nullable<T> object.

Returns

Boolean

`true` if the `n1` parameter is equal to the `n2` parameter; otherwise, `false`.

The return value depends on the HasValue and Value properties of the two parameters that are compared.

Expand table

Return Value	Description
`true`	The HasValue properties for `n1` and `n2` are `false`, or the HasValue properties for `n1` and `n2` are `true`, and the Value properties of the parameters are equal.
`false`	The HasValue property is `true` for one parameter and `false` for the other parameter, or the HasValue properties for `n1` and `n2` are `true`, and the Value properties of the parameters are unequal.

Applies to

Nullable.GetUnderlyingType(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the underlying type argument of the specified nullable type.

```
C#
public static Type? GetUnderlyingType (Type nullableType);
```

Parameters

`nullableType` Type

A Type object that describes a closed generic nullable type.

Returns

Type

The type argument of the `nullableType` parameter, if the `nullableType` parameter is a closed generic nullable type; otherwise, `null`.

Exceptions

ArgumentNullException

`nullableType` is `null`.

Examples

The following code example defines a method whose return value is of type Nullable<T> of Int32. The code example uses the GetUnderlyingType method to display the type argument of the return value.

```
C#
```

```
// This code example demonstrates the
// Nullable.GetUnderlyingType() method.

using System;
using System.Reflection;

class Sample
{
// Declare a type named Example.
// The MyMethod member of Example returns a Nullable of Int32.

    public class Example
    {
        public int? MyMethod()
        {
        return 0;
        }
    }

/*
   Use reflection to obtain a Type object for the Example type.
   Use the Type object to obtain a MethodInfo object for the MyMethod
method.
   Use the MethodInfo object to obtain the type of the return value of
     MyMethod, which is Nullable of Int32.
   Use the GetUnderlyingType method to obtain the type argument of the
     return value type, which is Int32.
*/
    public static void Main()
    {
        Type t = typeof(Example);
        MethodInfo mi = t.GetMethod("MyMethod");
        Type retval = mi.ReturnType;
        Console.WriteLine("Return value type ... {0}", retval);
        Type answer = Nullable.GetUnderlyingType(retval);
        Console.WriteLine("Underlying type ..... {0}", answer);
    }
}
/*
This code example produces the following results:

Return value type ... System.Nullable`1[System.Int32]
Underlying type ..... System.Int32

*/
```

Remarks

A generic type definition is a type declaration, such as Nullable<T>, that contains a type parameter list, and the type parameter list declares one or more type parameters. A

closed generic type is a type declaration where a particular type is specified for a type parameter.

For example, if the `nullableType` parameter is the type of `Nullable<Int32>` in C# (`Nullable(Of Int32)` in Visual Basic), the return value is the type of Int32 (that is, the type argument of the closed generic type).

Applies to

Product	Versions

Nullable.GetValueRefOrDefaultRef<T> (Nullable<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves a readonly reference to the location in the Nullable<T> instance where the value is stored.

C#

```
public static ref readonly T GetValueRefOrDefaultRef<T> (ref T? nullable)
where T : struct;
```

Type Parameters

T

The underlying value type of the Nullable<T> generic type.

Parameters

nullable Nullable<T>

The readonly reference to the input Nullable<T> value.

Returns

T

A readonly reference to the location where the instance's `T` value is stored. If the instance's HasValue is `false`, the current value at that location may be the default value.

Remarks

As the returned readonly reference refers to data that is stored in the input `nullable` value, this method should only ever be called when the input reference points to a value with an actual location and not an "rvalue" (an expression that may appear on the right

side but not left side of an assignment). That is, if this API is called and the input reference points to a value that is produced by the compiler as a defensive copy or a temporary copy, the behavior might not match the desired one.

Applies to

Product	Versions
.NET	7, 8, 9

Nullable<T> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value type that can be assigned `null`.

C#

```
public struct Nullable<T> where T : struct
```

Type Parameters

T

The underlying value type of the Nullable<T> generic type.

Inheritance Object → ValueType → Nullable<T>

Examples

The following code example defines three rows of a table in the Microsoft Pubs sample database. The table contains two columns that are not nullable and two columns that are nullable.

C#

```
using System;

class Sample
{
    // Define the "titleAuthor" table of the Microsoft "pubs" database.
    public struct titleAuthor
    {
      // Author ID; format ###-##-####
      public string au_id;
      // Title ID; format AA####
      public string title_id;
      // Author ORD is nullable.
      public short? au_ord;
      // Royalty Percent is nullable.
```

```
        public int? royaltyper;
      }

      public static void Main()
      {
        // Declare and initialize the titleAuthor array.
        titleAuthor[] ta = new titleAuthor[3];
        ta[0].au_id = "712-32-1176";
        ta[0].title_id = "PS3333";
        ta[0].au_ord = 1;
        ta[0].royaltyper = 100;

        ta[1].au_id = "213-46-8915";
        ta[1].title_id = "BU1032";
        ta[1].au_ord = null;
        ta[1].royaltyper = null;

        ta[2].au_id = "672-71-3249";
        ta[2].title_id = "TC7777";
        ta[2].au_ord = null;
        ta[2].royaltyper = 40;

        // Display the values of the titleAuthor array elements, and
        // display a legend.
        Display("Title Authors Table", ta);
        Console.WriteLine("Legend:");
        Console.WriteLine("An Author ORD of -1 means no value is defined.");
        Console.WriteLine("A Royalty % of 0 means no value is defined.");
      }

      // Display the values of the titleAuthor array elements.
      public static void Display(string dspTitle,
                                 titleAuthor[] dspAllTitleAuthors)
      {
        Console.WriteLine("*** {0} ***", dspTitle);
        foreach (titleAuthor dspTA in dspAllTitleAuthors) {
           Console.WriteLine("Author ID ... {0}", dspTA.au_id);
           Console.WriteLine("Title ID .... {0}", dspTA.title_id);
           Console.WriteLine("Author ORD .. {0}", dspTA.au_ord ?? -1);
           Console.WriteLine("Royalty % ... {0}", dspTA.royaltyper ?? 0);
           Console.WriteLine();
        }
      }
  }
  // The example displays the following output:
  //     *** Title Authors Table ***
  //     Author ID ... 712-32-1176
  //     Title ID .... PS3333
  //     Author ORD .. 1
  //     Royalty % ... 100
  //
  //     Author ID ... 213-46-8915
  //     Title ID .... BU1032
  //     Author ORD .. -1
  //     Royalty % ... 0
```

```
//
//      Author ID ... 672-71-3249
//      Title ID .... TC7777
//      Author ORD .. -1
//      Royalty % ... 40
//
//      Legend:
//      An Author ORD of -1 means no value is defined.
//      A Royalty % of 0 means no value is defined.
```

Remarks

For more information about this API, see Supplemental API remarks for Nullable<T>.

Constructors

Expand table

Nullable<T>(T)	Initializes a new instance of the Nullable<T> structure to the specified value.

Properties

Expand table

Has Value	Gets a value indicating whether the current Nullable<T> object has a valid value of its underlying type.
Value	Gets the value of the current Nullable<T> object if it has been assigned a valid underlying value.

Methods

Expand table

Equals(Object)	Indicates whether the current Nullable<T> object is equal to a specified object.
GetHashCode()	Retrieves the hash code of the object returned by the Value property.
GetValue OrDefault()	Retrieves the value of the current Nullable<T> object, or the default value of the underlying type.

GetValueOrDefault(T)	Retrieves the value of the current Nullable<T> object, or the specified default value.
ToString()	Returns the text representation of the value of the current Nullable<T> object.

Operators

Expand table

Explicit(Nullable<T> to T)	Defines an explicit conversion of a Nullable<T> instance to its underlying value.
Implicit(T to Nullable<T>)	Creates a new Nullable<T> object initialized to a specified value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Nullable<T>(T) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Nullable<T> structure to the specified value.

C#

```
public Nullable (T value);
```

Parameters

`value` T

A value type.

Remarks

The Nullable<T> constructor initializes the HasValue property of the new Nullable<T> object to `true`, and the Value property to the value of the `value` parameter.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Nullable<T>.HasValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Nullable<T> object has a valid value of its underlying type.

```
C#

public bool HasValue { get; }
```

Property Value

Boolean

`true` if the current Nullable<T> object has a value; `false` if the current Nullable<T> object has no value.

Examples

The following example uses the HasValue property of a `Nullable<int>` (`Nullable(Of Integer)` in Visual Basic) object to determine whether it should display the object's Value property or its GetValueOrDefault property.

```
C#

using System;

public class Example
{
   public static void Main()
   {
      Nullable<int> n1 = new Nullable<int>(10);
      Nullable<int> n2 = null;
      Nullable<int> n3 = new Nullable<int>(20);
      n3 = null;
      Nullable<int>[] items = { n1, n2, n3 };

      foreach (var item in items) {
```

```
            Console.WriteLine("Has a value: {0}", item.HasValue);
            if (item.HasValue) {
               Console.WriteLine("Type: {0}", item.GetType().Name);
               Console.WriteLine("Value: {0}", item.Value);
            }
            else {
               Console.WriteLine("Null: {0}", item == null);
               Console.WriteLine("Default Value: {0}",
item.GetValueOrDefault());
            }
            Console.WriteLine();
         }
      }
}
// The example displays the following output:
//       Has a value: True
//       Type: Int32
//       Value: 10
//
//       Has a value: False
//       Null: True
//       Default Value: 0
//
//       Has a value: False
//       Null: True
//       Default Value: 0
```

Remarks

If the HasValue property is `true`, the value of the current Nullable<T> object can be accessed with the Value property. Otherwise, attempting to access its value throws an InvalidOperationException exception.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Nullable<T>.Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Nullable<T> object if it has been assigned a valid underlying value.

```
C#

public T Value { get; }
```

Property Value

T

The value of the current Nullable<T> object if the HasValue property is `true`. An exception is thrown if the HasValue property is `false`.

Exceptions

InvalidOperationException

The HasValue property is `false`.

Examples

The following example uses the HasValue property of a `Nullable<int>` (`Nullable(Of Integer)` in Visual Basic) object to determine whether it should display the object's Value property or its GetValueOrDefault property.

```
C#

using System;

public class Example
{
   public static void Main()
   {
      Nullable<int> n1 = new Nullable<int>(10);
```

```
        Nullable<int> n2 = null;
        Nullable<int> n3 = new Nullable<int>(20);
        n3 = null;
        Nullable<int>[] items = { n1, n2, n3 };

        foreach (var item in items) {
           Console.WriteLine("Has a value: {0}", item.HasValue);
           if (item.HasValue) {
              Console.WriteLine("Type: {0}", item.GetType().Name);
              Console.WriteLine("Value: {0}", item.Value);
           }
           else {
              Console.WriteLine("Null: {0}", item == null);
              Console.WriteLine("Default Value: {0}",
item.GetValueOrDefault());
           }
           Console.WriteLine();
        }
    }
}
// The example displays the following output:
//       Has a value: True
//       Type: Int32
//       Value: 10
//
//       Has a value: False
//       Null: True
//       Default Value: 0
//
//       Has a value: False
//       Null: True
//       Default Value: 0
```

Remarks

If a value of type `T` has not been assigned to the Nullable<T> object, you can compare it to `null` and retrieve its HasValue property, but you cannot access its Value property or call its other members.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Nullable<T>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the current Nullable<T> object is equal to a specified object.

C#

```
public override bool Equals (object? other);
```

Parameters

`other` Object

An object.

Returns

Boolean

`true` if the `other` parameter is equal to the current Nullable<T> object; otherwise, `false`.

This table describes how equality is defined for the compared values:

Expand table

Return Value	Description
`true`	The HasValue property is `false`, and the `other` parameter is `null` (that is, two null values are equal by definition), OR the HasValue property is `true`, and the value returned by the Value property is equal to the `other` parameter.
`false`	The HasValue property for the current Nullable<T> structure is `true`, and the `other` parameter is `null`, OR the HasValue property for the current Nullable<T> structure is `false`, and the `other` parameter is not `null`, OR the HasValue property for the current Nullable<T> structure is `true`, and the value returned by the Value property is not equal to the `other` parameter.

Examples

The following code example determines whether an object and a Nullable<T> object are equal to the current Nullable<T> object.

C#

```
// This code example demonstrates the Nullable<T>.Equals
// methods.

using System;

class Sample
{
    public static void Main()
    {
    int? nullInt1 = 100;
    int? nullInt2 = 200;
    object myObj;

// Determine if two nullable of System.Int32 values are equal.
// The nullable objects have different values.
    Console.Write("1) nullInt1 and nullInt2 ");
    if (nullInt1.Equals(nullInt2))
        Console.Write("are");
    else
        Console.Write("are not");
    Console.WriteLine(" equal.");

// Determine if a nullable of System.Int32 and an object
// are equal. The object contains the boxed value of the
// nullable object.

    myObj = (object)nullInt1;
    Console.Write("2) nullInt1 and myObj ");
    if (nullInt1.Equals(myObj))
        Console.Write("are");
    else
        Console.Write("are not");
    Console.WriteLine(" equal.");
    }
}

/*
This code example produces the following results:

1) nullInt1 and nullInt2 are not equal.
2) nullInt1 and myObj are equal.

*/
```

Remarks

If the HasValue property of the current Nullable<T> structure is `true` and the `other` argument is not `null`, equality is determined by passing the `other` parameter to the `Equals` method of the underlying value of the current Nullable<T> structure.

Applies to

Product	Versions

Nullable<T>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves the hash code of the object returned by the Value property.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code of the object returned by the Value property if the HasValue property is `true`, or zero if the HasValue property is `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Nullable<T>.GetValueOrDefault Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves the value of the current Nullable<T> object, or a default value.

Overloads

Expand table

GetValueOrDefault()	Retrieves the value of the current Nullable<T> object, or the default value of the underlying type.
GetValueOrDefault(T)	Retrieves the value of the current Nullable<T> object, or the specified default value.

Examples

The following code example retrieves the value of a Nullable<T> object if that value is defined; otherwise, it retrieves the default value or a specific default value.

C#

```
// This code example demonstrates the
// Nullable<T>.GetValueOrDefault methods.

using System;

class Sample
{
    public static void Main()
    {
    float? mySingle = 12.34f;
    float? yourSingle = -1.0f;

   Console.WriteLine("*** Display a value or the default value ***\n");
// Display the values of mySingle and yourSingle.

    Display("A1", mySingle, yourSingle);
```

```
// Assign the value of mySingle to yourSingle, then display the values
// of mySingle and yourSingle. The yourSingle variable is assigned the
// value 12.34 because mySingle has a value.

    yourSingle = mySingle.GetValueOrDefault();
    Display("A2", mySingle, yourSingle);

// Assign null (Nothing in Visual Basic) to mySingle, which means no value
is
// defined for mySingle. Then assign the value of mySingle to yourSingle and
// display the values of both variables. The default value of all binary
zeroes
// is assigned to yourSingle because mySingle has no value.

    mySingle = null;
    yourSingle = mySingle.GetValueOrDefault();
    Display("A3", mySingle, yourSingle);

// Reassign the original values of mySingle and yourSingle.
    mySingle = 12.34f;
    yourSingle = -1.0f;

    Console.Write("\n*** Display a value or the ");
    Console.WriteLine("specified default value ***\n");

// Display the values of mySingle and yourSingle.
    Display("B1", mySingle, yourSingle);

// Assign the value of mySingle to yourSingle, then display the values
// of mySingle and yourSingle. The yourSingle variable is assigned the
// value 12.34 because mySingle has a value.

    yourSingle = mySingle.GetValueOrDefault(-222.22f);
    Display("B2", mySingle, yourSingle);

// Assign null (Nothing in Visual Basic) to mySingle, which means no value
is
// defined for mySingle. Then assign the value of mySingle to yourSingle and
// display the values of both variables. The specified default value of
-333.33
// is assigned to yourSingle because mySingle has no value.

    mySingle = null;
    yourSingle = mySingle.GetValueOrDefault(-333.33f);
    Display("B3", mySingle, yourSingle);
    }

// Display the values of two nullable of System.Single structures.
// The Console.WriteLine method automatically calls the ToString methods of
// each input argument to display its values. If no value is defined for a
// nullable type, the ToString method for that argument returns the empty
// string ("").
    public static void Display(string title, float? dspMySingle, float?
dspYourSingle)
    {
```

```
    Console.WriteLine("{0}) mySingle = [{1}], yourSingle = [{2}]",
                      title, dspMySingle, dspYourSingle);
    }
}

/*
This code example produces the following results:

A1) mySingle = [12.34], yourSingle = [-1]
A2) mySingle = [12.34], yourSingle = [12.34]
A3) mySingle = [], yourSingle = [0]

*** Display a value or the specified default value ***

B1) mySingle = [12.34], yourSingle = [-1]
B2) mySingle = [12.34], yourSingle = [12.34]
B3) mySingle = [], yourSingle = [-333.33]

*/
```

GetValueOrDefault()

Retrieves the value of the current Nullable<T> object, or the default value of the underlying type.

```
C#

public readonly T GetValueOrDefault ();
```

Returns

T

The value of the Value property if the HasValue property is `true`; otherwise, the default value of the underlying type.

Remarks

The GetValueOrDefault method returns a value even if the HasValue property is `false` (unlike the Value property, which throws an exception). If the HasValue property is `false`, the method returns the default value of the underlying type.

UWP	10.0

GetValueOrDefault(T)

Retrieves the value of the current Nullable<T> object, or the specified default value.

C#

```
public readonly T GetValueOrDefault (T defaultValue);
```

Parameters

`defaultValue` T

A value to return if the HasValue property is `false`.

Returns

T

The value of the Value property if the HasValue property is `true`; otherwise, the `defaultValue` parameter.

Remarks

The GetValueOrDefault method returns a value even if the HasValue property is `false` (unlike the Value property, which throws an exception).

Nullable<T>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the text representation of the value of the current Nullable<T> object.

C#

```
public override string? ToString ();
```

Returns

String

The text representation of the value of the current Nullable<T> object if the HasValue property is `true`, or an empty string ("") if the HasValue property is `false`.

Examples

The following code example displays the value of the current Nullable<T> object.

C#

```
// This code example demonstrates the
// Nullable<T>.ToString method.

using System;

class Sample
{
    public static void Main()
    {
    DateTime? nullableDate;

// Display the current date and time.
    nullableDate = DateTime.Now;
    Display("1)", nullableDate);

// Assign null (Nothing in Visual Basic) to nullableDate, then
// display its value.
```

```
    nullableDate = null;
    Display("2)", nullableDate);
    }

// Display the text representation of a nullable DateTime.
    public static void Display(string title, DateTime? dspDT)
    {
    string msg = dspDT.ToString();

    Console.Write("{0} ", title);
    if (String.IsNullOrEmpty(msg))
        Console.WriteLine("The nullable DateTime has no defined value.");
    else
        Console.WriteLine("The current date and time is {0}.", msg);
    }
}

/*
This code example produces the following results:

1) The current date and time is 4/19/2005 8:28:14 PM.
2) The nullable DateTime has no defined value.

*/
```

Remarks

The ToString property returns the string yielded by calling the `ToString` property of the object returned by the Value property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Nullable<T>.Explicit(Nullable<T> to T) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines an explicit conversion of a Nullable<T> instance to its underlying value.

```
C#

public static explicit operator T (T? value);
```

Parameters

value Nullable<T>

A nullable value.

Returns

T

The value of the Value property for the `value` parameter.

Examples

The Explicit operator enables code such as the following, which converts a `Nullable(Of Int32)` value to an Int32 value.

```
C#

using System;

public class Example
{
   public static void Main()
   {
       var nullInt = new Nullable<int>(172);
       // Convert with CInt conversion method.
```

```
        Console.WriteLine((int)nullInt);
        // Convert with Convert.ChangeType.
        Console.WriteLine(Convert.ChangeType(nullInt, typeof(int)));
    }
}
// The example displays the following output:
//       172
//       172
```

Remarks

This operator supports the explicit conversion of the current Nullable<T> instance to type `T`, the type of Value. The syntax for such explicit conversions is language-dependent. You may also be able to perform the conversion by calling the Convert.ChangeType method.

The equivalent method for this operator is Nullable<T>.Value

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Nullable<T>.Implicit(T to Nullable<T>) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new Nullable<T> object initialized to a specified value.

C#

```
public static implicit operator T? (T value);
```

Parameters

`value` T

A value type.

Returns

Nullable<T>

A Nullable<T> object whose Value property is initialized with the `value` parameter.

Remarks

The Value property of the new Nullable<T> value is initialized to the `value` parameter and the HasValue property is initialized to `true`.

The equivalent method for this operator is Nullable<T>.Nullable<T>(T)

> **Note**
>
> In C# and Visual Basic, an implicit conversion from `T` to **Nullable<T>** does not invoke this operator because these languages have special rules for the conversion.

This operator is provided for the benefit of languages that do not have such special rules.

> **Note**
>
> In C# and Visual Basic, an implicit conversion from a `null` or `Nothing` literal to **Nullable<T>** produces a **Nullable<T>** value whose **HasValue** property is initialized to `false`. The conversion occurs at compile time in these languages and does not invoke any operator.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

NullReferenceException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to dereference a null object reference.

C#

```
public class NullReferenceException : SystemException
```

Inheritance Object → Exception → SystemException → NullReferenceException

Remarks

A NullReferenceException exception is thrown when you try to access a member on a type whose value is `null`. A NullReferenceException exception typically reflects developer error and is thrown in the following scenarios:

- You've forgotten to instantiate a reference type. In the following example, `names` is declared but never instantiated:

  C#

  ```
  using System;
  using System.Collections.Generic;

  public class Example
  {
     public static void Main(string[] args)
     {
        int value = Int32.Parse(args[0]);
        List<String> names;
        if (value > 0)
           names = new List<String>();

        names.Add("Major Major Major");
     }
  }
  // Compilation displays a warning like the following:
  ```

```
//    Example1.cs(10) : warning BC42104: Variable //names// is used
before it
//    has been assigned a value. A null reference exception could
result
//    at runtime.
//
//          names.Add("Major Major Major")
//          ~~~~~
// The example displays output like the following output:
//    Unhandled Exception: System.NullReferenceException: Object
reference
//    not set to an instance of an object.
//       at Example.Main()
```

Some compilers issue a warning when they compile this code. Others issue an error, and the compilation fails. To address this problem, instantiate the object so that its value is no longer `null`. The following example does this by calling a type's class constructor.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      List<String> names = new List<String>();
      names.Add("Major Major Major");
   }
}
```

- You've forgotten to dimension an array before initializing it. In the following example, `values` is declared to be an integer array, but the number of elements that it contains is never specified. The attempt to initialize its values therefore thrown a NullReferenceException exception.

C#

```
using System;

public class Example
{
   public static void Main()
   {
       int[] values = null;
       for (int ctr = 0; ctr <= 9; ctr++)
          values[ctr] = ctr * 2;
```

```
        foreach (var value in values)
           Console.WriteLine(value);
    }
}
// The example displays the following output:
//    Unhandled Exception:
//       System.NullReferenceException: Object reference not set to an
instance of an object.
//       at Example.Main()
```

You can eliminate the exception by declaring the number of elements in the array before initializing it, as the following example does.

C#

```
using System;

public class Example
{
   public static void Main()
   {
       int[] values = new int[10];
       for (int ctr = 0; ctr <= 9; ctr++)
          values[ctr] = ctr * 2;

       foreach (var value in values)
          Console.WriteLine(value);
   }
}
// The example displays the following output:
//    0
//    2
//    4
//    6
//    8
//    10
//    12
//    14
//    16
//    18
```

For more information on declaring and initializing arrays, see Arrays and Arrays.

- You get a **null** return value from a method, and then call a method on the returned type. This sometimes is the result of a documentation error; the documentation fails to note that a method call can return `null`. In other cases, your code erroneously assumes that the method will always return a non-**null** value.

The code in the following example assumes that the Array.Find method always returns `Person` object whose `FirstName` field matches a search string. Because there is no match, the runtime throws a NullReferenceException exception.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Person[] persons = Person.AddRange( new String[] { "Abigail", "Abra",
                                                "Abraham", "Adrian", "Ariella",
                                                "Arnold", "Aston", "Astor" } );
      String nameToFind = "Robert";
      Person found = Array.Find(persons, p => p.FirstName == nameToFind);
      Console.WriteLine(found.FirstName);
   }
}

public class Person
{
   public static Person[] AddRange(String[] firstNames)
   {
      Person[] p = new Person[firstNames.Length];
      for (int ctr = 0; ctr < firstNames.Length; ctr++)
         p[ctr] = new Person(firstNames[ctr]);

      return p;
   }

   public Person(String firstName)
   {
      this.FirstName = firstName;
   }

   public String FirstName;
}
// The example displays the following output:
//       Unhandled Exception: System.NullReferenceException:
//       Object reference not set to an instance of an object.
//          at Example.Main()
```

To address this problem, test the method's return value to ensure that it is not `null` before calling any of its members, as the following example does.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Person[] persons = Person.AddRange( new String[] { "Abigail",
"Abra",
                                          "Abraham", "Adrian",
"Ariella",
                                          "Arnold", "Aston", "Astor" }
);
      String nameToFind = "Robert";
      Person found = Array.Find(persons, p => p.FirstName ==
nameToFind);
      if (found != null)
         Console.WriteLine(found.FirstName);
      else
         Console.WriteLine("{0} not found.", nameToFind);
   }
}

public class Person
{
   public static Person[] AddRange(String[] firstNames)
   {
      Person[] p = new Person[firstNames.Length];
      for (int ctr = 0; ctr < firstNames.Length; ctr++)
         p[ctr] = new Person(firstNames[ctr]);

      return p;
   }

   public Person(String firstName)
   {
      this.FirstName = firstName;
   }

   public String FirstName;
}
// The example displays the following output:
//        Robert not found
```

- You're using an expression (for example, you're chaining a list of methods or properties together) to retrieve a value and, although you're checking whether the value is `null`, the runtime still throws a NullReferenceException exception. This occurs because one of the intermediate values in the expression returns `null`. As a result, your test for `null` is never evaluated.

The following example defines a `Pages` object that caches information about web pages, which are presented by `Page` objects. The `Example.Main` method checks whether the current web page has a non-null title and, if it does, displays the title. Despite this check, however, the method throws a NullReferenceException exception.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      var pages = new Pages();
      if (! String.IsNullOrEmpty(pages.CurrentPage.Title)) {
         String title = pages.CurrentPage.Title;
         Console.WriteLine("Current title: '{0}'", title);
      }
   }
}

public class Pages
{
   Page[] page = new Page[10];
   int ctr = 0;

   public Page CurrentPage
   {
      get { return page[ctr]; }
      set {
         // Move all the page objects down to accommodate the new one.
         if (ctr > page.GetUpperBound(0)) {
            for (int ndx = 1; ndx <= page.GetUpperBound(0); ndx++)
               page[ndx - 1] = page[ndx];
         }
         page[ctr] = value;
         if (ctr < page.GetUpperBound(0))
            ctr++;
      }
   }

   public Page PreviousPage
   {
      get {
         if (ctr == 0) {
            if (page[0] == null)
               return null;
            else
               return page[0];
         }
         else {
```

```
            ctr--;
            return page[ctr + 1];
         }
      }
   }
}

public class Page
{
   public Uri URL;
   public String Title;
}
// The example displays the following output:
//    Unhandled Exception:
//       System.NullReferenceException: Object reference not set to an
instance of an object.
//       at Example.Main()
```

The exception is thrown because `pages.CurrentPage` returns `null` if no page information is stored in the cache. This exception can be corrected by testing the value of the `CurrentPage` property before retrieving the current `Page` object's `Title` property, as the following example does:

C#

```
using System;

public class Example
{
   public static void Main()
   {
      var pages = new Pages();
      Page current = pages.CurrentPage;
      if (current != null) {
         String title = current.Title;
         Console.WriteLine("Current title: '{0}'", title);
      }
      else {
         Console.WriteLine("There is no page information in the
cache.");
      }
   }
}
// The example displays the following output:
//       There is no page information in the cache.
```

- You're enumerating the elements of an array that contains reference types, and your attempt to process one of the elements throws a NullReferenceException exception.

The following example defines a string array. A `for` statement enumerates the elements in the array and calls each string's Trim method before displaying the string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] values = { "one", null, "two" };
      for (int ctr = 0; ctr <= values.GetUpperBound(0); ctr++)
         Console.Write("{0}{1}", values[ctr].Trim(),
                        ctr == values.GetUpperBound(0) ? "" : ", ");
      Console.WriteLine();
   }
}
// The example displays the following output:
//    Unhandled Exception:
//       System.NullReferenceException: Object reference not set to an
instance of an object.
//       at Example.Main()
```

This exception occurs if you assume that each element of the array must contain a non-null value, and the value of the array element is in fact `null`. The exception can be eliminated by testing whether the element is `null` before performing any operation on that element, as the following example shows.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] values = { "one", null, "two" };
      for (int ctr = 0; ctr <= values.GetUpperBound(0); ctr++)
         Console.Write("{0}{1}",
                        values[ctr] != null ? values[ctr].Trim() : "",
                        ctr == values.GetUpperBound(0) ? "" : ", ");
      Console.WriteLine();
   }
}
// The example displays the following output:
//       one, , two
```

- A NullReferenceException exception can be thrown by a method when it accesses a member of one of its arguments, but that argument is `null`. The `PopulateNames` method in the following example throws the exception at the line `names.Add(arrName);`.

  C#

  ```
  using System;
  using System.Collections.Generic;

  public class Example
  {
     public static void Main()
     {
        List<String> names = GetData();
        PopulateNames(names);
     }

     private static void PopulateNames(List<String> names)
     {
        String[] arrNames = { "Dakota", "Samuel", "Nikita",
                              "Koani", "Saya", "Yiska", "Yumaevsky" };
        foreach (var arrName in arrNames)
           names.Add(arrName);
     }

     private static List<String> GetData()
     {
        return null;
     }
  }
  // The example displays output like the following:
  //    Unhandled Exception: System.NullReferenceException: Object
  reference
  //    not set to an instance of an object.
  //       at Example.PopulateNames(List`1 names)
  //       at Example.Main()
  ```

  To address this issue, make sure that the argument passed to the method is not `null`, or handle the thrown exception in a `try…catch…finally` block. For more information, see Exceptions.

The following Microsoft intermediate language (MSIL) instructions throw NullReferenceException: `callvirt`, `cpblk`, `cpobj`, `initblk`, `ldelem.<type>`, `ldelema`, `ldfld`, `ldflda`, `ldind.<type>`, `ldlen`, `stelem.<type>`, `stfld`, `stind.<type>`, `throw`, and `unbox`.

NullReferenceException uses the HRESULT COR_E_NULLREFERENCE, which has the value 0x80004003.

For a list of initial property values for an instance of NullReferenceException, see the NullReferenceException constructors.

Handling NullReferenceException in release code

It's usually better to avoid a NullReferenceException than to handle it after it occurs. Handling an exception can make your code harder to maintain and understand, and can sometimes introduce other bugs. A NullReferenceException is often a non-recoverable error. In these cases, letting the exception stop the app might be the best alternative.

However, there are many situations where handling the error can be useful:

- Your app can ignore objects that are null. For example, if your app retrieves and processes records in a database, you might be able to ignore some number of bad records that result in null objects. Recording the bad data in a log file or in the application UI might be all you have to do.
- You can recover from the exception. For example, a call to a web service that returns a reference type might return null if the connection is lost or the connection times out. You can attempt to reestablish the connection and try the call again.
- You can restore the state of your app to a valid state. For example, you might be performing a multi-step task that requires you to save information to a data store before you call a method that throws a NullReferenceException. If the uninitialized object would corrupt the data record, you can remove the previous data before you close the app.
- You want to report the exception. For example, if the error was caused by a mistake from the user of your app, you can generate a message to help them supply the correct information. You can also log information about the error to help you fix the problem. Some frameworks, like ASP.NET, have a high-level exception handler that captures all errors to that the app never crashes; in that case, logging the exception might be the only way you can know that it occurs.

Constructors

Expand table

NullReferenceException()	Initializes a new instance of the NullReferenceException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "The value

	'null' was found where an instance of an object was required." This message takes into account the current system culture.
NullReference Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NullReferenceException class with serialized data.
NullReference Exception(String)	Initializes a new instance of the NullReferenceException class with a specified error message.
NullReference Exception(String, Exception)	Initializes a new instance of the NullReferenceException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

NullReferenceException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the NullReferenceException class.

Overloads

Expand table

NullReferenceException()	Initializes a new instance of the NullReferenceException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "The value 'null' was found where an instance of an object was required." This message takes into account the current system culture.
NullReferenceException(String)	Initializes a new instance of the NullReferenceException class with a specified error message.
NullReferenceException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the NullReferenceException class with serialized data.
NullReferenceException(String, Exception)	Initializes a new instance of the NullReferenceException class with a specified error message and a reference to the inner exception that is the cause of this exception.

NullReferenceException()

Initializes a new instance of the NullReferenceException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "The value 'null' was found where an instance of an object was required." This message takes into account the current system culture.

```
C#
public NullReferenceException ();
```

Remarks

The following table shows the initial property values for an instance of NullReferenceException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NullReferenceException(String)

Initializes a new instance of the NullReferenceException class with a specified error message.

```
C#
public NullReferenceException (string? message);
```

Parameters

`message` String

A String that describes the error. The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of NullReferenceException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

NullReferenceException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the NullReferenceException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected NullReferenceException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions *(Obsolete)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

NullReferenceException(String, Exception)

Initializes a new instance of the NullReferenceException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public NullReferenceException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of NullReferenceException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Object Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Supports all classes in the .NET class hierarchy and provides low-level services to derived classes. This is the ultimate base class of all .NET classes; it is the root of the type hierarchy.

C#

```
public class Object
```

Examples

The following example defines a Point type derived from the Object class and overrides many of the virtual methods of the Object class. In addition, the example shows how to call many of the static and instance methods of the Object class.

C#

```
using System;

// The Point class is derived from System.Object.
class Point
{
    public int x, y;

    public Point(int x, int y)
    {
        this.x = x;
        this.y = y;
    }

    public override bool Equals(object obj)
    {
        // If this and obj do not refer to the same type, then they are not
equal.
        if (obj.GetType() != this.GetType()) return false;

        // Return true if  x and y fields match.
        var other = (Point) obj;
```

```
        return (this.x == other.x) && (this.y == other.y);
    }

    // Return the XOR of the x and y fields.
    public override int GetHashCode()
    {
        return x ^ y;
    }

    // Return the point's value as a string.
    public override String ToString()
    {
        return $"({x}, {y})";
    }

    // Return a copy of this point object by making a simple field copy.
    public Point Copy()
    {
        return (Point) this.MemberwiseClone();
    }
}

public sealed class App
{
    static void Main()
    {
        // Construct a Point object.
        var p1 = new Point(1,2);

        // Make another Point object that is a copy of the first.
        var p2 = p1.Copy();

        // Make another variable that references the first Point object.
        var p3 = p1;

        // The line below displays false because p1 and p2 refer to two
different objects.
        Console.WriteLine(Object.ReferenceEquals(p1, p2));

        // The line below displays true because p1 and p2 refer to two
different objects that have the same value.
        Console.WriteLine(Object.Equals(p1, p2));

        // The line below displays true because p1 and p3 refer to one
object.
        Console.WriteLine(Object.ReferenceEquals(p1, p3));

        // The line below displays: p1's value is: (1, 2)
        Console.WriteLine($"p1's value is: {p1.ToString()}");
    }
}

// This code example produces the following output:
//
// False
```

```
// True
// True
// p1's value is: (1, 2)
//
```

Remarks

For more information about this API, see Supplemental API remarks for Object.

Constructors

Expand table

Object()	Initializes a new instance of the Object class.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object.
Equals(Object, Object)	Determines whether the specified object instances are considered equal.
Finalize()	Allows an object to try to free resources and perform other cleanup operations before it is reclaimed by garbage collection.
GetHashCode()	Serves as the default hash function.
GetType()	Gets the Type of the current instance.
MemberwiseClone()	Creates a shallow copy of the current Object.
ReferenceEquals(Object, Object)	Determines whether the specified Object instances are the same instance.
ToString()	Returns a string that represents the current object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

Public static (`Shared` in Visual Basic) members of this type are thread safe. Instance members are not guaranteed to be thread-safe.

Object Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Object class.

C#

```
public Object ();
```

Remarks

This constructor is called by constructors in derived classes, but it can also be used to directly create an instance of the Object class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Object.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two object instances are equal.

Overloads

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object.
Equals(Object, Object)	Determines whether the specified object instances are considered equal.

Equals(Object)

Determines whether the specified object is equal to the current object.

C#

```
public virtual bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with the current object.

Returns

Boolean

`true` if the specified object is equal to the current object; otherwise, `false`.

Remarks

For more information about this API, see Supplemental API remarks for Object.Equals.

See also

- ReferenceEquals(Object, Object)
- GetHashCode()
- ValueType
- IComparable
- ArrayList
- Hashtable

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object, Object)

Determines whether the specified object instances are considered equal.

C#

```
public static bool Equals (object? objA, object? objB);
```

Parameters

objA Object

The first object to compare.

objB Object

The second object to compare.

Returns

Boolean

`true` if the objects are considered equal; otherwise, `false`. If both `objA` and `objB` are **null**, the method returns `true`.

Examples

The following example illustrates the Equals(Object, Object) method and compares it with the ReferenceEquals method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Dog m1 = new Dog("Alaskan Malamute");
      Dog m2 = new Dog("Alaskan Malamute");
      Dog g1 = new Dog("Great Pyrenees");
      Dog g2 = g1;
      Dog d1 = new Dog("Dalmation");
      Dog n1 = null;
      Dog n2 = null;

      Console.WriteLine("null = null: {0}", Object.Equals(n1, n2));
      Console.WriteLine("null Reference Equals null: {0}\n",
Object.ReferenceEquals(n1, n2));

      Console.WriteLine("{0} = {1}: {2}", g1, g2, Object.Equals(g1, g2));
      Console.WriteLine("{0} Reference Equals {1}: {2}\n", g1, g2,
Object.ReferenceEquals(g1, g2));

      Console.WriteLine("{0} = {1}: {2}", m1, m2, Object.Equals(m1, m2));
      Console.WriteLine("{0} Reference Equals {1}: {2}\n", m1, m2,
Object.ReferenceEquals(m1, m2));

      Console.WriteLine("{0} = {1}: {2}", m1, d1, Object.Equals(m1, d1));
      Console.WriteLine("{0} Reference Equals {1}: {2}", m1, d1,
Object.ReferenceEquals(m1, d1));
   }
}

public class Dog
{
```

```
    // Public field.
    public string Breed;

    // Class constructor.
    public Dog(string dogBreed)
    {
       this.Breed = dogBreed;
    }

    public override bool Equals(Object obj)
    {
       if (obj == null || !(obj is Dog))
          return false;
       else
          return this.Breed == ((Dog) obj).Breed;
    }

    public override int GetHashCode()
    {
       return this.Breed.GetHashCode();
    }

    public override string ToString()
    {
       return this.Breed;
    }
 }
 // The example displays the following output:
 //       null = null: True
 //       null Reference Equals null: True
 //
 //       Great Pyrenees = Great Pyrenees: True
 //       Great Pyrenees Reference Equals Great Pyrenees: True
 //
 //       Alaskan Malamute = Alaskan Malamute: True
 //       Alaskan Malamute Reference Equals Alaskan Malamute: False
 //
 //       Alaskan Malamute = Dalmation: False
 //       Alaskan Malamute Reference Equals Dalmation: False
```

Remarks

The static Equals(Object, Object) method indicates whether two objects, `objA` and `objB`, are equal. It also enables you to test objects whose value is **null** for equality. It compares `objA` and `objB` for equality as follows:

- It determines whether the two objects represent the same object reference. If they do, the method returns `true`. This test is equivalent to calling the ReferenceEquals method. In addition, if both `objA` and `objB` are **null**, the method returns `true`.

- It determines whether either `objA` or `objB` is **null**. If so, it returns `false`.
- If the two objects do not represent the same object reference and neither is **null**, it calls `objA.Equals(objB)` and returns the result. This means that if `objA` overrides the Object.Equals(Object) method, this override is called.

Object.Finalize Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Allows an object to try to free resources and perform other cleanup operations before it is reclaimed by garbage collection.

C#

```
~Object ();
```

Examples

The following example verifies that the Finalize method is called when an object that overrides Finalize is destroyed. Note that, in a production application, the Finalize method would be overridden to release unmanaged resources held by the object. Also note that the C# example provides a destructor instead of overriding the Finalize method.

C#

```
using System;
using System.Diagnostics;

public class ExampleClass
{
   Stopwatch sw;

   public ExampleClass()
   {
      sw = Stopwatch.StartNew();
      Console.WriteLine("Instantiated object");
   }

   public void ShowDuration()
   {
      Console.WriteLine("This instance of {0} has been in existence for
{1}",
                        this, sw.Elapsed);
   }
```

```
   ~ExampleClass()
   {
      Console.WriteLine("Finalizing object");
      sw.Stop();
      Console.WriteLine("This instance of {0} has been in existence for
{1}",
                        this, sw.Elapsed);
   }
}

public class Demo
{
   public static void Main()
   {
      ExampleClass ex = new ExampleClass();
      ex.ShowDuration();
   }
}
// The example displays output like the following:
//    Instantiated object
//    This instance of ExampleClass has been in existence for
00:00:00.0011060
//    Finalizing object
//    This instance of ExampleClass has been in existence for
00:00:00.0036294
```

For an additional example that overrides the Finalize method, see the GC.SuppressFinalize method.

Remarks

For more information about this API, see Supplemental API remarks for Object.Finalize.

Applies to

Object.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as the default hash function.

```
C#
public virtual int GetHashCode ();
```

Returns

Int32

A hash code for the current object.

Remarks

For more information about this API, see Supplemental API remarks for Object.GetHashCode.

Notes to Inheritors

A hash function is used to quickly generate a number (hash code) that corresponds to the value of an object. Hash functions are usually specific to each type and, for uniqueness, must use at least one of the instance fields as input. Hash codes should not be computed by using the values of static fields.

For classes derived from Object, the `GetHashCode` method can delegate to the base class GetHashCode() implementation only if the derived class defines equality to be reference equality. The default implementation of GetHashCode() for reference types returns a hash code that is equivalent to the one returned by the GetHashCode(Object) method. You can override GetHashCode() for immutable reference types. In general, for mutable reference types, you should override GetHashCode() only if:

- You can compute the hash code from fields that are not mutable; or

- You can ensure that the hash code of a mutable object does not change while the object is contained in a collection that relies on its hash code.

Otherwise, you might think that the mutable object is lost in the hash table. If you do choose to override GetHashCode() for a mutable reference type, your documentation should make it clear that users of your type should not modify object values while the object is stored in a hash table.

For value types, GetHashCode() provides a default hash code implementation that uses reflection. You should consider overriding it for better performance.

For more information and examples that compute hash codes in a variety of ways, see the Examples section.

A hash function must have the following properties:

- If two objects compare as equal, the GetHashCode() method for each object must return the same value. However, if two objects do not compare as equal, the GetHashCode() methods for the two objects do not have to return different values.

- The GetHashCode() method for an object must consistently return the same hash code as long as there is no modification to the object state that determines the return value of the object's System.Object.Equals method. Note that this is true only for the current execution of an application, and that a different hash code can be returned if the application is run again.

- For the best performance, a hash function should generate an even distribution for all input, including input that is heavily clustered. An implication is that small modifications to object state should result in large modifications to the resulting hash code for best hash table performance.

- Hash functions should be inexpensive to compute.

- The GetHashCode() method should not throw exceptions.

For example, the implementation of the GetHashCode() method provided by the String class returns identical hash codes for identical string values. Therefore, two String objects return the same hash code if they represent the same string value. Also, the method uses all the characters in the string to generate reasonably randomly distributed output, even when the input is clustered in certain ranges (for example, many users might have strings that contain only the lower 128 ASCII characters, even though a string can contain any of the 65,535 Unicode characters).

Providing a good hash function on a class can significantly affect the performance of adding those objects to a hash table. In a hash table with keys that provide a good

implementation of a hash function, searching for an element takes constant time (for example, an O(1) operation). In a hash table with a poor implementation of a hash function, the performance of a search depends on the number of items in the hash table (for example, an O(`n`) operation, where `n` is the number of items in the hash table). A malicious user can input data that increases the number of collisions, which can significantly degrade the performance of applications that depend on hash tables, under the following conditions:

- When hash functions produce frequent collisions.
- When a large proportion of objects in a hash table produce hash codes that are equal or approximately equal to one another.
- When users input the data from which the hash code is computed.

Derived classes that override GetHashCode() must also override Equals(Object) to guarantee that two objects considered equal have the same hash code; otherwise, the Hashtable type might not work correctly.

Object.GetType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the Type of the current instance.

```
C#

public Type GetType ();
```

Returns

Type

The exact runtime type of the current instance.

Examples

The following code example demonstrates that GetType returns the runtime type of the current instance.

```
C#

using System;

public class MyBaseClass {
}

public class MyDerivedClass: MyBaseClass {
}

public class Test
{
   public static void Main()
   {
      MyBaseClass myBase = new MyBaseClass();
      MyDerivedClass myDerived = new MyDerivedClass();
      object o = myDerived;
      MyBaseClass b = myDerived;
```

```
        Console.WriteLine("mybase: Type is {0}", myBase.GetType());
        Console.WriteLine("myDerived: Type is {0}", myDerived.GetType());
        Console.WriteLine("object o = myDerived: Type is {0}", o.GetType());
        Console.WriteLine("MyBaseClass b = myDerived: Type is {0}",
b.GetType());
    }
}
// The example displays the following output:
//    mybase: Type is MyBaseClass
//    myDerived: Type is MyDerivedClass
//    object o = myDerived: Type is MyDerivedClass
//    MyBaseClass b = myDerived: Type is MyDerivedClass
```

Remarks

Because System.Object is the base class for all types in the .NET type system, the GetType method can be used to return Type objects that represent all .NET types. .NET recognizes the following five categories of types:

- Classes, which are derived from System.Object,
- Value types, which are derived from System.ValueType.
- Interfaces, which are derived from System.Object starting with the .NET Framework 2.0.
- Enumerations, which are derived from System.Enum.
- Delegates, which are derived from System.MulticastDelegate.

For two objects `x` and `y` that have identical runtime types, `Object.ReferenceEquals(x.GetType(),y.GetType())` returns `true`. The following example uses the GetType method with the ReferenceEquals method to determine whether one numeric value is the same type as two other numeric values.

C#

```
int n1 = 12;
int n2 = 82;
long n3 = 12;

Console.WriteLine("n1 and n2 are the same type: {0}",
                  Object.ReferenceEquals(n1.GetType(), n2.GetType()));
Console.WriteLine("n1 and n3 are the same type: {0}",
                  Object.ReferenceEquals(n1.GetType(), n3.GetType()));

// The example displays the following output:
```

```
//       n1 and n2 are the same type: True
//       n1 and n3 are the same type: False
```

> **Note**
>
> To determine whether an object is a specific type, you can use your language's type comparison keyword or construct. For example, you can use the `TypeOf…Is` construct in Visual Basic or the `is` keyword in C#.

The GetType method is inherited by all types that derive from Object. This means that, in addition to using your own language's comparison keyword, you can use the GetType method to determine the type of a particular object, as the following example shows.

C#

```
object[] values = { (int) 12, (long) 10653, (byte) 12, (sbyte) -5,
                    16.3, "string" };
foreach (var value in values) {
   Type t = value.GetType();
   if (t.Equals(typeof(byte)))
      Console.WriteLine("{0} is an unsigned byte.", value);
   else if (t.Equals(typeof(sbyte)))
      Console.WriteLine("{0} is a signed byte.", value);
   else if (t.Equals(typeof(int)))
      Console.WriteLine("{0} is a 32-bit integer.", value);
   else if (t.Equals(typeof(long)))
      Console.WriteLine("{0} is a 64-bit integer.", value);
   else if (t.Equals(typeof(double)))
      Console.WriteLine("{0} is a double-precision floating point.",
                        value);
   else
      Console.WriteLine("'{0}' is another data type.", value);
}

// The example displays the following output:
//    12 is a 32-bit integer.
//    10653 is a 32-bit integer.
//    12 is an unsigned byte.
//    -5 is a signed byte.
//    16.3 is a double-precision floating point.
//    'string' is another data type.
```

The Type object exposes the metadata associated with the class of the current Object.

Object.MemberwiseClone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a shallow copy of the current Object.

C#

```
protected object MemberwiseClone ();
```

Returns

Object

A shallow copy of the current Object.

Examples

The following example illustrates the MemberwiseClone method. It defines a `ShallowCopy` method that calls the MemberwiseClone method to perform a shallow copy operation on a `Person` object. It also defines a `DeepCopy` method that performs a deep copy operation on a `Person` object.

C#

```
using System;

public class IdInfo
{
    public int IdNumber;

    public IdInfo(int IdNumber)
    {
        this.IdNumber = IdNumber;
    }
}

public class Person
{
```

```
    public int Age;
    public string Name;
    public IdInfo IdInfo;

    public Person ShallowCopy()
    {
       return (Person) this.MemberwiseClone();
    }

    public Person DeepCopy()
    {
       Person other = (Person) this.MemberwiseClone();
       other.IdInfo = new IdInfo(IdInfo.IdNumber);
       other.Name = String.Copy(Name);
       return other;
    }
}

public class Example
{
    public static void Main()
    {
        // Create an instance of Person and assign values to its fields.
        Person p1 = new Person();
        p1.Age = 42;
        p1.Name = "Sam";
        p1.IdInfo = new IdInfo(6565);

        // Perform a shallow copy of p1 and assign it to p2.
        Person p2 = p1.ShallowCopy();

        // Display values of p1, p2
        Console.WriteLine("Original values of p1 and p2:");
        Console.WriteLine("   p1 instance values: ");
        DisplayValues(p1);
        Console.WriteLine("   p2 instance values:");
        DisplayValues(p2);

        // Change the value of p1 properties and display the values of p1
and p2.
        p1.Age = 32;
        p1.Name = "Frank";
        p1.IdInfo.IdNumber = 7878;
        Console.WriteLine("\nValues of p1 and p2 after changes to p1:");
        Console.WriteLine("   p1 instance values: ");
        DisplayValues(p1);
        Console.WriteLine("   p2 instance values:");
        DisplayValues(p2);

        // Make a deep copy of p1 and assign it to p3.
        Person p3 = p1.DeepCopy();
        // Change the members of the p1 class to new values to show the deep
copy.
        p1.Name = "George";
        p1.Age = 39;
```

```
        p1.IdInfo.IdNumber = 8641;
        Console.WriteLine("\nValues of p1 and p3 after changes to p1:");
        Console.WriteLine("   p1 instance values: ");
        DisplayValues(p1);
        Console.WriteLine("   p3 instance values:");
        DisplayValues(p3);
    }

    public static void DisplayValues(Person p)
    {
        Console.WriteLine("      Name: {0:s}, Age: {1:d}", p.Name, p.Age);
        Console.WriteLine("      Value: {0:d}", p.IdInfo.IdNumber);
    }
}
// The example displays the following output:
//       Original values of p1 and p2:
//          p1 instance values:
//             Name: Sam, Age: 42
//             Value: 6565
//          p2 instance values:
//             Name: Sam, Age: 42
//             Value: 6565
//
//       Values of p1 and p2 after changes to p1:
//          p1 instance values:
//             Name: Frank, Age: 32
//             Value: 7878
//          p2 instance values:
//             Name: Sam, Age: 42
//             Value: 7878
//
//       Values of p1 and p3 after changes to p1:
//          p1 instance values:
//             Name: George, Age: 39
//             Value: 8641
//          p3 instance values:
//             Name: Frank, Age: 32
//             Value: 7878
```

In this example, the `Person.IdInfo` property returns an `IdInfo` object. As the output from the example shows, when a `Person` object is cloned by calling the MemberwiseClone method, the cloned `Person` object is an independent copy of the original object, except that they share the same `Person.IdInfo` object reference. As a result, modifying the clone's `Person.IdInfo` property changes the original object's `Person.IdInfo` property. On the other hand, when a deep copy operation is performed, the cloned `Person` object, including its `Person.IdInfo` property, can be modified without affecting the original object.

Remarks

The MemberwiseClone method creates a shallow copy by creating a new object, and then copying the nonstatic fields of the current object to the new object. If a field is a value type, a bit-by-bit copy of the field is performed. If a field is a reference type, the reference is copied but the referred object is not; therefore, the original object and its clone refer to the same object.

For example, consider an object called X that references objects A and B. Object B, in turn, references object C. A shallow copy of X creates new object X2 that also references objects A and B. In contrast, a deep copy of X creates a new object X2 that references the new objects A2 and B2, which are copies of A and B. B2, in turn, references the new object C2, which is a copy of C. The example illustrates the difference between a shallow and a deep copy operation.

There are numerous ways to implement a deep copy operation if the shallow copy operation performed by the MemberwiseClone method does not meet your needs. These include the following:

- Call a class constructor of the object to be copied to create a second object with property values taken from the first object. This assumes that the values of an object are entirely defined by its class constructor.
- Call the MemberwiseClone method to create a shallow copy of an object, and then assign new objects whose values are the same as the original object to any properties or fields whose values are reference types. The `DeepCopy` method in the example illustrates this approach.
- Serialize the object to be deep copied, and then restore the serialized data to a different object variable.
- Use reflection with recursion to perform the deep copy operation.

Object.ReferenceEquals(Object, Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified Object instances are the same instance.

C#

```
public static bool ReferenceEquals (object? objA, object? objB);
```

Parameters

objA Object

The first object to compare.

objB Object

The second object to compare.

Returns

Boolean

`true` if `objA` is the same instance as `objB` or if both are **null**; otherwise, `false`.

Examples

The following example uses ReferenceEquals to determine if two objects are the same instance.

C#

```
object o = null;
object p = null;
object q = new Object();
```

```
Console.WriteLine(Object.ReferenceEquals(o, p));
p = q;
Console.WriteLine(Object.ReferenceEquals(p, q));
Console.WriteLine(Object.ReferenceEquals(o, p));

// This code produces the following output:
//   True
//   True
//   False
```

Remarks

Unlike the Equals method and the equality operator, the ReferenceEquals method cannot be overridden. Because of this, if you want to test two object references for equality and you are unsure about the implementation of the `Equals` method, you can call the ReferenceEquals method.

However, the return value of the ReferenceEquals method may appear to be anomalous in these two scenarios:

- When comparing value types. If `objA` and `objB` are value types, they are boxed before they are passed to the ReferenceEquals method. This means that if both `objA` and `objB` represent the same instance of a value type, the ReferenceEquals method nevertheless returns `false`, as the following example shows.

  C#

  ```
  int int1 = 3;
  Console.WriteLine(Object.ReferenceEquals(int1, int1));
  Console.WriteLine(int1.GetType().IsValueType);

  // The example displays the following output:
  //       False
  //       True
  ```

  For information on boxing value types, see Boxing and Unboxing.

- When comparing strings. If `objA` and `objB` are strings, the ReferenceEquals method returns `true` if the string is interned. It does not perform a test for value equality. In the following example, `s1` and `s2` are equal because they are two instances of a single interned string. However, `s3` and `s4` are not equal, because although they have identical string values, that string is not interned.

  C#

```
String s1 = "String1";
String s2 = "String1";
Console.WriteLine("s1 = s2: {0}", Object.ReferenceEquals(s1, s2));
Console.WriteLine("{0} interned: {1}", s1,
                  String.IsNullOrEmpty(String.IsInterned(s1)) ? "No" :
"Yes");

String suffix = "A";
String s3 = "String" + suffix;
String s4 = "String" + suffix;
Console.WriteLine("s3 = s4: {0}", Object.ReferenceEquals(s3, s4));
Console.WriteLine("{0} interned: {1}", s3,
                  String.IsNullOrEmpty(String.IsInterned(s3)) ? "No" :
"Yes");

// The example displays the following output:
//       s1 = s2: True
//       String1 interned: Yes
//       s3 = s4: False
//       StringA interned: No
```

For more information about string interning, see String.IsInterned.

Object.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the current object.

```
C#
public virtual string? ToString ();
```

Returns

String

A string that represents the current object.

Remarks

For more information about this API, see Supplemental API remarks for Object.ToString.

Notes to Inheritors

When you implement your own types, you should override the ToString() method to return values that are meaningful for those types. Derived classes that require more control over formatting than ToString() provides can implement the IFormattable interface. Its ToString(String, IFormatProvider) method enables you to define format strings that control formatting and to use an IFormatProvider object that can provide for culture-specific formatting.

Overrides of the ToString() method should follow these guidelines:

- The returned string should be friendly and readable by humans.
- The returned string should uniquely identify the value of the object instance.
- The returned string should be as short as possible so that it is suitable for display by a debugger.

- Your ToString() override should not return Empty or a null string.
- Your ToString() override should not throw an exception.
- If the string representation of an instance is culture-sensitive or can be formatted in multiple ways, implement the IFormattable interface.
- If the returned string includes sensitive information, you should first demand an appropriate permission. If the demand succeeds, you can return the sensitive information; otherwise, you should return a string that excludes the sensitive information.
- Your ToString() override should have no observable side effects to avoid complications in debugging. For example, a call to the ToString() method should not change the value of instance fields.
- If your type implements a parsing method (or `Parse` or `TryParse` method, a constructor, or some other static method that instantiates an instance of the type from a string), you should ensure that the string returned by the ToString() method can be converted to an object instance.

ObjectDisposedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an operation is performed on a disposed object.

C#

```
public class ObjectDisposedException : InvalidOperationException
```

Inheritance Object → Exception → SystemException → InvalidOperationException → ObjectDisposedException

Examples

The following example demonstrates an error that causes the `ObjectDisposedException` exception to be thrown.

C#

```
using System;
using System.IO;

public class ObjectDisposedExceptionTest
{
   public static void Main()
   {
      MemoryStream ms = new MemoryStream(16);
      ms.Close();
      try
      {
         ms.ReadByte();
      }
      catch (ObjectDisposedException e)
      {
         Console.WriteLine("Caught: {0}", e.Message);
      }
   }
}
```

This code produces the following output:

```
Caught:
  Cannot access a closed Stream.
```

Remarks

An ObjectDisposedException is thrown when you try to access a member of an object that implements the IDisposable interface or IAsyncDisposable interface, and that object has been disposed. Typically, this exception is caused by one of the following conditions:

- You've called an `IDisposable` object's `Dispose` method (or an `IDisposableAsync` object's `DisposeAsync` method), and you're trying to access an instance member that gets or sets the object's state. The following example illustrates the ObjectDisposedException that is thrown when you try to reset the frequency of timer notifications after you call the Timer.Dispose method.

  C#

  ```
  using System;
  using System.Threading;

  public class Example
  {
     public static void Main()
     {
        Timer t = new Timer(TimerNotification, null,
                            100, Timeout.Infinite);
        Thread.Sleep(2000);
        t.Dispose();

        t.Change(200, 1000);
        Thread.Sleep(3000);
     }

     private static void TimerNotification(Object obj)
     {
        Console.WriteLine("Timer event fired at {0:F}", DateTime.Now);
     }
  }
  // The example displays output like the following:
  //    Timer event fired at Monday, July 14, 2014 11:54:08 AM
  //
  //    Unhandled Exception: System.ObjectDisposedException: Cannot
  access a disposed object.
  //       at System.Threading.TimerQueueTimer.Change(UInt32 dueTime,
  ```

```
UInt32 period)
//       at Example.Main()
```

- You've called an object's `Close` method, and you're trying to access an instance member that gets or sets the object's state. Often, the `Close` method provides a type's public implementation of the IDisposable.Dispose method. The same is true for `CloseAsync` and `<xref:System.IAsyncDisposable.DisposeAsync%2A?displayProperty=nameWithType>`.

- You've called an object's `Dispose` or `DisposeAsync` methods multiple times. Typically, this doesn't throw an exception. However, depending on how a type implements IDisposable.Dispose or IAsyncDisposable.DisposeAsync, it may not allow multiple calls to that method.

In most cases, this exception results from developer error. Instead of handling the error in a `try`/`catch` block, you should correct the error, typically by reinstantiating the object.

Constructors

Expand table

ObjectDisposedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ObjectDisposedException class with serialized data.
ObjectDisposedException(String)	Initializes a new instance of the ObjectDisposedException class with a string containing the name of the disposed object.
ObjectDisposedException(String, Exception)	Initializes a new instance of the ObjectDisposedException class with a specified error message and a reference to the inner exception that is the cause of this exception.
ObjectDisposedException(String, String)	Initializes a new instance of the ObjectDisposedException class with the specified object name and message.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the message that describes the error.
ObjectName	Gets the name of the disposed object.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Retrieves the SerializationInfo object with the parameter name and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)

MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ThrowIf(Boolean, Object)	Throws an ObjectDisposedException if the specified `condition` is `true`.
ThrowIf(Boolean, Type)	Throws an ObjectDisposedException if the specified `condition` is `true`.
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

ObjectDisposedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ObjectDisposedException class.

Overloads

Expand table

ObjectDisposedException(String)	Initializes a new instance of the ObjectDisposedException class with a string containing the name of the disposed object.
ObjectDisposedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the ObjectDisposedException class with serialized data.
ObjectDisposedException(String, Exception)	Initializes a new instance of the ObjectDisposedException class with a specified error message and a reference to the inner exception that is the cause of this exception.
ObjectDisposedException(String, String)	Initializes a new instance of the ObjectDisposedException class with the specified object name and message.

ObjectDisposedException(String)

Initializes a new instance of the ObjectDisposedException class with a string containing the name of the disposed object.

C#

```
public ObjectDisposedException (string? objectName);
```

Parameters

`objectName` String

A string containing the name of the disposed object.

Remarks

The Message property is initialized to a system-supplied message that describes the error and includes the `objectName` parameter. This message takes into account the current system culture.

The `InnerException` property of the new instance is initialized to `null`.

If `objectName` is `null`, the `Message` property contains only an error message.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ObjectDisposedException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the ObjectDisposedException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected ObjectDisposedException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ObjectDisposedException(String, Exception)

Initializes a new instance of the ObjectDisposedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public ObjectDisposedException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If `innerException` is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UWP	10.0

ObjectDisposedException(String, String)

Initializes a new instance of the ObjectDisposedException class with the specified object name and message.

C#

```
public ObjectDisposedException (string? objectName, string? message);
```

Parameters

`objectName` String

The name of the disposed object.

`message` String

The error message that explains the reason for the exception.

Remarks

The `InnerException` property of the new instance is initialized to `null`.

If `objectName` is `null`, the `Message` property contains only an error message.

ObjectDisposedException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the message that describes the error.

```
C#
public override string Message { get; }
```

Property Value

String

A string that describes the error.

Remarks

If the ObjectName property is not `null`, the message includes the name of the object.

This property overrides Exception.Message.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ObjectDisposedException.ObjectName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the disposed object.

```
C#
public string ObjectName { get; }
```

Property Value

String

A string containing the name of the disposed object.

Remarks

If the current property is not `null` or String.Empty, the value of this property is included in the string returned by the Message property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ObjectDisposedException.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Retrieves the SerializationInfo object with the parameter name and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

ObjectDisposedException.ThrowIf Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ThrowIf(Boolean, Object)	Throws an ObjectDisposedException if the specified `condition` is `true`.
ThrowIf(Boolean, Type)	Throws an ObjectDisposedException if the specified `condition` is `true`.

ThrowIf(Boolean, Object)

Throws an ObjectDisposedException if the specified `condition` is `true`.

C#

```
public static void ThrowIf (bool condition, object instance);
```

Parameters

`condition` Boolean

The condition to evaluate.

`instance` Object

The object whose type's full name should be included in any resulting ObjectDisposedException.

Exceptions

ObjectDisposedException

The `condition` is `true`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ThrowIf(Boolean, Type)

Throws an ObjectDisposedException if the specified `condition` is `true`.

C#

```
public static void ThrowIf (bool condition, Type type);
```

Parameters

`condition` Boolean

The condition to evaluate.

`type` Type

The type whose full name should be included in any resulting ObjectDisposedException.

Exceptions

ObjectDisposedException

The `condition` is `true`.

Applies to

▼ .NET 9 and other versions

ObsoleteAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Marks the program elements that are no longer in use. This class cannot be inherited.

C#

```
[System.AttributeUsage(System.AttributeTargets.Class |
System.AttributeTargets.Constructor | System.AttributeTargets.Delegate |
System.AttributeTargets.Enum | System.AttributeTargets.Event |
System.AttributeTargets.Field | System.AttributeTargets.Interface |
System.AttributeTargets.Method | System.AttributeTargets.Property |
System.AttributeTargets.Struct, Inherited=false)]
public sealed class ObsoleteAttribute : Attribute
```

Inheritance Object → Attribute → ObsoleteAttribute

Attributes AttributeUsageAttribute

Examples

The following example defines a class that contains a property and a method that are marked with the ObsoleteAttribute attribute. Accessing the value of the `OldProperty` property in code generates a compiler warning, but calling the `CallOldMethod` method generates a compiler error. The example also shows the output that results when you attempt to compile the source code.

C#

```
using System;
using System.Reflection;

public class Example
{
   // Mark OldProperty As Obsolete.
   [ObsoleteAttribute("This property is obsolete. Use NewProperty instead.",
false)]
   public static string OldProperty
```

```
    { get { return "The old property value."; } }

    public static string NewProperty
    { get { return "The new property value."; } }

    // Mark CallOldMethod As Obsolete.
    [ObsoleteAttribute("This method is obsolete. Call CallNewMethod
instead.", true)]
    public static string CallOldMethod()
    {
       return "You have called CallOldMethod.";
    }

    public static string CallNewMethod()
    {
       return "You have called CallNewMethod.";
    }

    public static void Main()
    {
       Console.WriteLine(OldProperty);
       Console.WriteLine();
       Console.WriteLine(CallOldMethod());
    }
}
// The attempt to compile this example produces output like the following
output:
//    Example.cs(31,25): error CS0619: 'Example.CallOldMethod()' is
obsolete:
//            'This method is obsolete. Call CallNewMethod instead.'
//    Example.cs(29,25): warning CS0618: 'Example.OldProperty' is obsolete:
//            'This property is obsolete. Use NewProperty instead.'
```

Remarks

ObsoleteAttribute is applicable to all program elements except assemblies, modules, parameters, and return values. Marking an element as obsolete informs users that the element may be removed in a future version of the product.

The string assigned to the Message property is emitted by the compiler when the attribute target is used in code. Ideally, the string should provide some workaround or programmatic alternative.

Use the IsError property to indicate to the compiler whether using the ObsoleteAttribute attribute should cause it to emit an error (IsError is `true`) or a warning (IsError is `false`).

For more information about using attributes, see Attributes.

Constructors

Expand table

ObsoleteAttribute()	Initializes a new instance of the ObsoleteAttribute class with default properties.
Obsolete Attribute(String)	Initializes a new instance of the ObsoleteAttribute class with a specified workaround message.
Obsolete Attribute(String, Boolean)	Initializes a new instance of the ObsoleteAttribute class with a workaround message and a Boolean value indicating whether the obsolete element usage is considered an error.

Properties

Expand table

Diagnostic Id	Gets or sets the ID that the compiler will use when reporting a use of the API.
IsError	Gets a value that indicates whether the compiler will treat usage of the obsolete program element as an error.
Message	Gets the workaround message.
TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)
UrlFormat	Gets or sets the URL for corresponding documentation. The API accepts a format string instead of an actual URL, creating a generic URL that includes the diagnostic ID.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance.

	(Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the ID that the compiler will use when reporting a use of the API.

C#

```
public string? DiagnosticId { get; set; }
```

Property Value

String

The unique diagnostic ID.

Remarks

The diagnostic ID is shown in build output for warnings and errors.

This property represents the unique ID that can be used to suppress the warnings or errors, if needed.

Choose an appropriate diagnostic ID such that it is unique.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

ObsoleteAttribute.IsError Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the compiler will treat usage of the obsolete program element as an error.

```
C#

public bool IsError { get; }
```

Property Value

Boolean

`true` if the obsolete element usage is considered an error; otherwise, `false`. The default is `false`.

Examples

The following example defines a class that contains two members marked as obsolete. The first, a property named `OldProperty`, produces a compiler warning if it is called. The second, a method named `CallOldMethod`, produces a compiler error. The example uses reflection to get information about the ObsoleteAttribute attributes applied to members of the type and displays the values of their Message and IsError properties.

```
C#

using System;
using System.Reflection;

public class Example
{
   // Mark OldProperty As Obsolete.
   [ObsoleteAttribute("This property is obsolete. Use NewProperty instead.",
false)]
   public string OldProperty
   { get { return "The old property value."; } }
```

```
   public string NewProperty
   { get { return "The new property value."; } }

   // Mark OldMethod As Obsolete.
   [ObsoleteAttribute("This method is obsolete. Call NewMethod instead.",
true)]
   public string OldMethod()
   {
      return "You have called OldMethod.";
   }

   public string NewMethod()
   {
      return "You have called NewMethod.";
   }

   public static void Main()
   {
      // Get all public members of this type.
      MemberInfo[] members = typeof(Example).GetMembers();
      // Count total obsolete members.
      int n = 0;

      // Try to get the ObsoleteAttribute for each public member.
      Console.WriteLine("Obsolete members in the Example class:\n");
      foreach (var member in members) {
         ObsoleteAttribute[] attribs = (ObsoleteAttribute[])

member.GetCustomAttributes(typeof(ObsoleteAttribute),
                                                                    false);
         if (attribs.Length > 0) {
            ObsoleteAttribute attrib = attribs[0];
            Console.WriteLine("Member Name: {0}.{1}",
member.DeclaringType.FullName, member.Name);
            Console.WriteLine("   Message: {0}", attrib.Message);
            Console.WriteLine("   Warning/Error: {0}", attrib.IsError ?
"Error" : "Warning");
            n++;
         }
      }

      if (n == 0)
         Console.WriteLine("The Example type has no obsolete attributes.");
   }
}
// The example displays the following output:
//       Obsolete members in the Example class:
//
//       Member Name: Example.OldMethod
//          Message: This method is obsolete. Call NewMethod instead.
//          Warning/Error: Error
//       Member Name: Example.OldProperty
//          Message: This property is obsolete. Use NewProperty instead.
//          Warning/Error: Warning
```

ObsoleteAttribute.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the workaround message.

C#

```
public string? Message { get; }
```

Property Value

String

The workaround text string.

Examples

The following example defines a class that contains two members marked as obsolete. The first, a property named `OldProperty`, produces a compiler warning if it is called. The second, a method named `CallOldMethod`, produces a compiler error. The example uses reflection to get information about the ObsoleteAttribute attributes applied to members of the type and displays the values of their Message and IsError properties.

C#

```
using System;
using System.Reflection;

public class Example
{
   // Mark OldProperty As Obsolete.
   [ObsoleteAttribute("This property is obsolete. Use NewProperty instead.",
false)]
   public string OldProperty
   { get { return "The old property value."; } }

   public string NewProperty
   { get { return "The new property value."; } }
```

```
   // Mark OldMethod As Obsolete.
   [ObsoleteAttribute("This method is obsolete. Call NewMethod instead.",
true)]
   public string OldMethod()
   {
      return "You have called OldMethod.";
   }

   public string NewMethod()
   {
      return "You have called NewMethod.";
   }

   public static void Main()
   {
      // Get all public members of this type.
      MemberInfo[] members = typeof(Example).GetMembers();
      // Count total obsolete members.
      int n = 0;

      // Try to get the ObsoleteAttribute for each public member.
      Console.WriteLine("Obsolete members in the Example class:\n");
      foreach (var member in members) {
         ObsoleteAttribute[] attribs = (ObsoleteAttribute[])

member.GetCustomAttributes(typeof(ObsoleteAttribute),
                                                                false);
         if (attribs.Length > 0) {
            ObsoleteAttribute attrib = attribs[0];
            Console.WriteLine("Member Name: {0}.{1}",
member.DeclaringType.FullName, member.Name);
            Console.WriteLine("   Message: {0}", attrib.Message);
            Console.WriteLine("   Warning/Error: {0}", attrib.IsError ?
"Error" : "Warning");
            n++;
         }
      }

      if (n == 0)
         Console.WriteLine("The Example type has no obsolete attributes.");
   }
}
// The example displays the following output:
//       Obsolete members in the Example class:
//
//       Member Name: Example.OldMethod
//          Message: This method is obsolete. Call NewMethod instead.
//          Warning/Error: Error
//       Member Name: Example.OldProperty
//          Message: This property is obsolete. Use NewProperty instead.
//          Warning/Error: Warning
```

ObsoleteAttribute.UrlFormat Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the URL for corresponding documentation. The API accepts a format string instead of an actual URL, creating a generic URL that includes the diagnostic ID.

C#

```
public string? UrlFormat { get; set; }
```

Property Value

String

The format string that represents a URL to corresponding documentation.

Remarks

An example format string is `https://contoso.com/obsoletion-warnings/{0}`.

Applies to

OperatingSystem Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents information about an operating system, such as the version and platform identifier. This class cannot be inherited.

C#

```
public sealed class OperatingSystem : ICloneable,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → OperatingSystem

Implements ICloneable , ISerializable

Examples

The following code example uses the OperatingSystem object to display information about the runtime operating system.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      var os = Environment.OSVersion;
      Console.WriteLine("Current OS Information:\n");
      Console.WriteLine("Platform: {0:G}", os.Platform);
      Console.WriteLine("Version String: {0}", os.VersionString);
      Console.WriteLine("Version Information:");
      Console.WriteLine("   Major: {0}", os.Version.Major);
      Console.WriteLine("   Minor: {0}", os.Version.Minor);
      Console.WriteLine("Service Pack: '{0}'", os.ServicePack);
   }
}
// If run on a Windows 8.1 system, the example displays output like the
```

```
following:
//       Current OS Information:
//
//       Platform: Win32NT
//       Version String: Microsoft Windows NT 6.2.9200.0
//       Version Information:
//          Major: 6
//          Minor: 2
//       Service Pack: ''
// If run on a Windows 7 system, the example displays output like the
following:
//       Current OS Information:
//
//       Platform: Win32NT
//       Version String: Microsoft Windows NT 6.1.7601 Service Pack 1
//       Version Information:
//          Major: 6
//          Minor: 1
//       Service Pack: 'Service Pack 1'
```

Remarks

The OperatingSystem class contains information about an operating system.

For information about the current runtime operating system, retrieve the OperatingSystem object returned by the Environment.OSVersion property. For a list of Windows operating system versions and their corresponding version numbers returned by the Version and VersionString properties and the ToString method, see Operating System Version.

By design, the OperatingSystem class is not a general purpose means of describing an operating system, and you cannot derive a more inclusive type from the OperatingSystem class. If you need a type to contain other information about an operating system, create your own type, then include a field of type OperatingSystem and any additional fields, properties, or methods that you require.

Constructors

Expand table

OperatingSystem(PlatformID, Version)	Initializes a new instance of the OperatingSystem class, using the specified platform identifier value and version object.

Properties

Expand table

Platform	Gets a PlatformID enumeration value that identifies the operating system platform.
Service Pack	Gets the service pack version represented by this OperatingSystem object.
Version	Gets a Version object that identifies the operating system.
Version String	Gets the concatenated string representation of the platform identifier, version, and service pack that are currently installed on the operating system.

Methods

Expand table

Clone()	Creates an OperatingSystem object that is identical to this instance.
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo object with the data necessary to deserialize this instance.
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsAndroid()	Indicates whether the current application is running on Android.
IsAndroidVersionAtLeast(Int32, Int32, Int32, Int32)	Checks if the Android version (returned by the Linux command `uname`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified version.
IsBrowser()	Indicates whether the current application is running as WASM in a browser.
IsFreeBSD()	Indicates whether the current application is running on FreeBSD.
IsFreeBSDVersionAtLeast(Int32, Int32, Int32, Int32)	Checks if the FreeBSD version (returned by the Linux command `uname`) is greater than or equal to the specified version. This

	method can be used to guard APIs that were added in the specified version.
IsIOS()	Indicates whether the current application is running on iOS or MacCatalyst.
IsIOSVersionAtLeast(Int32, Int32, Int32)	Checks if the iOS/MacCatalyst version (returned by `libobjc.get_operatingSystemVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified iOS version.
IsLinux()	Indicates whether the current application is running on Linux.
IsMacCatalyst()	Indicates whether the current application is running on Mac Catalyst.
IsMacCatalystVersion AtLeast(Int32, Int32, Int32)	Check for the Mac Catalyst version (iOS version as presented in Apple documentation) with a ≤ version comparison. Used to guard APIs that were added in the given Mac Catalyst release.
IsMacOS()	Indicates whether the current application is running on macOS.
IsMacOSVersionAtLeast(Int32, Int32, Int32)	Checks if the macOS version (returned by `libobjc.get_operatingSystemVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified macOS version.
IsOSPlatform(String)	Indicates whether the current application is running on the specified platform.
IsOSPlatformVersion AtLeast(String, Int32, Int32, Int32, Int32)	Checks if the operating system version is greater than or equal to the specified platform version. This method can be used to guard APIs that were added in the specified OS version.
IsTvOS()	Indicates whether the current application is running on tvOS.
IsTvOSVersionAtLeast(Int32, Int32, Int32)	Checks if the tvOS version (returned by `libobjc.get_operatingSystemVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified tvOS version.
IsWasi()	Indicates whether the current application is running as WASI.
IsWatchOS()	Indicates whether the current application is running on watchOS.
IsWatchOSVersion AtLeast(Int32, Int32, Int32)	Checks if the watchOS version (returned by `libobjc.get_operatingSystemVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified watchOS version.
IsWindows()	Indicates whether the current application is running on Windows.

IsWindowsVersionAtLeast(Int32, Int32, Int32, Int32)	Checks if the Windows version (returned by `RtlGetVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified Windows version.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Converts the value of this OperatingSystem object to its equivalent string representation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

OperatingSystem(PlatformID, Version) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the OperatingSystem class, using the specified platform identifier value and version object.

```
C#

public OperatingSystem (PlatformID platform, Version version);
```

Parameters

`platform` PlatformID

One of the PlatformID values that indicates the operating system platform.

`version` Version

A Version object that indicates the version of the operating system.

Exceptions

ArgumentNullException

`version` is `null`.

ArgumentException

`platform` is not a PlatformID enumeration value.

Notes to Callers

If you are using the OperatingSystem class to retrieve information about the runtime operating system, you should not call this constructor to instantiate an OperatingSystem object. Instead, you can retrieve an OperatingSystem object that describes the operating system from the OSVersion property.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OperatingSystem.Platform Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a PlatformID enumeration value that identifies the operating system platform.

C#

```
public PlatformID Platform { get; }
```

Property Value

PlatformID

One of the PlatformID values.

Examples

The following code example creates several OperatingSystem objects and displays the Platform property for each.

C#

```
// Example for the OperatingSystem.Platform and
// OperatingSystem.Version properties.
using System;

class PlatformVersionDemo
{
    // Create an OperatingSystem object and display the Platform
    // and Version properties.
    static void BuildOSObj( PlatformID pID, Version ver )
    {
        OperatingSystem opSys   = new OperatingSystem( pID, ver );
        PlatformID platform     = opSys.Platform;
        Version version         = opSys.Version;

        Console.WriteLine( "   Platform: {0,-15} Version: {1}",
            platform, version );
    }
```

```
    static void BuildOperatingSystemObjects( )
    {
        // The Version object does not need to correspond to an
        // actual OS version.
        Version verNull     = new Version( );
        Version verString   = new Version( "3.5.8.13" );
        Version verMajMin   = new Version( 6, 10 );
        Version verMMBld    = new Version( 5, 25, 5025 );
        Version verMMBVer   = new Version( 5, 6, 7, 8 );

        // All PlatformID members are shown here.
        BuildOSObj( PlatformID.Win32NT, verNull );
        BuildOSObj( PlatformID.Win32S, verString );
        BuildOSObj( PlatformID.Win32Windows, verMajMin );
        BuildOSObj( PlatformID.WinCE, verMMBld );
        BuildOSObj( PlatformID.Win32NT, verMMBVer );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of OperatingSystem.Platform " +
            "and OperatingSystem.Version \n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Create several OperatingSystem objects " +
            "and display their properties:\n" );

        BuildOperatingSystemObjects( );

        Console.WriteLine(
            "\nThe operating system of the host computer is:\n" );

        BuildOSObj(
            Environment.OSVersion.Platform,
            Environment.OSVersion.Version );
    }
}

/*
This example of OperatingSystem.Platform and OperatingSystem.Version
generates the following output.

Create several OperatingSystem objects and display their properties:

Platform: Win32NT         Version: 0.0
Platform: Win32S          Version: 3.5.8.13
Platform: Win32Windows    Version: 6.10
Platform: WinCE           Version: 5.25.5025
Platform: Win32NT         Version: 5.6.7.8

The operating system of the host computer is:
```

```
 Platform: Win32NT         Version: 5.1.2600.0
 */
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

OperatingSystem.ServicePack Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the service pack version represented by this OperatingSystem object.

C#

```
public string ServicePack { get; }
```

Property Value

String

The service pack version, if service packs are supported and at least one is installed; otherwise, an empty string ("").

Examples

The following code example demonstrates the ServicePack property.

C#

```
// This example demonstrates the OperatingSystem.ServicePack property.
using System;

class Sample
{
    public static void Main()
    {
    OperatingSystem os = Environment.OSVersion;
    String sp = os.ServicePack;
    Console.WriteLine("Service pack version = \"{0}\"", sp);
    }
}
/*
This example produces the following results:

Service pack version = "Service Pack 1"
```

```
*/
```

Remarks

A service pack is used to distribute software updates for the operating system on which it is installed. However, not every operating system uses service packs.

The service pack version, if available, is already correctly formatted for display.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

OperatingSystem.Version Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a Version object that identifies the operating system.

C#

```
public Version Version { get; }
```

Property Value

Version

A Version object that describes the major version, minor version, build, and revision numbers for the operating system.

Examples

The following code example creates several OperatingSystem objects and displays the Version property for each.

C#

```
// Example for the OperatingSystem.Platform and
// OperatingSystem.Version properties.
using System;

class PlatformVersionDemo
{
    // Create an OperatingSystem object and display the Platform
    // and Version properties.
    static void BuildOSObj( PlatformID pID, Version ver )
    {
        OperatingSystem opSys   = new OperatingSystem( pID, ver );
        PlatformID platform     = opSys.Platform;
        Version version         = opSys.Version;

        Console.WriteLine( "   Platform: {0,-15} Version: {1}",
            platform, version );
```

```
    }

    static void BuildOperatingSystemObjects( )
    {
        // The Version object does not need to correspond to an
        // actual OS version.
        Version verNull     = new Version( );
        Version verString   = new Version( "3.5.8.13" );
        Version verMajMin   = new Version( 6, 10 );
        Version verMMBld    = new Version( 5, 25, 5025 );
        Version verMMBVer   = new Version( 5, 6, 7, 8 );

        // All PlatformID members are shown here.
        BuildOSObj( PlatformID.Win32NT, verNull );
        BuildOSObj( PlatformID.Win32S, verString );
        BuildOSObj( PlatformID.Win32Windows, verMajMin );
        BuildOSObj( PlatformID.WinCE, verMMBld );
        BuildOSObj( PlatformID.Win32NT, verMMBVer );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of OperatingSystem.Platform " +
            "and OperatingSystem.Version \n" +
            "generates the following output.\n" );
        Console.WriteLine(
            "Create several OperatingSystem objects " +
            "and display their properties:\n" );

        BuildOperatingSystemObjects( );

        Console.WriteLine(
            "\nThe operating system of the host computer is:\n" );

        BuildOSObj(
            Environment.OSVersion.Platform,
            Environment.OSVersion.Version );
    }
}

/*
This example of OperatingSystem.Platform and OperatingSystem.Version
generates the following output.

Create several OperatingSystem objects and display their properties:

Platform: Win32NT         Version: 0.0
Platform: Win32S          Version: 3.5.8.13
Platform: Win32Windows    Version: 6.10
Platform: WinCE           Version: 5.25.5025
Platform: Win32NT         Version: 5.6.7.8

The operating system of the host computer is:
```

```
Platform: Win32NT         Version: 5.1.2600.0
*/
```

Remarks

For a list of Windows operating system versions and their corresponding version numbers, see Operating System Version.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OperatingSystem.VersionString Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the concatenated string representation of the platform identifier, version, and service pack that are currently installed on the operating system.

C#

```
public string VersionString { get; }
```

Property Value

String

The string representation of the values returned by the Platform, Version, and ServicePack properties.

Examples

The following code example demonstrates the VersionString property.

C#

```
// This example demonstrates the VersionString property.
using System;

class Sample
{
    public static void Main()
    {
    OperatingSystem os = Environment.OSVersion;
// Display the value of OperatingSystem.VersionString. By default, this is
// the same value as OperatingSystem.ToString.
    Console.WriteLine("This operating system is {0}", os.VersionString);
    }
}
/*
This example produces the following results:
```

```
This operating system is Microsoft Windows NT 5.1.2600.0 Service Pack 1
*/
```

Remarks

By default, the value returned by VersionString is the same as the value returned by the ToString method. However, an implementation of the .NET Framework for a different platform might return a more appropriate string for that platform.

For a list of Windows operating system versions and their corresponding version numbers, see Operating System Version.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OperatingSystem.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an OperatingSystem object that is identical to this instance.

C#

```
public object Clone ();
```

Returns

Object

An OperatingSystem object that is a copy of this instance.

Implements

Clone()

Examples

The following code example illustrates the use of the Clone method to make a copy of an OperatingSystem object. The clone is compared with the original object to show that they are not the same object.

C#

```
// Example for the OperatingSystem.Clone method.
using System;

class CloneCompareDemo
{
    // Copy, clone, and duplicate an OperatingSystem object.
    static void CopyOperatingSystemObjects( )
    {
        // The Version object does not need to correspond to an
        // actual OS version.
        Version verMMBVer = new Version( 5, 6, 7, 8 );
```

```
        OperatingSystem opCreate1 = new
            OperatingSystem( PlatformID.Win32NT, verMMBVer );

        // Create another OperatingSystem object with the same
        // parameters as opCreate1.
        OperatingSystem opCreate2 = new
            OperatingSystem( PlatformID.Win32NT, verMMBVer );

        // Clone opCreate1 and copy the opCreate1 reference.
        OperatingSystem opClone =
            (OperatingSystem)opCreate1.Clone( );
        OperatingSystem opCopy = opCreate1;

        // Compare the various objects for equality.
        Console.WriteLine( "{0,-50}{1}",
            "Is the second object the same as the original?",
            opCreate1.Equals( opCreate2 ) );
        Console.WriteLine( "{0,-50}{1}",
            "Is the object clone the same as the original?",
            opCreate1.Equals( opClone ) );
        Console.WriteLine( "{0,-50}{1}",
            "Is the copied object the same as the original?",
            opCreate1.Equals( opCopy ) );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of OperatingSystem.Clone( ) " +
            "generates the following output.\n" );
        Console.WriteLine(
            "Create an OperatingSystem object, and then " +
            "create another object with the \n" +
            "same parameters. Clone and copy the original " +
            "object, and then compare \n" +
            "each object with the original " +
            "using the Equals( ) method. Equals( ) \n" +
            "returns true only when both " +
            "references refer to the same object.\n" );

        CopyOperatingSystemObjects( );
    }
}

/*
This example of OperatingSystem.Clone( ) generates the following output.

Create an OperatingSystem object, and then create another object with the
same parameters. Clone and copy the original object, and then compare
each object with the original using the Equals( ) method. Equals( )
returns true only when both references refer to the same object.

Is the second object the same as the original?    False
Is the object clone the same as the original?     False
```

```
Is the copied object the same as the original?    True
*/
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

OperatingSystem.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo object with the data necessary to deserialize this instance.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public void GetObjectData (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to populate with serialization information.

`context` StreamingContext

The place to store and retrieve serialized data. Reserved for future use.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

Remarks

The `context` parameter is reserved for future use; it is currently not implemented in the GetObjectData method.

For more information, see the SerializationInfo.AddValue method.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

OperatingSystem.IsAndroidVersionAtLeast(Int32, Int32, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Checks if the Android version (returned by the Linux command `uname`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified version.

C#

```
public static bool IsAndroidVersionAtLeast (int major, int minor = 0, int build = 0, int revision = 0);
```

Parameters

`major` Int32

The major release number.

`minor` Int32

The minor release number.

`build` Int32

The build release number.

`revision` Int32

The revision release number.

Returns

Boolean

`true` if the current application is running on an Android version that is at least what was specified in the parameters; `false` otherwise.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

OperatingSystem.IsFreeBSDVersionAtLeast(Int32, Int32, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Checks if the FreeBSD version (returned by the Linux command `uname`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified version.

C#

```
public static bool IsFreeBSDVersionAtLeast (int major, int minor = 0, int
build = 0, int revision = 0);
```

Parameters

`major` Int32

The major release number.

`minor` Int32

The minor release number.

`build` Int32

The build release number.

`revision` Int32

The revision release number.

Returns

Boolean

`true` if the current application is running on a FreeBSD version that is at least what was specified in the parameters; `false` otherwise.

OperatingSystem.IsIOSVersionAtLeast(Int32, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Checks if the iOS/MacCatalyst version (returned by `libobjc.get_operatingSystemVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified iOS version.

C#

```
[System.Runtime.Versioning.SupportedOSPlatformGuard("maccatalyst")]
public static bool IsIOSVersionAtLeast (int major, int minor = 0, int build
= 0);
```

Parameters

`major` Int32

The major release number.

`minor` Int32

The minor release number.

`build` Int32

The build release number.

Returns

Boolean

`true` if the current application is running on an iOS/MacCatalyst version that is at least what was specified in the parameters; `false` otherwise.

OperatingSystem.IsWindows Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the current application is running on Windows.

C#

```
public static bool IsWindows ();
```

Returns

Boolean

`true` if the current application is running on Windows; `false` otherwise.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

OperatingSystem.IsWindowsVersionAtLeast(Int32, Int32, Int32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Checks if the Windows version (returned by `RtlGetVersion`) is greater than or equal to the specified version. This method can be used to guard APIs that were added in the specified Windows version.

C#

```
public static bool IsWindowsVersionAtLeast (int major, int minor = 0, int build = 0, int revision = 0);
```

Parameters

`major` Int32

The major release number.

`minor` Int32

The minor release number.

`build` Int32

The build release number.

`revision` Int32

The revision release number.

Returns

Boolean

`true` if the current application is running on a Windows version that is at least what was specified in the parameters; `false` otherwise.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Collaborate with us on GitHub

OperatingSystem.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this OperatingSystem object to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the values returned by the Platform, Version, and ServicePack properties.

Examples

The following code example illustrates the use of the ToString method to display OperatingSystem objects.

C#

```
// Example for the OperatingSystem constructor and the
// OperatingSystem.ToString( ) method.
using System;

class OpSysConstructDemo
{
    // Create and display an OperatingSystem object.
    static void BuildOSObj( PlatformID pID, Version ver )
    {
        OperatingSystem os = new OperatingSystem( pID, ver );

        Console.WriteLine( "   {0}", os.ToString( ) );
    }

    static void BuildOperatingSystemObjects( )
```

```
    {
        // The Version object does not need to correspond to an
        // actual OS version.
        Version verNull     = new Version( );
        Version verMajMin   = new Version( 3, 11 );
        Version verMMBld    = new Version( 5, 25, 625 );
        Version verMMBVer   = new Version( 5, 6, 7, 8 );
        Version verString   = new Version( "3.5.8.13" );

        // All PlatformID members are shown here.
        BuildOSObj( PlatformID.Win32NT, verNull );
        BuildOSObj( PlatformID.Win32S, verMajMin );
        BuildOSObj( PlatformID.Win32Windows, verMMBld );
        BuildOSObj( PlatformID.WinCE, verMMBVer );
        BuildOSObj( PlatformID.Win32NT, verString );
    }

    public static void Main( )
    {
        Console.WriteLine(
            "This example of the OperatingSystem constructor " +
            "and \nOperatingSystem.ToString( ) " +
            "generates the following output.\n" );
        Console.WriteLine(
            "Create and display several different " +
            "OperatingSystem objects:\n" );

        BuildOperatingSystemObjects( );

        Console.WriteLine(
            "\nThe OS version of the host computer is:\n\n   {0}",
            Environment.OSVersion.ToString( ) );
    }
}

/*
This example of the OperatingSystem constructor and
OperatingSystem.ToString( ) generates the following output.

Create and display several different OperatingSystem objects:

   Microsoft Windows NT 0.0
   Microsoft Win32S 3.11
   Microsoft Windows 98 5.25.625
   Microsoft Windows CE 5.6.7.8
   Microsoft Windows NT 3.5.8.13

The OS version of the host computer is:

   Microsoft Windows NT 5.1.2600.0
*/
```

Remarks

For a list of Windows operating system versions and their corresponding version numbers, see Operating System Version.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OperationCanceledException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown in a thread upon cancellation of an operation that the thread was executing.

C#

```
public class OperationCanceledException : SystemException
```

Inheritance Object → Exception → SystemException → OperationCanceledException

Derived System.Threading.Tasks.TaskCanceledException

Remarks

If the task that was canceled had an associated cancellation token, it is returned by the CancellationToken property, and the CancellationToken.IsCancellationRequested property of the token is set to `true`.

Constructors

Expand table

OperationCanceledException()	Initializes a new instance of the OperationCanceledException class with a system-supplied error message.
OperationCanceledException(CancellationToken)	Initializes a new instance of the OperationCanceledException class with a cancellation token.
OperationCanceledException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the OperationCanceledException class with serialized data.

OperationCanceledException(String)	Initializes a new instance of the OperationCanceledException class with a specified error message.
OperationCanceledException(String, CancellationToken)	Initializes a new instance of the OperationCanceledException class with a specified error message and a cancellation token.
OperationCanceledException(String, Exception)	Initializes a new instance of the OperationCanceledException class with a specified error message and a reference to the inner exception that is the cause of this exception.
OperationCanceledException(String, Exception, CancellationToken)	Initializes a new instance of the OperationCanceledException class with a specified error message, a reference to the inner exception that is the cause of this exception, and a cancellation token.

Properties

Expand table

CancellationToken	Gets a token associated with the operation that was canceled.
Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
InnerException	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception.

	(Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

OperationCanceledException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the OperationCanceledException class.

Overloads

Expand table

OperationCanceledException()	Initializes a new instance of the OperationCanceledException class with a system-supplied error message.
OperationCanceledException(String)	Initializes a new instance of the OperationCanceledException class with a specified error message.
OperationCanceledException(CancellationToken)	Initializes a new instance of the OperationCanceledException class with a cancellation token.
OperationCanceledException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the OperationCanceledException class with serialized data.
OperationCanceledException(String, Exception)	Initializes a new instance of the OperationCanceledException class with a specified error message and a reference to the inner exception that is the cause of this exception.
OperationCanceledException(String, CancellationToken)	Initializes a new instance of the OperationCanceledException class with a specified error message and a cancellation token.

OperationCanceledException(String, Exception, CancellationToken)	Initializes a new instance of the OperationCanceledException class with a specified error message, a reference to the inner exception that is the cause of this exception, and a cancellation token.

OperationCanceledException()

Initializes a new instance of the OperationCanceledException class with a system-supplied error message.

C#

```
public OperationCanceledException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The operation was canceled." This message takes into account the current system culture.

The following table shows the initial property values for an instance of OperationCanceledException.

Expand table

Property	Value
InnerException	A nullreference (`Nothing` in Visual Basic).
Message	The localized error message string.
CancellationToken	A cancellation token created in the non-canceled state.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

OperationCanceledException(String)

Initializes a new instance of the OperationCanceledException class with a specified error message.

C#

```
public OperationCanceledException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of OperationCanceledException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.
CancellationToken	A cancellation token created in the non-canceled state.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

OperationCanceledException(CancellationToken)

Initializes a new instance of the OperationCanceledException class with a cancellation token.

C#

```
public OperationCanceledException (System.Threading.CancellationToken
token);
```

Parameters

`token` CancellationToken

A cancellation token associated with the operation that was canceled.

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The operation was canceled." This message takes into account the current system culture.

The following table shows the initial property values for an instance of OperationCanceledException.

Expand table

Property	Value
InnerException	A nullreference (`Nothing` in Visual Basic).
Message	The localized error message string.
CancellationToken	`token`.

.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.6, 2.0, 2.1
UWP	10.0

OperationCanceledException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the OperationCanceledException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected OperationCanceledException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OperationCanceledException(String, Exception)

Initializes a new instance of the OperationCanceledException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public OperationCanceledException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

The content of `message` is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of OperationCanceledException.

Expand table

OperationCanceledException.CancellationToken Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a token associated with the operation that was canceled.

C#

```
public System.Threading.CancellationToken CancellationToken { get; }
```

Property Value

CancellationToken

A token associated with the operation that was canceled, or a default token.

Remarks

If the token is associated with a canceled operation, the CancellationToken.IsCancellationRequested property of the token returns `true`.

Applies to

Product	Versions

OutOfMemoryException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is not enough memory to continue the execution of a program.

```
C#
public class OutOfMemoryException : SystemException
```

Inheritance Object → Exception → SystemException → OutOfMemoryException

Derived System.InsufficientMemoryException

Remarks

OutOfMemoryException uses the HRESULT `COR_E_OUTOFMEMORY`, which has the value 0x8007000E.

For a list of initial property values for an instance of OutOfMemoryException, see the OutOfMemoryException constructors.

> **Note**
>
> The value of the inherited **Data** property is always `null`.

An OutOfMemoryException exception has two major causes:

- You are attempting to expand a StringBuilder object beyond the length defined by its StringBuilder.MaxCapacity property.
- The common language runtime cannot allocate enough contiguous memory to successfully perform an operation. This exception can be thrown by any property assignment or method call that requires a memory allocation. For more

information on the cause of the OutOfMemoryException exception, see the blog post "Out of Memory" Does Not Refer to Physical Memory.

This type of OutOfMemoryException exception represents a catastrophic failure. If you choose to handle the exception, you should include a `catch` block that calls the Environment.FailFast method to terminate your app and add an entry to the system event log, as the following example does.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      try {
         // Outer block to handle any unexpected exceptions.
         try {
            string s = "This";
            s = s.Insert(2, "is ");

            // Throw an OutOfMemoryException exception.
            throw new OutOfMemoryException();
         }
         catch (ArgumentException) {
            Console.WriteLine("ArgumentException in String.Insert");
         }

         // Execute program logic.
      }
      catch (OutOfMemoryException e) {
         Console.WriteLine("Terminating application unexpectedly...");
         Environment.FailFast(String.Format("Out of Memory: {0}",
                                            e.Message));
      }
   }
}
// The example displays the following output:
//        Terminating application unexpectedly...
```

Some of the conditions under which the exception is thrown and the actions you can take to eliminate it include the following:

You are calling the StringBuilder.Insert method.

You are attempting to increase the length of a StringBuilder object beyond the size specified by its StringBuilder.MaxCapacity property. The following example illustrates the OutOfMemoryException exception thrown by a call to the StringBuilder.Insert(Int32,

String, Int32) method when the example tries to insert a string that would cause the object's Length property to exceed its maximum capacity.

C#

```
using System;
using System.Text;

public class Example
{
   public static void Main()
   {
      StringBuilder sb = new StringBuilder(15, 15);
      sb.Append("Substring #1 ");
      try {
         sb.Insert(0, "Substring #2 ", 1);
      }
      catch (OutOfMemoryException e) {
         Console.WriteLine("Out of Memory: {0}", e.Message);
      }
   }
}
// The example displays the following output:
//    Out of Memory: Insufficient memory to continue the execution of the
program.
```

You can do either of the following to address the error:

- Replace the call to the StringBuilder.StringBuilder(Int32, Int32) constructor with a call any other StringBuilder constructor overload. The maximum capacity of your StringBuilder object will be set to its default value, which is Int32.MaxValue.
- Call the StringBuilder.StringBuilder(Int32, Int32) constructor with a `maxCapacity` value that is large enough to accommodate any expansions to the StringBuilder object.

Your app runs as a 32-bit process.

32-bit processes can allocate a maximum of 2GB of virtual user-mode memory on 32-bit systems, and 4GB of virtual user-mode memory on 64-bit systems. This can make it more difficult for the common language runtime to allocate sufficient contiguous memory when a large allocation is needed. In contrast, 64-bit processes can allocate up to 8TB of virtual memory. To address this exception, recompile your app to target a 64-bit platform. For information on targeting specific platforms in Visual Studio, see How to: Configure Projects to Target Platforms.

Your app is leaking unmanaged resources

Although the garbage collector is able to free memory allocated to managed types, it does not manage memory allocated to unmanaged resources such as operating system handles (including handles to files, memory-mapped files, pipes, registry keys, and wait handles) and memory blocks allocated directly by Windows API calls or by calls to memory allocation functions such as `malloc`. Types that consume unmanaged resources implement the IDisposable interface.

If you are consuming a type that uses unmanaged resources, you should be sure to call its IDisposable.Dispose method when you have finished using it. (Some types also implement a `Close` method that is identical in function to a `Dispose` method.) For more information, see the Using Objects That Implement IDisposable topic.

If you have created a type that uses unmanaged resources, make sure that you have implemented the Dispose pattern and, if necessary, supplied a finalizer. For more information, see Implementing a Dispose method and Object.Finalize.

You are attempting to create a large array in a 64-bit process

By default, the common language runtime in .NET Framework does not allow single objects whose size exceeds 2GB. To override this default, you can use the <gcAllowVeryLargeObjects> configuration file setting to enable arrays whose total size exceeds 2 GB. On .NET Core, support for arrays of greater than 2 GB is enabled by default.

You are working with very large sets of data (such as arrays, collections, or database data sets) in memory.

When data structures or data sets that reside in memory become so large that the common language runtime is unable to allocate enough contiguous memory for them, an OutOfMemoryException exception results.

To prevent the OutOfMemoryException exceptions, you must modify your application so that less data is resident in memory, or the data is divided into segments that require smaller memory allocations. For example:

- If you are retrieving all of the data from a database and then filtering it in your app to minimize trips to the server, you should modify your queries to return only the subset of data that your app needs. When working with large tables, multiple queries are almost always more efficient than retrieving all of the data in a single table and then manipulating it.

- If you are executing queries that users create dynamically, you should ensure that the number of records returned by the query is limited.

- If you are using large arrays or other collection objects whose size results in an OutOfMemoryException exception, you should modify your application to work the data in subsets rather than to work with it all at once.

The following example gets a array that consists of 200 million floating-point values and then calculates their mean. The output from the example shows that, because the example stores the entire array in memory before it calculates the mean, an OutOfMemoryException is thrown.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Double[] values = GetData();
      // Compute mean.
      Console.WriteLine("Sample mean: {0}, N = {1}",
                        GetMean(values), values.Length);
   }

   private static Double[] GetData()
   {
      Random rnd = new Random();
      List<Double> values = new List<Double>();
      for (int ctr = 1; ctr <= 200000000; ctr++) {
         values.Add(rnd.NextDouble());
         if (ctr % 10000000 == 0)
            Console.WriteLine("Retrieved {0:N0} items of data.",
                              ctr);
      }
      return values.ToArray();
   }

   private static Double GetMean(Double[] values)
   {
      Double sum = 0;
      foreach (var value in values)
         sum += value;

      return sum / values.Length;
   }
}
// The example displays output like the following:
//    Retrieved 10,000,000 items of data.
//    Retrieved 20,000,000 items of data.
//    Retrieved 30,000,000 items of data.
//    Retrieved 40,000,000 items of data.
//    Retrieved 50,000,000 items of data.
```

```
//    Retrieved 60,000,000 items of data.
//    Retrieved 70,000,000 items of data.
//    Retrieved 80,000,000 items of data.
//    Retrieved 90,000,000 items of data.
//    Retrieved 100,000,000 items of data.
//    Retrieved 110,000,000 items of data.
//    Retrieved 120,000,000 items of data.
//    Retrieved 130,000,000 items of data.
//
//    Unhandled Exception: OutOfMemoryException.
```

The following example eliminates the OutOfMemoryException exception by processing the incoming data without storing the entire data set in memory, serializing the data to a file if necessary to permit further processing (these lines are commented out in the example, since in this case they produce a file whose size is greater than 1GB), and returning the calculated mean and the number of cases to the calling routine.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      Tuple<Double, long> result = GetResult();
      Console.WriteLine("Sample mean: {0}, N = {1:N0}",
                        result.Item1, result.Item2);
   }

   private static Tuple<Double, long> GetResult()
   {
      int chunkSize = 50000000;
      int nToGet = 200000000;
      Random rnd = new Random();
      // FileStream fs = new FileStream(@".\data.bin", FileMode.Create);
      // BinaryWriter bin = new BinaryWriter(fs);
      // bin.Write((int)0);
      int n = 0;
      Double sum = 0;
      for (int outer = 0;
           outer <= ((int) Math.Ceiling(nToGet * 1.0 / chunkSize) - 1);
           outer++) {
         for (int inner = 0;
              inner <= Math.Min(nToGet - n - 1, chunkSize - 1);
              inner++) {
            Double value = rnd.NextDouble();
            sum += value;
            n++;
            // bin.Write(value);
         }
```

```
        }
        // bin.Seek(0, SeekOrigin.Begin);
        // bin.Write(n);
        // bin.Close();
        return new Tuple<Double, long>(sum/n, n);
    }
}
// The example displays output like the following:
//    Sample mean: 0.500022771458399, N = 200,000,000
```

You are repeatedly concatenating large strings.

Because strings are immutable, each string concatenation operation creates a new string. The impact for small strings, or for a small number of concatenation operations, is negligible. But for large strings or a very large number of concatenation operations, string concatenation can lead to a large number of memory allocations and memory fragmentation, poor performance, and possibly OutOfMemoryException exceptions.

When concatenating large strings or performing a large number of concatenation operations, you should use the StringBuilder class instead of the String class. When you have finished manipulating the string, convert the StringBuilder instance to a string by calling the StringBuilder.ToString method.

You pin a large number of objects in memory.

Pinning a large number of objects in memory for long periods can make it difficult for the garbage collector to allocate contiguous blocks of memory. If you've pinned a large number of objects in memory, for example by using the `fixed` statement in C# or by calling the GCHandle.Alloc(Object, GCHandleType) method with a handle type of GCHandleType.Pinned, you can do the following to address the OutOfMemoryException exception.

- Evaluate whether each object really needs to be pinned,
- Ensure that each object is unpinned as soon as possible.
- Make sure that each call to the GCHandle.Alloc(Object, GCHandleType) method to pin memory has a corresponding call to the GCHandle.Free method to unpin that memory.

The following Microsoft intermediate (MSIL) instructions throw an OutOfMemoryException exception:

- box
- newarr
- newobj

Constructors

Expand table

OutOfMemoryException()	Initializes a new instance of the OutOfMemoryException class.
OutOfMemoryException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the OutOfMemoryException class with serialized data.
OutOfMemoryException(String)	Initializes a new instance of the OutOfMemoryException class with a specified error message.
OutOfMemoryException(String, Exception)	Initializes a new instance of the OutOfMemoryException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

OutOfMemoryException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the OutOfMemoryException class.

Overloads

Expand table

OutOfMemoryException()	Initializes a new instance of the OutOfMemoryException class.
OutOfMemoryException(String)	Initializes a new instance of the OutOfMemoryException class with a specified error message.
OutOfMemoryException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the OutOfMemoryException class with serialized data.
OutOfMemoryException(String, Exception)	Initializes a new instance of the OutOfMemoryException class with a specified error message and a reference to the inner exception that is the cause of this exception.

OutOfMemoryException()

Initializes a new instance of the OutOfMemoryException class.

C#

```
public OutOfMemoryException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "There was not enough memory to continue the execution of the program." This message takes into account the current system culture.

The following table shows the initial property values for an instance of OutOfMemoryException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

OutOfMemoryException(String)

Initializes a new instance of the OutOfMemoryException class with a specified error message.

C#

```
public OutOfMemoryException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of OutOfMemoryException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

OutOfMemoryException(SerializationInfo, StreamingContext)

⊗ Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the OutOfMemoryException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected OutOfMemoryException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

Product	Versions *(Obsolete)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OutOfMemoryException(String, Exception)

Initializes a new instance of the OutOfMemoryException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public OutOfMemoryException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of OutOfMemoryException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

OverflowException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an arithmetic, casting, or conversion operation in a checked context results in an overflow.

C#

```
public class OverflowException : ArithmeticException
```

Inheritance Object → Exception → SystemException → ArithmeticException → OverflowException

Remarks

An OverflowException is thrown at run time under the following conditions:

- An arithmetic operation produces a result that is outside the range of the data type returned by the operation. The following example illustrates the OverflowException that is thrown by a multiplication operation that overflows the bounds of the Int32 type.

  C#

  ```
  int value = 780000000;
  checked {
  try {
     // Square the original value.
     int square = value * value;
     Console.WriteLine("{0} ^ 2 = {1}", value, square);
  }
  catch (OverflowException) {
     double square = Math.Pow(value, 2);
     Console.WriteLine("Exception: {0} > {1:E}.",
                       square, Int32.MaxValue);
  } }
  ```

```
// The example displays the following output:
//       Exception: 6.084E+17 > 2.147484E+009.
```

- A casting or conversion operation attempts to perform a narrowing conversion, and the value of the source data type is outside the range of the target data type. The following example illustrates the OverflowException that is thrown by the attempt to convert a large unsigned byte value to a signed byte value.

```C#
byte value = 241;
checked {
try {
   sbyte newValue = (sbyte) value;
   Console.WriteLine("Converted the {0} value {1} to the {2} value
{3}.",
                     value.GetType().Name, value,
                     newValue.GetType().Name, newValue);
}
catch (OverflowException) {
   Console.WriteLine("Exception: {0} > {1}.", value, SByte.MaxValue);
} }
// The example displays the following output:
//       Exception: 241 > 127.
```

In each case, the result of the operation is a value that is less than the `MinValue` property or greater than the `MaxValue` property of the data type that results from the operation.

For the arithmetic, casting, or conversion operation to throw an OverflowException, the operation must occur in a checked context. By default, arithmetic operations and overflows in Visual Basic are checked; in C# and F#, they are not. If the operation occurs in an unchecked context, the result is truncated by discarding any high-order bits that do not fit into the destination type. The following example illustrates such an unchecked conversion in C# or F#. It repeats the previous example in an unchecked context.

```C#
byte value = 241;
try {
   sbyte newValue = (sbyte) value;
   Console.WriteLine("Converted the {0} value {1} to the {2} value {3}.",
                     value.GetType().Name, value,
                     newValue.GetType().Name, newValue);
}
catch (OverflowException) {
   Console.WriteLine("Exception: {0} > {1}.", value, SByte.MaxValue);
}
```

```
// The example displays the following output:
//       Converted the Byte value 241 to the SByte value -15.
```

The following Microsoft intermediate language (MSIL) instructions throw an OverflowException:

- `add.ovf.` *<signed>*
- `conv.ovf.` *<to type>*
- `conv.ovf.` *<to type>* `.un`
- `mul.ovf.` *<type>*
- `sub.ovf.` *<type>*
- `newarr`

OverflowException uses the HRESULT COR_E_OVERFLOW, which has the value 0x80131516.

For a list of initial property values for an instance of OverflowException, see the OverflowException constructors.

Constructors

OverflowException()	Initializes a new instance of the OverflowException class.
OverflowException(String)	Initializes a new instance of the OverflowException class with a specified error message.
OverflowException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the OverflowException class with serialized data.
OverflowException(String, Exception)	Initializes a new instance of the OverflowException class with a specified error message and a reference to the inner exception that is the cause of this exception.

OverflowException()

Initializes a new instance of the OverflowException class.

C#

```
public OverflowException ();
```

Remarks

The following table shows the initial property values for an instance of OverflowException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

OverflowException(String)

Initializes a new instance of the OverflowException class with a specified error message.

C#

```
public OverflowException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of OverflowException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).

UWP	10.0

OverflowException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the OverflowException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
```

```
protected OverflowException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

OverflowException(String, Exception)

Initializes a new instance of the OverflowException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public OverflowException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of OverflowException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

ParamArrayAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that a method will allow a variable number of arguments in its invocation. This class cannot be inherited.

C#

```
[System.AttributeUsage(System.AttributeTargets.Parameter,
AllowMultiple=false, Inherited=true)]
public sealed class ParamArrayAttribute : Attribute
```

Inheritance Object → Attribute → ParamArrayAttribute

Attributes AttributeUsageAttribute

Examples

The following example defines a `Temperature` class that includes a `Display` method, which is intended to display one or more formatted temperature values. The method has a single parameter, `formats`, which is defined as a parameter array.

C#

```
using System;

public class Temperature
{
   private decimal temp;

   public Temperature(decimal temperature)
   {
      this.temp = temperature;
   }

   public override string ToString()
   {
      return ToString("C");
```

```
    }

    public string ToString(string format)
    {
       if (String.IsNullOrEmpty(format))
          format = "G";

       switch (format.ToUpper())
       {
          case "G":
          case "C":
             return temp.ToString("N") + "  °C";
          case "F":
             return (9 * temp / 5 + 32).ToString("N") + "  °F";
          case "K":
             return (temp + 273.15m).ToString("N") + "  °K";
          default:
             throw new FormatException(String.Format("The '{0}' format
specifier is not supported",
                                                      format));
       }
    }

    public void Display(params string []formats)
    {
       if (formats.Length == 0)
       {
          Console.WriteLine(this.ToString("G"));
       }
       else
       {
          foreach (string format in formats)
          {
             try {
                Console.WriteLine(this.ToString(format));
             }
             // If there is an exception, do nothing.
             catch { }
          }
       }
    }
}
```

The following example illustrates three different calls to the `Temperature.Display` method. In the first, the method is passed an array of format strings. In the second, the method is passed four individual format strings as arguments. In the third, the method is called with no arguments. As the output from the example illustrates, the Visual Basic and C# compilers translate this into a call to the `Display` method with an empty string array.

```
C#
```

```
public class Class1
{
   public static void Main()
   {
      Temperature temp1 = new Temperature(100);
      string[] formats = { "C", "G", "F", "K" };

      // Call Display method with a string array.
      Console.WriteLine("Calling Display with a string array:");
      temp1.Display(formats);
      Console.WriteLine();

      // Call Display method with individual string arguments.
      Console.WriteLine("Calling Display with individual arguments:");
      temp1.Display("C", "F", "K", "G");
      Console.WriteLine();

      // Call parameterless Display method.
      Console.WriteLine("Calling Display with an implicit parameter
array:");
      temp1.Display();
   }
}
// The example displays the following output:
//       Calling Display with a string array:
//       100.00  °C
//       100.00  °C
//       212.00  °F
//       373.15  °K
//
//       Calling Display with individual arguments:
//       100.00  °C
//       212.00  °F
//       373.15  °K
//       100.00  °C
//
//       Calling Display with an implicit parameter array:
//       100.00  °C
```

Remarks

The ParamArrayAttribute indicates that a method parameter is a parameter array. A parameter array allows the specification of an unknown number of arguments. A parameter array must be the last parameter in a formal parameter list, and it must be a single-dimension array. When the method is called, a parameter array permits arguments to a method to be specified in either of two ways:

- As a single expression of a type that is implicitly convertible to the parameter array type. The parameter array functions as a value parameter.

- As zero or more arguments, where each argument is an expression of a type that is implicitly convertible to the type of the parameter array element.

The example in the next section illustrates both calling conventions.

> **Note**
>
> Typically, the **ParamArrayAttribute** is not used directly in code. Instead, individual language keywords, such as `ParamArray` in Visual Basic and `params` in C#, are used as wrappers for the **ParamArrayAttribute** class. Some languages, such as C#, may even require the use of the language keyword and prohibit the use of **ParamArrayAttribute**.

During overload resolution, when compilers that support parameter arrays encounter a method overload that does not exist but has one fewer parameter than an overload that includes a parameter array, they will replace the method with the overload that includes the parameter array. For example, a call to the `String.Split()` instance method (which does not exist in the String class) is resolved as a call to the String.Split(Char[]) method. The compiler will also pass an empty array of the required type to the method. This means that the method must always be prepared to handle an array whose length is zero when it processes the elements in the parameter array. The example provides an illustration.

For more information about using attributes, see Attributes.

Constructors

Expand table

ParamArrayAttribute()	Initializes a new instance of the ParamArrayAttribute class with default properties.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

PlatformID Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Identifies the operating system, or platform, supported by an assembly.

C#

```
public enum PlatformID
```

Inheritance Object → ValueType → Enum → PlatformID

Fields

Expand table

MacOSX	6	The operating system is Macintosh. This value was returned by Silverlight. On .NET Core, its replacement is `Unix`.
Other	7	Any other operating system. This includes Browser (WASM).
Unix	4	The operating system is Unix.
Win32NT	2	The operating system is Windows NT or later.
Win32S	0	The operating system is Win32s. This value is no longer in use.
Win32Windows	1	The operating system is Windows 95 or Windows 98. This value is no longer in use.
WinCE	3	The operating system is Windows CE. This value is no longer in use.
Xbox	5	The development platform is Xbox 360. This value is no longer in use.

Examples

The following example demonstrates using the `PlatformID` class to identify the currently executing operating system:

C#

```
// This example demonstrates the PlatformID enumeration.
using System;

class Sample
{
    public static void Main()
    {
    string msg1 = "This is a Windows operating system.";
    string msg2 = "This is a Unix operating system.";
    string msg3 = "ERROR: This platform identifier is invalid.";

// Assume this example is run on a Windows operating system.

    OperatingSystem os = Environment.OSVersion;
    PlatformID     pid = os.Platform;
    switch (pid)
        {
        case PlatformID.Win32NT:
        case PlatformID.Win32S:
        case PlatformID.Win32Windows:
        case PlatformID.WinCE:
            Console.WriteLine(msg1);
            break;
        case PlatformID.Unix:
            Console.WriteLine(msg2);
            break;
        default:
            Console.WriteLine(msg3);
            break;
        }
    }
}
/*
This example produces the following results:

This is a Windows operating system.
*/
```

Remarks

Use the Environment.OSVersion and OperatingSystem.Platform properties to obtain the `PlatformID` enumeration for the currently executing operating system or development platform. Use the `PlatformID` enumeration to help determine whether the current operating system or development platform supports your application.

You can use the underlying integer value of each `PlatformID` enumeration member as the `PlatformId` argument for the SignTool.exe (Sign Tool) utility.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

PlatformNotSupportedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a feature does not run on a particular platform.

C#

```
public class PlatformNotSupportedException : NotSupportedException
```

Inheritance Object → Exception → SystemException → NotSupportedException → PlatformNotSupportedException

Remarks

`PlatformNotSupportedException` uses the HRESULT COR_E_PLATFORMNOTSUPPORTED, which has the value 0x80131539.

Constructors

Expand table

PlatformNotSupportedException()	Initializes a new instance of the PlatformNotSupportedException class with default properties.
PlatformNotSupportedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the PlatformNotSupportedException class with serialized data.
PlatformNotSupportedException(String)	Initializes a new instance of the PlatformNotSupportedException class with a specified error message.
PlatformNotSupportedException(String, Exception)	Initializes a new instance of the PlatformNotSupportedException class with a specified

	error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function.

	(Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

PlatformNotSupportedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the PlatformNotSupportedException class.

Overloads

Expand table

PlatformNotSupportedException()	Initializes a new instance of the PlatformNotSupportedException class with default properties.
PlatformNotSupportedException(String)	Initializes a new instance of the PlatformNotSupportedException class with a specified error message.
PlatformNotSupportedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the PlatformNotSupportedException class with serialized data.
PlatformNotSupportedException(String, Exception)	Initializes a new instance of the PlatformNotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

PlatformNotSupportedException()

Initializes a new instance of the PlatformNotSupportedException class with default properties.

C#

```
public PlatformNotSupportedException ();
```

Remarks

When an instance of the PlatformNotSupportedException class is created by a call to this constructor, the following properties are initialized to the specified values:

Expand table

Property	Value
InnerException	`null`.
Message	The empty string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

PlatformNotSupportedException(String)

Initializes a new instance of the PlatformNotSupportedException class with a specified error message.

C#

```
public PlatformNotSupportedException (string? message);
```

Parameters

`message` String

The text message that explains the reason for the exception.

Remarks

When an instance of the PlatformNotSupportedException class is created by a call to this constructor, the following properties are initialized to the specified values:

Expand table

Property	Value
InnerException	`null`.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

PlatformNotSupportedException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the PlatformNotSupportedException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected PlatformNotSupportedException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

PlatformNotSupportedException(String, Exception)

Initializes a new instance of the PlatformNotSupportedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public PlatformNotSupportedException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of PlatformNotSupportedException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Predicate<T> Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the method that defines a set of criteria and determines whether the specified object meets those criteria.

```
C#
public delegate bool Predicate<in T>(T obj);
```

Type Parameters

T

The type of the object to compare.
This type parameter is contravariant. That is, you can use either the type you specified or any type that is less derived. For more information about covariance and contravariance, see Covariance and Contravariance in Generics.

Parameters

obj T

The object to compare against the criteria defined within the method represented by this delegate.

Return Value

Boolean

`true` if `obj` meets the criteria defined within the method represented by this delegate; otherwise, `false`.

Examples

The following code example uses a Predicate<T> delegate with the Array.Find method to search an array of Point structures. The example explicitly defines a Predicate<T>

delegate named `predicate` and assigns it a method named `FindPoints` that returns `true` if the product of the Point.X and Point.Y fields is greater than 100,000. Note that it is customary to use a lambda expression rather than to explicitly define a delegate of type Predicate<T>, as the second example illustrates.

C#

```
using System;
using System.Drawing;

public class Example
{
   public static void Main()
   {
      // Create an array of Point structures.
      Point[] points = { new Point(100, 200),
                         new Point(150, 250), new Point(250, 375),
                         new Point(275, 395), new Point(295, 450) };

      // Define the Predicate<T> delegate.
      Predicate<Point> predicate = FindPoints;

      // Find the first Point structure for which X times Y
      // is greater than 100000.
      Point first = Array.Find(points, predicate);

      // Display the first structure found.
      Console.WriteLine("Found: X = {0}, Y = {1}", first.X, first.Y);
   }

   private static bool FindPoints(Point obj)
   {
      return obj.X * obj.Y > 100000;
   }
}
// The example displays the following output:
//        Found: X = 275, Y = 395
```

The following example is identical to the previous example, except that it uses a lambda expression to represent the Predicate<T> delegate. Each element of the `points` array is passed to the lambda expression until the expression finds an element that meets the search criteria. In this case, the lambda expression returns `true` if the product of the X and Y fields is greater than 100,000.

C#

```
using System;
using System.Drawing;

public class Example
```

```
{
   public static void Main()
   {
      // Create an array of Point structures.
      Point[] points = { new Point(100, 200),
                         new Point(150, 250), new Point(250, 375),
                         new Point(275, 395), new Point(295, 450) };

      // Find the first Point structure for which X times Y
      // is greater than 100000.
      Point first = Array.Find(points, x => x.X * x.Y > 100000 );

      // Display the first structure found.
      Console.WriteLine("Found: X = {0}, Y = {1}", first.X, first.Y);
   }
}
// The example displays the following output:
//        Found: X = 275, Y = 395
```

Remarks

This delegate is used by several methods of the Array and List<T> classes to search for elements in the collection.

Typically, the Predicate<T> delegate is represented by a lambda expression. Because locally scoped variables are available to the lambda expression, it is easy to test for a condition that is not precisely known at compile time. This is simulated in the following example, which defines a `HockeyTeam` class that contains information about a National Hockey League team and the year in which it was founded. The example defines an array of integer values that represent years, and randomly assigns one element of the array to `foundedBeforeYear`, which is a variable that is locally scoped to the example's `Main` method. Because locally scoped variables are available to a lambda expression, the lambda expression passed to the List<T>.FindAll method is able to return a `HockeyTeam` object for each team founded on or before that year.

C#

```
using System;
using System.Collections.Generic;

public class HockeyTeam
{
   private string _name;
   private int _founded;

   public HockeyTeam(string name, int year)
   {
```

```
        _name = name;
        _founded = year;
    }

    public string Name {
        get { return _name; }
    }

    public int Founded {
        get { return _founded; }
    }
}

public class Example
{
    public static void Main()
    {
        Random rnd = new Random();
        List<HockeyTeam> teams = new List<HockeyTeam>();
        teams.AddRange( new HockeyTeam[] { new HockeyTeam("Detroit Red Wings",
1926),
                                           new HockeyTeam("Chicago
Blackhawks", 1926),
                                           new HockeyTeam("San Jose Sharks",
1991),
                                           new HockeyTeam("Montreal
Canadiens", 1909),
                                           new HockeyTeam("St. Louis Blues",
1967) } );
        int[] years = { 1920, 1930, 1980, 2000 };
        int foundedBeforeYear = years[rnd.Next(0, years.Length)];
        Console.WriteLine("Teams founded before {0}:", foundedBeforeYear);
        foreach (var team in teams.FindAll( x => x.Founded <=
foundedBeforeYear))
            Console.WriteLine("{0}: {1}", team.Name, team.Founded);
    }
}
// The example displays output similar to the following:
//       Teams founded before 1930:
//       Detroit Red Wings: 1926
//       Chicago Blackhawks: 1926
//       Montreal Canadiens: 1909
```

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Progress<T> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides an IProgress<T> that invokes callbacks for each reported progress value.

C#

```
public class Progress<T> : IProgress<T>
```

Type Parameters

T

Specifies the type of the progress report value.

Inheritance Object → Progress<T>

Implements IProgress<T>

Remarks

Any handler provided to the constructor or event handlers registered with the ProgressChanged event are invoked through a SynchronizationContext instance captured when the instance is constructed. If there is no current SynchronizationContext at the time of construction, the callbacks will be invoked on the ThreadPool.

For more information and a code example, see the article Async in 4.5: Enabling Progress and Cancellation in Async APIs in the .NET Framework blog.

Constructors

Expand table

Progress<T>()	Initializes the Progress<T> object.

Progress<T>(Action<T>)	Initializes the Progress<T> object with the specified callback.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnReport(T)	Reports a progress change.
ToString()	Returns a string that represents the current object. (Inherited from Object)

Events

Expand table

ProgressChanged	Raised for each reported progress value.

Explicit Interface Implementations

Expand table

IProgress<T>.Report(T)	Reports a progress change.

Applies to

Progress<T>(Action<T>)

Initializes the Progress<T> object with the specified callback.

```
C#
public Progress (Action<T> handler);
```

Parameters

`handler` Action<T>

A handler to invoke for each reported progress value. This handler will be invoked in addition to any delegates registered with the ProgressChanged event. Depending on the SynchronizationContext instance captured by the Progress<T> at construction, it is possible that this handler instance could be invoked concurrently with itself.

Exceptions

ArgumentNullException

`handler` is `null` (`Nothing` in Visual Basic).

Random Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a pseudo-random number generator, which is an algorithm that produces a sequence of numbers that meet certain statistical requirements for randomness.

C#

```
public class Random
```

Inheritance Object → Random

Examples

The following example creates a single random number generator and calls its NextBytes, Next, and NextDouble methods to generate sequences of random numbers within different ranges.

C#

```
// Instantiate random number generator using system-supplied value as seed.
var rand = new Random();

// Generate and display 5 random byte (integer) values.
var bytes = new byte[5];
rand.NextBytes(bytes);
Console.WriteLine("Five random byte values:");
foreach (byte byteValue in bytes)
    Console.Write("{0, 5}", byteValue);
Console.WriteLine();

// Generate and display 5 random integers.
Console.WriteLine("Five random integer values:");
for (int ctr = 0; ctr <= 4; ctr++)
    Console.Write("{0,15:N0}", rand.Next());
Console.WriteLine();

// Generate and display 5 random integers between 0 and 100.
Console.WriteLine("Five random integers between 0 and 100:");
```

```
for (int ctr = 0; ctr <= 4; ctr++)
    Console.Write("{0,8:N0}", rand.Next(101));
Console.WriteLine();

// Generate and display 5 random integers from 50 to 100.
Console.WriteLine("Five random integers between 50 and 100:");
for (int ctr = 0; ctr <= 4; ctr++)
    Console.Write("{0,8:N0}", rand.Next(50, 101));
Console.WriteLine();

// Generate and display 5 random floating point values from 0 to 1.
Console.WriteLine("Five Doubles.");
for (int ctr = 0; ctr <= 4; ctr++)
    Console.Write("{0,8:N3}", rand.NextDouble());
Console.WriteLine();

// Generate and display 5 random floating point values from 0 to 5.
Console.WriteLine("Five Doubles between 0 and 5.");
for (int ctr = 0; ctr <= 4; ctr++)
    Console.Write("{0,8:N3}", rand.NextDouble() * 5);

// The example displays output like the following:
//    Five random byte values:
//      194  185  239   54  116
//    Five random integer values:
//        507,353,531  1,509,532,693  2,125,074,958  1,409,512,757
652,767,128
//    Five random integers between 0 and 100:
//          16      78      94      79      52
//    Five random integers between 50 and 100:
//          56      66      96      60      65
//    Five Doubles.
//       0.943   0.108   0.744   0.563   0.415
//    Five Doubles between 0 and 5.
//       2.934   3.130   0.292   1.432   4.369
```

The following example generates a random integer that it uses as an index to retrieve a string value from an array.

C#

```
Random rnd = new Random();
string[] malePetNames = { "Rufus", "Bear", "Dakota", "Fido",
                          "Vanya", "Samuel", "Koani", "Volodya",
                          "Prince", "Yiska" };
string[] femalePetNames = { "Maggie", "Penny", "Saya", "Princess",
                            "Abby", "Laila", "Sadie", "Olivia",
                            "Starlight", "Talla" };

// Generate random indexes for pet names.
int mIndex = rnd.Next(malePetNames.Length);
int fIndex = rnd.Next(femalePetNames.Length);
```

```
// Display the result.
Console.WriteLine("Suggested pet name of the day: ");
Console.WriteLine("   For a male:     {0}", malePetNames[mIndex]);
Console.WriteLine("   For a female:   {0}", femalePetNames[fIndex]);

// The example displays output similar to the following:
//       Suggested pet name of the day:
//          For a male:     Koani
//          For a female:   Maggie
```

Remarks

For more information about this API, see Supplemental API remarks for Random.

Notes to Inheritors

In .NET Framework 2.0 and later, the behavior of the Next(), Next(Int32, Int32), and NextBytes(Byte[]) methods have changed so that these methods do not necessarily call the derived class implementation of the Sample() method. As a result, classes derived from Random that target .NET Framework 2.0 and later should also override these three methods.

Notes to Callers

The implementation of the random number generator in the Random class isn't guaranteed to remain the same across major versions of .NET. As a result, you shouldn't assume that the same seed will result in the same pseudo-random sequence in different versions of .NET.

Constructors

Expand table

Random()	Initializes a new instance of the Random class using a default seed value.
Random(Int32)	Initializes a new instance of the Random class, using the specified seed value.

Properties

Expand table

Shared	Provides a thread-safe Random instance that may be used concurrently from any thread.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetItems<T>(ReadOnlySpan<T>, Int32)	Creates an array populated with items chosen at random from the provided set of choices.
GetItems<T>(ReadOnlySpan<T>, Span<T>)	Fills the elements of a specified span with items chosen at random from the provided set of choices.
GetItems<T>(T[], Int32)	Creates an array populated with items chosen at random from the provided set of choices.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Next()	Returns a non-negative random integer.
Next(Int32)	Returns a non-negative random integer that is less than the specified maximum.
Next(Int32, Int32)	Returns a random integer that is within a specified range.
NextBytes(Byte[])	Fills the elements of a specified array of bytes with random numbers.
NextBytes(Span<Byte>)	Fills the elements of a specified span of bytes with random numbers.
NextDouble()	Returns a random floating-point number that is greater than or equal to 0.0, and less than 1.0.
NextInt64()	Returns a non-negative random integer.
NextInt64(Int64)	Returns a non-negative random integer that is less than the specified maximum.

NextInt64(Int64, Int64)	Returns a random integer that is within a specified range.
NextSingle()	Returns a random floating-point number that is greater than or equal to 0.0, and less than 1.0.
Sample()	Returns a random floating-point number between 0.0 and 1.0.
Shuffle<T>(Span<T>)	Performs an in-place shuffle of a span.
Shuffle<T>(T[])	Performs an in-place shuffle of an array.
ToString()	Returns a string that represents the current object. (Inherited from Object)

Random Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Random class.

Overloads

Expand table

Random()	Initializes a new instance of the Random class using a default seed value.
Random(Int32)	Initializes a new instance of the Random class, using the specified seed value.

Random()

Initializes a new instance of the Random class using a default seed value.

C#

```
public Random ();
```

Examples

The following example uses the parameterless constructor to instantiate three Random objects and displays a sequence of five random integers for each. If it is run on .NET Framework, because the first two Random objects are created in close succession, they are instantiated using identical seed values based on the system clock and, therefore, they produce an identical sequence of random numbers. On the other hand, the parameterless constructor of the third Random object is called after a two-second delay caused by calling the Thread.Sleep method. Because this produces a different seed value for the third Random object, it produces a different sequence of random numbers.

C#

```
using System;
using System.Threading;

public class RandomNumbers
{
   public static void Main()
   {
      Random rand1 = new Random();
      Random rand2 = new Random();
      Thread.Sleep(2000);
      Random rand3 = new Random();
      ShowRandomNumbers(rand1);
      ShowRandomNumbers(rand2);
      ShowRandomNumbers(rand3);
   }

   private static void ShowRandomNumbers(Random rand)
   {
      Console.WriteLine();
      byte[] values = new byte[5];
      rand.NextBytes(values);
      foreach (byte value in values)
         Console.Write("{0, 5}", value);
      Console.WriteLine();
   }
}
// The example displays an output similar to the following:
//       28   35  133  224   58
//
//       28   35  133  224   58
//
//       32  222   43  251   49
```

Remarks

In .NET Framework, the default seed value is derived from the system clock, which has finite resolution. As a result, different Random objects that are created in close succession by a call to the parameterless constructor have identical default seed values and, therefore, produce identical sets of random numbers. You can avoid this problem by using a single Random object to generate all random numbers. You can also work around it by generating your own random seed value and passing it to the Random(Int32) constructor. For more information, see the Random(Int32) constructor.

In .NET Core, the default seed value is produced by the thread-static, pseudo-random number generator, so the previously described limitation does not apply.

Different Random objects created in close succession produce different sets of random numbers in .NET Core.

Call this constructor if you want your random number generator to generate a random sequence of numbers. To generate a fixed sequence of random numbers that will be the same for different random number generators, call the Random(Int32) constructor with a fixed seed value. This Random constructor overload is frequently used when testing apps that use random numbers.

Once you've instantiated the random number generator, you call individual Random methods, such as Next() or NextDouble(), to generate random numbers.

Applies to

Random(Int32)

Initializes a new instance of the Random class, using the specified seed value.

C#

```
public Random (int Seed);
```

Parameters

Seed Int32

A number used to calculate a starting value for the pseudo-random number sequence. If a negative number is specified, the absolute value of the number is used.

Examples

The following example creates Random objects with the class constructor that takes a seed parameter and generates a sequence of random integers and doubles. The example illustrates that the same sequence is generated when the Random object is created again with the constructor and seed parameter.

C#

```
// Example of the Random class constructors and Random.NextDouble()
// method.
using System;
using System.Threading;

public class RandomObjectDemo
{
    // Generate random numbers from the specified Random object.
    static void RunIntNDoubleRandoms(Random randObj)
    {
        // Generate the first six random integers.
        for(int j = 0; j < 6; j++)
            Console.Write(" {0,10} ", randObj.Next());
        Console.WriteLine();

        // Generate the first six random doubles.
        for(int j = 0; j < 6; j++)
            Console.Write(" {0:F8} ", randObj.NextDouble());
        Console.WriteLine();
    }

    // Create a Random object with the specified seed.
    static void FixedSeedRandoms(int seed)
    {
        Console.WriteLine(
            "\nRandom numbers from a Random object with " +
            "seed = {0}:", seed);
        Random fixRand = new Random(seed);

        RunIntNDoubleRandoms(fixRand);
    }

    // Create a random object with a timer-generated seed.
    static void AutoSeedRandoms()
    {
        // Wait to allow the timer to advance.
        Thread.Sleep(1);

        Console.WriteLine(
            "\nRandom numbers from a Random object " +
            "with an auto-generated seed:");
        Random autoRand = new Random();
```

```
        RunIntNDoubleRandoms(autoRand);
    }

    static void Main()
    {
        Console.WriteLine(
            "This example of the Random class constructors and " +
            "Random.NextDouble() \n" +
            "generates the following output.\n");
        Console.WriteLine(
            "Create Random objects, and then generate and " +
            "display six integers and \nsix doubles from each.");

        FixedSeedRandoms(123);
        FixedSeedRandoms(123);

        FixedSeedRandoms(456);
        FixedSeedRandoms(456);

        AutoSeedRandoms();
        AutoSeedRandoms();
        AutoSeedRandoms();
    }
}

/*
This example of the Random class constructors and Random.NextDouble()
generates an output similar to the following:

Create Random objects, and then generate and display six integers and
six doubles from each.

Random numbers from a Random object with seed = 123:
 2114319875  1949518561  1596751841  1742987178  1586516133   103755708

*/
```

Remarks

Providing an identical seed value to different Random objects causes each instance to produce identical sequences of random numbers. This is often done when testing apps that rely on random number generators.

If your application requires different random number sequences, invoke this constructor repeatedly with different seed values. One way to produce a unique seed value is to make it time-dependent. For example, derive the seed value from the system clock, as the Random() overload does. However, the system clock might not have sufficient resolution to provide different invocations of this constructor with a different seed value. On the .NET Framework, this results in random number generators that generate identical sequences of pseudo-random numbers, as illustrated by the first two Random objects in the following example. To prevent this, apply an algorithm to differentiate the seed value in each invocation, or call the Thread.Sleep method to ensure that you provide each constructor with a different seed value.

C#

```
using System;
using System.Threading;

public class Example
{
   public static void Main()
   {
      Random rand1 = new Random((int) DateTime.Now.Ticks & 0x0000FFFF);
      Random rand2 = new Random((int) DateTime.Now.Ticks & 0x0000FFFF);
      Thread.Sleep(20);
      Random rand3 = new Random((int) DateTime.Now.Ticks & 0x0000FFFF);
      ShowRandomNumbers(rand1);
      ShowRandomNumbers(rand2);
      ShowRandomNumbers(rand3);
   }

   private static void ShowRandomNumbers(Random rand)
   {
      Console.WriteLine();
      byte[] values = new byte[4];
      rand.NextBytes(values);
      foreach (var value in values)
```

```
            Console.Write("{0, 5}", value);

        Console.WriteLine();
    }
}
// The example displays output similar to the following:
//   145  214  177  134  173
//
//   145  214  177  134  173
//
//   126  185  175  249  157
```

Another option is to instantiate a single Random object that you use to generate all the random numbers in your application. This yields slightly better performance, since instantiating a random number generator is fairly expensive.

Random.Shared Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a thread-safe Random instance that may be used concurrently from any thread.

C#

```
public static Random Shared { get; }
```

Property Value

Random

A Random instance.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Random.GetItems Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetItems<T>(ReadOnlySpan<T>, Int32)	Creates an array populated with items chosen at random from the provided set of choices.
GetItems<T>(ReadOnlySpan<T>, Span<T>)	Fills the elements of a specified span with items chosen at random from the provided set of choices.
GetItems<T>(T[], Int32)	Creates an array populated with items chosen at random from the provided set of choices.

GetItems<T>(ReadOnlySpan<T>, Int32)

Creates an array populated with items chosen at random from the provided set of choices.

C#

```
public T[] GetItems<T> (ReadOnlySpan<T> choices, int length);
```

Type Parameters

T

The type of array.

Parameters

choices ReadOnlySpan<T>

The items to use to populate the array.

`length` Int32

The length of array to return.

Returns

T[]

An array populated with random items.

Exceptions

ArgumentException

`choices` is empty.

ArgumentOutOfRangeException

`length` is not zero or a positive number.

Remarks

The method uses Next(Int32) to select items randomly from `choices` by index. This is used to populate a newly-created array.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

GetItems<T>(ReadOnlySpan<T>, Span<T>)

Fills the elements of a specified span with items chosen at random from the provided set of choices.

```
C#

public void GetItems<T> (ReadOnlySpan<T> choices, Span<T> destination);
```

Type Parameters

`T`

The type of span.

Parameters

`choices` ReadOnlySpan<T>

The items to use to populate the span.

`destination` Span<T>

The span to be filled with items.

Exceptions

ArgumentException

`choices` is empty.

Remarks

The method uses Next(Int32) to select items randomly from `choices` by index and populate `destination`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

GetItems<T>(T[], Int32)

Creates an array populated with items chosen at random from the provided set of choices.

```
C#
public T[] GetItems<T> (T[] choices, int length);
```

Type Parameters

`T`

The type of array.

Parameters

`choices` T[]

The items to use to populate the array.

`length` Int32

The length of array to return.

Returns

T[]

An array populated with random items.

Exceptions

ArgumentException

`choices` is empty.

ArgumentNullException

`choices` is `null`.

ArgumentOutOfRangeException

`length` is not zero or a positive number.

Remarks

The method uses Next(Int32) to select items randomly from `choices` by index. This is used to populate a newly-created array.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Random.Next Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a random integer.

Overloads

Expand table

Next()	Returns a non-negative random integer.
Next(Int32)	Returns a non-negative random integer that is less than the specified maximum.
Next(Int32, Int32)	Returns a random integer that is within a specified range.

Next()

Returns a non-negative random integer.

C#

```
public virtual int Next ();
```

Returns

Int32

A 32-bit signed integer that is greater than or equal to 0 and less than Int32.MaxValue.

Examples

The following example makes repeated calls to the Next method to generate a specific number of random numbers requested by the user. The Console.ReadLine method is used to get customer input.

C#

```
Random rnd = new Random();

Console.WriteLine("Generating 10 random numbers:");

for (uint ctr = 1; ctr <= 10; ctr++)
   Console.WriteLine($"{rnd.Next(),15:N0}");

// The example displays output like the following:
//
//     Generating 10 random numbers:
//         1,733,189,596
//           566,518,090
//         1,166,108,546
//         1,931,426,514
//         1,532,939,448
//           762,207,767
//           815,074,920
//         1,521,208,785
//         1,950,436,671
//         1,266,596,666
```

The following example derives a class from Random to generate a sequence of random numbers whose distribution differs from the uniform distribution generated by the Sample method of the base class. It overrides the Sample method to provide the distribution of random numbers, and overrides the Random.Next method to use series of random numbers.

C#

```
using System;

// This derived class converts the uniformly distributed random
// numbers generated by base.Sample() to another distribution.
public class RandomProportional : Random
{
    // The Sample method generates a distribution proportional to the
value
    // of the random numbers, in the range [0.0, 1.0].
    protected override double Sample()
    {
        return Math.Sqrt(base.Sample());
    }

    public override int Next()
```

```
    {
        return (int) (Sample() * int.MaxValue);
    }
}

public class RandomSampleDemo
{
    static void Main()
    {
        const int rows = 4, cols = 6;
        const int runCount = 1000000;
        const int distGroupCount = 10;
        const double intGroupSize =
            ((double)int.MaxValue + 1.0) / (double)distGroupCount;

        RandomProportional randObj = new RandomProportional();

        int[ ]      intCounts = new int[ distGroupCount ];
        int[ ]      realCounts = new int[ distGroupCount ];

        Console.WriteLine(
            "\nThe derived RandomProportional class overrides " +
            "the Sample method to \ngenerate random numbers " +
            "in the range [0.0, 1.0]. The distribution \nof " +
            "the numbers is proportional to their numeric values. " +
            "For example, \nnumbers are generated in the " +
            "vicinity of 0.75 with three times the \n" +
            "probability of those generated near 0.25.");
        Console.WriteLine(
            "\nRandom doubles generated with the NextDouble() " +
            "method:\n");

        // Generate and display [rows * cols] random doubles.
        for (int i = 0; i < rows; i++)
        {
            for (int j = 0; j < cols; j++)
                Console.Write("{0,12:F8}", randObj.NextDouble());
            Console.WriteLine();
        }

        Console.WriteLine(
            "\nRandom integers generated with the Next() " +
            "method:\n");

        // Generate and display [rows * cols] random integers.
        for (int i = 0; i < rows; i++)
        {
            for (int j = 0; j < cols; j++)
                Console.Write("{0,12}", randObj.Next());
            Console.WriteLine();
        }

        Console.WriteLine(
            "\nTo demonstrate the proportional distribution, " +
            "{0:N0} random \nintegers and doubles are grouped " +
```

```
            "into {1} equal value ranges. This \n" +
            "is the count of values in each range:\n",
            runCount, distGroupCount);
        Console.WriteLine(
            "{0,21}{1,10}{2,20}{3,10}", "Integer Range",
            "Count", "Double Range", "Count");
        Console.WriteLine(
            "{0,21}{1,10}{2,20}{3,10}", "-------------",
            "-----", "------------", "-----");

        // Generate random integers and doubles, and then count
        // them by group.
        for (int i = 0; i < runCount; i++)
        {
            intCounts[ (int)((double)randObj.Next() /
                intGroupSize) ]++;
            realCounts[ (int)(randObj.NextDouble() *
                (double)distGroupCount) ]++;
        }

        // Display the count of each group.
        for (int i = 0; i < distGroupCount; i++)
            Console.WriteLine(
                "{0,10}-{1,10}{2,10:N0}{3,12:N5}-{4,7:N5}{5,10:N0}",
                (int)((double)i * intGroupSize),
                (int)((double)(i + 1) * intGroupSize - 1.0),
                intCounts[ i ],
                ((double)i) / (double)distGroupCount,
                ((double)(i + 1)) / (double)distGroupCount,
                realCounts[ i ]);
    }
}

/*
This example of Random.Sample() displays output similar to the following:

   The derived RandomProportional class overrides the Sample method to
   generate random numbers in the range [0.0, 1.0). The distribution
   of the numbers is proportional to the number values. For example,
   numbers are generated in the vicinity of 0.75 with three times the
   probability of those generated near 0.25.

   Random doubles generated with the NextDouble() method:

     0.59455719  0.17589882  0.83134398  0.35795862  0.91467727
0.54022658
     0.93716947  0.54817519  0.94685080  0.93705478  0.18582318
0.71272428
     0.77708682  0.95386216  0.70412393  0.86099417  0.08275804
0.79108316
     0.71019941  0.84205103  0.41685082  0.58186880  0.89492302
0.73067715

   Random integers generated with the Next() method:
```

```
     1570755704  1279192549  1747627711  1705700211  1372759203
1849655615
     2046235980  1210843924  1554274149  1307936697  1480207570
1057595022
      337854215   844109928  2028310798  1386669369  2073517658
1291729809
     1537248240  1454198019  1934863511  1640004334  2032620207
534654791

   To demonstrate the proportional distribution, 1,000,000 random
   integers and doubles are grouped into 10 equal value ranges. This
   is the count of values in each range:

           Integer Range     Count        Double Range     Count
           -------------     -----        ------------     -----
            0- 214748363    10,079     0.00000-0.10000    10,148
    214748364- 429496728    29,835     0.10000-0.20000    29,849
    429496729- 644245093    49,753     0.20000-0.30000    49,948
    644245094- 858993458    70,325     0.30000-0.40000    69,656
    858993459-1073741823    89,906     0.40000-0.50000    90,337
   1073741824-1288490187   109,868     0.50000-0.60000   110,225
   1288490188-1503238552   130,388     0.60000-0.70000   129,986
   1503238553-1717986917   149,231     0.70000-0.80000   150,428
   1717986918-1932735282   170,234     0.80000-0.90000   169,610
   1932735283-2147483647   190,381     0.90000-1.00000   189,813
*/
```

Remarks

Random.Next generates a random number whose value ranges from 0 to less than Int32.MaxValue. To generate a random number whose value ranges from 0 to some other positive number, use the Random.Next(Int32) method overload. To generate a random number within a different range, use the Random.Next(Int32, Int32) method overload.

Notes to Inheritors

Starting with the .NET Framework version 2.0, if you derive a class from Random and override the Sample() method, the distribution provided by the derived class implementation of the Sample() method is not used in calls to the base class implementation of the Next() method. Instead, the uniform distribution returned by the base Random class is used. This behavior improves the overall performance of the Random class. To modify this behavior to call the Sample() method in the derived class, you must also override the Next() method.

Next(Int32)

Returns a non-negative random integer that is less than the specified maximum.

C#

```
public virtual int Next (int maxValue);
```

Parameters

`maxValue` Int32

The exclusive upper bound of the random number to be generated. `maxValue` must be greater than or equal to 0.

Returns

Int32

A 32-bit signed integer that is greater than or equal to 0, and less than `maxValue`; that is, the range of return values ordinarily includes 0 but not `maxValue`. However, if `maxValue` equals 0, 0 is returned.

Exceptions

ArgumentOutOfRangeException

`maxValue` is less than 0.

Examples

The following example generates random integers with various overloads of the Next method.

C#

```
Console.WriteLine(
    "This example of the Random.Next() methods\n" +
    "generates the following output.\n");
Console.WriteLine(
    "Create Random objects all with the same seed and " +
    "generate\nsequences of numbers with different " +
    "bounds. Note the effect\nthat the various " +
    "combinations of bounds have on the sequences.");

NoBoundsRandoms(234);

UpperBoundRandoms(234, Int32.MaxValue);
UpperBoundRandoms(234, 2000000000);
UpperBoundRandoms(234, 200000000);

BothBoundsRandoms(234, 0, Int32.MaxValue);
BothBoundsRandoms(234, Int32.MinValue, Int32.MaxValue);
BothBoundsRandoms(234, -2000000000, 2000000000);
BothBoundsRandoms(234, -200000000, 200000000);
BothBoundsRandoms(234, -2000, 2000);

// Generate random numbers with no bounds specified.
void NoBoundsRandoms(int seed)
{
    Console.WriteLine(
        "\nRandom object, seed = {0}, no bounds:", seed);
    Random randObj = new Random(seed);

    // Generate six random integers from 0 to int.MaxValue.
    for (int j = 0; j < 6; j++)
        Console.Write("{0,11} ", randObj.Next());
    Console.WriteLine();
}

// Generate random numbers with an upper bound specified.
void UpperBoundRandoms(int seed, int upper)
{
    Console.WriteLine(
        "\nRandom object, seed = {0}, upper bound = {1}:",
        seed, upper);
    Random randObj = new Random(seed);

    // Generate six random integers from 0 to the upper bound.
```

```
    for (int j = 0; j < 6; j++)
        Console.Write("{0,11} ", randObj.Next(upper));
    Console.WriteLine();
}

// Generate random numbers with both bounds specified.
void BothBoundsRandoms(int seed, int lower, int upper)
{
    Console.WriteLine(
        "\nRandom object, seed = {0}, lower = {1}, " +
        "upper = {2}:", seed, lower, upper);
    Random randObj = new Random(seed);

    // Generate six random integers from the lower to
    // upper bounds.
    for (int j = 0; j < 6; j++)
        Console.Write("{0,11} ",
            randObj.Next(lower, upper));
    Console.WriteLine();
}

/*
This example of the Random.Next() methods
generates the following output.

Create Random objects all with the same seed and generate
sequences of numbers with different bounds. Note the effect
that the various combinations of bounds have on the sequences.

Random object, seed = 234, no bounds:
2091148258  1024955023   711273344  1081917183  1833298756   109460588

Random object, seed = 234, upper bound = 2147483647:
2091148258  1024955023   711273344  1081917183  1833298756   109460588

Random object, seed = 234, upper bound = 2000000000:
1947533580   954563751   662424922  1007613896  1707392518   101943116

Random object, seed = 234, upper bound = 200000000:
194753358    95456375    66242492   100761389   170739251    10194311

Random object, seed = 234, lower = 0, upper = 2147483647:
2091148258  1024955023   711273344  1081917183  1833298756   109460588

Random object, seed = 234, lower = -2147483648, upper = 2147483647:
2034812868   -97573602  -724936960    16350718  1519113864 -1928562472

Random object, seed = 234, lower = -2000000000, upper = 2000000000:
1895067160   -90872498  -675150156    15227793  1414785036 -1796113767

Random object, seed = 234, lower = -200000000, upper = 200000000:
189506716    -9087250   -67515016     1522779   141478503  -179611377

Random object, seed = 234, lower = -2000, upper = 2000:
```

```
    1895          -91         -676           15         1414        -1797
*/
```

The following example generates a random integer that it uses as an index to retrieve a string value from an array. Because the highest index of the array is one less than its length, the value of the Array.Length property is supplied as a the `maxValue` parameter.

C#

```
Random rnd = new Random();
string[] malePetNames = { "Rufus", "Bear", "Dakota", "Fido",
                          "Vanya", "Samuel", "Koani", "Volodya",
                          "Prince", "Yiska" };
string[] femalePetNames = { "Maggie", "Penny", "Saya", "Princess",
                            "Abby", "Laila", "Sadie", "Olivia",
                            "Starlight", "Talla" };

// Generate random indexes for pet names.
int mIndex = rnd.Next(malePetNames.Length);
int fIndex = rnd.Next(femalePetNames.Length);

// Display the result.
Console.WriteLine("Suggested pet name of the day: ");
Console.WriteLine("   For a male:     {0}", malePetNames[mIndex]);
Console.WriteLine("   For a female:   {0}", femalePetNames[fIndex]);

// The example displays output similar to the following:
//       Suggested pet name of the day:
//          For a male:     Koani
//          For a female:   Maggie
```

Remarks

The Next(Int32) overload returns random integers that range from 0 to `maxValue` - 1. However, if `maxValue` is 0, the method returns 0.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Next(Int32, Int32)

Returns a random integer that is within a specified range.

C#

```
public virtual int Next (int minValue, int maxValue);
```

Parameters

`minValue` Int32

The inclusive lower bound of the random number returned.

`maxValue` Int32

The exclusive upper bound of the random number returned. `maxValue` must be greater than or equal to `minValue`.

Returns

Int32

A 32-bit signed integer greater than or equal to `minValue` and less than `maxValue`; that is, the range of return values includes `minValue` but not `maxValue`. If `minValue` equals `maxValue`, `minValue` is returned.

Exceptions

ArgumentOutOfRangeException

`minValue` is greater than `maxValue`.

Examples

The following example uses the Random.Next(Int32, Int32) method to generate random integers with three distinct ranges. Note that the exact output from the example depends on the system-supplied seed value passed to the Random class constructor.

C#

```
Random rnd = new Random();

Console.WriteLine("\n20 random integers from -100 to 100:");
for (int ctr = 1; ctr <= 20; ctr++)
{
   Console.Write("{0,6}", rnd.Next(-100, 101));
   if (ctr % 5 == 0) Console.WriteLine();
}

Console.WriteLine("\n20 random integers from 1000 to 10000:");
for (int ctr = 1; ctr <= 20; ctr++)
{
   Console.Write("{0,8}", rnd.Next(1000, 10001));
   if (ctr % 5 == 0) Console.WriteLine();
}

Console.WriteLine("\n20 random integers from 1 to 10:");
for (int ctr = 1; ctr <= 20; ctr++)
{
   Console.Write("{0,6}", rnd.Next(1, 11));
   if (ctr % 5 == 0) Console.WriteLine();
}

// The example displays output similar to the following:
//       20 random integers from -100 to 100:
//           65   -95   -10    90   -35
//          -83   -16   -15   -19    41
//          -67   -93    40    12    62
//          -80   -95    67   -81   -21
//
//       20 random integers from 1000 to 10000:
//           4857    9897    4405    6606    1277
//           9238    9113    5151    8710    1187
//           2728    9746    1719    3837    3736
//           8191    6819    4923    2416    3028
//
//       20 random integers from 1 to 10:
//            9     8     5     9     9
//            9     1     2     3     8
//            1     4     8    10     5
//            9     7     9    10     5
```

The following example generates a random integer that it uses as an index to retrieve a string value from an array. Because the highest index of the array is one less than its length, the value of the Array.Length property is supplied as a the `maxValue` parameter.

C#

```
Random rnd = new Random();
string[] malePetNames = { "Rufus", "Bear", "Dakota", "Fido",
                          "Vanya", "Samuel", "Koani", "Volodya",
                          "Prince", "Yiska" };
string[] femalePetNames = { "Maggie", "Penny", "Saya", "Princess",
                            "Abby", "Laila", "Sadie", "Olivia",
                            "Starlight", "Talla" };

// Generate random indexes for pet names.
int mIndex = rnd.Next(0, malePetNames.Length);
int fIndex = rnd.Next(0, femalePetNames.Length);

// Display the result.
Console.WriteLine("Suggested pet name of the day: ");
Console.WriteLine("   For a male:     {0}", malePetNames[mIndex]);
Console.WriteLine("   For a female:   {0}", femalePetNames[fIndex]);

// The example displays the following output:
//       Suggested pet name of the day:
//          For a male:     Koani
//          For a female:   Maggie
```

Remarks

The Next(Int32, Int32) overload returns random integers that range from `minValue` to `maxValue` - 1. However, if `maxValue` equals `minValue`, the method returns `minValue`.

Unlike the other overloads of the Next method, which return only non-negative values, this method can return a negative random integer.

Notes to Inheritors

Starting with the .NET Framework version 2.0, if you derive a class from Random and override the Sample() method, the distribution provided by the derived class implementation of the Sample() method is not used in calls to the base class implementation of the Next(Int32, Int32) method overload if the difference between the `minValue` and `maxValue` parameters is greater than Int32.MaxValue. Instead, the uniform distribution returned by the base Random class is used. This behavior improves the overall performance of the Random class. To modify this behavior to

call the Sample() method in the derived class, you must also override the Next(Int32, Int32) method overload.

Random.NextBytes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

NextBytes(Span<Byte>)	Fills the elements of a specified span of bytes with random numbers.
NextBytes(Byte[])	Fills the elements of a specified array of bytes with random numbers.

NextBytes(Span<Byte>)

Fills the elements of a specified span of bytes with random numbers.

C#

```
public virtual void NextBytes (Span<byte> buffer);
```

Parameters

`buffer` Span<Byte>

The array to be filled with random numbers.

Remarks

Each element of the span of bytes is set to a random number greater than or equal to 0 and less than or equal to MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

NextBytes(Byte[])

Fills the elements of a specified array of bytes with random numbers.

C#

```
public virtual void NextBytes (byte[] buffer);
```

Parameters

`buffer` Byte[]

The array to be filled with random numbers.

Exceptions

ArgumentNullException

`buffer` is `null`.

Examples

The following example demonstrates how to use the NextBytes method to fill an array of bytes with random byte values.

C#

```
Random rnd = new Random();
Byte[] b = new Byte[10];
rnd.NextBytes(b);
Console.WriteLine("The Random bytes are: ");
for (int i = 0; i <= b.GetUpperBound(0); i++)
    Console.WriteLine("{0}: {1}", i, b[i]);

// The example displays output similar to the following:
//       The Random bytes are:
//       0: 131
//       1: 96
//       2: 226
//       3: 213
//       4: 176
```

```
//       5: 208
//       6: 99
//       7: 89
//       8: 226
//       9: 194
```

Remarks

Each element of the array of bytes is set to a random number greater than or equal to 0, and less than or equal to MaxValue.

For example, to generate a cryptographically secured random number suitable for creating a random password, use a method such as RNGCryptoServiceProvider.GetBytes.

Notes to Inheritors

Starting with the .NET Framework version 2.0, if you derive a class from Random and override the Sample() method, the distribution provided by the derived class implementation of the Sample() method is not used in calls to the base class implementation of the NextBytes(Byte[]) method. Instead, the uniform distribution returned by the base Random class is used. This behavior improves the overall performance of the Random class. To modify this behavior to call the Sample() method in the derived class, you must also override the NextBytes(Byte[]) method.

Random.NextDouble Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a random floating-point number that is greater than or equal to 0.0, and less than 1.0.

C#

```
public virtual double NextDouble ();
```

Returns

Double

A double-precision floating point number that is greater than or equal to 0.0, and less than 1.0.

Examples

The following example uses the NextDouble method to generate sequences of random doubles.

C#

```
// Example of the Random class constructors and Random.NextDouble()
// method.
using System;
using System.Threading;

public class RandomObjectDemo
{
    // Generate random numbers from the specified Random object.
    static void RunIntNDoubleRandoms(Random randObj)
    {
        // Generate the first six random integers.
        for(int j = 0; j < 6; j++)
            Console.Write(" {0,10} ", randObj.Next());
        Console.WriteLine();
```

```
        // Generate the first six random doubles.
        for(int j = 0; j < 6; j++)
            Console.Write(" {0:F8} ", randObj.NextDouble());
        Console.WriteLine();
    }

    // Create a Random object with the specified seed.
    static void FixedSeedRandoms(int seed)
    {
        Console.WriteLine(
            "\nRandom numbers from a Random object with " +
            "seed = {0}:", seed);
        Random fixRand = new Random(seed);

        RunIntNDoubleRandoms(fixRand);
    }

    // Create a random object with a timer-generated seed.
    static void AutoSeedRandoms()
    {
        // Wait to allow the timer to advance.
        Thread.Sleep(1);

        Console.WriteLine(
            "\nRandom numbers from a Random object " +
            "with an auto-generated seed:");
        Random autoRand = new Random();

        RunIntNDoubleRandoms(autoRand);
    }

    static void Main()
    {
        Console.WriteLine(
            "This example of the Random class constructors and " +
            "Random.NextDouble() \n" +
            "generates the following output.\n");
        Console.WriteLine(
            "Create Random objects, and then generate and " +
            "display six integers and \nsix doubles from each.");

        FixedSeedRandoms(123);
        FixedSeedRandoms(123);

        FixedSeedRandoms(456);
        FixedSeedRandoms(456);

        AutoSeedRandoms();
        AutoSeedRandoms();
        AutoSeedRandoms();
    }
}

/*
This example of the Random class constructors and Random.NextDouble()
```

```
generates an output similar to the following:

Create Random objects, and then generate and display six integers and
six doubles from each.

Random numbers from a Random object with seed = 123:
 2114319875  1949518561  1596751841  1742987178  1586516133   103755708
 0.01700087  0.14935942  0.19470390  0.63008947  0.90976122  0.49519146

Random numbers from a Random object with seed = 123:
 2114319875  1949518561  1596751841  1742987178  1586516133   103755708

*/
```

The following example calls the NextDouble method to generate 100 random numbers and displays their frequency distribution.

C#

```
int[] frequency = new int[10];
double number;
Random rnd = new Random();

for (int ctr = 0; ctr <= 99; ctr++) {
   number = rnd.NextDouble();
   frequency[(int) Math.Floor(number*10)] ++;
}
Console.WriteLine("Distribution of Random Numbers:");
for (int ctr = frequency.GetLowerBound(0); ctr <=
frequency.GetUpperBound(0); ctr++)
   Console.WriteLine("0.{0}0-0.{0}9       {1}", ctr, frequency[ctr]);

// The following example displays output similar to the following:
```

```
//       Distribution of Random Numbers:
//       0.00-0.09       16
//       0.10-0.19       8
//       0.20-0.29       8
//       0.30-0.39       11
//       0.40-0.49       9
//       0.50-0.59       6
//       0.60-0.69       13
//       0.70-0.79       6
//       0.80-0.89       9
//       0.90-0.99       14
```

Remarks

The actual upper bound of the random number returned by this method is 0.99999999999999978.

To retrieve random floating-point values within a range other than 0.0 and 1.0, see the "Retrieve floating-point values in a specified range" section of the Random class topic.

This method is the public version of the protected method, Sample.

Applies to

Random.NextInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

NextInt64()	Returns a non-negative random integer.
NextInt64(Int64)	Returns a non-negative random integer that is less than the specified maximum.
NextInt64(Int64, Int64)	Returns a random integer that is within a specified range.

NextInt64()

Returns a non-negative random integer.

C#

```
public virtual long NextInt64 ();
```

Returns

Int64

A 64-bit signed integer that is greater than or equal to 0 and less than Int64.MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

NextInt64(Int64)

Returns a non-negative random integer that is less than the specified maximum.

```
C#
public virtual long NextInt64 (long maxValue);
```

Parameters

`maxValue` Int64

The exclusive upper bound of the random number to be generated. `maxValue` must be greater than or equal to 0.

Returns

Int64

A 64-bit signed integer that is greater than or equal to 0, and less than `maxValue`; that is, the range of return values ordinarily includes 0 but not `maxValue`. However, if `maxValue` equals 0, `maxValue` is returned.

Exceptions

ArgumentOutOfRangeException

`maxValue` is less than 0.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

NextInt64(Int64, Int64)

Returns a random integer that is within a specified range.

```
C#
public virtual long NextInt64 (long minValue, long maxValue);
```

Parameters

`minValue` Int64

The inclusive lower bound of the random number returned.

`maxValue` Int64

The exclusive upper bound of the random number returned. `maxValue` must be greater than or equal to `minValue`.

Returns

Int64

A 64-bit signed integer greater than or equal to `minValue` and less than `maxValue`; that is, the range of return values includes `minValue` but not `maxValue`. If minValue equals `maxValue`, `minValue` is returned.

Exceptions

ArgumentOutOfRangeException

`minValue` is greater than `maxValue`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Random.NextSingle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a random floating-point number that is greater than or equal to 0.0, and less than 1.0.

C#

```
public virtual float NextSingle ();
```

Returns

Single

A single-precision floating point number that is greater than or equal to 0.0, and less than 1.0.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Random.Sample Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a random floating-point number between 0.0 and 1.0.

C#

```
protected virtual double Sample ();
```

Returns

Double

A double-precision floating point number that is greater than or equal to 0.0, and less than 1.0.

Examples

The following example derives a class from Random and overrides the Sample method to generate a distribution of random numbers. This distribution is different than the uniform distribution generated by the Sample method of the base class.

C#

```
using System;

// This derived class converts the uniformly distributed random
// numbers generated by base.Sample() to another distribution.
public class RandomProportional : Random
{
    // The Sample method generates a distribution proportional to the value
    // of the random numbers, in the range [0.0, 1.0].
    protected override double Sample()
    {
        return Math.Sqrt(base.Sample());
    }

    public override int Next()
    {
```

```
        return (int) (Sample() * int.MaxValue);
    }
}

public class RandomSampleDemo
{
    static void Main()
    {
        const int rows = 4, cols = 6;
        const int runCount = 1000000;
        const int distGroupCount = 10;
        const double intGroupSize =
            ((double)int.MaxValue + 1.0) / (double)distGroupCount;

        RandomProportional randObj = new RandomProportional();

        int[ ]      intCounts = new int[ distGroupCount ];
        int[ ]      realCounts = new int[ distGroupCount ];

        Console.WriteLine(
            "\nThe derived RandomProportional class overrides " +
            "the Sample method to \ngenerate random numbers " +
            "in the range [0.0, 1.0]. The distribution \nof " +
            "the numbers is proportional to their numeric values. " +
            "For example, \nnumbers are generated in the " +
            "vicinity of 0.75 with three times the \n" +
            "probability of those generated near 0.25.");
        Console.WriteLine(
            "\nRandom doubles generated with the NextDouble() " +
            "method:\n");

        // Generate and display [rows * cols] random doubles.
        for (int i = 0; i < rows; i++)
        {
            for (int j = 0; j < cols; j++)
                Console.Write("{0,12:F8}", randObj.NextDouble());
            Console.WriteLine();
        }

        Console.WriteLine(
            "\nRandom integers generated with the Next() " +
            "method:\n");

        // Generate and display [rows * cols] random integers.
        for (int i = 0; i < rows; i++)
        {
            for (int j = 0; j < cols; j++)
                Console.Write("{0,12}", randObj.Next());
            Console.WriteLine();
        }

        Console.WriteLine(
            "\nTo demonstrate the proportional distribution, " +
            "{0:N0} random \nintegers and doubles are grouped " +
            "into {1} equal value ranges. This \n" +
```

```
            "is the count of values in each range:\n",
            runCount, distGroupCount);
        Console.WriteLine(
            "{0,21}{1,10}{2,20}{3,10}", "Integer Range",
            "Count", "Double Range", "Count");
        Console.WriteLine(
            "{0,21}{1,10}{2,20}{3,10}", "-------------",
            "-----", "------------", "-----");

        // Generate random integers and doubles, and then count
        // them by group.
        for (int i = 0; i < runCount; i++)
        {
            intCounts[ (int)((double)randObj.Next() /
                intGroupSize) ]++;
            realCounts[ (int)(randObj.NextDouble() *
                (double)distGroupCount) ]++;
        }

        // Display the count of each group.
        for (int i = 0; i < distGroupCount; i++)
            Console.WriteLine(
                "{0,10}-{1,10}{2,10:N0}{3,12:N5}-{4,7:N5}{5,10:N0}",
                (int)((double)i * intGroupSize),
                (int)((double)(i + 1) * intGroupSize - 1.0),
                intCounts[ i ],
                ((double)i) / (double)distGroupCount,
                ((double)(i + 1)) / (double)distGroupCount,
                realCounts[ i ]);
    }
}

/*
This example of Random.Sample() displays output similar to the following:

   The derived RandomProportional class overrides the Sample method to
   generate random numbers in the range [0.0, 1.0). The distribution
   of the numbers is proportional to the number values. For example,
   numbers are generated in the vicinity of 0.75 with three times the
   probability of those generated near 0.25.

   Random doubles generated with the NextDouble() method:

     0.59455719  0.17589882  0.83134398  0.35795862  0.91467727  0.54022658
     0.93716947  0.54817519  0.94685080  0.93705478  0.18582318  0.71272428
     0.77708682  0.95386216  0.70412393  0.86099417  0.08275804  0.79108316
     0.71019941  0.84205103  0.41685082  0.58186880  0.89492302  0.73067715

   Random integers generated with the Next() method:

     1570755704  1279192549  1747627711  1705700211  1372759203  1849655615
     2046235980  1210843924  1554274149  1307936697  1480207570  1057595022
      337854215   844109928  2028310798  1386669369  2073517658  1291729809
     1537248240  1454198019  1934863511  1640004334  2032620207   534654791
```

```
    To demonstrate the proportional distribution, 1,000,000 random
    integers and doubles are grouped into 10 equal value ranges. This
    is the count of values in each range:

            Integer Range     Count        Double Range     Count
            -------------     -----        ------------     -----
             0- 214748363    10,079     0.00000-0.10000    10,148
     214748364- 429496728    29,835     0.10000-0.20000    29,849
     429496729- 644245093    49,753     0.20000-0.30000    49,948
     644245094- 858993458    70,325     0.30000-0.40000    69,656
     858993459-1073741823    89,906     0.40000-0.50000    90,337
    1073741824-1288490187   109,868     0.50000-0.60000   110,225
    1288490188-1503238552   130,388     0.60000-0.70000   129,986
    1503238553-1717986917   149,231     0.70000-0.80000   150,428
    1717986918-1932735282   170,234     0.80000-0.90000   169,610
    1932735283-2147483647   190,381     0.90000-1.00000   189,813
*/
```

Remarks

To produce a different random distribution or a different random number generator principle, derive a class from the Random class and override the Sample method.

> ⓘ **Important**
>
> The **Sample** method is `protected`, which means that it is accessible only within the **Random** class and its derived classes. To generate a random number between 0 and 1 from a **Random** instance, call the **NextDouble** method.

Notes to Inheritors

Starting with the .NET Framework version 2.0, if you derive a class from Random and override the Sample() method, the distribution provided by the derived class implementation of the Sample() method is not used in calls to the base class implementation of the following methods:

- The NextBytes(Byte[]) method.
- The Next() method.
- The Next(Int32, Int32) method, if (`maxValue` - `minValue`) is greater than Int32.MaxValue.

Instead, the uniform distribution provided by the base Random class is used. This behavior improves the overall performance of the Random class. To modify this behavior to call the implementation of the Sample() method in the derived class, you must also override the behavior of these three members. The example provides an illustration.

Random.Shuffle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Shuffle<T>(Span<T>)	Performs an in-place shuffle of a span.
Shuffle<T>(T[])	Performs an in-place shuffle of an array.

Shuffle<T>(Span<T>)

Performs an in-place shuffle of a span.

```
C#
public void Shuffle<T> (Span<T> values);
```

Type Parameters

T

The type of span.

Parameters

values Span<T>

The span to shuffle.

Remarks

This method uses Next(Int32, Int32) to choose values for shuffling. This method is an O(n) operation.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Shuffle<T>(T[])

Performs an in-place shuffle of an array.

```
C#
public void Shuffle<T> (T[] values);
```

Type Parameters

`T`

The type of array.

Parameters

`values` T[]

The array to shuffle.

Exceptions

ArgumentNullException

`values` is `null`.

Remarks

This method uses Next(Int32, Int32) to choose values for shuffling. This method is an O(n) operation.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Range Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a range that has start and end indexes.

C#

```
public readonly struct Range : IEquatable<Range>
```

Inheritance Object → ValueType → Range

Implements IEquatable<Range>

Remarks

`Range` is used by the C# compiler to support the range syntax:

C#

```
int[] someArray = new int[5] { 1, 2, 3, 4, 5 };
int[] subArray1 = someArray[0..2];               // { 1, 2 }
int[] subArray2 = someArray[1..^0];              // { 2, 3, 4, 5 }
```

Constructors

Expand table

Range(Index, Index)	Instantiates a new Range instance with the specified starting and ending indexes.

Properties

Expand table

All	Gets a Range object that starts from the first element to the end.
End	Gets an Index that represents the exclusive end index of the range.
Start	Gets the inclusive start index of the Range.

Methods

Expand table

EndAt(Index)	Creates a Range object starting from the first element in the collection to a specified end index.
Equals(Object)	Returns a value that indicates whether the current instance is equal to a specified object.
Equals(Range)	Returns a value that indicates whether the current instance is equal to another Range object.
GetHashCode()	Returns the hash code for this instance.
GetOffsetAndLength(Int32)	Calculates the start offset and length of the range object using a collection length.
StartAt(Index)	Returns a new Range instance starting from a specified start index to the end of the collection.
ToString()	Returns the string representation of the current Range object.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Range.All Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a Range object that starts from the first element to the end.

C#

```
public static Range All { get; }
```

Property Value

Range

A range from the start to the end.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.End Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an Index that represents the exclusive end index of the range.

C#

```
public Index End { get; }
```

Property Value

Index

The end index of the range.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.Start Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the inclusive start index of the Range.

C#

```
public Index Start { get; }
```

Property Value

Index

The inclusive start index of the range.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.EndAt(Index) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a Range object starting from the first element in the collection to a specified end index.

```
C#
public static Range EndAt (Index end);
```

Parameters

end Index

The position of the last element up to which the Range object will be created.

Returns

Range

A range that starts from the first element to `end`.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current instance is equal to a specified object.
Equals(Range)	Returns a value that indicates whether the current instance is equal to another Range object.

Equals(Object)

Returns a value that indicates whether the current instance is equal to a specified object.

```
C#
public override bool Equals (object? value);
```

Parameters

`value` Object

An object to compare with this Range object.

Returns

Boolean

`true` if `value` is of type Range and is equal to the current instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Equals(Range)

Returns a value that indicates whether the current instance is equal to another Range object.

```
C#
public bool Equals (Range other);
```

Parameters

`other` Range

A Range object to compare with this Range object.

Returns

Boolean

`true` if the current instance is equal to `other`; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.GetOffsetAndLength(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the start offset and length of the range object using a collection length.

```
C#
public (int Offset, int Length) GetOffsetAndLength (int length);
```

Parameters

`length` Int32

A positive integer that represents the length of the collection that the range will be used with.

Returns

ValueTuple<Int32,Int32>

The start offset and length of the range.

Exceptions

ArgumentOutOfRangeException

`length` is outside the bounds of the current range.

Remarks

For performance reasons, this method does't validate `length` to ensure that it is not negative. It does ensure that `length` is within the current `Range` instance.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Range.StartAt(Index) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new Range instance starting from a specified start index to the end of the collection.

```
C#
public static Range StartAt (Index start);
```

Parameters

`start` Index

The position of the first element from which the Range will be created.

Returns

Range

A range from `start` to the end of the collection.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Range.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of the current Range object.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the range.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

RankException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an array with the wrong number of dimensions is passed to a method.

C#

```
public class RankException : SystemException
```

Inheritance Object → Exception → SystemException → RankException

Remarks

RankException uses the HRESULT COR_E_RANK, that has the value 0x80131517.

For a list of initial property values for an instance of RankException, see the RankException constructors.

Constructors

Expand table

RankException()	Initializes a new instance of the RankException class.
RankException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the RankException class with serialized data.
RankException(String)	Initializes a new instance of the RankException class with a specified error message.
RankException(String, Exception)	Initializes a new instance of the RankException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.**

	When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

RankException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the RankException class.

Overloads

Expand table

RankException()	Initializes a new instance of the RankException class.
RankException(String)	Initializes a new instance of the RankException class with a specified error message.
RankException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the RankException class with serialized data.
RankException(String, Exception)	Initializes a new instance of the RankException class with a specified error message and a reference to the inner exception that is the cause of this exception.

RankException()

Initializes a new instance of the RankException class.

C#

```
public RankException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The two arrays must have the

same number of dimensions." This message takes into account the current system culture.

The following table shows the initial property values for an instance of RankException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

RankException(String)

Initializes a new instance of the RankException class with a specified error message.

C#

```
public RankException (string? message);
```

Parameters

`message` String

A String that describes the error.

Remarks

The content of the `message` parameter should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of RankException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

RankException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the RankException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected RankException (System.Runtime.Serialization.SerializationInfo
info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

RankException(String, Exception)

Initializes a new instance of the RankException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public RankException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of RankException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

See also

- Exception
- Handling and Throwing Exceptions

Applies to

ReadOnlyMemory<T> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a contiguous region of memory, similar to ReadOnlySpan<T>. Unlike ReadOnlySpan<T>, it is not a byref-like type.

C#

```
public readonly struct ReadOnlyMemory<T> : IEquatable<ReadOnlyMemory<T>>
```

Type Parameters

T

The object type from which the contiguous region of memory will be read.

Inheritance Object → ValueType → ReadOnlyMemory<T>

Implements IEquatable<ReadOnlyMemory<T>>

Constructors

Expand table

ReadOnlyMemory<T>(T[])	Creates a new memory region over the entirety of the target array.
ReadOnlyMemory<T>(T[], Int32, Int32)	Creates a new memory region over the portion of the target array beginning at a specified position and including a specified number of elements.

Properties

Expand table

Empty	Gets an empty ReadOnlyMemory<T>.
IsEmpty	Gets a value that indicates whether this read-only memory region is empty.
Length	Gets the number of items in the memory region.
Span	Gets a span from the memory region.

Methods

Expand table

CopyTo(Memory<T>)	Copies the contents of the read-only memory region into a destination memory region.
Equals(Object)	Determines whether the specified object is equal to the current read-only memory region.
Equals(ReadOnlyMemory<T>)	Determines whether the current instance and a specified ReadOnlyMemory<T> objects are equal.
GetHashCode()	Returns the hash code for this ReadOnlyMemory<T>.
Pin()	Creates a handle for the memory.
Slice(Int32)	Forms a slice out of the given memory region, beginning at a specified position and continuing to its end.
Slice(Int32, Int32)	Forms a slice out of the given memory region starting at `start` position for `length` elements.
ToArray()	Copies the contents from the memory region into a new array.
ToString()	Returns the string representation of this read-only memory instance.
TryCopyTo(Memory<T>)	Tries to copy the contents of the readonly-only memory into the destination and returns a value that indicates whether the copy operation succeeded.

Operators

Expand table

Implicit(ArraySegment<T> to ReadOnlyMemory<T>)	Defines an implicit conversion of a ArraySegment<T> to a ReadOnlyMemory<T>.

Implicit(T[] to ReadOnlyMemory<T>)	Defines an implicit conversion of an array to a ReadOnlyMemory<T>.

Extension Methods

Expand table

Trim<T>(ReadOnlyMemory<T>, T)	Removes all leading and trailing occurrences of a specified element from a read-only memory region.
Trim<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.
TrimEnd<T>(ReadOnlyMemory<T>, T)	Removes all trailing occurrences of a specified element from a read-only memory region.
TrimEnd<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only memory region.
TrimStart<T>(ReadOnlyMemory<T>, T)	Removes all leading occurrences of a specified element from a memory region.
TrimStart<T>(ReadOnlyMemory<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from a memory region.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlyMemory<T> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ReadOnlyMemory<T>(T[])	Creates a new memory region over the entirety of the target array.
ReadOnlyMemory<T>(T[], Int32, Int32)	Creates a new memory region over the portion of the target array beginning at a specified position and including a specified number of elements.

ReadOnlyMemory<T>(T[])

Creates a new memory region over the entirety of the target array.

C#

```
public ReadOnlyMemory (T[]? array);
```

Parameters

array T[]

The target array.

Exceptions

ArrayTypeMismatchException

`array` is covariant, and the type of array is not exactly `T[]`.

Remarks

Returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlyMemory<T>(T[], Int32, Int32)

Creates a new memory region over the portion of the target array beginning at a specified position and including a specified number of elements.

C#

```
public ReadOnlyMemory (T[]? array, int start, int length);
```

Parameters

`array` T[]

The target array.

`start` Int32

The index at which to begin the memory region.

`length` Int32

The number of items in the memory region.

Exceptions

ArrayTypeMismatchException

`array` is covariant, and the type of array is not exactly `T[]`.

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` identify a position outside the range of the array.

Remarks

Returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

ReadOnlyMemory<T>.IsEmpty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether this read-only memory region is empty.

C#

```
public bool IsEmpty { get; }
```

Property Value

Boolean

`true` if the read-only memory region is empty (that is, its Length is 0); otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.CopyTo(Memory<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of the read-only memory region into a destination memory region.

```
C#
public void CopyTo (Memory<T> destination);
```

Parameters

`destination` Memory<T>

The memory region to copy items into.

Exceptions

ArgumentException

`destination` is smaller than the source memory region.

Remarks

If the source and `destination` overlap, this method behaves as if the original values are in a temporary location before the destination is overwritten.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Object)	Determines whether the specified object is equal to the current read-only memory region.
Equals(ReadOnlyMemory<T>)	Determines whether the current instance and a specified ReadOnlyMemory<T> objects are equal.

Equals(Object)

Determines whether the specified object is equal to the current read-only memory region.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare.

Returns

Boolean

`true` if the current instance and `obj` are equal; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Equals(ReadOnlyMemory<T>)

Determines whether the current instance and a specified ReadOnlyMemory<T> objects are equal.

C#

```
public bool Equals (ReadOnlyMemory<T> other);
```

Parameters

`other` ReadOnlyMemory<T>

The read-only memory to compare.

Returns

Boolean

`true` if the current instance and `other` are equal; otherwise, `false`.

Implements

Equals(T)

Remarks

[!IMPORTANT]

Two ReadOnlyMemory<T> objects are equal if the memory regions point to the same array and have the same length. The method does not check to see if the contents are equal.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlyMemory<T>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this ReadOnlyMemory<T>.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.Pin Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a handle for the memory.

C#

```
public System.Buffers.MemoryHandle Pin ();
```

Returns

MemoryHandle

A handle for the memory.

Exceptions

ArgumentException

An instance with nonprimitive (non-blittable) members cannot be pinned.

Remarks

> **Important**
>
> The garbage collector will not move the memory until the returned **MemoryHandle** is disposed, which enables taking and using the memory's address.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.Slice Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Slice(Int32)	Forms a slice out of the given memory region, beginning at a specified position and continuing to its end.
Slice(Int32, Int32)	Forms a slice out of the given memory region starting at `start` position for `length` elements.

Slice(Int32)

Forms a slice out of the given memory region, beginning at a specified position and continuing to its end.

C#

```
public ReadOnlyMemory<T> Slice (int start);
```

Parameters

start Int32

The index at which to begin this slice.

Returns

ReadOnlyMemory<T>

A read-only memory region representing the desired slice.

Exceptions

ArgumentOutOfRangeException

`start` is less than 0 or greater than Length.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Slice(Int32, Int32)

Forms a slice out of the given memory region starting at `start` position for `length` elements.

```
C#

public ReadOnlyMemory<T> Slice (int start, int length);
```

Parameters

`start` Int32

The index at which to begin this slice.

`length` Int32

The desired length for the slice.

Returns

ReadOnlyMemory<T>

A read-only memory region representing the desired slice.

Exceptions

ArgumentOutOfRangeException

`start`, `length`, or `start` + `length` are outside the range of the current instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlyMemory<T>.ToArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents from the memory region into a new array.

```
C#
public T[] ToArray ();
```

Returns

T[]

An array.

Remarks

`ToArray` allocates on the heap and so should generally be avoided. However, it is sometimes necessary to bridge the gap with APIs written in terms of arrays.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of this read-only memory instance.

C#

```
public override string ToString ();
```

Returns

String

For ReadOnlyMemory<T> with char elements, returns an instance of string that represents the characters pointed to by the memory. Otherwise, returns a String with the name of the type and the number of elements.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.TryCopyTo(Memory<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to copy the contents of the readonly-only memory into the destination and returns a value that indicates whether the copy operation succeeded.

```
C#
public bool TryCopyTo (Memory<T> destination);
```

Parameters

`destination` Memory<T>

The memory region to copy items into.

Returns

Boolean

`true` if the copy operation succeeded. `false` if `destination` is smaller than the current instance, and no data is written to `destination`.

Remarks

If the source and `destination` overlap, this method behaves as if the original values are in a temporary location before the destination is overwritten.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlyMemory<T>.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(ArraySegment<T> to ReadOnlyMemory<T>)	Defines an implicit conversion of a ArraySegment<T> to a ReadOnlyMemory<T>.
Implicit(T[] to ReadOnlyMemory<T>)	Defines an implicit conversion of an array to a ReadOnlyMemory<T>.

Implicit(ArraySegment<T> to ReadOnlyMemory<T>)

Defines an implicit conversion of a ArraySegment<T> to a ReadOnlyMemory<T>.

C#

```
public static implicit operator ReadOnlyMemory<T> (ArraySegment<T>
segment);
```

Parameters

`segment` ArraySegment<T>

The array segment to convert.

Returns

ReadOnlyMemory<T>

A read-only memory representation of the array segment.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Implicit(T[] to ReadOnlyMemory<T>)

Defines an implicit conversion of an array to a ReadOnlyMemory<T>.

C#

```
public static implicit operator ReadOnlyMemory<T> (T[]? array);
```

Parameters

`array` T[]

An array of type T to convert.

Returns

ReadOnlyMemory<T>

The read-only memory representation of the array of type T.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ReadOnlySpan<T>.Enumerator Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides an enumerator for the elements of a ReadOnlySpan<T>.

```
C#
public ref struct ReadOnlySpan<T>.Enumerator
```

Type Parameters

T

Inheritance Object → ValueType → ReadOnlySpan<T>.Enumerator

Remarks

The C# foreach of the C# language and the For Each...Next construct in Visual Basic hides the complexity of enumerators. Instead of directly manipulating the enumerator, using `foreach` or `For Each...Next` is recommended.

Initially, the enumerator is positioned before the first element in the ReadOnlySpan<T>. At this position, Current is undefined. You must call MoveNext to advance the enumerator to the first item in the ReadOnlySpan<T> before reading the value of Current.

Current returns the same value until MoveNext is called. MoveNext sets Current to the next item in the ReadOnlySpan<T>.

If MoveNext passes the end of the ReadOnlySpan<T>, MoveNext returns `false`. When the enumerator is at this state, subsequent calls to MoveNext also return `false` and Current is undefined. You cannot set Current to the first item in the ReadOnlySpan<T> again; you must create a new enumerator instance instead.

Though the ReadOnlySpan<T> is allocated on the stack, the underlying data on which the ReadOnlySpan<T> points to, may not be. Therefore, enumerating through a ReadOnlySpan<T> is intrinsically not a thread-safe procedure. To guarantee thread safety during enumeration, you must implement your own synchronization.

Unlike some other enumerator structures in .NET, the ReadOnlySpan<T>.Enumerator:

- Does not implement the IEnumerator or IEnumerator<T> interface. This is because ReadOnlySpan<T>.Enumerator is a ref struct and cannot be boxed.
- Does not include a `Reset` method, which can set the enumerator to its initial position before the first element in the span. (The IEnumerator.Reset() method must be implemented as part of the interface, but most implementors either throw an exception or provide no implementation.)

Properties

Expand table

Current	Gets a reference to the item at the current position of the enumerator.

Methods

Expand table

MoveNext()	Advances the enumerator to the next item of the ReadOnlySpan<T>.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Enumerator.Current Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a reference to the item at the current position of the enumerator.

```
C#
public ref readonly T Current { get; }
```

Property Value

T

The element in the ReadOnlySpan<T> at the current position of the enumerator.

Remarks

`Current` is undefined under either of the following conditions:

- Immediately after the enumerator is created, the enumerator is positioned before the first element in the span. MoveNext must be called to advance the enumerator to the first element of the span before reading the value of `Current`.
- The last call to MoveNext returned `false`, which indicates the end of the span.

`Current` returns the same value until MoveNext is called. MoveNext sets `Current` to the next item in the span.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

ReadOnlySpan<T>.Enumerator.MoveNext Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Advances the enumerator to the next item of the ReadOnlySpan<T>.

```
C#
public bool MoveNext ();
```

Returns

Boolean

`true` if the enumerator successfully advanced to the next item; `false` if the end of the span has been passed.

Remarks

After an enumerator is created, it is positioned before the first element in the span, and the first call to `MoveNext` advances the enumerator to the first item in the span.

If `MoveNext` passes the end of the span, `MoveNext` returns `false`. When the enumerator is at this state, subsequent calls to `MoveNext` also return `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a type-safe and memory-safe read-only representation of a contiguous region of arbitrary memory.

C#

```
[System.Runtime.InteropServices.Marshalling.NativeMarshalling(typeof(System.
Runtime.InteropServices.Marshalling.ReadOnlySpanMarshaller<,>))]
public readonly ref struct ReadOnlySpan<T>
```

Type Parameters

T

The type of items in the ReadOnlySpan<T>.

Inheritance Object → ValueType → ReadOnlySpan<T>

Attributes NativeMarshallingAttribute

Remarks

`ReadOnlySpan<T>` is a ref struct that is allocated on the stack and can never escape to the managed heap. Ref struct types have a number of restrictions to ensure that they cannot be promoted to the managed heap, including that they can't be boxed, captured in lambda expressions, assigned to variables of type Object, assigned to `dynamic` variables, and they cannot implement any interface type.

A `ReadOnlySpan<T>` instance is often used to reference the elements of an array or a portion of an array. Unlike an array, however, a `ReadOnlySpan<T>` instance can point to managed memory, native memory, or memory managed on the stack.

Constructors

Expand table

ReadOnlySpan<T>(T)	Creates a new ReadOnlySpan<T> of length 1 around the specified reference.
ReadOnlySpan<T>(T[])	Creates a new ReadOnlySpan<T> over the entirety of a specified array.
ReadOnlySpan<T>(T[], Int32, Int32)	Creates a new ReadOnlySpan<T> that includes a specified number of elements of an array starting at a specified index.
ReadOnlySpan<T>(Void*, Int32)	Creates a new ReadOnlySpan<T> from a specified number of `T` elements starting at a specified memory address.

Properties

Expand table

Empty	Returns an empty ReadOnlySpan<T>.
IsEmpty	Returns a value that indicates the current read-only span is empty.
Item[Int32]	Gets an item from the read-only span at the specified zero-based index.
Length	The number of items in the read-only span.

Methods

Expand table

CopyTo(Span<T>)	Copies the contents of this ReadOnlySpan<T> into a destination Span<T>.
Equals(Object)	**Obsolete.** Not supported. Throws a NotSupportedException.
GetEnumerator()	Returns an enumerator for this ReadOnlySpan<T>.
GetHashCode()	**Obsolete.** Not supported. Throws a NotSupportedException.
GetPinnable Reference()	Returns a read-only reference to an object of type T that can be used for pinning. This method is intended to support .NET compilers and is not intended to be called by user code.

Slice(Int32)	Forms a slice out of the current read-only span that begins at a specified index.
Slice(Int32, Int32)	Forms a slice out of the current read-only span starting at a specified index for a specified length.
ToArray()	Copies the contents of this read-only span into a new array.
ToString()	Returns the string representation of this ReadOnlySpan<T>.
TryCopyTo(Span<T>)	Attempts to copy the contents of this ReadOnlySpan<T> into a Span<T> and returns a value to indicate whether or not the operation succeeded.

Operators

Expand table

Equality(ReadOnlySpan<T>, ReadOnlySpan<T>)	Returns a value that indicates whether two ReadOnlySpan<T> instances are equal.
Implicit(ArraySegment<T> to ReadOnlySpan<T>)	Defines an implicit conversion of an ArraySegment<T> to a ReadOnlySpan<T>.
Implicit(T[] to ReadOnlySpan<T>)	Defines an implicit conversion of an array to a ReadOnlySpan<T>.
Inequality(ReadOnlySpan<T>, ReadOnlySpan<T>)	Returns a value that indicates whether two ReadOnlySpan<T> instances are not equal.

Extension Methods

Expand table

ToImmutableArray<T>(ReadOnlySpan<T>)	Produce an immutable array of contents from specified elements.
BinarySearch<T>(ReadOnlySpan<T>, IComparable<T>)	Searches an entire sorted ReadOnlySpan<T> for a value using the specified IComparable<T> generic interface.
BinarySearch<T,TComparer>(ReadOnlySpan<T>, T, TComparer)	Searches an entire sorted ReadOnlySpan<T> for a specified value using the specified `TComparer` generic type.
BinarySearch<T,TComparable>(ReadOnlySpan<T>, TComparable)	Searches an entire sorted ReadOnlySpan<T> for a value using the specified `TComparable` generic

	type.
CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Finds the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines the length of any common prefix shared between `span` and `other`.
Contains<T>(ReadOnlySpan<T>, T)	Indicates whether a specified value is found in a read-only span. Values are compared using IEquatable{T}.Equals(T).
ContainsAny<T>(ReadOnlySpan<T>, T, T)	Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for any value other than the specified `value`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for any value other than `value0` or `value1`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for any value other than `value0`, `value1`, or `value2`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for any value other than the specified `values`.
ContainsAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
ContainsAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for any value in the range between `lowInclusive` and `highInclusive`, inclusive, and returns `true` if found. If not found, returns `false`.

Count<T>(ReadOnlySpan<T>, T)	Counts the number of times the specified `value` occurs in the `span`.
Count<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Counts the number of times `value` occurs in `span`.
EndsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether the specified sequence appears at the end of a read-only span.
IndexOf<T>(ReadOnlySpan<T>, T)	Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOfAny<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the first index of any of the specified values.
IndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for the first index of any value other than the specified `value`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value other than the specified `value0` or `value1`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.

IndexOfAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the first index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOf<T>(ReadOnlySpan<T>, T)	Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOf<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOfAny<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, T, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the last index of any of the specified values.
LastIndexOfAny<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T)	Searches for the last index of any value other than the specified `value`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value other than the specified `value0` or `value1`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, T, T, T)	Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, SearchValues<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExceptInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyInRange<T>(ReadOnlySpan<T>, T, T)	Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.

Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether two read-only sequences overlap in memory.
Overlaps<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, Int32)	Determines whether two read-only sequences overlap in memory and outputs the element offset.
Replace<T>(ReadOnlySpan<T>, Span<T>, T, T)	Copies `source` to `destination`, replacing all occurrences of `oldValue` with `newValue`.
SequenceCompareTo<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines the relative order of two read-only sequences by comparing their elements using IComparable{T}.CompareTo(T).
SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether two read-only sequences are equal by comparing the elements using IEquatable{T}.Equals(T).
SequenceEqual<T>(ReadOnlySpan<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.
StartsWith<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Determines whether a specified sequence appears at the start of a read-only span.
Trim<T>(ReadOnlySpan<T>, T)	Removes all leading and trailing occurrences of a specified element from a read-only span.
Trim<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a read-only span.
TrimEnd<T>(ReadOnlySpan<T>, T)	Removes all trailing occurrences of a specified element from a read-only span.
TrimEnd<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a read-only span.
TrimStart<T>(ReadOnlySpan<T>, T)	Removes all leading occurrences of a specified element from the span.
TrimStart<T>(ReadOnlySpan<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from the span.

Applies to

ReadOnlySpan<T> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ReadOnlySpan<T>(T)	Creates a new ReadOnlySpan<T> of length 1 around the specified reference.
ReadOnlySpan<T>(T[])	Creates a new ReadOnlySpan<T> over the entirety of a specified array.
ReadOnlySpan<T>(Void*, Int32)	Creates a new ReadOnlySpan<T> from a specified number of `T` elements starting at a specified memory address.
ReadOnlySpan<T>(T[], Int32, Int32)	Creates a new ReadOnlySpan<T> that includes a specified number of elements of an array starting at a specified index.

ReadOnlySpan<T>(T)

Creates a new ReadOnlySpan<T> of length 1 around the specified reference.

C#

```
public ReadOnlySpan (ref T reference);
```

Parameters

`reference` T

A reference to data.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ReadOnlySpan<T>(T[])

Creates a new ReadOnlySpan<T> over the entirety of a specified array.

```
C#
public ReadOnlySpan (T[]? array);
```

Parameters

`array` T[]

The array from which to create the ReadOnlySpan<T>.

Remarks

If the array is null, this constructor returns a null `ReadOnlySpan<T>`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>(Void*, Int32)

> Important
>
> This API is not CLS-compliant.

Creates a new ReadOnlySpan<T> from a specified number of `T` elements starting at a specified memory address.

```C#
[System.CLSCompliant(false)]
public ReadOnlySpan (void* pointer, int length);
```

Parameters

`pointer` Void*

A pointer to the starting address of a specified number of `T` elements in memory.

`length` Int32

The number of `T` elements to be included in the ReadOnlySpan<T>.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`T` is a reference type or contains references and therefore cannot be stored in unmanaged memory.

ArgumentOutOfRangeException

`length` is negative.

Remarks

This constructor should be used with care, since it creates arbitrarily typed `T`s from a block of memory.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>(T[], Int32, Int32)

Creates a new ReadOnlySpan<T> that includes a specified number of elements of an array starting at a specified index.

```
C#

public ReadOnlySpan (T[]? array, int start, int length);
```

Parameters

array T[]

The array from which to create the ReadOnlySpan<T>.

start Int32

The index of the first element to include.

length Int32

The number of elements to include.

Exceptions

ArgumentOutOfRangeException

`array` is `null`, but `start` or `length` is non-zero.

-or-

`start` is outside the bounds of the array.

-or-

`start` and `length` exceeds the number of elements in the array.

Remarks

This method returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

ReadOnlySpan<T>.Empty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an empty ReadOnlySpan<T>.

C#

```
public static ReadOnlySpan<T> Empty { get; }
```

Property Value

ReadOnlySpan<T>

An empty ReadOnlySpan<T>.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.IsEmpty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates the current read-only span is empty.

C#

```
public bool IsEmpty { get; }
```

Property Value

Boolean

`true` when the current span is empty; otherwise `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an item from the read-only span at the specified zero-based index.

C#

```
public ref readonly T this[int index] { get; }
```

Parameters

`index` Int32

The zero-based index of the element to get.

Property Value

T

The element from the read-only span.

Exceptions

IndexOutOfRangeException

`index` is less then zero or greater than or equal to Length.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The number of items in the read-only span.

C#

```
public int Length { get; }
```

Property Value

Int32

The number of items.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>.CopyTo(Span<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of this ReadOnlySpan<T> into a destination Span<T>.

```
C#
public void CopyTo (Span<T> destination);
```

Parameters

destination Span<T>

The span to copy items into.

Exceptions

ArgumentException

`destination` is shorter than the source ReadOnlySpan<T>.

Remarks

If the `source` and `destination` overlap, the entirety of `source` is handled as if it was copied to a temporary location before it is copied to `destination`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Equals() on ReadOnlySpan will always throw an exception. Use the equality operator instead.

Not supported. Throws a NotSupportedException.

C#

```
[System.Obsolete("Equals() on ReadOnlySpan will always throw an exception.
Use the equality operator instead.")]
public override bool Equals (object? obj);
```

Parameters

obj Object

Not supported.

Returns

Boolean

Not supported.

Attributes ObsoleteAttribute

Exceptions

NotSupportedException

Always thrown by this method.

Remarks

Not supported.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Standard	*(2.1)*

ReadOnlySpan<T>.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumerator for this ReadOnlySpan<T>.

C#

```
public ReadOnlySpan<T>.Enumerator GetEnumerator ();
```

Returns

ReadOnlySpan<T>.Enumerator

An enumerator for this read-only span.

Remarks

Instead of calling the GetEnumerator method directly, you can use the C# `foreach` statement and the Visual Basic `For Each`...`Next` construct to enumerate a ReadOnlySpan<T>.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> GetHashCode() on ReadOnlySpan will always throw an exception.

Not supported. Throws a NotSupportedException.

C#

```
[System.Obsolete("GetHashCode() on ReadOnlySpan will always throw an exception.")]
public override int GetHashCode ();
```

Returns

Int32

Not supported.

Attributes ObsoleteAttribute

Exceptions

NotSupportedException

Always thrown by this method.

Remarks

Not supported.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Standard	*(2.1)*

ReadOnlySpan<T>.GetPinnableReference Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a read-only reference to an object of type T that can be used for pinning.

This method is intended to support .NET compilers and is not intended to be called by user code.

```
C#

public ref readonly T GetPinnableReference ();
```

Returns

T

A reference to the element of the span at index 0, or `null` if the span is empty.

Examples

The following example demonstrates creating an integer array, pinning it, and writing each element to the console.

```
C#

using System;

// Note: you must compile this sample using the unsafe flag.
// From the command line, type the following: csc sample.cs /unsafe

public class Example
{
    public static unsafe void Main()
    {
        int[] array = CreateInt32Array();

        // Create a span, pin it, and print its elements.
```

```
        Span<int> span = array.AsSpan();
        fixed (int* spanPtr = span)
        {
            Console.WriteLine($"Span contains {span.Length} elements:");
            for (int i = 0; i < span.Length; i++)
            {
                Console.WriteLine(spanPtr[i]);
            }
            Console.WriteLine();
        }

        // Create a read-only span, pin it, and print its elements.
        ReadOnlySpan<int> readonlyspan = array.AsSpan();
        fixed (int* readonlyspanPtr = readonlyspan)
        {
            Console.WriteLine($"ReadOnlySpan contains {readonlyspan.Length}
elements:");
            for (int i = 0; i < readonlyspan.Length; i++)
            {
                Console.WriteLine(readonlyspanPtr[i]);
            }
            Console.WriteLine();
        }
    }

    private static int[] CreateInt32Array()
    {
        return new int[] { 100, 200, 300, 400, 500 };
    }
}

// The example displays the following output:
//       Span contains 5 elements:
//       100
//       200
//       300
//       400
//       500
//
//       ReadOnlySpan contains 5 elements:
//       100
//       200
//       300
//       400
//       500
```

Remarks

Applications should not directly call `GetPinnableReference`. Instead, callers should use their language's normal pinning syntax, such as C#'s `fixed` statement.

If pinning a `ReadOnlySpan<char>`, the resulting `char*` **is not** assumed to be null-terminated. This behavior is different from pinning a `string`, where the resulting `char*` is guaranteed to be null-terminated.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Slice Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Slice(Int32)	Forms a slice out of the current read-only span that begins at a specified index.
Slice(Int32, Int32)	Forms a slice out of the current read-only span starting at a specified index for a specified length.

Slice(Int32)

Forms a slice out of the current read-only span that begins at a specified index.

C#

```
public ReadOnlySpan<T> Slice (int start);
```

Parameters

`start` Int32

The index at which to begin the slice.

Returns

ReadOnlySpan<T>

A span that consists of all elements of the current span from `start` to the end of the span.

Exceptions

ArgumentOutOfRangeException

`start` is greater than the number of items in the read-only span.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Slice(Int32, Int32)

Forms a slice out of the current read-only span starting at a specified index for a specified length.

```
C#

public ReadOnlySpan<T> Slice (int start, int length);
```

Parameters

`start` Int32

The index at which to begin this slice.

`length` Int32

The desired length for the slice.

Returns

ReadOnlySpan<T>

A read-only span that consists of `length` elements from the current span starting at `start`.

Exceptions

ArgumentOutOfRangeException

`start` is less than zero or greater than Length.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>.ToArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of this read-only span into a new array.

C#

```
public T[] ToArray ();
```

Returns

T[]

An array containing the data in the current span.

Remarks

This method performs a heap allocation and data copy, and therefore, should be avoided if possible. It it sometimes necessary when APIs that support ReadOnlySpan<T> are not available, but APIs that work with arrays are.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of this ReadOnlySpan<T>.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this instance.

Remarks

For a `ReadOnlySpan<Char>`, the `ToString` method returns a String that contains the characters pointed to by the span. Otherwise, it returns a String with the name of the type and the number of elements that the span contains.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>.TryCopyTo(Span<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Attempts to copy the contents of this ReadOnlySpan<T> into a Span<T> and returns a value to indicate whether or not the operation succeeded.

```
C#

public bool TryCopyTo (Span<T> destination);
```

Parameters

destination Span<T>

The target of the copy operation.

Returns

Boolean

`true` if the copy operation succeeded; otherwise, `false`.

Remarks

If the `source` and `destination` overlap, the entirety of `source` is handled as if it was copied to a temporary location before it is copied to `destination`.

If the `destination` length is shorter than `source`, no items are copied and the method returns `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two ReadOnlySpan<T> instances are equal.

```
C#

public static bool operator == (ReadOnlySpan<T> left, ReadOnlySpan<T>
right);
```

Parameters

left ReadOnlySpan<T>

The first span to compare.

right ReadOnlySpan<T>

The second span to compare.

Returns

Boolean

`true` if the two ReadOnlySpan<T> instances are equal; otherwise, `false`.

Remarks

This tests if two ReadOnlySpan<T> instances point to the same starting memory location, and have the same Length values. This does not compare the contents of two ReadOnlySpan<T> instances.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

ReadOnlySpan<T>.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(ArraySegment<T> to ReadOnlySpan<T>)	Defines an implicit conversion of an ArraySegment<T> to a ReadOnlySpan<T>.
Implicit(T[] to ReadOnlySpan<T>)	Defines an implicit conversion of an array to a ReadOnlySpan<T>.

Implicit(ArraySegment<T> to ReadOnlySpan<T>)

Defines an implicit conversion of an ArraySegment<T> to a ReadOnlySpan<T>.

C#

```
public static implicit operator ReadOnlySpan<T> (ArraySegment<T>
segment);
```

Parameters

`segment` ArraySegment<T>

The array segment to be converted to a ReadOnlySpan<T>.

Returns

ReadOnlySpan<T>

A read-only span that corresponds to the array segment.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Implicit(T[] to ReadOnlySpan<T>)

Defines an implicit conversion of an array to a ReadOnlySpan<T>.

C#

```
public static implicit operator ReadOnlySpan<T> (T[]? array);
```

Parameters

`array` T[]

The array to convert to a ReadOnlySpan<T>.

Returns

ReadOnlySpan<T>

The read-only span that corresponds to `array`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

ReadOnlySpan<T>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two ReadOnlySpan<T> instances are not equal.

```
C#

public static bool operator != (ReadOnlySpan<T> left, ReadOnlySpan<T>
right);
```

Parameters

left ReadOnlySpan<T>

The first read-only span to compare.

right ReadOnlySpan<T>

The second read-only span to compare.

Returns

Boolean

`true` if the two ReadOnlySpan<T> instances are not equal; otherwise, `false`.

Remarks

Two ReadOnlySpan<T> instances are not equal if they have different lengths or if the corresponding elements of `left` and `right` point to different memory locations.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

ResolveEventArgs Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides data for loader resolution events, such as the TypeResolve, ResourceResolve, ReflectionOnlyAssemblyResolve, and AssemblyResolve events.

C#

```
public class ResolveEventArgs : EventArgs
```

Inheritance Object → EventArgs → ResolveEventArgs

Remarks

When the loader cannot resolve an assembly reference and a handler has been provided for the appropriate loader resolution event, the event is raised and the ResolveEventArgs contains information about the item to be resolved.

- The Name property contains the name of the item to be resolved.
- Beginning with the .NET Framework 4, the RequestingAssembly property contains the assembly that requested an assembly that can provide the named item. For more information, see the RequestingAssembly property.

Constructors

Expand table

ResolveEventArgs(String)	Initializes a new instance of the ResolveEventArgs class, specifying the name of the item to resolve.
ResolveEventArgs(String, Assembly)	Initializes a new instance of the ResolveEventArgs class, specifying the name of the item to resolve and the assembly whose dependency is being resolved.

Properties

Expand table

Name	Gets the name of the item to resolve.
RequestingAssembly	Gets the assembly whose dependency is being resolved.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ResolveEventArgs Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ResolveEventArgs class.

Overloads

Expand table

ResolveEventArgs(String)	Initializes a new instance of the ResolveEventArgs class, specifying the name of the item to resolve.
ResolveEventArgs(String, Assembly)	Initializes a new instance of the ResolveEventArgs class, specifying the name of the item to resolve and the assembly whose dependency is being resolved.

ResolveEventArgs(String)

Initializes a new instance of the ResolveEventArgs class, specifying the name of the item to resolve.

C#

```
public ResolveEventArgs (string name);
```

Parameters

`name` String

The name of an item to resolve.

Remarks

This constructor is typically called only by the common language runtime.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ResolveEventArgs(String, Assembly)

Initializes a new instance of the ResolveEventArgs class, specifying the name of the item to resolve and the assembly whose dependency is being resolved.

C#

```
public ResolveEventArgs (string name, System.Reflection.Assembly?
requestingAssembly);
```

Parameters

`name` String

The name of an item to resolve.

`requestingAssembly` Assembly

The assembly whose dependency is being resolved.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

ResolveEventArgs.Name Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the name of the item to resolve.

```
C#
public string Name { get; }
```

Property Value

String

The name of the item to resolve.

Remarks

For the AssemblyResolve event, Name is the assembly name before policy is applied.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ResolveEventArgs.RequestingAssembly Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the assembly whose dependency is being resolved.

C#

```
public System.Reflection.Assembly? RequestingAssembly { get; }
```

Property Value

Assembly

The assembly that requested the item specified by the Name property.

Remarks

The assembly that is returned by this property is an assembly that was unable to resolve the item specified by the Name property, because the item did not exist in that assembly, in any of its loaded dependencies, or in any dependencies the loader could find through probing.

For example, suppose the current assembly uses the Assembly.LoadFile method to load assembly A from a directory outside the probing path, in order to use class CA. Suppose further that class CA uses class CB, in assembly B, and that assembly A has a compile-time reference to assembly B, also located outside the probing path. When the current assembly attempts to instantiate CA, the loader attempts to resolve the reference to assembly B. However, because assembly A was loaded by using the Assembly.LoadFile method, the loader cannot resolve the dependency. If there is a handler for the AppDomain.AssemblyResolve event, the event is raised, and the RequestingAssembly property of the resulting ResolveEventArgs object contains assembly A, because assembly A is the assembly that is missing a dependency.

The semantics of the RequestingAssembly property vary, depending on how the requesting assembly was loaded:

- Load context: The value of the property might be `null`. The load context is load-order independent, and the identity of the requesting assembly is not necessarily meaningful. A non-null example occurs when the Type.GetType method is called and the specified type is not known to the requesting assembly or any of its dependencies.
- Load-from context: The property can be used as a probing hint, but the event handler should not get more than one request for a given assembly name.
- No context (that is, the requesting assembly was loaded by using the Assembly.LoadFile method, or as a byte stream, or in mixed mode): The handler can use the RequestingAssembly property to load different implementations of the same assembly based on the identity of the requesting assembly.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ResolveEventHandler Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a method that handles the TypeResolve, ResourceResolve, or AssemblyResolve event of an AppDomain.

```
C#

public delegate System.Reflection.Assembly? ResolveEventHandler(object?
sender, ResolveEventArgs args);
```

Parameters

sender Object

The source of the event.

args ResolveEventArgs

The event data.

Return Value

Assembly

The assembly that resolves the type, assembly, or resource; or `null` if the assembly cannot be resolved.

Remarks

If the runtime class loader cannot resolve a reference to an assembly, type, or resource, the corresponding events are raised to give the callback a chance to tell the runtime which assembly the referenced assembly, type, or resource is in. It is the responsibility of the ResolveEventHandler to return the assembly that resolves the type, assembly, or resource, or to return null if the assembly is not recognized. For more information, see Resolving Assembly Loads and the AppDomain.ResourceResolve, AppDomain.AssemblyResolve, and AppDomain.ReflectionOnlyAssemblyResolve events.

> **Important**
>
> Beginning with the .NET Framework 4, the **System.ResolveEventHandler** event is raised for all assemblies, including resource assemblies. In earlier versions, the event was not raised for resource assemblies. If the operating system is localized, the handler might be called multiple times: once for each culture in the fallback chain.

Every derived class of Delegate and MulticastDelegate has a constructor and an `Invoke` method. See the C++ code example in the description for the Delegate class.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

RuntimeArgumentHandle Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

References a variable-length argument list.

C#

```
public ref struct RuntimeArgumentHandle
```

Inheritance Object → ValueType → RuntimeArgumentHandle

Remarks

This structure has no members other than those that it inherits from the Object and ValueType classes. It exists only to support C/C++ programming language functions that take a variable number of parameters. An instance of the structure is passed to the ArgIterator constructor.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeFieldHandle Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a field using an internal metadata token.

C#

```
public struct RuntimeFieldHandle : IEquatable<RuntimeFieldHandle>,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → ValueType → RuntimeFieldHandle

Implements ISerializable , IEquatable<RuntimeFieldHandle>

Remarks

The value of an instance of the RuntimeFieldHandle structure is a handle to the field represented by the instance.

Properties

Expand table

Value	Gets a handle to the field represented by the current instance.

Methods

Expand table

Equals(Object)	Indicates whether the current instance is equal to the specified object.
Equals(RuntimeFieldHandle)	Indicates whether the current instance is equal to the

	specified RuntimeFieldHandle.
FromIntPtr(IntPtr)	Returns a new RuntimeFieldHandle object created from a handle to a RuntimeFieldInfo.
GetHashCode()	Returns the hash code for this instance.
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo with the data necessary to deserialize the field represented by the current instance.
ToIntPtr(RuntimeFieldHandle)	Returns the internal pointer representation of a RuntimeFieldHandle object.

Operators

Expand table

Equality(RuntimeFieldHandle, RuntimeFieldHandle)	Indicates whether two RuntimeFieldHandle structures are equal.
Inequality(RuntimeFieldHandle, RuntimeFieldHandle)	Indicates whether two RuntimeFieldHandle structures are not equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeFieldHandle.Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a handle to the field represented by the current instance.

C#

```
public IntPtr Value { get; }
```

Property Value

IntPtr

An IntPtr that contains the handle to the field represented by the current instance.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeFieldHandle.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether an object represents the same field as the current RuntimeFieldHandle.

Overloads

Expand table

Equals(Object)	Indicates whether the current instance is equal to the specified object.
Equals(RuntimeFieldHandle)	Indicates whether the current instance is equal to the specified RuntimeFieldHandle.

Equals(Object)

Indicates whether the current instance is equal to the specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare to the current instance.

Returns

Boolean

`true` if `obj` is a RuntimeFieldHandle and equal to the value of the current instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(RuntimeFieldHandle)

Indicates whether the current instance is equal to the specified RuntimeFieldHandle.

C#

```
public bool Equals (RuntimeFieldHandle handle);
```

Parameters

`handle` RuntimeFieldHandle

The RuntimeFieldHandle to compare to the current instance.

Returns

Boolean

`true` if the value of `handle` is equal to the value of the current instance; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

RuntimeFieldHandle.FromIntPtr(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new RuntimeFieldHandle object created from a handle to a RuntimeFieldInfo.

C#

```
public static RuntimeFieldHandle FromIntPtr (IntPtr value);
```

Parameters

`value` IntPtr

An IntPtr handle to a RuntimeFieldInfo to create a RuntimeFieldHandle object from.

Returns

RuntimeFieldHandle

A new RuntimeFieldHandle object that corresponds to the value parameter.

Applies to

Product	Versions
.NET	7, 8, 9

RuntimeFieldHandle.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer that is the hash code for this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

RuntimeFieldHandle.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo with the data necessary to deserialize the field represented by the current instance.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public void GetObjectData (System.Runtime.Serialization.SerializationInfo
info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo object to populate with serialization information.

`context` StreamingContext

(Reserved) The place to store and retrieve serialized data.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

SerializationException

The Value property of the current instance is not a valid handle.

Remarks

The `context` parameter is reserved; it does not currently participate in this operation.

For more information, see the SerializationInfo.AddValue method.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeFieldHandle.ToIntPtr(RuntimeFieldHandle) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the internal pointer representation of a RuntimeFieldHandle object.

C#

```
public static IntPtr ToIntPtr (RuntimeFieldHandle value);
```

Parameters

`value` RuntimeFieldHandle

A RuntimeFieldHandle object to retrieve an internal pointer representation from.

Returns

IntPtr

An IntPtr object that represents a RuntimeFieldHandle object.

Applies to

Product	Versions
.NET	7, 8, 9

RuntimeFieldHandle.Equality(RuntimeFieldHandle, RuntimeFieldHandle) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two RuntimeFieldHandle structures are equal.

C#

```
public static bool operator == (RuntimeFieldHandle left, RuntimeFieldHandle right);
```

Parameters

`left` RuntimeFieldHandle

The RuntimeFieldHandle to compare to `right`.

`right` RuntimeFieldHandle

The RuntimeFieldHandle to compare to `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Remarks

The equivalent method for this operator is RuntimeFieldHandle.Equals(RuntimeFieldHandle).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeFieldHandle.Inequality(RuntimeFieldHandle, RuntimeFieldHandle) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two RuntimeFieldHandle structures are not equal.

C#

```
public static bool operator != (RuntimeFieldHandle left, RuntimeFieldHandle right);
```

Parameters

`left` RuntimeFieldHandle

The RuntimeFieldHandle to compare to `right`.

`right` RuntimeFieldHandle

The RuntimeFieldHandle to compare to `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Remarks

The equivalent method for this operator is RuntimeFieldHandle.Equals(RuntimeFieldHandle).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

RuntimeMethodHandle Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

RuntimeMethodHandle is a handle to the internal metadata representation of a method.

C#

```
public struct RuntimeMethodHandle : IEquatable<RuntimeMethodHandle>,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → ValueType → RuntimeMethodHandle

Implements ISerializable , IEquatable<RuntimeMethodHandle>

Properties

Expand table

Value	Gets the value of this instance.

Methods

Expand table

Equals(Object)	Indicates whether this instance is equal to a specified object.
Equals(RuntimeMethodHandle)	Indicates whether this instance is equal to a specified RuntimeMethodHandle.
FromIntPtr(IntPtr)	Returns a new RuntimeMethodHandle object created from a handle to a RuntimeMethodInfo.
GetFunctionPointer()	Obtains a pointer to the method represented by this instance.

GetHashCode()	Returns the hash code for this instance.
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo with the data necessary to deserialize the field represented by this instance.
ToIntPtr(RuntimeMethodHandle)	Returns the internal pointer representation of a RuntimeMethodHandle object.

RuntimeMethodHandle.FromIntPtr(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new RuntimeMethodHandle object created from a handle to a RuntimeMethodInfo.

C#

```
public static RuntimeMethodHandle FromIntPtr (IntPtr value);
```

Parameters

`value` IntPtr

An IntPtr handle to a RuntimeMethodInfo to create a RuntimeMethodHandle object from.

Returns

RuntimeMethodHandle

A new RuntimeMethodHandle object that corresponds to the value parameter.

Applies to

Product	Versions
.NET	7, 8, 9

RuntimeMethodHandle.GetFunctionPointer Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Obtains a pointer to the method represented by this instance.

```
C#
public IntPtr GetFunctionPointer ();
```

Returns

IntPtr

A pointer to the method represented by this instance.

Exceptions

SecurityException

The caller does not have the necessary permission to perform this operation.

Remarks

If the method has the System.Runtime.InteropServices.UnmanagedCallersOnlyAttribute attribute, then the returned value is an unmanaged function pointer with the same calling convention as specified in the attribute. If the method this handle represents is static, then the returned value can be cast to a C# managed function pointer type with the same signature. For instance method handles, the value is not easily usable from user code and is meant exclusively for usage within the runtime.

For methods that don't have the System.Runtime.InteropServices.UnmanagedCallersOnlyAttribute, use Marshal.GetFunctionPointerForDelegate to get a function pointer that can be passed to native code.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

RuntimeMethodHandle.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

RuntimeMethodHandle.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo with the data necessary to deserialize the field represented by this instance.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public void GetObjectData (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to populate with serialization information.

`context` StreamingContext

(Reserved) The place to store and retrieve serialized data.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

SerializationException

Value is invalid.

Remarks

The `context` parameter is reserved; it does not currently participate in this operation.

For more information, see the SerializationInfo.AddValue method.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeMethodHandle.ToIntPtr(RuntimeMethodHandle) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the internal pointer representation of a RuntimeMethodHandle object.

C#

```
public static IntPtr ToIntPtr (RuntimeMethodHandle value);
```

Parameters

`value` RuntimeMethodHandle

A RuntimeMethodHandle object to retrieve an internal pointer representation from.

Returns

IntPtr

An IntPtr object that represents a RuntimeMethodHandle object.

Applies to

Product	Versions
.NET	7, 8, 9

RuntimeMethodHandle.Equality(RuntimeMethodHandle, RuntimeMethodHandle) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two instances of RuntimeMethodHandle are equal.

C#

```
public static bool operator == (RuntimeMethodHandle left,
RuntimeMethodHandle right);
```

Parameters

`left` RuntimeMethodHandle

A RuntimeMethodHandle to compare to `right`.

`right` RuntimeMethodHandle

A RuntimeMethodHandle to compare to `left`.

Returns

Boolean

`true` if the value of `left` is equal to the value of `right`; otherwise, `false`.

Remarks

The equivalent method for this operator is RuntimeMethodHandle.Equals(RuntimeMethodHandle).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

RuntimeMethodHandle.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two instances of RuntimeMethodHandle are not equal.

C#

```
public static bool operator != (RuntimeMethodHandle left,
RuntimeMethodHandle right);
```

Parameters

`left` RuntimeMethodHandle

A RuntimeMethodHandle to compare to `right`.

`right` RuntimeMethodHandle

A RuntimeMethodHandle to compare to `left`.

Returns

Boolean

`true` if the value of `left` is unequal to the value of `right`; otherwise, `false`.

Remarks

The equivalent method for this operator is RuntimeMethodHandle.Equals(RuntimeMethodHandle).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeTypeHandle Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a type using an internal metadata token.

C#

```
public struct RuntimeTypeHandle : IEquatable<RuntimeTypeHandle>,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → ValueType → RuntimeTypeHandle

Implements ISerializable , IEquatable<RuntimeTypeHandle>

Examples

The following example demonstrates how to obtain a RuntimeTypeHandle from a type or from an object, and how to turn the handle back into a type.

C#

```
using System;
using System.Reflection;

public class MyClass1
{
    private int x=0;
    public int MyMethod()
    {
        return x;
    }
}

public class MyClass2
{
    public static void Main()
    {
        MyClass1 myClass1 = new MyClass1();
```

```
        // Get the RuntimeTypeHandle from an object.
        RuntimeTypeHandle myRTHFromObject = Type.GetTypeHandle(myClass1);
        // Get the RuntimeTypeHandle from a type.
        RuntimeTypeHandle myRTHFromType = typeof(MyClass1).TypeHandle;

        Console.WriteLine("\nmyRTHFromObject.Value:  {0}",
myRTHFromObject.Value);
        Console.WriteLine("myRTHFromObject.GetType():  {0}",
myRTHFromObject.GetType());
        Console.WriteLine("Get the type back from the handle...");
        Console.WriteLine("Type.GetTypeFromHandle(myRTHFromObject):  {0}",
            Type.GetTypeFromHandle(myRTHFromObject));

        Console.WriteLine("\nmyRTHFromObject.Equals(myRTHFromType):  {0}",
            myRTHFromObject.Equals(myRTHFromType));

        Console.WriteLine("\nmyRTHFromType.Value:  {0}",
myRTHFromType.Value);
        Console.WriteLine("myRTHFromType.GetType():  {0}",
myRTHFromType.GetType());
        Console.WriteLine("Get the type back from the handle...");
        Console.WriteLine("Type.GetTypeFromHandle(myRTHFromType):  {0}",
            Type.GetTypeFromHandle(myRTHFromType));
    }
}

/* This code example produces output similar to the following:

myRTHFromObject.Value:  799464
myRTHFromObject.GetType():  System.RuntimeTypeHandle
Get the type back from the handle...
Type.GetTypeFromHandle(myRTHFromObject):  MyClass1

myRTHFromObject.Equals(myRTHFromType):  True

myRTHFromType.Value:  799464
myRTHFromType.GetType():  System.RuntimeTypeHandle
Get the type back from the handle...
Type.GetTypeFromHandle(myRTHFromType):  MyClass1
 */
```

Properties

Expand table

Value	Gets a handle to the type represented by this instance.

Methods

Expand table

Equals(Object)	Indicates whether the specified object is equal to the current RuntimeTypeHandle structure.
Equals(RuntimeTypeHandle)	Indicates whether the specified RuntimeTypeHandle structure is equal to the current RuntimeTypeHandle structure.
FromIntPtr(IntPtr)	Returns a new RuntimeTypeHandle object created from a handle to a RuntimeType.
GetHashCode()	Returns the hash code for the current instance.
GetModuleHandle()	Gets a handle to the module that contains the type represented by the current instance.
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo with the data necessary to deserialize the type represented by the current instance.
ToIntPtr(RuntimeTypeHandle)	Returns the internal pointer representation of a RuntimeTypeHandle object.

Operators

Expand table

Equality(Object, RuntimeTypeHandle)	Indicates whether an object and a RuntimeTypeHandle structure are equal.
Equality(RuntimeTypeHandle, Object)	Indicates whether a RuntimeTypeHandle structure is equal to an object.
Inequality(Object, RuntimeTypeHandle)	Indicates whether an object and a RuntimeTypeHandle structure are not equal.
Inequality(RuntimeTypeHandle, Object)	Indicates whether a RuntimeTypeHandle structure is not equal to an object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

RuntimeTypeHandle.Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a handle to the type represented by this instance.

C#

```
public IntPtr Value { get; }
```

Property Value

IntPtr

A handle to the type represented by this instance.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeTypeHandle.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two RuntimeTypeHandle structures are equal.

Overloads

Expand table

Equals(Object)	Indicates whether the specified object is equal to the current RuntimeTypeHandle structure.
Equals(RuntimeTypeHandle)	Indicates whether the specified RuntimeTypeHandle structure is equal to the current RuntimeTypeHandle structure.

Equals(Object)

Indicates whether the specified object is equal to the current RuntimeTypeHandle structure.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare to the current instance.

Returns

Boolean

`true` if `obj` is a RuntimeTypeHandle structure and is equal to the value of this instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(RuntimeTypeHandle)

Indicates whether the specified RuntimeTypeHandle structure is equal to the current RuntimeTypeHandle structure.

C#

```
public bool Equals (RuntimeTypeHandle handle);
```

Parameters

`handle` RuntimeTypeHandle

The RuntimeTypeHandle structure to compare to the current instance.

Returns

Boolean

`true` if the value of `handle` is equal to the value of this instance; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

RuntimeTypeHandle.FromIntPtr(IntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new RuntimeTypeHandle object created from a handle to a RuntimeType.

C#

```
public static RuntimeTypeHandle FromIntPtr (IntPtr value);
```

Parameters

`value` IntPtr

An IntPtr handle to a RuntimeType to create a RuntimeTypeHandle object from.

Returns

RuntimeTypeHandle

A new RuntimeTypeHandle object that corresponds to the value parameter.

Applies to

Product	Versions
.NET	7, 8, 9

RuntimeTypeHandle.GetModuleHandle Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Gets a handle to the module that contains the type represented by the current instance.

C#

```
public ModuleHandle GetModuleHandle ();
```

Returns

ModuleHandle

A ModuleHandle structure representing a handle to the module that contains the type represented by the current instance.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeTypeHandle.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo with the data necessary to deserialize the type represented by the current instance.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public void GetObjectData (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to be populated with serialization information.

`context` StreamingContext

(Reserved) The location where serialized data will be stored and retrieved.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

SerializationException

Value is invalid.

Remarks

The `context` parameter is reserved; it does not currently participate in this operation.

For more information about the serialization operation performed by this method, see the SerializationInfo.AddValue(String, Object, Type) method.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

RuntimeTypeHandle.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether an object and a RuntimeTypeHandle structure are equal.

Overloads

Expand table

Equality(Object, RuntimeTypeHandle)	Indicates whether an object and a RuntimeTypeHandle structure are equal.
Equality(RuntimeTypeHandle, Object)	Indicates whether a RuntimeTypeHandle structure is equal to an object.

Equality(Object, RuntimeTypeHandle)

Indicates whether an object and a RuntimeTypeHandle structure are equal.

C#

```
public static bool operator == (object? left, RuntimeTypeHandle right);
```

Parameters

`left` Object

An object to compare to `right`.

`right` RuntimeTypeHandle

A RuntimeTypeHandle structure to compare to `left`.

Returns

Boolean

`true` if `left` is a RuntimeTypeHandle structure and is equal to `right`; otherwise, `false`.

Remarks

Using this operator to compare two variables of type RuntimeTypeHandle causes an ambiguous overload resolution error when compiled. Use the Equals method instead.

The equivalent method for this operator is RuntimeTypeHandle.Equals(Object).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equality(RuntimeTypeHandle, Object)

Indicates whether a RuntimeTypeHandle structure is equal to an object.

C#

```
public static bool operator == (RuntimeTypeHandle left, object? right);
```

Parameters

`left` RuntimeTypeHandle

A RuntimeTypeHandle structure to compare to `right`.

`right` Object

An object to compare to `left`.

Returns

Boolean

`true` if `right` is a RuntimeTypeHandle and is equal to `left`; otherwise, `false`.

Remarks

Using this operator to compare two variables of type RuntimeTypeHandle causes an ambiguous overload resolution error when compiled. Use the Equals method instead.

The equivalent method for this operator is RuntimeTypeHandle.Equals(Object)>.

Applies to

▼ .NET 9 and other versions

Product	Versions

Overloads

Expand table

Inequality(Object, RuntimeTypeHandle)	Indicates whether an object and a RuntimeTypeHandle structure are not equal.
Inequality(RuntimeTypeHandle, Object)	Indicates whether a RuntimeTypeHandle structure is not equal to an object.

Inequality(Object, RuntimeTypeHandle)

Indicates whether an object and a RuntimeTypeHandle structure are not equal.

C#

```
public static bool operator != (object? left, RuntimeTypeHandle right);
```

Parameters

`left` Object

An object to compare to `right`.

`right` RuntimeTypeHandle

A RuntimeTypeHandle structure to compare to `left`.

Returns

Boolean

`true` if `left` is a RuntimeTypeHandle and is not equal to `right`; otherwise, `false`.

Remarks

Using this operator to compare two variables of type RuntimeTypeHandle causes an ambiguous overload resolution error when compiled. Use the Equals method instead.

The equivalent method for this operator is RuntimeTypeHandle.Equals(Object).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Inequality(RuntimeTypeHandle, Object)

Indicates whether a RuntimeTypeHandle structure is not equal to an object.

C#

```
public static bool operator != (RuntimeTypeHandle left, object? right);
```

Parameters

`left` RuntimeTypeHandle

A RuntimeTypeHandle structure to compare to `right`.

`right` Object

An object to compare to `left`.

Returns

Boolean

`true` if `right` is a RuntimeTypeHandle structure and is not equal to `left`; otherwise, `false`.

Remarks

Using this operator to compare two variables of type RuntimeTypeHandle causes an ambiguous overload resolution error when compiled. Use the Equals method instead.

The equivalent method for this operator is RuntimeTypeHandle.Equals(Object).

Remarks

The SByte value type represents integers with values ranging from negative 128 to positive 127.

> **Important**
>
> The **SByte** type is not CLS-compliant. The CLS-compliant alternative type is **Int16**. **Byte** can be used instead to replace a positive **SByte** value that ranges from zero to **MaxValue**. For more information about CLS compliance, see **Language Independence and Language-Independent Components**.

SByte provides methods to compare instances of this type, convert the value of an instance to its string representation, and convert the string representation of a number to an instance of this type.

For information about how format specification codes control the string representation of value types, see Formatting Types.

Fields

Expand table

MaxValue	Represents the largest possible value of SByte. This field is constant.
MinValue	Represents the smallest possible value of SByte. This field is constant.

Methods

Expand table

Abs(SByte)	Computes the absolute of a value.
Clamp(SByte, SByte, SByte)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares this instance to a specified object and returns an

	indication of their relative values.
CompareTo(SByte)	Compares this instance to a specified 8-bit signed integer and returns an indication of their relative values.
CopySign(SByte, SByte)	Copies the sign of a value to the sign of another value.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(SByte, SByte)	Computes the quotient and remainder of two values.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(SByte)	Returns a value indicating whether this instance is equal to a specified SByte value.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type SByte.
IsEvenInteger(SByte)	Determines if a value represents an even integral number.
IsNegative(SByte)	Determines if a value is negative.
IsOddInteger(SByte)	Determines if a value represents an odd integral number.
IsPositive(SByte)	Determines if a value is positive.
IsPow2(SByte)	Determines if a value is a power of two.
LeadingZeroCount(SByte)	Computes the number of leading zeros in a value.
Log2(SByte)	Computes the log2 of a value.
Max(SByte, SByte)	Compares two values to compute which is greater.
MaxMagnitude(SByte, SByte)	Compares two values to compute which is greater.
Min(SByte, SByte)	Compares two values to compute which is lesser.
MinMagnitude(SByte, SByte)	Compares two values to compute which is lesser.

Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number that is in a specified style and culture-specific format to its 8-bit signed equivalent.
Parse(String)	Converts the string representation of a number to its 8-bit signed integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 8-bit signed integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 8-bit signed integer equivalent.
Parse(String, NumberStyles, IFormat Provider)	Converts the string representation of a number that is in a specified style and culture-specific format to its 8-bit signed equivalent.
PopCount(SByte)	Computes the number of bits that are set in a value.
RotateLeft(SByte, Int32)	Rotates a value left by a given amount.
RotateRight(SByte, Int32)	Rotates a value right by a given amount.
Sign(SByte)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
TrailingZeroCount(SByte)	Computes the number of trailing zeros in a value.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current 8-bit signed integer instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, SByte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, SByte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, SByte)	Tries to convert a UTF-8 character span containing the string representation of a number to its 8-bit signed integer equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, SByte)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, SByte)	Tries to convert the span representation of a number in a specified style and culture-specific format to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, SByte)	Tries to convert the span representation of a number to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, SByte)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, SByte)	Tries to convert the string representation of a number in a specified style and culture-specific format to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, SByte)	Tries to convert the string representation of a number to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.

Explicit Interface Implementations

Expand table

IAdditionOperators<SByte,SByte,SByte>.Addition(SByte, SByte)	Adds two values together to compute their sum.

IAdditionOperators<SByte,SByte,SByte>.CheckedAddition(SByte, SByte)	Adds two values together to compute their sum.
IAdditiveIdentity<SByte,SByte>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<SByte>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<SByte>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<SByte>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, SByte)	
IBinaryInteger<SByte>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, SByte)	
IBinaryInteger<SByte>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<SByte>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<SByte>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<SByte,SByte,SByte>.BitwiseAnd(SByte, SByte)	Computes the bitwise-and of two values.
IBitwiseOperators<SByte,SByte,SByte>.BitwiseOr(SByte, SByte)	Computes the bitwise-or of two values.
IBitwiseOperators<SByte,SByte,SByte>.ExclusiveOr(SByte, SByte)	Computes the exclusive-or of two values.
IBitwiseOperators<SByte,SByte,SByte>.OnesComplement(SByte)	Computes the ones-complement representation of a given value.
IComparisonOperators<SByte,SByte,Boolean>.GreaterThan(SByte, SByte)	Compares two values to determine which is greater.
IComparisonOperators<SByte,SByte,Boolean>.GreaterThanOrEqual(SByte, SByte)	Compares two values to determine which is greater or equal.
IComparisonOperators<SByte,SByte,Boolean>.LessThan(SByte, SByte)	Compares two values to determine which is less.
IComparisonOperators<SByte,SByte,Boolean>.LessThanOrEqual(SByte, SByte)	Compares two values to determine which is less or equal.

IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to do so throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<SByte>.Checked Decrement(SByte)	Decrements a value.
IDecrementOperators<SByte>.Decrement(SByte)	Decrements a value.

IDivisionOperators<SByte,SByte,SByte>.Division(SByte, SByte)	Divides one value by another to compute their quotient.
IEqualityOperators<SByte,SByte,Boolean>.Equality(SByte, SByte)	Compares two values to determine equality.
IEqualityOperators<SByte,SByte,Boolean>.Inequality(SByte, SByte)	Compares two values to determine inequality.
IIncrementOperators<SByte>.CheckedIncrement(SByte)	Increments a value.
IIncrementOperators<SByte>.Increment(SByte)	Increments a value.
IMinMaxValue<SByte>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<SByte>.MinValue	Gets the minimum value of the current type.
IModulusOperators<SByte,SByte,SByte>.Modulus(SByte, SByte)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<SByte,SByte>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
IMultiplyOperators<SByte,SByte,SByte>.CheckedMultiply(SByte, SByte)	Multiplies two values together to compute their product.
IMultiplyOperators<SByte,SByte,SByte>.Multiply(SByte, SByte)	Multiplies two values together to compute their product.
INumber<SByte>.MaxNumber(SByte, SByte)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<SByte>.MinNumber(SByte, SByte)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<SByte>.IsCanonical(SByte)	Determines if a value is in its canonical representation.
INumberBase<SByte>.IsComplexNumber(SByte)	Determines if a value represents a complex number.
INumberBase<SByte>.IsFinite(SByte)	Determines if a value is finite.
INumberBase<SByte>.IsImaginaryNumber(SByte)	Determines if a value represents a pure imaginary number.
INumberBase<SByte>.IsInfinity(SByte)	Determines if a value is infinite.

INumberBase<SByte>.IsInteger(SByte)	Determines if a value represents an integral number.
INumberBase<SByte>.IsNaN(SByte)	Determines if a value is NaN.
INumberBase<SByte>.IsNegativeInfinity(SByte)	Determines if a value is negative infinity.
INumberBase<SByte>.IsNormal(SByte)	Determines if a value is normal.
INumberBase<SByte>.IsPositiveInfinity(SByte)	Determines if a value is positive infinity.
INumberBase<SByte>.IsRealNumber(SByte)	Determines if a value represents a real number.
INumberBase<SByte>.IsSubnormal(SByte)	Determines if a value is subnormal.
INumberBase<SByte>.IsZero(SByte)	Determines if a value is zero.
INumberBase<SByte>.MaxMagnitudeNumber(SByte, SByte)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<SByte>.MinMagnitudeNumber(SByte, SByte)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<SByte>.One	Gets the value `1` for the type.
INumberBase<SByte>.Radix	Gets the radix, or base, for the type.
INumberBase<SByte>.TryConvertFromChecked<TOther>(TOther, SByte)	
INumberBase<SByte>.TryConvertFromSaturating<TOther>(TOther, SByte)	
INumberBase<SByte>.TryConvertFromTruncating<TOther>(TOther, SByte)	
INumberBase<SByte>.TryConvertToChecked<TOther>(SByte, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<SByte>.TryConvertToSaturating<TOther>(SByte, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

INumberBase<SByte>.TryConvertToTruncating<TOther>(SByte, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<SByte>.Zero	Gets the value `0` for the type.
IShiftOperators<SByte,Int32,SByte>.LeftShift(SByte, Int32)	Shifts a value left by a given amount.
IShiftOperators<SByte,Int32,SByte>.RightShift(SByte, Int32)	Shifts a value right by a given amount.
IShiftOperators<SByte,Int32,SByte>.UnsignedRightShift(SByte, Int32)	Shifts a value right by a given amount.
ISignedNumber<SByte>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<SByte,SByte,SByte>.CheckedSubtraction(SByte, SByte)	Subtracts two values to compute their difference.
ISubtractionOperators<SByte,SByte,SByte>.Subtraction(SByte, SByte)	Subtracts two values to compute their difference.
IUnaryNegationOperators<SByte,SByte>.CheckedUnaryNegation(SByte)	Computes the checked unary negation of a value.
IUnaryNegationOperators<SByte,SByte>.UnaryNegation(SByte)	Computes the unary negation of a value.
IUnaryPlusOperators<SByte,SByte>.UnaryPlus(SByte)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

SByte.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of SByte. This field is constant.

C#

```
public const sbyte MaxValue = 127;
```

Field Value

***Value** = 127*

SByte

Examples

The following example uses the MinValue and MaxValue fields to verify that an Int64 value is within the range of the SByte type before it performs a type conversion. This verification prevents an OverflowException at run time.

C#

```
long longValue = -130;
sbyte byteValue;

if (longValue <= sbyte.MaxValue &&
    longValue >= sbyte.MinValue)
{
   byteValue = (sbyte) longValue;
   Console.WriteLine("Converted long integer value to {0}.", byteValue);
}
else
{
   sbyte rangeLimit;
   string relationship;

   if (longValue > sbyte.MaxValue)
   {
      rangeLimit = sbyte.MaxValue;
```

```
        relationship = "greater";
    }
    else
    {
        rangeLimit = sbyte.MinValue;
        relationship = "less";
    }

    Console.WriteLine("Conversion failure: {0:n0} is {1} than {2}.",
                      longValue,
                      relationship,
                      rangeLimit);
}
```

Remarks

The value of this constant is 127; that is, hexadecimal 0x7F.

Applies to

SByte.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of SByte. This field is constant.

C#

```
public const sbyte MinValue = -128;
```

Field Value

***Value* = -128**

SByte

Examples

The following example uses the MinValue and MaxValue fields to verify that an Int64 value is within the range of the SByte type before it performs a type conversion. This verification prevents an OverflowException at run time.

C#

```
long longValue = -130;
sbyte byteValue;

if (longValue <= sbyte.MaxValue &&
    longValue >= sbyte.MinValue)
{
   byteValue = (sbyte) longValue;
   Console.WriteLine("Converted long integer value to {0}.", byteValue);
}
else
{
   sbyte rangeLimit;
   string relationship;

   if (longValue > sbyte.MaxValue)
   {
      rangeLimit = sbyte.MaxValue;
```

```
        relationship = "greater";
    }
    else
    {
        rangeLimit = sbyte.MinValue;
        relationship = "less";
    }

    Console.WriteLine("Conversion failure: {0:n0} is {1} than {2}.",
                      longValue,
                      relationship,
                      rangeLimit);
}
```

Remarks

The value of this constant is -128; that is, hexadecimal 0x80.

SByte.Abs(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static sbyte Abs (sbyte value);
```

Parameters

`value` SByte

The value for which to get its absolute.

Returns

SByte

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.Clamp(SByte, SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static sbyte Clamp (sbyte value, sbyte min, sbyte max);
```

Parameters

`value` SByte

The value to clamp.

`min` SByte

The inclusive minimum to which `value` should clamp.

`max` SByte

The inclusive maximum to which `value` should clamp.

Returns

SByte

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or SByte and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CompareTo(SByte)	Compares this instance to a specified 8-bit signed integer and returns an indication of their relative values.

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? obj);
```

Parameters

obj Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `obj`.

Expand table

Return Value	Description
Less than zero	This instance is less than `obj`.
Zero	This instance is equal to `obj`.
Greater than zero	This instance is greater than `obj`, or `obj` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not an SByte.

Remarks

Any instance of SByte, regardless of its value, is considered greater than `null`.

The `obj` parameter must be `null` or an instance of SByte; otherwise, an exception is thrown.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.0, 2.1

CompareTo(SByte)

Compares this instance to a specified 8-bit signed integer and returns an indication of their relative values.

```
C#
public int CompareTo (sbyte value);
```

Parameters

`value` SByte

An 8-bit signed integer to compare.

Returns

Int32

A signed integer that indicates the relative order of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                      "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;

y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;
```

```
    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the SByte.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine if its compiler performs implicit widening conversions on numeric types.

SByte.CopySign(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

```
C#
public static sbyte CopySign (sbyte value, sbyte sign);
```

Parameters

`value` SByte

The value whose magnitude is used in the result.

`sign` SByte

The value whose sign is used in the result.

Returns

SByte

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

public static sbyte CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

SByte

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.CreateSaturating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static sbyte CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

TOther

The type of `value`.

Parameters

value TOther

The value that's used to create the instance of `TSelf`.

Returns

SByte

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.CreateTruncating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static sbyte CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

SByte

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.DivRem(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (sbyte Quotient, sbyte Remainder) DivRem (sbyte left, sbyte
right);
```

Parameters

`left` SByte

The value which `right` divides.

`right` SByte

The value which divides `left`.

Returns

ValueTuple<SByte,SByte>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or SByte.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(SByte)	Returns a value indicating whether this instance is equal to a specified SByte value.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is an instance of SByte and equals the value of this instance; otherwise, `false`.

See also

- CompareTo(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(SByte)

Returns a value indicating whether this instance is equal to a specified SByte value.

C#

```
public bool Equals (sbyte obj);
```

Parameters

`obj` SByte

An SByte value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

SByte.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type SByte.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, SByte.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

SByte.IsEvenInteger(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (sbyte value);
```

Parameters

value SByte

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IsNegative(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
public static bool IsNegative (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Remarks

A return value of `false` does not imply that IsPositive(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions

SByte.IsOddInteger(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (sbyte value);
```

Parameters

value SByte

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

SByte.IsPositive(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

C#

```
public static bool IsPositive (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

SByte.IsPow2(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.LeadingZeroCount(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static sbyte LeadingZeroCount (sbyte value);
```

Parameters

`value` SByte

The value whose leading zeroes are to be counted.

Returns

SByte

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.Log2(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static sbyte Log2 (sbyte value);
```

Parameters

`value` SByte

The value whose log2 is to be computed.

Returns

SByte

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.Max(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static sbyte Max (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.MaxMagnitude(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static sbyte MaxMagnitude (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

SByte.Min(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static sbyte Min (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.MinMagnitude(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static sbyte MinMagnitude (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `minimumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

SByte.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 8-bit signed integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number that is in a specified style and culture-specific format to its 8-bit signed equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number that is in a specified style and culture-specific format to its 8-bit signed equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 8-bit signed integer equivalent.
Parse(String)	Converts the string representation of a number to its 8-bit signed integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 8-bit signed integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> | | |
> |---|---|
> | CLS-compliant alternative | System.Int16.Parse(String, NumberStyles, IFormatProvider) |

Converts the string representation of a number that is in a specified style and culture-specific format to its 8-bit signed equivalent.

```
C#

public static sbyte Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains the number to convert. The string is interpreted by using the style specified by `style`.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`. If `provider` is `null`, the thread current culture is used.

Returns

SByte

An 8-bit signed byte value that is equivalent to the number specified in the `s` parameter.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber.

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in a format that is compliant with `style`.

OverflowException

`s` represents a number that is less than SByte.MinValue or greater than SByte.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example illustrates the use of the Parse(String, NumberStyles, IFormatProvider) method to convert various string representations of numbers to signed integer values.

C#

```
using System;
using System.Globalization;

public class SByteConversion
{
   NumberFormatInfo provider = NumberFormatInfo.CurrentInfo;

   public static void Main()
   {
      string stringValue;
      NumberStyles style;

      stringValue = "   123   ";
      style = NumberStyles.None;
      CallParseOperation(stringValue, style);
```

```
        stringValue = "000,000,123";
        style = NumberStyles.Integer | NumberStyles.AllowThousands;
        CallParseOperation(stringValue, style);

        stringValue = "-100";
        style = NumberStyles.AllowLeadingSign;
        CallParseOperation(stringValue, style);

        stringValue = "100-";
        style = NumberStyles.AllowLeadingSign;
        CallParseOperation(stringValue, style);

        stringValue = "100-";
        style = NumberStyles.AllowTrailingSign;
        CallParseOperation(stringValue, style);

        stringValue = "$100";
        style = NumberStyles.AllowCurrencySymbol;
        CallParseOperation(stringValue, style);

        style = NumberStyles.Integer;
        CallParseOperation(stringValue, style);

        style = NumberStyles.AllowDecimalPoint;
        CallParseOperation("100.0", style);

        stringValue = "1e02";
        style = NumberStyles.AllowExponent;
        CallParseOperation(stringValue, style);

        stringValue = "(100)";
        style = NumberStyles.AllowParentheses;
        CallParseOperation(stringValue, style);
    }

    private static void CallParseOperation(string stringValue,
                                           NumberStyles style)
    {
        sbyte number;

        if (stringValue == null)
            Console.WriteLine("Cannot parse a null string...");

        try
        {
            number = sbyte.Parse(stringValue, style);
            Console.WriteLine("SByte.Parse('{0}', {1})) = {2}",
                              stringValue, style, number);
        }
        catch (FormatException)
        {
            Console.WriteLine("'{0}' and {1} throw a FormatException",
                              stringValue, style);
        }
        catch (OverflowException)
```

```
        {
            Console.WriteLine("'{0}' is outside the range of a signed byte",
                              stringValue);
        }
    }
}
// The example displays the following information to the console:
//       '   123   ' and None throw a FormatException
//       SByte.Parse('000,000,123', Integer, AllowThousands)) = 123
//       SByte.Parse('-100', AllowLeadingSign)) = -100
//       '100-' and AllowLeadingSign throw a FormatException
//       SByte.Parse('100-', AllowTrailingSign)) = -100
//       SByte.Parse('$100', AllowCurrencySymbol)) = 100
//       '$100' and Integer throw a FormatException
//       SByte.Parse('100.0', AllowDecimalPoint)) = 100
//       SByte.Parse('1e02', AllowExponent)) = 100
//       SByte.Parse('(100)', AllowParentheses)) = -100
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive or negative sign symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

If `style` includes AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.

Element	Description
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0-9 if `style` includes the NumberStyles.AllowExponent flag, or one or more occurrences of the digit 0 if it does not. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

Note

Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, if style does not include the NumberStyles.AllowExponent flag, *fractional_digits* must consist of only one or more 0 digits; otherwise, an OverflowException is thrown.
NumberStyles.AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A positive sign before *digits*.
NumberStyles.AllowTrailingSign	A positive sign after *digits*.
NumberStyles.AllowParentheses	Parentheses before and after *digits* to indicate a negative value.
NumberStyles.AllowThousands	The group separator (,) element. Although the group separator can appear in `s`, it must be preceded by only one or more 0 digits.
NumberStyles.AllowCurrencySymbol	The currency ($) element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. Valid hexadecimal digits are 0-9, a-f, and A-F. The only other flags that can be combined with it are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

> **Note**
>
> If the `s` parameter is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the parse operation to throw an exception.

If `s` represents a hexadecimal number, the Parse(String, NumberStyles) method interprets the high-order bit of the byte as a sign bit.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Applies to

UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the span representation of a number that is in a specified style and culture-specific format to its 8-bit signed equivalent.

C#

```
public static sbyte Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert. The span is interpreted by using the style specified by `style`.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`. If `provider` is `null`, the thread current culture is used.

Returns

SByte

An 8-bit signed byte value that is equivalent to the number specified in the `s` parameter.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static sbyte Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

SByte

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int16.Parse(String)**

Converts the string representation of a number in a specified culture-specific format to its 8-bit signed integer equivalent.

```
C#
public static sbyte Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that represents a number to convert. The string is interpreted using the Integer style.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`. If `provider` is `null`, the thread current culture is used.

Returns

SByte

An 8-bit signed integer that is equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example defines a custom NumberFormatInfo object that defines the tilde (~) as the negative sign. It then parses a number of numeric strings using this custom NumberFormatInfo object as well as a CultureInfo object that represents the invariant culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      NumberFormatInfo nf = new NumberFormatInfo();
      nf.NegativeSign = "~";

      string[] values = { "-103", "+12", "~16", "  1", "~255" };
      IFormatProvider[] providers = { nf, CultureInfo.InvariantCulture };

      foreach (IFormatProvider provider in providers)
      {
         Console.WriteLine("Conversions using {0}:", ((object)
provider).GetType().Name);
         foreach (string value in values)
         {
            try {
               Console.WriteLine("   Converted '{0}' to {1}.",
                                 value, SByte.Parse(value, provider));
            }
            catch (FormatException) {
               Console.WriteLine("   Unable to parse '{0}'.", value);
            }
            catch (OverflowException) {
               Console.WriteLine("   '{0}' is out of range of the SByte
type.", value);
            }
         }
```

```
        }
    }
}
// The example displays the following output:
//       Conversions using NumberFormatInfo:
//          Unable to parse '-103'.
//          Converted '+12' to 12.
//          Converted '~16' to -16.
//          Converted '  1' to 1.
//          '~255' is out of range of the SByte type.
//       Conversions using CultureInfo:
//          Converted '-103' to -103.
//          Converted '+12' to 12.
//          Unable to parse '~16'.
//          Converted '  1' to 1.
//          Unable to parse '~255'.
```

Remarks

The `s` parameter contains a number of the form:

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the Integer style. In addition to the byte value's decimal digits, only leading and trailing spaces with a leading sign are allowed. To explicitly define the style elements with the culture-specific formatting information that can be present in `s`, use the Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

UWP	10.0

Parse(String)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int16.Parse(String)**

Converts the string representation of a number to its 8-bit signed integer equivalent.

```C#
public static sbyte Parse (string s);
```

Parameters

s String

A string that represents a number to convert. The string is interpreted using the Integer style.

Returns

SByte

An 8-bit signed integer that is equivalent to the number contained in the `s` parameter.

Exceptions

ArgumentException

`s` is `null`.

FormatException

`s` does not consist of an optional sign followed by a sequence of digits (zero through nine).

OverflowException

`s` represents a number less than SByte.MinValue or greater than SByte.MaxValue.

Examples

The following example demonstrates how to convert a string value into a signed byte value using the Parse method. The resulting signed byte value is then displayed to the console.

```C#
// Define an array of numeric strings.
string[] values = { "-16", "  -3", "+ 12", " +12 ", "  12  ",
                    "+120", "(103)", "192", "-160" };

// Parse each string and display the result.
foreach (string value in values)
```

```
{
   try {
      Console.WriteLine("Converted '{0}' to the SByte value {1}.",
                        value, SByte.Parse(value));
   }
   catch (FormatException) {
      Console.WriteLine("'{0}' cannot be parsed successfully by SByte
type.",
                        value);
   }
   catch (OverflowException) {
      Console.WriteLine("'{0}' is out of range of the SByte type.",
                        value);
   }
}
// The example displays the following output:
//       Converted '-16' to the SByte value -16.
//       Converted '  -3' to the SByte value -3.
//       '+ 12' cannot be parsed successfully by SByte type.
//       Converted ' +12 ' to the SByte value 12.
//       Converted '  12  ' to the SByte value 12.
//       Converted '+120' to the SByte value 120.
//       '(103)' cannot be parsed successfully by SByte type.
//       '192' is out of range of the SByte type.
//       '-160' is out of range of the SByte type.
```

Remarks

The `s` parameter contains a number of the form:

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign.
digits	A sequence of digits ranging from 0 to 9.

The `s` parameter is interpreted using the NumberStyles.Integer style. In addition to the byte value's decimal digits, only leading and trailing spaces with a leading positive or negative sign are allowed. To explicitly define the style elements that can

be present in `s`, use either the Parse(String, NumberStyles) or the Parse(String, NumberStyles, IFormatProvider) method.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse a string by using the formatting information of some other culture, use the Parse(String, NumberStyles, IFormatProvider) method.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static sbyte Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

SByte

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static sbyte Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

utf8Text ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

SByte

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, NumberStyles)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int16.Parse(String)**

Converts the string representation of a number in a specified style to its 8-bit signed integer equivalent.

C#

```
public static sbyte Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string that contains a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

Returns

SByte

An 8-bit signed integer that is equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in a format that is compliant with `style`.

OverflowException

`s` represents a number less than SByte.MinValue or greater than SByte.MaxValue.

-or-

`s` includes non-zero, fractional digits.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example parses string representations of SByte values with the Parse(String, NumberStyles) method. The current culture for the example is en-US.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      NumberStyles style;
      sbyte number;

      // Parse value with no styles allowed.
```

```
      string[] values1 = { " 121 ", "121", "-121" };
      style = NumberStyles.None;
      Console.WriteLine("Styles: {0}", style.ToString());
      foreach (string value in values1)
      {
         try {
            number = SByte.Parse(value, style);
            Console.WriteLine("   Converted '{0}' to {1}.", value,
number);
         }
         catch (FormatException) {
            Console.WriteLine("   Unable to parse '{0}'.", value);
         }
      }
      Console.WriteLine();

      // Parse value with trailing sign.
      style = NumberStyles.Integer | NumberStyles.AllowTrailingSign;
      string[] values2 = { " 103+", " 103 +", "+103", "(103)", "   +103
" };
      Console.WriteLine("Styles: {0}", style.ToString());
      foreach (string value in values2)
      {
         try {
            number = SByte.Parse(value, style);
            Console.WriteLine("   Converted '{0}' to {1}.", value,
number);
         }
         catch (FormatException) {
            Console.WriteLine("   Unable to parse '{0}'.", value);
         }
         catch (OverflowException) {
            Console.WriteLine("   '{0}' is out of range of the SByte
type.", value);
         }
      }
      Console.WriteLine();
   }
}
// The example displays the following output:
//       Styles: None
//          Unable to parse ' 121 '.
//          Converted '121' to 121.
//          Unable to parse '-121'.
//
//       Styles: Integer, AllowTrailingSign
//          Converted ' 103+' to 103.
//          Converted ' 103 +' to 103.
//          Converted '+103' to 103.
//          Unable to parse '(103)'.
//          Converted '   +103   ' to 103.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive or negative sign symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may contain the following elements:

[*ws*]*hexdigits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if style includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyPositivePattern property of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0-9 if `style` includes the NumberStyles.AllowExponent flag, or one or more occurrences of the digit 0 if it does not. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.

Element	Description
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	One or more occurrences of the digit 0-9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite NumberStyles values	Elements permitted in *s* in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, if `style` does not include the NumberStyles.AllowExponent flag, *fractional_digits* must consist of only one or more 0 digits; otherwise, an OverflowException is thrown.
NumberStyles.AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A positive sign before *digits*.

Non-composite NumberStyles values	Elements permitted in *s* in addition to digits
NumberStyles.AllowTrailingSign	A positive sign after *digits*.
NumberStyles.AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
NumberStyles.AllowThousands	The group separator (,) element. Although the group separator can appear in `s`, it must be preceded by only one or more 0 digits.
NumberStyles.AllowCurrencySymbol	The currency ($) element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. Valid hexadecimal digits are 0-9, a-f, and A-F. A prefix such as "0x" is not supported and causes the parse operation to fail. The only other flags that can be combined included in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

> **Note**
>
> If the `s` parameter is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the parse operation to throw an exception.

If `s` represents a hexadecimal number, the Parse(String, NumberStyles) method interprets the high-order bit of the byte as a sign bit.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To use the formatting information of some other culture, call the Parse(String, NumberStyles, IFormatProvider) overload.

SByte.PopCount(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static sbyte PopCount (sbyte value);
```

Parameters

`value` SByte

The value whose set bits are to be counted.

Returns

SByte

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.RotateLeft(SByte, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

C#

```
public static sbyte RotateLeft (sbyte value, int rotateAmount);
```

Parameters

`value` SByte

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

SByte

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.RotateRight(SByte, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

C#

```
public static sbyte RotateRight (sbyte value, int rotateAmount);
```

Parameters

`value` SByte

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

SByte

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.Sign(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (sbyte value);
```

Parameters

`value` SByte

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

SByte.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, consisting of a negative sign if the value is negative, and a sequence of digits ranging from 0 to 9 with no leading zeroes.

Examples

The following example displays an SByte value using the default ToString() method. It also displays the string representations of the SByte value that results from using a number of standard format specifiers. The examples are displayed using the formatting conventions of the en-US culture.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      sbyte value = -123;
      // Display value using default ToString method.
      Console.WriteLine(value.ToString());            // Displays -123
      // Display value using some standard format specifiers.
      Console.WriteLine(value.ToString("G"));         // Displays -123
      Console.WriteLine(value.ToString("C"));         // Displays
($-123.00)
      Console.WriteLine(value.ToString("D"));         // Displays -123
      Console.WriteLine(value.ToString("F"));         // Displays -123.00
      Console.WriteLine(value.ToString("N"));         // Displays -123.00
      Console.WriteLine(value.ToString("X"));         // Displays 85
   }
}
```

Remarks

The ToString() method formats an SByte value in the default ("G", or general) format of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

To use format	For culture	Use the overload
A specific format	A specific culture	ToString(String, IFormatProvider)

The return value is formatted using the general numeric format specifier ("G") The string representation of the SByte value includes a negative sign if its value is negative, and a sequence of digits ranging from 0 to 9 without leading zeros. The negative sign is defined by the NumberFormatInfo object for the current culture.

To define the formatting of the signed byte value's string representation, call the ToString(String) method.

See also

- Formatting Types in .NET
- Standard Numeric Format Strings
- Custom Numeric Format Strings

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance, as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example defines a custom NumberFormatInfo object and assigns the "~" character to its NegativeSign property. The example then uses this custom object as well as the NumberFormatInfo object of the invariant culture to format a series of SByte values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define a custom NumberFormatInfo object with "~" as its negative
sign.
      NumberFormatInfo nfi = new NumberFormatInfo();
      nfi.NegativeSign = "~";

      // Initialize an array of SByte values.
      sbyte[] bytes = { -122, 17, 124 };

      // Display the formatted result using the custom provider.
      Console.WriteLine("Using the custom NumberFormatInfo object:");
      foreach (sbyte value in bytes)
         Console.WriteLine(value.ToString(nfi));

      Console.WriteLine();

      // Display the formatted result using the invariant culture.
      Console.WriteLine("Using the invariant culture:");
      foreach (sbyte value in bytes)
```

```
Console.WriteLine(value.ToString(NumberFormatInfo.InvariantInfo));
    }
}
// The example displays the following output:
//       Using the custom NumberFormatInfo object:
//       ~122
//       17
//       124
//
//       Using the invariant culture:
//       -122
//       17
//       124
```

Remarks

The ToString(IFormatProvider) method formats an SByte value in the default ("G", or general) format of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string returned by this method. If `provider` is `null`, the SByte value is formatted using the NumberFormatInfo object of the current culture. The only property of the NumberFormatInfo object that controls the string representation of the SByte value using the general format specifier is NumberFormatInfo.NegativeSign, which defines the character that represents the negative sign.

The `provider` parameter can be one of the following:

- A CultureInfo object that represents the culture that supplies formatting information.
- The NumberFormatInfo object that supplies formatting information.

- A custom object that implements IFormatProvider. Its GetFormat method returns the NumberFormatInfo object that supplies formatting information.

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A standard or custom numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid.

Examples

The following example initializes an array of SByte values and displays them by using each standard format string and some custom format strings.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      sbyte[] values = { -124, 0, 118 };
      string[] specifiers = { "G", "C", "D3", "E2", "e3", "F",
                              "N", "P", "X", "00.0", "#.0",
                              "000;(0);**Zero**" };

      foreach (sbyte value in values)
      {
         foreach (string specifier in specifiers)
            Console.WriteLine("{0}: {1}", specifier,
value.ToString(specifier));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       G: -124
//       C: ($124.00)
//       D3: -124
//       E2: -1.24E+002
//       e3: -1.240e+002
//       F: -124.00
//       N: -124.00
//       P: -12,400.00 %
//       X: 84
//       00.0: -124.0
//       #.0: -124.0
//       000;(0);**Zero**: (124)
//
//       G: 0
//       C: $0.00
```

```
//        D3: 000
//        E2: 0.00E+000
//        e3: 0.000e+000
//        F: 0.00
//        N: 0.00
//        P: 0.00 %
//        X: 0
//        00.0: 00.0
//        #.0: .0
//        000;(0);**Zero**: **Zero**
//
//        G: 118
//        C: $118.00
//        D3: 118
//        E2: 1.18E+002
//        e3: 1.180e+002
//        F: 118.00
//        N: 118.00
//        P: 11,800.00 %
//        X: 76
//        00.0: 118.0
//        #.0: 118.0
//        000;(0);**Zero**: 118
```

Remarks

The ToString(String) method formats an SByte value in a specified format by using the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be any valid standard numeric format specifier, or any combination of custom numeric format specifiers. If `format` is equal to String.Empty or is `null`, the return value of the current SByte object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

The format of the returned string is determined by the NumberFormatInfo object for the current culture. Depending on the `format` parameter, this object controls symbols such as the negative sign, the group separator, and the decimal point symbol in the output string. To provide formatting information for cultures other than the current culture, call the ToString(String, IFormatProvider) overload.

UWP	10.0

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

```C#
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A standard or custom numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` is invalid.

Examples

The following example displays both a positive and a negative SByte value using the standard numeric format specifiers and a number of specific CultureInfo objects.

```C#
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define cultures whose formatting conventions are to be used.
      CultureInfo[] cultures = { CultureInfo.CreateSpecificCulture("en-
```

```
US"),
                                    CultureInfo.CreateSpecificCulture("fr-
FR"),
                                    CultureInfo.CreateSpecificCulture("es-
ES") };
      sbyte positiveNumber = 119;
      sbyte negativeNumber = -45;
      string[] specifiers = {"G", "C", "D4", "E2", "F", "N", "P", "X2"};

      foreach (string specifier in specifiers)
      {
         foreach (CultureInfo culture in cultures)
            Console.WriteLine("{0,2} format using {1} culture: {2, 16}
{3, 16}",
                              specifier, culture.Name,
                              positiveNumber.ToString(specifier,
culture),
                              negativeNumber.ToString(specifier,
culture));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//     G format using en-US culture:              119              -45
//     G format using fr-FR culture:              119              -45
//     G format using es-ES culture:              119              -45
//
//     C format using en-US culture:          $119.00         ($45.00)
//     C format using fr-FR culture:         119,00 €         -45,00 €
//     C format using es-ES culture:         119,00 €         -45,00 €
//
//    D4 format using en-US culture:             0119            -0045

//     P format using en-US culture:      11,900.00 %      -4,500.00 %
//     P format using fr-FR culture:      11 900,00 %      -4 500,00 %
//     P format using es-ES culture:      11.900,00 %      -4.500,00 %
//
//    X2 format using en-US culture:               77               D3
//    X2 format using fr-FR culture:               77               D3
//    X2 format using es-ES culture:               77               D3
```

Remarks

The ToString(String, IFormatProvider) method formats an SByte value in a specified format of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be any valid standard numeric format specifier, or any combination of custom numeric format specifiers. If `format` is equal to String.Empty or is `null`, the return value of the current SByte object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string returned by this method. When the ToString(String, IFormatProvider) method is invoked, it calls the `provider` parameter's IFormatProvider.GetFormat method and passes it a Type object that represents the NumberFormatInfo type. The GetFormat method then returns the NumberFormatInfo object that provides information for formatting the `value` parameter, such as the negative sign symbol, the group separator symbol, or the decimal point symbol. There are three ways to use the `provider` parameter to supply formatting information to the ToString(String, IFormatProvider) method:

- You can pass a CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- You can pass the actual NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- You can pass a custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the formatting of the returned string is based on the NumberFormatInfo object of the current culture.

SByte.TrailingZeroCount(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static sbyte TrailingZeroCount (sbyte value);
```

Parameters

`value` SByte

The value whose trailing zeroes are to be counted.

Returns

SByte

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current 8-bit signed integer instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current 8-bit signed integer instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

SByte.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 8-bit signed integer equivalent. A return code indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, SByte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, SByte)	Tries to convert the span representation of a number to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, SByte)	Tries to convert the string representation of a number to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, SByte)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, SByte)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, SByte)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, SByte)	Tries to convert a UTF-8 character span containing the string representation of a number to its 8-bit signed integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, SByte)	Tries to convert the span representation of a number in a specified style and culture-specific format to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.
TryParse(String, NumberStyles, IFormatProvider, SByte)	Tries to convert the string representation of a number in a specified style and culture-specific format to its

	SByte equivalent, and returns a value that indicates whether the conversion succeeded.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, SByte)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out sbyte result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` SByte

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, SByte)

> Important
>
> This API is not CLS-compliant.

Tries to convert the span representation of a number to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out sbyte result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`result` SByte

When this method returns, contains the 8-bit signed integer value that is equivalent to the number contained in `s` if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in the correct format, or represents a number that is less than SByte.MinValue or greater than SByte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, SByte)

> Important
>
> This API is not CLS-compliant.

Tries to convert the string representation of a number to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.

```
C#
public static bool TryParse (string? s, out sbyte result);
```

Parameters

`s` String

A string that contains a number to convert.

`result` SByte

When this method returns, contains the 8-bit signed integer value that is equivalent to the number contained in `s` if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in the correct format, or represents a number that is less than SByte.MinValue or greater than SByte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example tries to convert the strings in an array to SByte values by calling the TryParse(String, SByte) method.

```
C#
string[] numericStrings = {"-3.6", "12.8", "+16.7", "    3    ", "(17)",
                           "-17", "+12", "18-", "987", "1,024", "  127
```

```
"};
sbyte number;
foreach (string numericString in numericStrings)
{
   if (sbyte.TryParse(numericString, out number))
      Console.WriteLine("Converted '{0}' to {1}.", numericString,
number);
   else
      Console.WriteLine("Cannot convert '{0}' to an SByte.",
numericString);
}
// The example displays the following output to the console:
//       Cannot convert '-3.6' to an SByte.
//       Cannot convert '12.8' to an SByte.
//       Cannot convert '+16.7' to an SByte.
//       Converted '    3   ' to 3.
//       Cannot convert '(17)' to an SByte.
//       Converted '-17' to -17.
//       Converted '+12' to 12.
//       Cannot convert '18-' to an SByte.
//       Cannot convert '987' to an SByte.
//       Cannot convert '1,024' to an SByte.
//       Converted '  127 ' to 127.
```

Remarks

The SByte.TryParse(String, SByte) method is like the SByte.Parse(String) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `value` is invalid and cannot be successfully parsed.

The `s` parameter should be the string representation of a decimal number in the following form:

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture.

Element	Description
digits	A sequence of decimal digits ranging from 0 to 9.

> **Note**
>
> The string specified by the `value` parameter cannot contain any group separators or decimal separator, and it cannot have a decimal portion.

The `s` parameter is interpreted by using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces with a leading sign are allowed. To explicitly define the style elements with the culture-specific formatting information that can be present in `value`, call the TryParse(String, NumberStyles, IFormatProvider, SByte) method.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object for the current culture. For more information, see NumberFormatInfo.CurrentInfo.

This overload interprets all digits in the `value` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the TryParse(String, NumberStyles, IFormatProvider, SByte) overload instead.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, SByte)

Tries to parse a span of characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out sbyte result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` SByte

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, SByte)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
sbyte result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` SByte

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, SByte)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
sbyte result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` SByte

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, SByte)

Tries to convert a UTF-8 character span containing the string representation of a number to its 8-bit signed integer equivalent.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text, out sbyte
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` SByte

When this method returns, contains the 8-bit signed integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, SByte)

> Important
>
> This API is not CLS-compliant.

Tries to convert the span representation of a number in a specified style and culture-specific format to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
sbyte result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` SByte

When this method returns, contains the 8-bit signed integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than SByte.MinValue or greater than SByte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, SByte)

Important

This API is not CLS-compliant.

CLS-compliant alternative **System.Int16.TryParse(String, Int16)**

Tries to convert the string representation of a number in a specified style and culture-specific format to its SByte equivalent, and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out sbyte result);
```

Parameters

`s` String

A string representing a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` SByte

When this method returns, contains the 8-bit signed integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than SByte.MinValue or greater than SByte.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the TryParse(String, NumberStyles, IFormatProvider, SByte) method with a number of different string and NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      numericString = "106";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      numericString = "-106";
      styles = NumberStyles.None;
      CallTryParse(numericString, styles);

      numericString = "103.00";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "103.72";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "10E-01";
      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(numericString, styles);

      numericString = "12E-01";
      CallTryParse(numericString, styles);

      numericString = "12E01";
      CallTryParse(numericString, styles);

      numericString = "C8";
```

```
        CallTryParse(numericString, NumberStyles.HexNumber);

        numericString = "0x8C";
        CallTryParse(numericString, NumberStyles.HexNumber);
    }

    private static void CallTryParse(string stringToConvert, NumberStyles
styles)
    {
        sbyte number;
        bool result = SByte.TryParse(stringToConvert, styles,
                                     CultureInfo.InvariantCulture, out
number);
        if (result)
            Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
        else
            Console.WriteLine($"Attempted conversion of '{stringToConvert}'
failed.");
    }
}
// The example displays the following output:
//       Converted '106' to 106.
//       Attempted conversion of '-106' failed.
//       Converted '103.00' to 103.
//       Attempted conversion of '103.72' failed.
//       Converted '10E-01' to 1.
//       Attempted conversion of '12E-01' failed.
//       Converted '12E01' to 120.
//       Converted 'C8' to -56.
//       Attempted conversion of '0x8C' failed.
```

Remarks

The TryParse(String, NumberStyles, IFormatProvider, SByte) method is like the Parse(String, NumberStyles, IFormatProvider) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `value` is invalid and cannot be parsed successfully.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `value` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `value` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

If the `style` parameter includes AllowHexSpecifier, the `value` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the start of `value` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `value` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `value` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the start of `value` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `value` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `value` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
,	A culture-specific group separator. The group separator of the culture specified by `provider` can appear in `value` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `value` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `value` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `value` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `value` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.

Element	Description
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `value`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
None	Decimal digits only.
AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits, or the method returns `false`.
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*. If `value` represents a number in exponential notation, it cannot have a non-zero, fractional component.
AllowLeadingWhite	The *ws* element at the start of `value`.
AllowTrailingWhite	The *ws* element at the end of `value`.
AllowLeadingSign	The *sign* element before *digits*.
AllowTrailingSign	The *sign* element after *digits*.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
Currency	All elements. However, `value` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `value`, *sign* at the start of `value`, and the decimal point (.) symbol. The `value` parameter can also use exponential notation.
Number	The *ws*, *sign*, group separator (,), and decimal point (.) elements.
Any	All elements. However, `value` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `value` must be a hexadecimal value. Valid hexadecimal digits are 0-9, a-f, and A-F. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, HexNumber, that includes both white-space flags.)

> **Note**
>
> If `value` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `value`. The `provider` parameter can be any one of the following:

- A CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- A NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- A custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

SByte.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is unused.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

SByte.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is unused.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

SByte.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

C#

```
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(SByte) method.

Applies to

SByte.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to do so throws an InvalidCastException.

C#

```
DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

None. This conversion is not supported.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

SByte.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is unused.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(SByte) method.

Applies to

Product	Versions

SByte.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(SByte) method.

Applies to

Product	Versions

SByte.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

```
C#
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

SByte.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

SByte.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

SByte.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, unchanged.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

SByte.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

SByte.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

`type` Type

The Type to which to convert this SByte value.

`provider` IFormatProvider

A IFormatProvider implementation that provides information about the format of the returned value.

Returns

Object

The value of the current instance, converted to an object of type `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

SByte.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToUInt16(IFormatProvider).

```
C#
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToUInt16(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1

SByte.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToUInt32(IFormatProvider).

```
C#
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToUInt32(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

SByte.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToUInt64(IFormatProvider).

```
C#
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the SByte instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToUInt64(SByte) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

SByte.IAdditionOperators<SByte,SByte,SByte>.AdditionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static sbyte IAdditionOperators<sbyte,sbyte,sbyte>.operator + (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to which `right` is added.

`right` SByte

The value that's added to `left`.

Returns

SByte

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IAdditionOperators<SByte,SByte,SByte>.CheckedAddition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static sbyte IAdditionOperators<sbyte,sbyte,sbyte>.op_CheckedAddition (sbyte
left, sbyte right);
```

Parameters

`left` SByte

The value to which `right` is added.

`right` SByte

The value that's added to `left`.

Returns

SByte

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.IBinaryInteger<SByte>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<sbyte>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IBinaryInteger<SByte>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<sbyte>.TryWriteLittleEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteLittleEndian(Span<Byte>, Int32)

Applies to

SByte.IBitwise Operators<SByte,SByte,SByte>.Bitwise And Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static sbyte IBitwiseOperators<sbyte,sbyte,sbyte>.operator & (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to `and` with `right`.

`right` SByte

The value to `and` with `left`.

Returns

SByte

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IBitwiseOperators<SByte,SByte,SByte>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static sbyte IBitwiseOperators<sbyte,sbyte,sbyte>.operator | (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to `or` with `right`.

`right` SByte

The value to `or` with `left`.

Returns

SByte

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IBitwiseOperators<SByte,SByte,SByte>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static sbyte IBitwiseOperators<sbyte,sbyte,sbyte>.operator ^ (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to xor with `right`.

`right` SByte

The value to xor with `left`.

Returns

SByte

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IComparisonOperators<SByte,SByte,Boolean>.GreaterThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<sbyte,sbyte,bool>.operator > (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to compare with `right`.

`right` SByte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IComparisonOperators<SByte,SByte,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<sbyte,sbyte,bool>.operator >= (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to compare with `right`.

`right` SByte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IComparisonOperators<SByte,SByte,Boolean>.Less Than Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<sbyte,sbyte,bool>.operator < (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to compare with `right`.

`right` SByte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static sbyte IDecrementOperators<sbyte>.op_CheckedDecrement (sbyte value);
```

Parameters

`value` SByte

The value to decrement.

Returns

SByte

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IDecrementOperators<SByte>.Decrement(SByte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static sbyte IDecrementOperators<sbyte>.operator -- (sbyte value);
```

Parameters

`value` SByte

The value to decrement.

Returns

SByte

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IDivisionOperators<SByte,SByte,SByte>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static sbyte IDivisionOperators<sbyte,sbyte,sbyte>.operator / (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value that `right` divides.

`right` SByte

The value that divides `left`.

Returns

SByte

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IEqualityOperators<SByte,SByte,Boolean>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<sbyte,sbyte,bool>.operator == (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to compare with `right`.

`right` SByte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IEqualityOperators<SByte,SByte,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<sbyte,sbyte,bool>.operator != (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value to compare with `right`.

`right` SByte

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IIncrementOperators<SByte>.CheckedIncrement(SByte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static sbyte IIncrementOperators<sbyte>.op_CheckedIncrement (sbyte value);
```

Parameters

`value` SByte

The value to increment.

Returns

SByte

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IIncrementOperators<SByte>.Increment(SByte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static sbyte IIncrementOperators<sbyte>.operator ++ (sbyte value);
```

Parameters

`value` SByte

The value to increment.

Returns

SByte

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IMinMaxValue<SByte>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static sbyte System.Numerics.IMinMaxValue<System.SByte>.MaxValue { get; }
```

Property Value

SByte

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IMinMaxValue<SByte>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static sbyte System.Numerics.IMinMaxValue<System.SByte>.MinValue { get; }
```

Property Value

SByte

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IModulusOperators<SByte,SByte,SByte>.Modulus(SByte, SByte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static sbyte IModulusOperators<sbyte,sbyte,sbyte>.operator % (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value that `right` divides.

`right` SByte

The value that divides `left`.

Returns

SByte

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IMultiplicativeIdentity<SByte,SByte>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static sbyte
System.Numerics.IMultiplicativeIdentity<System.SByte,System.SByte>.MultiplicativeIdentity { get; }
```

Property Value

SByte

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IMultiplyOperators<SByte,SByte,SByte>.CheckedMultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static sbyte IMultiplyOperators<sbyte,sbyte,sbyte>.op_CheckedMultiply (sbyte
left, sbyte right);
```

Parameters

`left` SByte

The value that `right` multiplies.

`right` SByte

The value that multiplies `left`.

Returns

SByte

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.IMultiplyOperators<SByte,SByte,SByte>.MultiplyOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static sbyte IMultiplyOperators<sbyte,sbyte,sbyte>.operator * (sbyte left,
sbyte right);
```

Parameters

`left` SByte

The value that `right` multiplies.

`right` SByte

The value that multiplies `left`.

Returns

SByte

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumber<SByte>.MaxNumber(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

C#

```
static sbyte INumber<sbyte>.MaxNumber (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.INumber<SByte>.MinNumber(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static sbyte INumber<sbyte>.MinNumber (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.IsCanonical(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<sbyte>.IsCanonical (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.INumberBase<SByte>.IsComplexNumber(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<sbyte>.IsComplexNumber (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.IsFinite(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<sbyte>.IsFinite (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.IsImaginaryNumber(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<sbyte>.IsImaginaryNumber (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.IsInfinity(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<sbyte>.IsInfinity (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.IsInteger(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<sbyte>.IsInteger (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.IsNaN(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<sbyte>.IsNaN (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.INumberBase<SByte>.IsNegativeInfinity(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

```
C#
static bool INumberBase<sbyte>.IsNegativeInfinity (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.INumberBase<SByte>.IsNormal(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<sbyte>.IsNormal (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

SByte.INumberBase<SByte>.IsRealNumber(SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<sbyte>.IsRealNumber (sbyte value);
```

Parameters

`value` SByte

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.MaxMagnitudeNumber(SByte, SByte) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#

static sbyte INumberBase<sbyte>.MaxMagnitudeNumber (sbyte x, sbyte y);
```

Parameters

x SByte

The value to compare with `y`.

y SByte

The value to compare with `x`.

Returns

SByte

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<sbyte>.TryConvertToChecked<TOther> (sbyte value, out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` SByte

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<sbyte>.TryConvertToSaturating<TOther> (sbyte value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` SByte

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.INumberBase<SByte>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<sbyte>.TryConvertToTruncating<TOther> (sbyte value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` SByte

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.IShift Operators<SByte,Int32,SByte>.Left Shift(SByte, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static sbyte IShiftOperators<sbyte,int,sbyte>.operator << (sbyte value, int
shiftAmount);
```

Parameters

`value` SByte

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

SByte

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IShift Operators<SByte,Int32,SByte>.Right Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static sbyte IShiftOperators<sbyte,int,sbyte>.operator >> (sbyte value, int
shiftAmount);
```

Parameters

`value` SByte

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

SByte

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IShift Operators<SByte,Int32,SByte>.UnsignedRightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static sbyte IShiftOperators<sbyte,int,sbyte>.op_UnsignedRightShift (sbyte
value, int shiftAmount);
```

Parameters

`value` SByte

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

SByte

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.ISubtractionOperators<SByte,SByte,SByte>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static sbyte ISubtractionOperators<sbyte,sbyte,sbyte>.op_CheckedSubtraction
(sbyte left, sbyte right);
```

Parameters

`left` SByte

The value from which `right` is subtracted.

`right` SByte

The value that's subtracted from `left`.

Returns

SByte

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.ISubtractionOperators<SByte,SByte,SByte>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static sbyte ISubtractionOperators<sbyte,sbyte,sbyte>.operator - (sbyte
left, sbyte right);
```

Parameters

`left` SByte

The value from which `right` is subtracted.

`right` SByte

The value that's subtracted from `left`.

Returns

SByte

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.IUnaryNegationOperators<SByte,SByte>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static sbyte IUnaryNegationOperators<sbyte,sbyte>.op_CheckedUnaryNegation
(sbyte value);
```

Parameters

`value` SByte

The value for which to compute the unary negation.

Returns

SByte

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

SByte.IUnaryNegationOperators<SByte,SByte>.UnaryNegation(SByte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static sbyte IUnaryNegationOperators<sbyte,sbyte>.operator - (sbyte value);
```

Parameters

`value` SByte

The value for which to compute the unary negation.

Returns

SByte

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

SByte.IUnaryPlusOperators<SByte,SByte>.UnaryPlus(SByte) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static sbyte IUnaryPlusOperators<sbyte,sbyte>.operator + (sbyte value);
```

Parameters

`value` SByte

The value for which to compute the unary plus.

Returns

SByte

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

SequencePosition Struct

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Represents a position in a non-contiguous set of memory. Properties of this type should not be interpreted by anything but the type that created it.

C#

```
public readonly struct SequencePosition : IEquatable<SequencePosition>
```

Inheritance Object → ValueType → SequencePosition

Implements IEquatable<SequencePosition>

Constructors

Expand table

SequencePosition(Object, Int32)	Initializes a new instance of the SequencePosition struct.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current instance is equal to another object.
Equals(SequencePosition)	Indicates whether the current instance is equal to another SequencePosition.
GetHashCode()	Returns the hash code for this instance.
GetInteger()	Returns the integer part of this SequencePosition.
GetObject()	Returns the object part of this SequencePosition.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

SequencePosition(Object, Int32) Constructor

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Initializes a new instance of the SequencePosition struct.

```
C#
public SequencePosition (object? object, int integer);
```

Parameters

`object` Object

A non-contiguous set of memory.

`integer` Int32

The position in `object`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

SequencePosition.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current instance is equal to another object.
Equals(SequencePosition)	Indicates whether the current instance is equal to another SequencePosition.

Equals(Object)

Returns a value that indicates whether the current instance is equal to another object.

```
C#

public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with the current instance.

Returns

Boolean

`true` if `obj` is of type SequencePosition and is equal to the current instance; otherwise, `false`.

Remarks

Equality does not guarantee that the two instances point to the same location in a ReadOnlySequence<T>.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Equals(SequencePosition)

Indicates whether the current instance is equal to another SequencePosition.

C#

```
public bool Equals (SequencePosition other);
```

Parameters

`other` SequencePosition

The sequence position to compare with the current instance.

Returns

Boolean

`true` if the two instances are equal; `false` otherwise.

Implements

Equals(T)

Remarks

Equality does not guarantee that the two instances point to the same location in a ReadOnlySequence<T>.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

SequencePosition.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Memory.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for this instance.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

SerializableAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that a class can be serialized using binary or XML serialization. This class cannot be inherited.

C#

```
[System.AttributeUsage(System.AttributeTargets.Class |
System.AttributeTargets.Delegate | System.AttributeTargets.Enum |
System.AttributeTargets.Struct, Inherited=false)]
public sealed class SerializableAttribute : Attribute
```

Inheritance Object → Attribute → SerializableAttribute

Attributes AttributeUsageAttribute

Examples

The following example demonstrates SOAP serialization of an object that's marked with the SerializableAttribute attribute.

C#

```
using System;
using System.IO;
using System.Runtime.Serialization.Formatters.Soap;

public class Test {
   public static void Main()  {

      // Creates a new TestSimpleObject object.
      TestSimpleObject obj = new TestSimpleObject();

      Console.WriteLine("Before serialization the object contains: ");
      obj.Print();

      // Opens a file and serializes the object into it in binary format.
      Stream stream = File.Open("data.xml", FileMode.Create);
```

```
        SoapFormatter formatter = new SoapFormatter();

        formatter.Serialize(stream, obj);
        stream.Close();

        // Empties obj.
        obj = null;

        // Opens file "data.xml" and deserializes the object from it.
        stream = File.Open("data.xml", FileMode.Open);
        formatter = new SoapFormatter();

        obj = (TestSimpleObject)formatter.Deserialize(stream);
        stream.Close();

        Console.WriteLine("");
        Console.WriteLine("After deserialization the object contains: ");
        obj.Print();
    }
}

// A test object that needs to be serialized.
[Serializable()]
public class TestSimpleObject  {

    public int member1;
    public string member2;
    public string member3;
    public double member4;

    // A field that is not serialized.
    [NonSerialized()] public string member5;

    public TestSimpleObject() {

        member1 = 11;
        member2 = "hello";
        member3 = "hello";
        member4 = 3.14159265;
        member5 = "hello world!";
    }

    public void Print() {

        Console.WriteLine("member1 = '{0}'", member1);
        Console.WriteLine("member2 = '{0}'", member2);
        Console.WriteLine("member3 = '{0}'", member3);
        Console.WriteLine("member4 = '{0}'", member4);
        Console.WriteLine("member5 = '{0}'", member5);
    }
}
```

Remarks

Apply the SerializableAttribute attribute to a type to indicate that instances of this type can be serialized using binary or XML serialization. The common language runtime throws SerializationException if any type in the graph of objects being serialized does not have the SerializableAttribute attribute applied.

Apply the SerializableAttribute attribute even if the class also implements the ISerializable interface to control the binary serialization process.

When you apply the SerializableAttribute attribute to a type, all private and public fields are serialized by default. You can control binary serialization more granularly by implementing the ISerializable interface to override the serialization process.

Or you can exclude fields from serialization by applying the NonSerializedAttribute attribute to the field. If a field of a binary-serializable type contains a pointer, a handle, or some other data structure that is specific to a particular environment, and cannot be meaningfully reconstituted in a different environment, then you might want to apply the NonSerializedAttribute attribute to that field.

For more information about using attributes, see Attributes. For more information about binary serialization, see System.Runtime.Serialization.

> **Note**
>
> This attribute does not apply to JSON serialization using **System.Text.Json**.

Constructors

Expand table

SerializableAttribute()	Initializes a new instance of the SerializableAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Remarks

For more information about this API, see Supplemental API remarks for Single.

Fields

Expand table

E	Represents the natural logarithmic base, specified by the constant, e.
Epsilon	Represents the smallest positive Single value that is greater than zero. This field is constant.
MaxValue	Represents the largest possible value of Single. This field is constant.
MinValue	Represents the smallest possible value of Single. This field is constant.
NaN	Represents not a number (`NaN`). This field is constant.
Negative Infinity	Represents negative infinity. This field is constant.
NegativeZero	Represents the number negative zero (-0).
Pi	Represents the ratio of the circumference of a circle to its diameter, specified by the constant, π.
PositiveInfinity	Represents positive infinity. This field is constant.
Tau	Represents the number of radians in one turn, specified by the constant, τ.

Methods

Expand table

Abs(Single)	Computes the absolute of a value.
Acos(Single)	Computes the arc-cosine of a value.
Acosh(Single)	Computes the hyperbolic arc-cosine of a value.
AcosPi(Single)	Computes the arc-cosine of a value and divides the result by `pi`.
Asin(Single)	Computes the arc-sine of a value.
Asinh(Single)	Computes the hyperbolic arc-sine of a value.
AsinPi(Single)	Computes the arc-sine of a value and divides the result by `pi`.
Atan(Single)	Computes the arc-tangent of a value.
Atan2(Single, Single)	Computes the arc-tangent of the quotient of two values.
Atan2Pi(Single, Single)	Computes the arc-tangent for the quotient of two values and divides the result by `pi`.
Atanh(Single)	Computes the hyperbolic arc-tangent of a value.
AtanPi(Single)	Computes the arc-tangent of a value and divides the result by pi.
BitDecrement(Single)	Decrements a value to the smallest value that compares less than a given value.
BitIncrement(Single)	Increments a value to the smallest value that compares greater than a given value.
Cbrt(Single)	Computes the cube-root of a value.
Ceiling(Single)	Computes the ceiling of a value.
Clamp(Single, Single, Single)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.
CompareTo(Single)	Compares this instance to a specified single-precision floating-point number and returns an integer that indicates

	whether the value of this instance is less than, equal to, or greater than the value of the specified single-precision floating-point number.
CopySign(Single, Single)	Copies the sign of a value to the sign of another value.
Cos(Single)	Computes the cosine of a value.
Cosh(Single)	Computes the hyperbolic cosine of a value.
CosPi(Single)	Computes the cosine of a value that has been multipled by `pi`.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DegreesToRadians(Single)	Converts a given value from degrees to radians.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(Single)	Returns a value indicating whether this instance and a specified Single object represent the same value.
Exp(Single)	Computes `E` raised to a given power.
Exp10(Single)	Computes `10` raised to a given power.
Exp10M1(Single)	Computes `10` raised to a given power and subtracts one.
Exp2(Single)	Computes `2` raised to a given power.
Exp2M1(Single)	Computes `2` raised to a given power and subtracts one.
ExpM1(Single)	Computes `E` raised to a given power and subtracts one.
Floor(Single)	Computes the floor of a value.
FusedMultiplyAdd(Single, Single, Single)	Computes the fused multiply-add of three values.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type Single.

Hypot(Single, Single)	Computes the hypotenuse given two values representing the lengths of the shorter sides in a right-angled triangle.
Ieee754Remainder(Single, Single)	Computes the remainder of two values as specified by IEEE 754.
ILogB(Single)	Computes the integer logarithm of a value.
IsEvenInteger(Single)	Determines if a value represents an even integral number.
IsFinite(Single)	Determines whether the specified value is finite (zero, subnormal or normal).
IsInfinity(Single)	Returns a value indicating whether the specified number evaluates to negative or positive infinity.
IsInteger(Single)	Determines if a value represents an integral value.
IsNaN(Single)	Returns a value that indicates whether the specified value is not a number (NaN).
IsNegative(Single)	Determines whether the specified value is negative.
IsNegativeInfinity(Single)	Returns a value indicating whether the specified number evaluates to negative infinity.
IsNormal(Single)	Determines whether the specified value is normal.
IsOddInteger(Single)	Determines if a value represents an odd integral number.
IsPositive(Single)	Determines if a value is positive.
IsPositiveInfinity(Single)	Returns a value indicating whether the specified number evaluates to positive infinity.
IsPow2(Single)	Determines if a value is a power of two.
IsRealNumber(Single)	Determines if a value represents a real number.
IsSubnormal(Single)	Determines whether the specified value is subnormal.
Lerp(Single, Single, Single)	Performs a linear interpolation between two values based on the given weight.
Log(Single)	Computes the natural (`base-E` logarithm of a value.
Log(Single, Single)	Computes the logarithm of a value in the specified base.
Log10(Single)	Computes the base-10 logarithm of a value.
Log10P1(Single)	Computes the base-10 logarithm of a value plus one.
Log2(Single)	Computes the log2 of a value.

Log2P1(Single)	Computes the base-2 logarithm of a value plus one.
LogP1(Single)	Computes the natural (`base-E`) logarithm of a value plus one.
Max(Single, Single)	Compares two values to compute which is greater.
MaxMagnitude(Single, Single)	Compares two values to compute which is greater.
MaxMagnitudeNumber(Single, Single)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
MaxNumber(Single, Single)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
Min(Single, Single)	Compares two values to compute which is lesser.
MinMagnitude(Single, Single)	Compares two values to compute which is lesser.
MinMagnitudeNumber(Single, Single)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
MinNumber(Single, Single)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts a character span that contains the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.
Parse(String)	Converts the string representation of a number to its single-precision floating-point number equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its single-precision floating-point number equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its single-precision floating-point number equivalent.
Parse(String, NumberStyles, IFormat Provider)	Converts the string representation of a number in a specified style and culture-specific format to its single-

	precision floating-point number equivalent.
Pow(Single, Single)	Computes a value raised to a given power.
RadiansToDegrees(Single)	Converts a given value from radians to degrees.
ReciprocalEstimate(Single)	Computes an estimate of the reciprocal of a value.
ReciprocalSqrtEstimate(Single)	Computes an estimate of the reciprocal square root of a value.
RootN(Single, Int32)	Computes the n-th root of a value.
Round(Single)	Rounds a value to the nearest integer using the default rounding mode (ToEven).
Round(Single, Int32)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Single, Int32, MidpointRounding)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Single, MidpointRounding)	Rounds a value to the nearest integer using the specified rounding mode.
ScaleB(Single, Int32)	Computes the product of a value and its base-radix raised to the specified power.
Sign(Single)	Computes the sign of a value.
Sin(Single)	Computes the sine of a value.
SinCos(Single)	Computes the sine and cosine of a value.
SinCosPi(Single)	Computes the sine and cosine of a value.
Sinh(Single)	Computes the hyperbolic sine of a value.
SinPi(Single)	Computes the sine of a value that has been multiplied by `pi`.
Sqrt(Single)	Computes the square-root of a value.
Tan(Single)	Computes the tangent of a value.
Tanh(Single)	Computes the hyperbolic tangent of a value.
TanPi(Single)	Computes the tangent of a value that has been multipled by `pi`.
ToString()	Converts the numeric value of this instance to its equivalent string representation.

ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
Truncate(Single)	Truncates a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current float number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Single)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Single)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Single)	Tries to convert a UTF-8 character span containing the string representation of a number to its single-precision floating-point number equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, Single)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Single)	Converts the span representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, Single)	Converts the string representation of a number in a character span to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, Single)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, Single)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(String, Single)	Converts the string representation of a number to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Operators

Expand table

Equality(Single, Single)	Returns a value that indicates whether two specified Single values are equal.
GreaterThan(Single, Single)	Returns a value that indicates whether a specified Single value is greater than another specified Single value.
GreaterThan OrEqual(Single, Single)	Returns a value that indicates whether a specified Single value is greater than or equal to another specified Single value.
Inequality(Single, Single)	Returns a value that indicates whether two specified Single values are not equal.
LessThan(Single, Single)	Returns a value that indicates whether a specified Single value is less than another specified Single value.
LessThanOrEqual(Single, Single)	Returns a value that indicates whether a specified Single value is less than or equal to another specified Single value.

Explicit Interface Implementations

Expand table

IAddition Operators<Single,Single,Single>.Addition(Single, Single)	Adds two values together to compute their sum.
IAdditiveIdentity<Single,Single>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryNumber<Single>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<Single,Single,Single>.Bitwise And(Single, Single)	Computes the bitwise-and of two values.
IBitwiseOperators<Single,Single,Single>.Bitwise Or(Single, Single)	Computes the bitwise-or of two values.

IBitwiseOperators<Single,Single,Single>.ExclusiveOr(Single, Single)	Computes the exclusive-or of two values.
IBitwiseOperators<Single,Single,Single>.OnesComplement(Single)	Computes the ones-complement representation of a given value.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).

IDecrementOperators<Single>.Decrement(Single)	Decrements a value.
IDivisionOperators<Single,Single,Single>.Division(Single, Single)	Divides one value by another to compute their quotient.
IFloatingPoint<Single>.GetExponentByteCount()	Gets the number of bytes that will be written as part of TryWriteExponentLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Single>.GetExponentShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current exponent.
IFloatingPoint<Single>.GetSignificandBitLength()	Gets the length, in bits, of the current significand.
IFloatingPoint<Single>.GetSignificandByteCount()	Gets the number of bytes that will be written as part of TryWriteSignificandLittleEndian(Span<Byte>, Int32).
IFloatingPoint<Single>.TryWriteExponentBigEndian(Span<Byte>, Int32)	Tries to write the current exponent, in big-endian format, to a given span.
IFloatingPoint<Single>.TryWriteExponentLittleEndian(Span<Byte>, Int32)	Tries to write the current exponent, in little-endian format, to a given span.
IFloatingPoint<Single>.TryWriteSignificandBigEndian(Span<Byte>, Int32)	Tries to write the current significand, in big-endian format, to a given span.
IFloatingPoint<Single>.TryWriteSignificandLittleEndian(Span<Byte>, Int32)	Tries to write the current significand, in little-endian format, to a given span.
IFloatingPointConstants<Single>.E	Gets the mathematical constant `e`.
IFloatingPointConstants<Single>.Pi	Gets the mathematical constant `pi`.
IFloatingPointConstants<Single>.Tau	Gets the mathematical constant `tau`.
IFloatingPointIeee754<Single>.Epsilon	Gets the smallest value such that can be added to `0` that does not result in `0`.
IFloatingPointIeee754<Single>.NaN	Gets a value that represents `NaN`.
IFloatingPointIeee754<Single>.NegativeInfinity	Gets a value that represents negative `infinity`.
IFloatingPointIeee754<Single>.NegativeZero	Gets a value that represents negative `zero`.

IFloatingPointIeee754<Single>.PositiveInfinity	Gets a value that represents positive `infinity`.
IIncrementOperators<Single>.Increment(Single)	Increments a value.
IMinMaxValue<Single>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<Single>.MinValue	Gets the minimum value of the current type.
IModulus Operators<Single,Single,Single>.Modulus(Single, Single)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<Single,Single>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiply Operators<Single,Single,Single>.Multiply(Single, Single)	Multiplies two values together to compute their product.
INumberBase<Single>.IsCanonical(Single)	Determines if a value is in its canonical representation.
INumberBase<Single>.IsComplexNumber(Single)	Determines if a value represents a complex number.
INumberBase<Single>.IsImaginaryNumber(Single)	Determines if a value represents a pure imaginary number.
INumberBase<Single>.IsZero(Single)	Determines if a value is zero.
INumberBase<Single>.One	Gets the value `1` for the type.
INumberBase<Single>.Radix	Gets the radix, or base, for the type.
INumberBase<Single>.TryConvertFromChecked<TOther>(TOther, Single)	
INumberBase<Single>.TryConvertFromSaturating<TOther>(TOther, Single)	
INumberBase<Single>.TryConvertFromTruncating<TOther>(TOther, Single)	
INumberBase<Single>.TryConvertToChecked<TOther> (Single, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<Single>.TryConvertToSaturating<TOther> (Single, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

INumberBase<Single>.TryConvertToTruncating<TOther>(Single, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<Single>.Zero	Gets the value `0` for the type.
ISignedNumber<Single>.NegativeOne	Gets the value `-1` for the type.
ISubtractionOperators<Single,Single,Single>.Subtraction(Single, Single)	Subtracts two values to compute their difference.
IUnaryNegationOperators<Single,Single>.UnaryNegation(Single)	Computes the unary negation of a value.
IUnaryPlusOperators<Single,Single>.UnaryPlus(Single)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

Single.E Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the natural logarithmic base, specified by the constant, e.

C#

```
public const float E = 2.71828175;
```

Field Value

Value* = *2.71828175

Single

Remarks

This is known as Euler's number and is approximately 2.7182818284590452354.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Epsilon Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest positive Single value that is greater than zero. This field is constant.

```
C#
public const float Epsilon = 1.401298E-45;
```

Field Value

Value = 1.401298E-45

Single

Remarks

For more information about this API, see Supplemental API remarks for Single.Epsilon.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of Single. This field is constant.

```
C#

public const float MaxValue = 3.40282347E+38;
```

Field Value

Value* = *3.40282347E+38

Single

Examples

The following code example demonstrates the MaxValue constant.

```
C#

if (s > Single.MaxValue)
{
    Console.WriteLine("Your number is larger than a Single.");
}
```

Remarks

The value of this constant is positive 3.40282347E+38.

The result of an operation that exceeds Single.MaxValue is Single.PositiveInfinity. In the following example, Single.PositiveInfinity results from addition, multiplication, and exponentiation operations when the result exceeds Single.MaxValue.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      float result1 = 1.867e38f + 2.385e38f;
      Console.WriteLine("{0} (Positive Infinity: {1})",
                        result1, Single.IsPositiveInfinity(result1));

      float result2 = 1.5935e25f * 7.948e20f;
      Console.WriteLine("{0} (Positive Infinity: {1})",
                        result2, Single.IsPositiveInfinity(result2));
   }
}
// The example displays the following output:
//    Infinity (Positive Infinity: True)
//    Infinity (Positive Infinity: True)
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of Single. This field is constant.

```
C#

public const float MinValue = -3.40282347E+38;
```

Field Value

***Value* = -3.40282347E+38**

Single

Examples

The following code example demonstrates the MinValue constant.

```
C#

if (s < Single.MinValue)
{
    Console.WriteLine("Your number is smaller than a Single.");
}
```

Remarks

The value of this constant is negative 3.402823e38.

The result of an operation that is less than Single.MinValue is Single.NegativeInfinity. In the following example, Single.NegativeInfinity results from subtraction and multiplication operations when the result is less than Single.MinValue.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      float result1 = -8.997e37f + -2.985e38f;
      Console.WriteLine("{0} (Negative Infinity: {1})",
                        result1, Single.IsNegativeInfinity(result1));

      float result2 = -1.5935e25f * 7.948e32f;
      Console.WriteLine("{0} (Negative Infinity: {1})",
                        result2, Single.IsNegativeInfinity(result2));
   }
}
// The example displays the following output:
//    -Infinity (Negative Infinity: True)
//    -Infinity (Negative Infinity: True)
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.NaN Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents not a number (`NaN`). This field is constant.

C#

```
public const float NaN = NaN;
```

Field Value

Value* = *NaN

Single

Examples

The following example demonstrates the NaN constant.

C#

```
Single zero = 0;

// This condition will return false.
if ((0 / zero) == Single.NaN)
{
    Console.WriteLine("0 / 0 can be tested with Single.NaN.");
}
else
{
    Console.WriteLine("0 / 0 cannot be tested with Single.NaN; use
Single.IsNan() instead.");
}
```

Remarks

A method or operator returns NaN when the result of an operation is undefined. For example, the result of dividing zero by zero is NaN, as the following example shows. (But note that dividing a non-zero number by zero returns either PositiveInfinity or NegativeInfinity, depending on the sign of the divisor.)

C#

```
float zero = 0.0f;
Console.WriteLine("{0} / {1} = {2}", zero, zero, zero/zero);
// The example displays the following output:
//         0 / 0 = NaN
```

In addition, a method call with a NaN value or an operation on a NaN value returns NaN, as the following example shows.

C#

```
float nan1 = Single.NaN;

Console.WriteLine("{0} + {1} = {2}", 3, nan1, 3 + nan1);
Console.WriteLine("Abs({0}) = {1}", nan1, Math.Abs(nan1));
// The example displays the following output:
//       3 + NaN = NaN
//       Abs(NaN) = NaN
```

Use the IsNaN method to determine whether a value is not a number. In general, Single operators cannot be used to compare Single.NaN with other Single values, although comparison methods (such as Equals and CompareTo) can. The following example illustrates the difference in behavior between Single comparison operators and methods.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Console.WriteLine("NaN == NaN: {0}", Single.NaN == Single.NaN);
      Console.WriteLine("NaN != NaN: {0}", Single.NaN != Single.NaN);
      Console.WriteLine("NaN.Equals(NaN): {0}",
Single.NaN.Equals(Single.NaN));
      Console.WriteLine("! NaN.Equals(NaN): {0}", !
Single.NaN.Equals(Single.NaN));
      Console.WriteLine("IsNaN: {0}", Double.IsNaN(Double.NaN));

      Console.WriteLine("\nNaN > NaN: {0}", Single.NaN > Single.NaN);
```

```
        Console.WriteLine("NaN >= NaN: {0}", Single.NaN >= Single.NaN);
        Console.WriteLine("NaN < NaN: {0}", Single.NaN < Single.NaN);
        Console.WriteLine("NaN < 100.0: {0}", Single.NaN < 100.0f);
        Console.WriteLine("NaN <= 100.0: {0}", Single.NaN <= 100.0f);
        Console.WriteLine("NaN >= 100.0: {0}", Single.NaN > 100.0f);
        Console.WriteLine("NaN.CompareTo(NaN): {0}",
Single.NaN.CompareTo(Single.NaN));
        Console.WriteLine("NaN.CompareTo(100.0): {0}",
Single.NaN.CompareTo(100.0f));
        Console.WriteLine("(100.0).CompareTo(Single.NaN): {0}",
(100.0f).CompareTo(Single.NaN));
    }
}
// The example displays the following output:
//       NaN == NaN: False
//       NaN != NaN: True
//       NaN.Equals(NaN): True
//       ! NaN.Equals(NaN): False
//       IsNaN: True
//
//       NaN > NaN: False
//       NaN >= NaN: False
//       NaN < NaN: False
//       NaN < 100.0: False
//       NaN <= 100.0: False
//       NaN >= 100.0: False
//       NaN.CompareTo(NaN): 0
//       NaN.CompareTo(100.0): -1
//       (100.0).CompareTo(Single.NaN): 1
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Single.NegativeInfinity Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents negative infinity. This field is constant.

C#

```
public const float NegativeInfinity = -Infinity;
```

Field Value

Value* = *-Infinity

Single

Examples

The following code example demonstrates the NegativeInfinity constant.

C#

```
// This will equal Infinity.
Console.WriteLine("10.0 minus NegativeInfinity equals {0}.", (10.0 -
Single.NegativeInfinity).ToString());
```

Remarks

The value of this constant is the result of dividing a negative number by zero.

This constant is returned when the result of an operation is less than MinValue.

Use IsNegativeInfinity to determine whether a value evaluates to negative infinity.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.NegativeZero Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number negative zero (-0).

C#

```
public const float NegativeZero = 0;
```

Field Value

Value* = *0

Single

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.Pi Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the ratio of the circumference of a circle to its diameter, specified by the constant, π.

C#

```
public const float Pi = 3.14159274;
```

Field Value

Value = 3.14159274

Single

Remarks

Pi is approximately 3.1415926535897932385.

Applies to

Product	Versions
.NET	7, 8, 9

Single.PositiveInfinity Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents positive infinity. This field is constant.

C#

```
public const float PositiveInfinity = Infinity;
```

Field Value

Value* = *Infinity

Single

Examples

The following code example demonstrates the PositiveInfinity constant.

C#

```
// This will equal Infinity.
Console.WriteLine("PositiveInfinity plus 10.0 equals {0}.",
(Single.PositiveInfinity + 10.0).ToString());
```

Remarks

The value of this constant is the result of dividing a positive number by zero.

This constant is returned when the result of an operation is greater than MaxValue.

Use IsPositiveInfinity to determine whether a value evaluates to positive infinity.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.Tau Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of radians in one turn, specified by the constant, τ.

C#

```
public const float Tau = 6.28318548;
```

Field Value

Value* = *6.28318548

Single

Remarks

Tau is approximately 6.2831853071795864769.

Single.Abs(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

C#

```
public static float Abs (float value);
```

Parameters

`value` Single

The value for which to get its absolute.

Returns

Single

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Acos(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-cosine of a value.

```
C#
public static float Acos (float x);
```

Parameters

x Single

The value, in radians, whose arc-cosine is to be computed.

Returns

Single

The arc-cosine of `x`.

Implements

Acos(TSelf)

Remarks

This computes `arccos(x)` in the interval `[+0, +π]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Acosh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic arc-cosine of a value.

C#

```
public static float Acosh (float x);
```

Parameters

x Single

The value, in radians, whose hyperbolic arc-cosine is to be computed.

Returns

Single

The hyperbolic arc-cosine of `x`.

Implements

Acosh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.AcosPi(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-cosine of a value and divides the result by `pi`.

```
C#
public static float AcosPi (float x);
```

Parameters

x Single

The value whose arc-cosine is to be computed.

Returns

Single

The arc-cosine of `x`, divided by `pi`.

Implements

AcosPi(TSelf)

Remarks

This computes `arccos(x) / π` in the interval `[-0.5, +0.5]`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Asin(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-sine of a value.

C#

```
public static float Asin (float x);
```

Parameters

x Single

The value, in radians, whose arc-sine is to be computed.

Returns

Single

The arc-sine of `x`.

Implements

Asin(TSelf)

Remarks

This computes `arcsin(x)` in the interval `[-π / 2, +π / 2]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Atan(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of a value.

C#

```
public static float Atan (float x);
```

Parameters

x Single

The value, in radians, whose arc-tangent is to be computed.

Returns

Single

The arc-tangent of `x`.

Implements

Atan(TSelf)

Remarks

This computes `arctan(x)` in the interval `[-π / 2, +π / 2]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Atan2(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent of the quotient of two values.

C#

```
public static float Atan2 (float y, float x);
```

Parameters

y Single

The y-coordinate of a point.

x Single

The x-coordinate of a point.

Returns

Single

The arc-tangent of `y` divided-by `x`.

Implements

Atan2(TSelf, TSelf)

Remarks

This computes `arctan(y / x)` in the interval `[-π, +π]` radians.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Atan2Pi(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the arc-tangent for the quotient of two values and divides the result by `pi`.

```
C#
public static float Atan2Pi (float y, float x);
```

Parameters

y Single

The y-coordinate of a point.

x Single

The x-coordinate of a point.

Returns

Single

The arc-tangent of `y` divided-by `x`, divided by `pi`.

Implements

Atan2Pi(TSelf, TSelf)

Remarks

This computes `arctan(y / x) / π` in the interval `[-1, +1]`.

Applies to

Product	Versions
.NET	7, 8, 9

Single.Clamp(Single, Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static float Clamp (float value, float min, float max);
```

Parameters

`value` Single

The value to clamp.

`min` Single

The inclusive minimum to which `value` should clamp.

`max` Single

The inclusive maximum to which `value` should clamp.

Returns

Single

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or to another Single instance and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object or the other Single instance.

Overloads

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.
CompareTo(Single)	Compares this instance to a specified single-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified single-precision floating-point number.

CompareTo(Object)

Compares this instance to a specified object and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified object.

C#

```
public int CompareTo (object? value);
```

Parameters

value Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`, or this instance is not a number (NaN) and `value` is a number.
Zero	This instance is equal to `value`, or this instance and value are both not a number (NaN), PositiveInfinity, or NegativeInfinity.
Greater than zero	This instance is greater than `value`, OR this instance is a number and `value` is not a number (NaN), OR `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a Single.

Examples

The following code example demonstrates the CompareTo method.

C#

```
obj1 = (Single)450;

if (a.CompareTo(obj1) < 0)
{
    Console.WriteLine("{0} is less than {1}.", a.ToString(),
obj1.ToString());
}

if (a.CompareTo(obj1) > 0)
{
    Console.WriteLine("{0} is greater than {1}.", a.ToString(),
obj1.ToString());
}
```

```
if (a.CompareTo(obj1) == 0)
{
    Console.WriteLine("{0} equals {1}.", a.ToString(), obj1.ToString());
}
```

Remarks

For more information about this API, see Supplemental API remarks for Single.CompareTo.

.NET Standard	2.0, 2.1

CompareTo(Single)

Compares this instance to a specified single-precision floating-point number and returns an integer that indicates whether the value of this instance is less than, equal to, or greater than the value of the specified single-precision floating-point number.

C#

```
public int CompareTo (float value);
```

Parameters

`value` Single

A single-precision floating-point number to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`, or this instance is not a number (NaN) and `value` is a number.
Zero	This instance is equal to `value`, or both this instance and `value` are not a number (NaN), PositiveInfinity, or NegativeInfinity.
Greater than zero	This instance is greater than `value`, or this instance is a number and `value` is not a number (NaN).

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";
```

```
    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223

Single.CopySign(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

```
C#
public static float CopySign (float value, float sign);
```

Parameters

`value` Single

The value whose magnitude is used in the result.

`sign` Single

The value whose sign is used in the result.

Returns

Single

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Cos(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cosine of a value.

```
C#
public static float Cos (float x);
```

Parameters

x Single

The value, in radians, whose cosine is to be computed.

Returns

Single

The cosine of `x`.

Implements

Cos(TSelf)

Remarks

This computes `cos(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Single.Cosh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic cosine of a value.

C#

```
public static float Cosh (float x);
```

Parameters

x Single

The value, in radians, whose hyperbolic cosine is to be computed.

Returns

Single

The hyperbolic cosine of `x`.

Implements

Cosh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.CosPi(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the cosine of a value that has been multipled by `pi`.

```
C#
public static float CosPi (float x);
```

Parameters

x Single

The value, in half-revolutions, whose cosine is to be computed.

Returns

Single

The cosine of `x` multiplied-by `pi`.

Implements

CosPi(TSelf)

Remarks

This computes `cos(x * π)`.

Applies to

Product	Versions
.NET	7, 8, 9

Single.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

public static float CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Single

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static float CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Single

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

```
C#

public static float CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

Single

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Single.DegreesToRadians(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a given value from degrees to radians.

```
C#
public static float DegreesToRadians (float degrees);
```

Parameters

degrees Single

The value to convert to radians.

Returns

Single

The value of `degrees` converted to radians.

Implements

DegreesToRadians(TSelf)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Single.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two instances of Single represent the same value.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(Single)	Returns a value indicating whether this instance and a specified Single object represent the same value.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is an instance of Single and equals the value of this instance; otherwise, `false`.

Examples

The following code example demonstrates the Equals method.

```
C#

obj1 = (Single)500;
if (a.Equals(obj1)) {
    Console.WriteLine("The value type and reference type values are
equal.");
}
```

Remarks

The Equals method should be used with caution, because two apparently equivalent values can be unequal due to the differing precision of the two values. The following example reports that the Single value .3333 and the Single returned by dividing 1 by 3 are unequal.

```
C#

// Initialize two floats with apparently identical values
float float1 = .33333f;
object float2 = 1/3;
// Compare them for equality
Console.WriteLine(float1.Equals(float2));    // displays false
```

Rather than comparing for equality, one recommended technique involves defining an acceptable margin of difference between two values (such as .01% of one of the values). If the absolute value of the difference between the two values is less than or equal to that margin, the difference is likely to be due to differences in precision and, therefore, the values are likely to be equal. The following example uses this technique to compare .33333 and 1/3, the two Single values that the previous code example found to be unequal.

```
C#

// Initialize two floats with apparently identical values
float float1 = .33333f;
object float2 = (float) 1/3;
// Define the tolerance for variation in their values
float difference = Math.Abs(float1 * .0001f);

// Compare the values
// The output to the console indicates that the two values are equal
if (Math.Abs(float1 - (float) float2) <= difference)
```

```
    Console.WriteLine("float1 and float2 are equal.");
else
    Console.WriteLine("float1 and float2 are unequal.");
```

In this case, the values are equal.

> **Note**
>
> Because **Epsilon** defines the minimum expression of a positive value whose range is near zero, the margin of difference must be greater than **Epsilon**. Typically, it is many times greater than **Epsilon**.

The precision of floating-point numbers beyond the documented precision is specific to the implementation and version of the .NET Framework. Consequently, a comparison of two particular numbers might change between versions of the .NET Framework because the precision of the numbers' internal representation might change.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Object) method overloads. If an implicit conversion between the `obj` argument and a Single is defined and the argument is not typed as an Object, compilers may perform an implicit conversion and call the Equals(Single) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a Single value. The following example illustrates the difference in behavior between the two method overloads. In the case of all primitive numeric types except for Double in Visual Basic and except for Decimal and Double in C#, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Single) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
    static float value = 112;

    public static void Main()
    {
        byte byte1= 112;
```

```
        Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
        TestObjectForEquality(byte1);

        short short1 = 112;
        Console.WriteLine("value = short1: {0,16}", value.Equals(short1));
        TestObjectForEquality(short1);

        int int1 = 112;
        Console.WriteLine("value = int1: {0,18}", value.Equals(int1));
        TestObjectForEquality(int1);

        long long1 = 112;
        Console.WriteLine("value = long1: {0,17}", value.Equals(long1));
        TestObjectForEquality(long1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,16}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,18}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,17}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:              True
//       112 (Single) = 112 (Byte): False
//
//       value = short1:              True
//       112 (Single) = 112 (Int16): False
```

```
//
//       value = int1:                True
//       112 (Single) = 112 (Int32): False
//
//       value = long1:               True
//       112 (Single) = 112 (Int64): False
//
//       value = sbyte1:              True
//       112 (Single) = 112 (SByte): False
//
//       value = ushort1:              True
//       112 (Single) = 112 (UInt16): False
//
//       value = uint1:                True
//       112 (Single) = 112 (UInt32): False
//
//       value = ulong1:               True
//       112 (Single) = 112 (UInt64): False
//
//       value = dec1:                  False
//       112 (Single) = 112 (Decimal): False
//
//       value = dbl1:                 False
//       112 (Single) = 112 (Double): False
```

.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Single)

Returns a value indicating whether this instance and a specified Single object represent the same value.

```
C#

public bool Equals (float obj);
```

Parameters

obj Single

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is equal to this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

For more information about this API, see Supplemental API remarks for Single.Equals.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(Object) method overloads. If an implicit conversion between the `obj` argument and a Single is defined and the argument is not typed as an Object, compilers may perform an implicit conversion and call the Equals(Single) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a Single value. The following example illustrates the difference in behavior between the two method overloads. In the case of all primitive numeric types except for Double in Visual Basic and except for Decimal and Double in C#, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(Single) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

```
C#
```

```
using System;

public class Example
{
   static float value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,16}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,18}", value.Equals(int1));
      TestObjectForEquality(int1);

      long long1 = 112;
      Console.WriteLine("value = long1: {0,17}", value.Equals(long1));
      TestObjectForEquality(long1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,16}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);

      ushort ushort1 = 112;
      Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
      TestObjectForEquality(ushort1);

      uint uint1 = 112;
      Console.WriteLine("value = uint1: {0,18}", value.Equals(uint1));
      TestObjectForEquality(uint1);

      ulong ulong1 = 112;
      Console.WriteLine("value = ulong1: {0,17}", value.Equals(ulong1));
      TestObjectForEquality(ulong1);

      decimal dec1 = 112m;
      Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
      TestObjectForEquality(dec1);

      double dbl1 = 112;
      Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
      TestObjectForEquality(dbl1);
   }

   private static void TestObjectForEquality(Object obj)
   {
      Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                        value, value.GetType().Name,
```

```
                        obj, obj.GetType().Name,
                        value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (Single) = 112 (Byte): False
//
//       value = short1:             True
//       112 (Single) = 112 (Int16): False
//
//       value = int1:               True
//       112 (Single) = 112 (Int32): False
//
//       value = long1:              True
//       112 (Single) = 112 (Int64): False
//
//       value = sbyte1:             True
//       112 (Single) = 112 (SByte): False
//
//       value = ushort1:             True
//       112 (Single) = 112 (UInt16): False
//
//       value = uint1:               True
//       112 (Single) = 112 (UInt32): False
//
//       value = ulong1:              True
//       112 (Single) = 112 (UInt64): False
//
//       value = dec1:                 False
//       112 (Single) = 112 (Decimal): False
//
//       value = dbl1:                False
//       112 (Single) = 112 (Double): False
```

Single.Exp(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `E` raised to a given power.

```
C#
public static float Exp (float x);
```

Parameters

x Single

The power to which `E` is raised.

Returns

Single

`E` raised to the power of `x`.

Implements

Exp(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Exp10(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `10` raised to a given power.

```
C#
public static float Exp10 (float x);
```

Parameters

x Single

The power to which `10` is raised.

Returns

Single

10^x

Implements

Exp10(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Exp10M1(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `10` raised to a given power and subtracts one.

```
C#
public static float Exp10M1 (float x);
```

Parameters

x Single

The power to which `10` is raised.

Returns

Single

`10ˣ - 1`

Implements

Exp10M1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Exp2(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes `2` raised to a given power.

```
C#
public static float Exp2 (float x);
```

Parameters

x Single

The power to which `2` is raised.

Returns

Single

2^x

Implements

Exp2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Floor(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the floor of a value.

C#

```
public static float Floor (float x);
```

Parameters

x Single

The value whose floor is to be computed.

Returns

Single

The floor of `x`.

Implements

Floor(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.FusedMultiplyAdd(Single, Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the fused multiply-add of three values.

```
C#

public static float FusedMultiplyAdd (float left, float right, float
addend);
```

Parameters

`left` Single

The value which `right` multiplies.

`right` Single

The value which multiplies `left`.

`addend` Single

The value that is added to the product of `left` and `right`.

Returns

Single

The result of `left` times `right` plus `addend` computed as one ternary operation.

Implements

FusedMultiplyAdd(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type Single.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, Single.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Single.Hypot(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hypotenuse given two values representing the lengths of the shorter sides in a right-angled triangle.

```
C#
public static float Hypot (float x, float y);
```

Parameters

x Single

The value to square and add to `y`.

y Single

The value to square and add to `x`.

Returns

Single

The square root of `x`-squared plus `y`-squared.

Implements

Hypot(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Ieee754Remainder(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the remainder of two values as specified by IEEE 754.

C#

```
public static float Ieee754Remainder (float left, float right);
```

Parameters

`left` Single

The value which `right` divides.

`right` Single

The value which divides `left`.

Returns

Single

The remainder of `left` divided-by `right` as specified by IEEE 754.

Implements

Ieee754Remainder(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.ILogB(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the integer logarithm of a value.

C#

```
public static int ILogB (float x);
```

Parameters

x Single

The value whose integer logarithm is to be computed.

Returns

Int32

The integer logarithm of `x`.

Implements

ILogB(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

Single.IsEvenInteger(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IsFinite(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is finite (zero, subnormal or normal).

C#

```
public static bool IsFinite (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if the specified value is finite (zero, subnormal or normal); otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Single.IsInfinity(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to negative or positive infinity.

```
C#

public static bool IsInfinity (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if `f` evaluates to PositiveInfinity or NegativeInfinity; otherwise, `false`.

Implements

IsInfinity(TSelf)

Examples

The following code example demonstrates the IsInfinity method.

```
C#

// This will return "true".
Console.WriteLine("IsInfinity(3.0F / 0) == {0}.", Single.IsInfinity(3.0F /
0) ? "true" : "false");
```

Remarks

Floating-point operations return PositiveInfinity or NegativeInfinity to signal an overflow condition.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.IsInteger(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral value.

```
C#
public static bool IsInteger (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` and `3.0` will return `true` while `2.2` and `3.3` will return `false`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IsNaN(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the specified value is not a number (NaN).

C#

```
public static bool IsNaN (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if `f` evaluates to not a number (NaN); otherwise, `false`.

Implements

IsNaN(TSelf)

Examples

The following code example demonstrates the IsNaN method.

C#

```
// This will return true.
if (Single.IsNaN(0 / zero))
{
    Console.WriteLine("Single.IsNan() can determine whether a value is not-
a-number.");
}
```

Remarks

Floating-point operations return NaN to signal that result of the operation is undefined. For example, dividing 0.0 by 0.0 results in NaN.

> **Note**
>
> IsNaN returns `false` if a Single value is either PositiveInfinity or NegativeInfinity. To test for these values, use the IsInfinity, IsPositiveInfinity, and IsNegativeInfinity methods.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.IsNegative(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is negative.

C#

```
public static bool IsNegative (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if negative, `false` otherwise.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Single.IsNegativeInfinity(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to negative infinity.

C#

```
public static bool IsNegativeInfinity (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if `f` evaluates to NegativeInfinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Examples

The following code example demonstrates the IsNegativeInfinity method.

C#

```
// This will return true.
Console.WriteLine("IsNegativeInfinity(-5.0F / 0) == {0}.",
Single.IsNegativeInfinity(-5.0F / 0) ? "true" : "false");
```

Remarks

Floating-point operations return NegativeInfinity to signal an overflow condition.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Single.IsNormal(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is normal.

C#

```
public static bool IsNormal (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if `f` is normal; `false` otherwise.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Single.IsOddInteger(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (float value);
```

Parameters

value Single

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IsPositive(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
public static bool IsPositive (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Remarks

A return value of `false` does not imply that IsNegative(TSelf) will return `true`. A complex number, `a + bi` for non-zero `b`, is not positive or negative

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IsPositiveInfinity(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether the specified number evaluates to positive infinity.

C#

```
public static bool IsPositiveInfinity (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if `f` evaluates to PositiveInfinity; otherwise, `false`.

Implements

IsPositiveInfinity(TSelf)

Examples

The following code example demonstrates the IsPositiveInfinity method.

C#

```
// This will return true.
Console.WriteLine("IsPositiveInfinity(4.0F / 0) == {0}.",
Single.IsPositiveInfinity(4.0F / 0) ? "true" : "false");
```

Remarks

Floating-point operations return PositiveInfinity to signal an overflow condition.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.IsPow2(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.IsRealNumber(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
public static bool IsRealNumber (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Remarks

This function returns `true` for a complex number `a + bi` where `b` is zero.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IsSubnormal(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified value is subnormal.

C#

```
public static bool IsSubnormal (float f);
```

Parameters

`f` Single

A single-precision floating-point number.

Returns

Boolean

`true` if `f` is subnormal; `false` otherwise.

Implements

IsSubnormal(TSelf)

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Single.Lerp(Single, Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Performs a linear interpolation between two values based on the given weight.

C#

```
public static float Lerp (float value1, float value2, float amount);
```

Parameters

`value1` Single

The first value, which is intended to be the lower bound.

`value2` Single

The second value, which is intended to be the upper bound.

`amount` Single

A value, intended to be between 0 and 1, that indicates the weight of the interpolation.

Returns

Single

The interpolated value.

Implements

Lerp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	8, 9

Single.Log Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Log(Single, Single)	Computes the logarithm of a value in the specified base.
Log(Single)	Computes the natural (`base-E` logarithm of a value.

Log(Single, Single)

Computes the logarithm of a value in the specified base.

C#

```
public static float Log (float x, float newBase);
```

Parameters

x Single

The value whose logarithm is to be computed.

newBase Single

The base in which the logarithm is to be computed.

Returns

Single

The base-`newBase` logarithm of `x`.

Implements

Log(TSelf, TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Log(Single)

Computes the natural (`base-E` logarithm of a value.

```
C#

public static float Log (float x);
```

Parameters

`x` Single

The value whose natural logarithm is to be computed.

Returns

Single

The natural logarithm of `x`.

Implements

Log(TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Single.Log10(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the base-10 logarithm of a value.

C#

```
public static float Log10 (float x);
```

Parameters

x Single

The value whose base-10 logarithm is to be computed.

Returns

Single

The base-10 logarithm of `x`.

Implements

Log10(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Log10P1(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the base-10 logarithm of a value plus one.

C#

```
public static float Log10P1 (float x);
```

Parameters

x Single

The value to which one is added before computing the base-10 logarithm.

Returns

Single

$\log_{10}(x + 1)$

Implements

Log10P1(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Max(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static float Max (float x, float y);
```

Parameters

x Single

The value to compare with `y`.

y Single

The value to compare with `x`.

Returns

Single

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.MaxMagnitude(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static float MaxMagnitude (float x, float y);
```

Parameters

x Single

The value to compare with `y`.

y Single

The value to compare with `x`.

Returns

Single

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitude` function. This requires NaN inputs to not be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.MaxMagnitudeNumber(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#
public static float MaxMagnitudeNumber (float x, float y);
```

Parameters

x Single

The value to compare with `y`.

y Single

The value to compare with `x`.

Returns

Single

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Remarks

For IFloatingPointIeee754<TSelf> this method matches the IEEE 754:2019 `maximumMagnitudeNumber` function. This requires NaN inputs to not be propagated back

to the caller and for `-0.0` to be treated as less than `+0.0`.

Single.Min(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static float Min (float x, float y);
```

Parameters

x Single

The value to compare with `y`.

y Single

The value to compare with `x`.

Returns

Single

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its single-precision floating-point number equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts a character span that contains the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its single-precision floating-point number equivalent.
Parse(String)	Converts the string representation of a number to its single-precision floating-point number equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its single-precision floating-point number equivalent.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.

```
C#

public static float Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Single

A single-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a numeric value.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number that is less than Single.MinValue or greater than Single.MaxValue.

Examples

The following code example uses the Parse(String, NumberStyles, IFormatProvider) method to parse the string representations of Single values. Each string in an array is parsed using the formatting conventions of the en-US, nl-NL, and a custom culture. The custom culture defines its group separator symbol as the underscore ("_") and its group size as two.

C#

```
using System;
using System.Globalization;

public class Example
{
    public static void Main()
    {
      // Define an array of string values.
      string[] values = { " 987.654E-2", " 987,654E-2",  "(98765,43210)",
                          "9,876,543.210", "9.876.543,210",
"98_76_54_32,19" };
      // Create a custom culture based on the invariant culture.
      CultureInfo ci = new CultureInfo("");
      ci.NumberFormat.NumberGroupSizes = new int[] { 2 };
      ci.NumberFormat.NumberGroupSeparator = "_";

      // Define an array of format providers.
```

```
      CultureInfo[] providers = { new CultureInfo("en-US"),
                                  new CultureInfo("nl-NL"), ci };

      // Define an array of styles.
      NumberStyles[] styles = { NumberStyles.Currency, NumberStyles.Float
};

      // Iterate the array of format providers.
      foreach (CultureInfo provider in providers)
      {
         Console.WriteLine("Parsing using the {0} culture:",
                           provider.Name == String.Empty ? "Invariant" :
provider.Name);
         // Parse each element in the array of string values.
         foreach (string value in values)
         {
            foreach (NumberStyles style in styles)
            {
               try {
                  float number = Single.Parse(value, style, provider);
                  Console.WriteLine("   {0} ({1}) -> {2}",
                                    value, style, number);
               }
               catch (FormatException) {
                  Console.WriteLine("   '{0}' is invalid using {1}.",
value, style);
               }
               catch (OverflowException) {
                  Console.WriteLine("   '{0}' is out of the range of a
Single.", value);
               }
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
// Parsing using the en-US culture:
//    ' 987.654E-2' is invalid using Currency.
//     987.654E-2 (Float) -> 9.87654
//    ' 987,654E-2' is invalid using Currency.
//    ' 987,654E-2' is invalid using Float.
//    (98765,43210) (Currency) -> -9.876543E+09
//    '(98765,43210)' is invalid using Float.

//    '98_76_54_32,19' is invalid using Float.
//
// Parsing using the Invariant culture:
//    ' 987.654E-2' is invalid using Currency.
//     987.654E-2 (Float) -> 9.87654
//    ' 987,654E-2' is invalid using Currency.
//    ' 987,654E-2' is invalid using Float.
//    (98765,43210) (Currency) -> -9.876543E+09
//    '(98765,43210)' is invalid using Float.
//    9,876,543.210 (Currency) -> 9876543
//    '9,876,543.210' is invalid using Float.
//    '9.876.543,210' is invalid using Currency.
//    '9.876.543,210' is invalid using Float.
//    98_76_54_32,19 (Currency) -> 9.876543E+09
//    '98_76_54_32,19' is invalid using Float.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The `style` parameter defines the style elements (such as white space, thousands separators, and currency symbols) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- AllowHexSpecifier
- HexNumber

The `s` parameter can contain NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, or NumberFormatInfo.NaNSymbol for the culture specified by `provider`. Depending on the value of `style`, it can also take the form:

[*ws*] [*$*] [*sign*][*integral-digits*,]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Elements framed in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white-space characters. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	A negative sign symbol (-) or a positive sign symbol (+). The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
,	A culture-specific group separator. The current culture's group separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Single type. The remaining System.Globalization.NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles flags affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in `s` in addition to digits
None	The *integral-digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation. This flag by itself supports values in the form *digits*E*digits*; additional flags are needed to successfully parse strings with such elements as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The thousands separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, thousands separator (,) and decimal point (.) elements.

NumberStyles value	Elements permitted in `s` in addition to digits
Any	All elements. However, `s` cannot represent a hexadecimal number.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `value`. Typically, `provider` can be any one of the following:

- A CultureInfo object that represents the culture that provides numeric formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information.
- A NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat just returns itself.)
- A custom object that implements IFormatProvider and uses the GetFormat method to instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

If `s` is out of range of the Single data type, the method throws an OverflowException on .NET Framework and .NET Core 2.2 and earlier versions. On .NET Core 3.0 and later versions, it returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts a character span that contains the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent.

C#

```
public static float Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A character span that contains the number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicate the style elements that can be present in `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Single

A single-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Exceptions

FormatException

`s` does not represent a numeric value.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

If `s` is out of range of the Single data type, the method returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static float Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.AllowThousands |
System.Globalization.NumberStyles.Float, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Single

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its single-precision floating-point number equivalent.

```
C#
public static float Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that contains a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

Single

A single-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number less than Single.MinValue or greater than Single.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to a Single value.

C#

```
protected void OkToSingle_Click(object sender, EventArgs e)
{
    string locale;
    float number;
    CultureInfo culture;

    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;

    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = Single.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
        return;
    }
    catch (Exception)
    {
        return;
    }
    // Output number to label on web form
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

This overload is typically used to convert text that can be formatted in a variety of ways to a Single value. For example, it can be used to convert the text entered by a user into an HTML text box to a numeric value.

The `s` parameter is interpreted using a combination of the NumberStyles.Float and NumberStyles.AllowThousands flags. The `s` parameter can contain NumberFormatInfo.PositiveInfinitySymbol, NumberFormatInfo.NegativeInfinitySymbol, or NumberFormatInfo.NaNSymbol for the culture specified by `provider`, or it can contain a string of the form:

[*ws*][*sign*]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Optional elements are framed in square brackets ([and]). Elements that contain the term "digits" consist of a series of numeric characters ranging from 0 to 9.

Expand table

Element	Description
ws	A series of white-space characters.
sign	A negative sign symbol (-) or a positive sign symbol (+).
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. Runs of *integral-digits* can be partitioned by a group-separator symbol. For example, in some cultures a comma (,) separates groups of thousands. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
.	A culture-specific decimal point symbol.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

For more information about numeric formats, see the Formatting Types topic.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific formatting information. When the Parse(String, IFormatProvider) method is invoked, it calls the `provider` parameter's GetFormat method and passes it a Type object that represents the NumberFormatInfo type. The GetFormat method then returns the NumberFormatInfo object that provides information about the format of the `s` parameter. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass a CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- You can pass the actual NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- You can pass a custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null` or a NumberFormatInfo cannot be obtained, the formatting information for the current system culture is used.

If `s` is out of range of the Single data type, the method throws an OverflowException on .NET Framework and .NET Core 2.2 and earlier versions. On .NET Core 3.0 and later versions, it returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Some examples of `s` are "100", "-123,456,789", "123.45e+6", "+500", "5e2", "3.1416", "600.", "-.123", and "-Infinity".

UWP	10.0

Parse(String)

Converts the string representation of a number to its single-precision floating-point number equivalent.

C#

```
public static float Parse (string s);
```

Parameters

s String

A string that contains a number to convert.

Returns

Single

A single-precision floating-point number equivalent to the numeric value or symbol specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not represent a number in a valid format.

OverflowException
.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number less than Single.MinValue or greater than Single.MaxValue.

Examples

The following example uses the Parse(String) method to convert an array of strings to equivalent Single values.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] values = { "100", "(100)", "-123,456,789", "123.45e+6",
                          "+500", "5e2", "3.1416", "600.", "-.123",
                          "-Infinity", "-1E-16",
Double.MaxValue.ToString(),
                          Single.MinValue.ToString(), String.Empty };
      foreach (string value in values)
      {
         try {
            float number = Single.Parse(value);
            Console.WriteLine("{0} -> {1}", value, number);
         }
         catch (FormatException) {
            Console.WriteLine("'{0}' is not in a valid format.", value);
         }
         catch (OverflowException) {
            Console.WriteLine("{0} is outside the range of a Single.",
value);
         }
      }
   }
}
// The example displays the following output:
//       100 -> 100
//       '(100)' is not in a valid format.
//       -123,456,789 -> -1.234568E+08
//       123.45e+6 -> 1.2345E+08
//       +500 -> 500
//       5e2 -> 500
//       3.1416 -> 3.1416
//       600. -> 600
//       -.123 -> -0.123
//       -Infinity -> -Infinity
```

```
//       -1E-16 -> -1E-16
//       1.79769313486232E+308 is outside the range of a Single.
//       -3.402823E+38 -> -3.402823E+38
//       '' is not in a valid format.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The `s` parameter can contain the current culture's PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or a string of the form:

[*ws*][*sign*] [*integral-digits*[,]]*integral-digits*[.[*fractional-digits*]][e[*sign*]*exponential-digits*] [*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white space characters.
sign	A negative sign symbol or a positive sign symbol. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture. Only a leading sign can be used.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. Runs of *integral-digits* can be partitioned by a group-separator symbol. For example, in some cultures a comma (,) separates groups of thousands. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.
,	A culture-specific thousands separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation.

Element	Description
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

The `s` parameter is interpreted using a combination of the NumberStyles.Float and NumberStyles.AllowThousands flags. This means that white space and thousands separators are allowed but currency symbols are not. To explicitly define the elements (such as currency symbols, thousands separators, and white space) that can be present in `s`, use the Parse(String, NumberStyles) method overload.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see CurrentInfo. To parse a string by using the formatting information of a specific culture, use the Parse(String, IFormatProvider) or Parse(String, NumberStyles, IFormatProvider) method.

Ordinarily, if you pass the Parse method a string that is created by calling the ToString method, the original Single value is returned. However, because of a loss of precision, the values may not be equal.

If `s` is out of range of the Single data type, the method throws an OverflowException on .NET Framework and .NET Core 2.2 and earlier versions. On .NET Core 3.0 and later versions, it returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static float Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

Single

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static float Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

Single

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its single-precision floating-point number equivalent.

```
C#

public static float Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string that contains a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Float combined with AllowThousands.

Returns

Single

A single-precision floating-point number that is equivalent to the numeric value or symbol specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not a number in a valid format.

OverflowException

.NET Framework and .NET Core 2.2 and earlier versions only: `s` represents a number that is less than Single.MinValue or greater than Single.MaxValue.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` includes the AllowHexSpecifier value.

Examples

The following example uses the Parse(String, NumberStyles) method to parse the string representations of Single values. The example uses formatting information for the en-US culture.

C#

```
using System;
using System.Globalization;

        ShowNumericValue(value, styles);
    }

    private static void ShowNumericValue(string value, NumberStyles
styles)
    {
        Single number;
        try
        {
            number = Single.Parse(value, styles);
            Console.WriteLine("Converted '{0}' using {1} to {2}.",
                              value, styles.ToString(), number);
        }
        catch (FormatException)
        {
            Console.WriteLine("Unable to parse '{0}' with styles {1}.",
                              value, styles.ToString());
        }
        Console.WriteLine();
    }
}
// The example displays the following output to the console:
//    Unable to parse '-1.063E-02' with styles AllowExponent.
//
//    Converted '-1.063E-02' using AllowTrailingSign, AllowThousands,
Float to -0.01063.
//
//    Converted ' $ 6,164.3299  ' using Number, AllowCurrencySymbol to
6164.3299.
//
//    Unable to parse '(4,320.64)' with styles AllowTrailingSign,
AllowParentheses, Float.
//
//    Converted '(4,320.64)' using AllowTrailingSign, AllowParentheses,
AllowThousands, Float to -4320.64.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

The `style` parameter defines the style elements (such as white space, thousands separators, and currency symbols) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. The following NumberStyles members are not supported:

- AllowHexSpecifier

- HexNumber

The `s` parameter can contain the current culture's PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol. Depending on the value of `style`, it can also take the form:

[*ws*][*$*][*sign*][*integral-digits*[,]]*integral-digits*[.[*fractional-digits*]][E[*sign*]*exponential-digits*][*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

ws A series of white-space characters. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.

$ A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.

sign A negative sign symbol (-) or a positive sign symbol (+). The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.

integral-digits A series of digits ranging from 0 to 9 that specify the integral part of the number. The *integral-digits* element can be absent if the string contains the *fractional-digits* element.

, A culture-specific group separator. The current culture's group separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag

. A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.

fractional-digits A series of digits ranging from 0 to 9 that specify the fractional part of the number. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.

E The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `value` parameter can represent a number in

exponential notation if `style` includes the NumberStyles.AllowExponent flag.

exponential-digits A series of digits ranging from 0 to 9 that specify an exponent.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Single type. The remaining System.Globalization.NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles flags affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in `s` in addition to digits
None	The *integral-digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation. This flag by itself supports values in the form *digits*E*digits*; additional flags are needed to successfully parse strings with such elements as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The thousands separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the decimal point (.) symbol. The `s` parameter can also use

NumberStyles value	Elements permitted in `s` in addition to digits
	exponential notation.
Number	The `ws`, `sign`, thousands separator (,) and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

Some examples of `s` are "100", "-123,456,789", "123.45e+6", "+500", "5e2", "3.1416", "600.", "-.123", and "-Infinity".

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To specify the culture whose formatting information is used for the parse operation, call the Parse(String, NumberStyles, IFormatProvider) overload.

Ordinarily, if you pass the Parse method a string that is created by calling the ToString method, the original Single value is returned. However, because of a loss of precision, the values may not be equal.

If `s` is out of range of the Single data type, the method throws an OverflowException on .NET Framework and .NET Core 2.2 and earlier versions. On .NET Core 3.0 and later versions, it returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Single.Pow(Single, Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes a value raised to a given power.

```
C#
public static float Pow (float x, float y);
```

Parameters

x Single

The value which is raised to the power of `x`.

y Single

The power to which `x` is raised.

Returns

Single

`x` raised to the power of `y`.

Implements

Pow(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.RadiansToDegrees(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a given value from radians to degrees.

C#

```
public static float RadiansToDegrees (float radians);
```

Parameters

`radians` Single

The value to convert to degrees.

Returns

Single

The value of `radians` converted to degrees.

Implements

RadiansToDegrees(TSelf)

Applies to

Product	Versions
.NET	8, 9

Single.ReciprocalEstimate(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes an estimate of the reciprocal of a value.

```
C#
public static float ReciprocalEstimate (float x);
```

Parameters

x Single

The value whose estimate of the reciprocal is to be computed.

Returns

Single

An estimate of the reciprocal of `x`.

Implements

ReciprocalEstimate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.ReciprocalSqrtEstimate(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes an estimate of the reciprocal square root of a value.

C#

```
public static float ReciprocalSqrtEstimate (float x);
```

Parameters

x Single

The value whose estimate of the reciprocal square root is to be computed.

Returns

Single

An estimate of the reciprocal square root of `x`.

Implements

ReciprocalSqrtEstimate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.RootN(Single, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the n-th root of a value.

```
C#
public static float RootN (float x, int n);
```

Parameters

x Single

The value whose `n`-th root is to be computed.

n Int32

The degree of the root to be computed.

Returns

Single

The `n`-th root of `x`.

Implements

RootN(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Single.Round Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Round(Single)	Rounds a value to the nearest integer using the default rounding mode (ToEven).
Round(Single, Int32)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).
Round(Single, MidpointRounding)	Rounds a value to the nearest integer using the specified rounding mode.
Round(Single, Int32, MidpointRounding)	Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

Round(Single)

Rounds a value to the nearest integer using the default rounding mode (ToEven).

C#

```
public static float Round (float x);
```

Parameters

x Single

The value to round.

Returns

Single

The result of rounding `x` to the nearest integer using the default rounding mode.

Implements

Round(TSelf)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Single, Int32)

Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

C#

```
public static float Round (float x, int digits);
```

Parameters

`x` Single

The value to round.

`digits` Int32

The number of fractional digits to which `x` should be rounded.

Returns

Single

The result of rounding `x` to `digits` fractional-digits using the default rounding mode.

Implements

Round(TSelf, Int32)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Single, MidpointRounding)

Rounds a value to the nearest integer using the specified rounding mode.

C#

```
public static float Round (float x, MidpointRounding mode);
```

Parameters

`x` Single

The value to round.

`mode` MidpointRounding

The mode under which `x` should be rounded.

Returns

Single

The result of rounding `x` to the nearest integer using `mode`.

Implements

Round(TSelf, MidpointRounding)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Round(Single, Int32, MidpointRounding)

Rounds a value to a specified number of fractional-digits using the default rounding mode (ToEven).

```
C#

public static float Round (float x, int digits, MidpointRounding mode);
```

Parameters

`x` Single

The value to round.

`digits` Int32

The number of fractional digits to which `x` should be rounded.

`mode` MidpointRounding

The mode under which `x` should be rounded.

Returns

Single

The result of rounding `x` to `digits` fractional-digits using `mode`.

Implements

Round(TSelf, Int32, MidpointRounding)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Single.ScaleB(Single, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the product of a value and its base-radix raised to the specified power.

```
C#
public static float ScaleB (float x, int n);
```

Parameters

x Single

The value which base-radix raised to the power of `n` multiplies.

n Int32

The value to which base-radix is raised before multipliying `x`.

Returns

Single

The product of `x` and base-radix raised to the power of `n`.

Implements

ScaleB(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Sign(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (float value);
```

Parameters

`value` Single

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Sin(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine of a value.

```
C#
public static float Sin (float x);
```

Parameters

x Single

The value, in radians, whose sine is to be computed.

Returns

Single

The sine of `x`.

Implements

Sin(TSelf)

Remarks

This computes `sin(x)`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.SinCos(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine and cosine of a value.

C#

```
public static (float Sin, float Cos) SinCos (float x);
```

Parameters

x Single

The value, in radians, whose sine and cosine are to be computed.

Returns

ValueTuple<Single,Single>

The sine and cosine of `x`.

Implements

SinCos(TSelf)

Remarks

This computes `(sin(x), cos(x))`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.SinCosPi(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine and cosine of a value.

```
C#
public static (float SinPi, float CosPi) SinCosPi (float x);
```

Parameters

x Single

The value, in radians, whose sine and cosine are to be computed.

Returns

ValueTuple<Single,Single>

The sine and cosine of `x`.

Implements

SinCosPi(TSelf)

Remarks

This computes `(sin(x), cos(x))`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.Sinh(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the hyperbolic sine of a value.

C#

```
public static float Sinh (float x);
```

Parameters

x Single

The value, in radians, whose hyperbolic sine is to be computed.

Returns

Single

The hyperbolic sine of `x`.

Implements

Sinh(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.SinPi(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sine of a value that has been multiplied by `pi`.

C#

```
public static float SinPi (float x);
```

Parameters

x Single

The value, in half-revolutions, that is multipled by `pi` before computing its sine.

Returns

Single

The sine of `x` multiplied-by `pi`.

Implements

SinPi(TSelf)

Remarks

This computes `sin(x * π)`.

Applies to

Product	Versions
.NET	7, 8, 9

Single.Tan(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the tangent of a value.

```
C#
public static float Tan (float x);
```

Parameters

x Single

The value, in radians, whose tangent is to be computed.

Returns

Single

The tangent of `x`.

Implements

Tan(TSelf)

Remarks

This computes `tan(x)`.

Single.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance.

Examples

The following example uses the default Single.ToString method to display the string representations of a number of Single values.

C#

```
float number;

number = 1.6E20F;
// Displays 1.6E+20.
Console.WriteLine(number.ToString());

number = 1.6E2F;
// Displays 160.
Console.WriteLine(number.ToString());

number = -3.541F;
// Displays -3.541.
Console.WriteLine(number.ToString());

number = -1502345222199E-07F;
// Displays -150234.5222199.
Console.WriteLine(number.ToString());

number = -150234522219901995 74E-09F;
// Displays -15023452221.9902.
Console.WriteLine(number.ToString());

number = .60344F;
// Displays 0.60344.
Console.WriteLine(number.ToString());

number = .000000001F;
// Displays 1E-09.
Console.WriteLine(number.ToString());
```

The following code example illustrates the use of the Parse(String) method along with the ToString() method.

C#

```
bool done = false;
string inp;
do
{
    Console.Write("Enter a real number: ");
    inp = Console.ReadLine();
    try
    {
        s = Single.Parse(inp);
```

```
        Console.WriteLine("You entered {0}.", s.ToString());
        done = true;
    }
    catch (FormatException)
    {
        Console.WriteLine("You did not enter a number.");
    }
    catch (Exception e)
    {
        Console.WriteLine("An exception occurred while parsing your
response: {0}", e.ToString());
    }
} while (!done);
```

Remarks

The ToString() method formats a Single value in the default ("G", or general) format of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or a string of the form:

[sign]integral-digits[.[fractional-digits]][e[sign]exponential-digits]

Optional elements are framed in square brackets ([and]). Elements that contain the term "digits" consist of a series of numeric characters ranging from 0 to 9. The following table lists each element:

Expand table

Element	Description
sign	A negative sign or positive sign symbol.
integral-digits	A series of digits specifying the integral part of the number. Integral-digits can be absent if there are fractional-digits.

Element	Description
'.'	A culture-specific decimal point symbol.
fractional-digits	A series of digits specifying the fractional part of the number.
'e'	A lowercase character 'e', indicating exponential (scientific) notation.
exponential-digits	A series of digits specifying an exponent.

Some examples of the return value are "100", "-123,456,789", "123.45e+6", "500", "3.1416", "600", "-0.123", and "-Infinity".

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

```
C#

public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Implements

ToString(IFormatProvider)

Examples

The following example displays the string representation of two Single values using CultureInfo objects that represent several different cultures.

```
C#

float value;

value = -16325.62015F;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));

value = 16034.125E21F;
// Display value using the invariant culture.
Console.WriteLine(value.ToString(CultureInfo.InvariantCulture));
// Display value using the en-GB culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("en-
```

```
GB")));
// Display value using the de-DE culture.
Console.WriteLine(value.ToString(CultureInfo.CreateSpecificCulture("de-
DE")));
// This example displays the following output to the console:
//       -16325.62015
//       -16325.62015
//       -16325,62015
//       1.6034125E+25
//       1.6034125E+25
//       1,6034125E+25
```

Remarks

The ToString(IFormatProvider) method formats a Single value in the default ("G", or general) format of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or a string of the form:

[sign]integral-digits[.[fractional-digits]][e[sign]exponential-digits]

Optional elements are framed in square brackets ([and]). Elements containing the term "digits" consist of a series of numeric characters ranging from 0 to 9. The following table lists each element.

Expand table

Element	Description
sign	A negative sign or positive sign symbol.
integral-digits	A series of digits specifying the integral part of the number. Integral-digits can be absent if there are fractional-digits.
'.'	A culture-specific decimal point symbol.

Element	Description
fractional-digits	A series of digits specifying the fractional part of the number.
'e'	A lowercase character 'e', indicating exponential (scientific) notation.
exponential-digits	A series of digits specifying an exponent.

Some examples of the return value are "100", "-123,456,789", "123.45e+6", "500", "3.1416", "600", "-0.123", and "-Infinity".

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a CultureInfo object or a NumberFormatInfo object. The `provider` parameter supplies culture-specific information used in formatting. If `provider` is `null`, the return value is formatted using the NumberFormatInfo data for the current culture.

To convert a Single value to its string representation using a specified culture and a specific format string, call the Single.ToString(String, IFormatProvider) method.

UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid.

Examples

The following example defines a numeric value and formats it as a currency value by using the "C" standard numeric format string and as a numeric value to three decimal places by using the "N" standard numeric format string. The result strings are formatted by using the conventions of the en-US culture. For more information on numeric format strings, see Standard Numeric Format Strings and Custom Numeric Format Strings.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Double number = 1764.3789;

      // Format as a currency value.
      Console.WriteLine(number.ToString("C"));

      // Format as a numeric value with 3 decimal places.
      Console.WriteLine(number.ToString("N3"));
   }
}
// The example displays the following output:
//       $1,764.38
//       1,764.379
```

The following example displays several Single values using each of the supported standard numeric format specifiers together with two custom numeric format strings. One of those custom format strings illustrates how to pad a Single value with leading zeros. In converting the numeric values to strings, the example uses the formatting conventions of the en-US culture.

C#

```
float[] numbers= { 1054.32179F, -195489100.8377F, 1.0437E21F,
                   -1.0573e-05F };
string[] specifiers = { "C", "E", "e", "F", "G", "N", "P",
                        "R", "#,000.000", "0.###E-000",
                        "000,000,000,000.00###" };

foreach (float number in numbers)
{
   Console.WriteLine("Formatting of {0}:", number);
   foreach (string specifier in specifiers)
      Console.WriteLine("   {0,5}: {1}",
                        specifier, number.ToString(specifier));

   Console.WriteLine();
}
// The example displays the following output to the console:
//       Formatting of 1054.32179:
//              C: $1,054.32
//              E: 1.054322E+003
//              e: 1.054322e+003
//              F: 1054.32
//              G: 1054.32179
```

```
//              N: 1,054.32
//              P: 105,432.18 %
//              R: 1054.32179
//         #,000.000: 1,054.322
//         0.###E-000: 1.054E003
//         000,000,000,000.00###: 000,000,001,054.322
//
//       Formatting of -195489100.8377:
//              C: ($195,489,100.84)
//              E: -1.954891E+008

//              E: -1.057300E-005
//              e: -1.057300e-005
//              F: 0.00
//              G: -1.0573E-05
//              N: 0.00
//              P: 0.00 %
//              R: -1.0573E-05
//         #,000.000: 000.000
//         0.###E-000: -1.057E-005
//         000,000,000,000.00###: -000,000,000,000.00001
```

Remarks

The ToString(String) method formats a Single value in a specified format by using the conventions of the current culture. If you want to use the default ("G", or general)

format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or the string representation of the value of the current instance, as specified by `format`.

The `format` parameter can be any valid standard numeric format specifier except for D and X, as well as any combination of custom numeric format specifiers. If format is `null` or an empty string, the return value is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

By default, the return value only contains 7 digits of precision although a maximum of 9 digits is maintained internally. If the value of this instance has greater than 7 digits, ToString(String) returns PositiveInfinitySymbol or NegativeInfinitySymbol instead of the expected number. If you require more precision, specify `format` with the "G9" format specification, which always returns 9 digits of precision, or "R", which returns 7 digits if the number can be represented with that precision or 9 digits if the number can only be represented with maximum precision.

UWP	10.0

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

```
C#

public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Examples

The following example displays a Single value using each of the supported standard numeric format specifiers for several different cultures.

C#

```
float value = 16325.62901F;
string specifier;
CultureInfo culture;

// Use standard numeric format specifiers.
specifier = "G";
culture = CultureInfo.CreateSpecificCulture("eu-ES");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325,62901
Console.WriteLine(value.ToString(specifier,
CultureInfo.InvariantCulture));
// Displays:    16325.62901

specifier = "C";
culture = CultureInfo.CreateSpecificCulture("en-US");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    $16,325.63
culture = CultureInfo.CreateSpecificCulture("en-GB");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    £16,325.63

specifier = "E04";
culture = CultureInfo.CreateSpecificCulture("sv-SE");
Console.WriteLine(value.ToString(specifier, culture));
// Displays: 1,6326E+004
 culture = CultureInfo.CreateSpecificCulture("en-NZ");
 Console.WriteLine(value.ToString(specifier, culture));
// Displays:    1.6326E+004

specifier = "F";
culture = CultureInfo.CreateSpecificCulture("fr-FR");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325,63
culture = CultureInfo.CreateSpecificCulture("en-CA");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16325.63

specifier = "N";
culture = CultureInfo.CreateSpecificCulture("es-ES");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16.325,63
culture = CultureInfo.CreateSpecificCulture("fr-CA");
Console.WriteLine(value.ToString(specifier, culture));
// Displays:    16 325,63

specifier = "P";
```

```
culture = CultureInfo.InvariantCulture;
Console.WriteLine((value/10000).ToString(specifier, culture));
// Displays:    163.26 %
culture = CultureInfo.CreateSpecificCulture("ar-EG");
Console.WriteLine((value/10000).ToString(specifier, culture));
// Displays:    163.256 %
```

Remarks

The ToString(String, IFormatProvider) method formats a Single value in a specified format of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The return value can be PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol, or the string representation of the value of the current instance, as specified by `format`.

The `format` parameter can be any valid standard numeric format specifier except for D and X, as well as any combination of custom numeric format specifiers. If `format` is `null` or an empty string, the return value for this instance is formatted with the general numeric format specifier ("G").

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object. Typically, `provider` is a CultureInfo object or a NumberFormatInfo object. The `provider` parameter supplies culture-

specific information used in formatting. If `provider` is `null`, the return value is formatted with the NumberFormatInfo object for the current culture.

By default, the return value only contains 7 digits of precision although a maximum of 9 digits is maintained internally. If the value of this instance has greater than 7 digits, ToString returns PositiveInfinitySymbol or NegativeInfinitySymbol instead of the expected number. If you require more precision, specify `format` with the "G9" format specification, which always returns 9 digits of precision, or "R", which returns 7 digits if the number can be represented with that precision or 9 digits if the number can only be represented with maximum precision.

Single.Truncate(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Truncates a value.

```
C#
public static float Truncate (float x);
```

Parameters

x Single

The value to truncate.

Returns

Single

The truncation of `x`.

Implements

Truncate(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current float number instance into the provided span of characters.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current float number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the charactes that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

```
C#
```

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Single.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, IFormatProvider, Single)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, Single)	Converts the string representation of a number in a character span to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, Single)	Converts the string representation of a number to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, Single)	Tries to parse a span of UTF-8 characters into a value.
TryParse(String, IFormatProvider, Single)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Single)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, Single)	Tries to convert a UTF-8 character span containing the string representation of a number to its single-precision floating-point number equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Single)	Converts the span representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent. A return

	value indicates whether the conversion succeeded or failed.
TryParse(String, NumberStyles, IFormatProvider, Single)	Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

TryParse(ReadOnlySpan<Char>, IFormatProvider, Single)

Tries to parse a span of characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out float result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

result Single

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, Single)

Converts the string representation of a number in a character span to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, out float result);
```

Parameters

`s` ReadOnlySpan<Char>

>A character span that contains the string representation of the number to convert.

`result` Single

When this method returns, contains the single-precision floating-point number equivalent of the `s` parameter, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or empty or is not a number in a valid format. If `s` is a valid number less than Single.MinValue, `result` is NegativeInfinity. If `s` is a valid number greater than Single.MaxValue, `result` is PositiveInfinity. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, Single)

Converts the string representation of a number to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, out float result);
```

Parameters

`s` String

A string representing a number to convert.

`result` Single

When this method returns, contains single-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty or is not a number in a valid format. It also fails on .NET Framework and .NET Core 2.2 and earlier versions if `s` represents a number less than Single.MinValue or greater than Single.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example uses the TryParse(String, Single) method to convert the string representations of numeric values to Single values. It assumes that en-US is the current culture.

C#

```
string value;
float number;

// Parse a floating-point value with a thousands separator.
value = "1,643.57";
if (Single.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);

// Parse a floating-point value with a currency symbol and a
// thousands separator.
value = "$1,643.57";
if (Single.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);

// Parse value in exponential notation.
value = "-1.643e6";
if (Single.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);

// Parse a negative integer value.
value = "-168934617882109132";
if (Single.TryParse(value, out number))
   Console.WriteLine(number);
else
   Console.WriteLine("Unable to parse '{0}'.", value);
// The example displays the following output:
//       1643.57
//       Unable to parse '$1,643.57'.
//       -164300
//       -1.689346E+17
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

This overload differs from the Single.Parse(String) method by returning a Boolean value that indicates whether the parse operation succeeded instead of returning the parsed numeric value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `s` parameter can contain PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol (the string comparison is case-sensitive), or a string of the form:

[ws][sign][integral-digits,]integral-digits[.[fractional-digits]][e[sign]exponential-digits][ws]

Elements in square brackets are optional. The following table describes each element.

Expand table

Element	Description
ws	A series of white-space characters.
sign	A negative sign or positive sign symbol.
integral-digits	A series of numeric characters ranging from 0 to 9 that specify the integral part of the number. Integral-digits can be absent if there are fractional-digits.
,	A culture-specific group separator symbol.
.	A culture-specific decimal point symbol.
fractional-digits	A series of numeric characters ranging from 0 to 9 that specify the fractional part of the number.
E	An uppercase or lowercase character 'e', that indicates exponential (scientific) notation.
exponential-digits	A series of numeric characters ranging from 0 to 9 that specify an exponent.

The `s` parameter is interpreted using a combination of the NumberStyles.Float and NumberStyles.AllowThousands flags. This means that white space and thousands separators are allowed but currency symbols are not. To explicitly define the elements (such as currency symbols, thousands separators, and white space) that can be present in `s`, use the TryParse(String, NumberStyles, IFormatProvider, Single) method overload.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse a string using the formatting information of some other specified culture, use the TryParse(String, NumberStyles, IFormatProvider, Single) method overload.

Ordinarily, if you pass the Single.TryParse method a string that is created by calling the Single.ToString method, the original Single value is returned. However, because of a loss of precision, the values may not be equal.

If `s` is out of range of the Single data type, the method returns `false` on .NET Framework and .NET Core 2.2 and earlier versions. On .NET Core 3.0 and later versions, it returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, Single)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out float result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Single

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, IFormatProvider, Single)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
float result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` Single

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, Single)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
float result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` Single

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, Single)

Tries to convert a UTF-8 character span containing the string representation of a number to its single-precision floating-point number equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out float
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A read-only UTF-8 character span that contains the number to convert.

`result` Single

When this method returns, contains a single-precision floating-point number equivalent of the numeric value or symbol contained in `utf8Text` if the conversion succeeded or zero if the conversion failed. The conversion fails if the `utf8Text` is Empty or is not in a valid format. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, Single)

Converts the span representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#

public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
float result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only character span that contains the number to convert. The span is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Single

When this method returns, contains the single-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, represents a number less than Single.MinValue or greater than Single.MaxValue, or if `style` is not a valid combination of NumberStyles enumerated constants. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, Single)

Converts the string representation of a number in a specified style and culture-specific format to its single-precision floating-point number equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out float result);
```

Parameters

`s` String

A string representing a number to convert.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Float combined with AllowThousands.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` Single

When this method returns, contains the single-precision floating-point number equivalent to the numeric value or symbol contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or if `style` is not a valid combination of NumberStyles enumeration constants. It also fails on .NET Framework or .NET Core 2.2 and earlier versions if `s` represents a number less than Single.MinValue or greater than Single.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is the AllowHexSpecifier value.

Examples

The following example demonstrates the use of the Single.TryParse(String, NumberStyles, IFormatProvider, Single) method to parse the string representation of numbers that have a particular style and are formatted using the conventions of a particular culture.

C#

```
string value;
System.Globalization.NumberStyles style;
System.Globalization.CultureInfo culture;
float number;

// Parse currency value using en-GB culture.
value = "£1,097.63";
style = System.Globalization.NumberStyles.Number |
        System.Globalization.NumberStyles.AllowCurrencySymbol;
culture = System.Globalization.CultureInfo.CreateSpecificCulture("en-
GB");
if (Single.TryParse(value, style, culture, out number))
```

```
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);

value = "1345,978";
style = System.Globalization.NumberStyles.AllowDecimalPoint;
culture = System.Globalization.CultureInfo.CreateSpecificCulture("fr-
FR");
if (Single.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);

value = "1.345,978";
style = System.Globalization.NumberStyles.AllowDecimalPoint |
        System.Globalization.NumberStyles.AllowThousands;
culture = System.Globalization.CultureInfo.CreateSpecificCulture("es-
ES");
if (Single.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);

value = "1 345,978";
if (Single.TryParse(value, style, culture, out number))
   Console.WriteLine("Converted '{0}' to {1}.", value, number);
else
   Console.WriteLine("Unable to convert '{0}'.", value);
// The example displays the following output:
//       Converted '£1,097.63' to 1097.63.
//       Converted '1345,978' to 1345.978.
//       Converted '1.345,978' to 1345.978.
//       Unable to convert '1 345,978'.
```

Remarks

In .NET Core 3.0 and later, values that are too large to represent are rounded to PositiveInfinity or NegativeInfinity as required by the IEEE 754 specification. In prior versions, including .NET Framework, parsing a value that was too large to represent resulted in failure.

This overload differs from the Parse(String, NumberStyles, IFormatProvider) method by returning a Boolean value that indicates whether the parse operation succeeded instead of returning the parsed numeric value. It eliminates the need to use exception handling to test for a FormatException in the event that `s` is invalid and cannot be successfully parsed.

The `style` parameter defines the allowable format of the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles

enumeration. The following NumberStyles members are not supported:

- NumberStyles.AllowHexSpecifier
- NumberStyles.HexNumber

The `s` parameter can contain PositiveInfinitySymbol, NegativeInfinitySymbol, NaNSymbol for the culture indicated by `provider`. In addition, depending on the value of `style`, the `s` parameter may include the following elements:

[ws] [$] [sign][integral-digits,]integral-digits[.fractional-digits][e[sign]exponential-digits][ws]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag. It can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern or NumberFormatInfo.CurrencyPositivePattern properties of the NumberFormatInfo object returned by the IFormatProvider.GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
integral-digits	A series of digits ranging from 0 to 9 that specify the integral part of the number. Integral-digits can be absent if there are fractional-digits.
,	A culture-specific thousands separator symbol. The current culture's thousands separator symbol can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.

Element	Description
fractional-digits	A series of digits ranging from 0 to 9 that specify the fractional part of the number. Fractional digits can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
e	The e or E character, which indicates that `s` can represent a number using exponential notation. The `s` parameter can represent a number in exponential notation if style includes the NumberStyles.AllowExponent flag.
exponential-digits	A series of digits ranging from 0 to 9 that specify an exponent.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the Single type. The remaining System.Globalization.NumberStyles members control elements that may be but are not required to be present in the input string. The following table indicates how individual NumberStyles flags affect the elements that may be present in `s`.

Expand table

NumberStyles value	Elements permitted in s in addition to digits
None	The *integral-digits* element only.
AllowDecimalPoint	The . and *fractional-digits* elements.
AllowExponent	The `s` parameter can also use exponential notation. This flag by itself supports values in the form *integral-digits*E*exponential-digits*; additional flags are needed to successfully parse strings in exponential notation with such elements as positive or negative signs and decimal point symbols.
AllowLeadingWhite	The *ws* element at the beginning of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the beginning of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.

NumberStyles value	Elements permitted in s in addition to digits
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The , element.
AllowCurrencySymbol	The *$* element.
Currency	All. The `s` parameter cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the beginning or end of `s`, *sign* at the beginning of `s`, and the . symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, thousands separator (*,*), and decimal point (.) elements.
Any	All styles, except `s` cannot represent a hexadecimal number.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific formatting information. When the TryParse(String, NumberStyles, IFormatProvider, Single) method is invoked, it calls the `provider` parameter's GetFormat method and passes it a Type object that represents the NumberFormatInfo type. The GetFormat method then returns the NumberFormatInfo object that provides information about the format of the `s` parameter. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass a CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- You can pass the actual NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- You can pass a custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the formatting of `s` is interpreted based on the NumberFormatInfo object of the current culture.

If `s` is out of range of the Single data type, the method throws an OverflowException on .NET Framework and .NET Core 2.2 and earlier versions. On .NET Core 3.0 and

later versions, it returns Single.NegativeInfinity if `s` is less than Single.MinValue and Single.PositiveInfinity if `s` is greater than Single.MaxValue.

If a separator is encountered in the `s` parameter during a parse operation, and the applicable currency or number decimal and group separators are the same, the parse operation assumes that the separator is a decimal separator rather than a group separator. For more information about separators, see CurrencyDecimalSeparator, NumberDecimalSeparator, CurrencyGroupSeparator, and NumberGroupSeparator.

Single.Equality(Single, Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two specified Single values are equal.

```
C#
public static bool operator == (float left, float right);
```

Parameters

`left` Single

The first value to compare.

`right` Single

The second value to compare.

Returns

Boolean

`true` if `left` and `right` are equal; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Remarks

The Equality method defines the equality operator for Single values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.GreaterThan(Single, Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Single value is greater than another specified Single value.

```
C#
public static bool operator > (float left, float right);
```

Parameters

`left` Single

The first value to compare.

`right` Single

The second value to compare.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Remarks

The GreaterThan method defines the operation of the greater-than operator for Single values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.GreaterThanOrEqual(Single, Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Single value is greater than or equal to another specified Single value.

C#

```
public static bool operator >= (float left, float right);
```

Parameters

`left` Single

The first value to compare.

`right` Single

The second value to compare.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Remarks

The GreaterThanOrEqual method defines the operation of the greater-than-or-equal operator for Single values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.Inequality(Single, Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two specified Single values are not equal.

```
C#
public static bool operator != (float left, float right);
```

Parameters

`left` Single

The first value to compare.

`right` Single

The second value to compare.

Returns

Boolean

`true` if `left` and `right` are not equal; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Remarks

The Inequality method defines the inequality operator for Single values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.LessThan(Single, Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Single value is less than another specified Single value.

```
C#
public static bool operator < (float left, float right);
```

Parameters

`left` Single

The first value to compare.

`right` Single

The second value to compare.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Remarks

The LessThan method defines the operation of the less-than operator for Single values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.LessThanOrEqual(Single, Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether a specified Single value is less than or equal to another specified Single value.

C#

```
public static bool operator <= (float left, float right);
```

Parameters

`left` Single

The first value to compare.

`right` Single

The second value to compare.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Remarks

The LessThanOrEqual method defines the operation of the less-than-or-equal operator for Single values.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Single.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

C#

```
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

This conversion is not supported. No value is returned.

Implements

ToChar(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Single.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.To Decimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.To Double(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

C#

```
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Single.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.To Int32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#

int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToSByte(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.To Single(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

C#

```
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, unchanged.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to which to convert this Single value.

provider IFormatProvider

An object that supplies information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Single.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt16(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Single.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the Single instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt64(Single) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Single.IAdditionOperators<Single,Single,Single>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static float IAdditionOperators<float,float,float>.operator + (float left,
float right);
```

Parameters

`left` Single

The value to which `right` is added.

`right` Single

The value that's added to `left`.

Returns

Single

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Single.IAdditiveIdentity<Single,Single>.AdditiveIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the additive identity of the current type.

C#

```
static float
System.Numerics.IAdditiveIdentity<System.Single,System.Single>.AdditiveIdentity { get; }
```

Property Value

Single

Implements

AdditiveIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Single.IBinaryNumber<Single>.AllBits Set Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an instance of the binary type in which all bits are set.

C#

```
static float System.Numerics.IBinaryNumber<System.Single>.AllBitsSet { get;
}
```

Property Value

Single

Implements

AllBitsSet

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IBitwiseOperators<Single,Single,Single>.BitwiseAnd Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static float IBitwiseOperators<float,float,float>.operator & (float left,
float right);
```

Parameters

`left` Single

The value to `and` with `right`.

`right` Single

The value to `and` with `left`.

Returns

Single

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IBitwiseOperators<Single,Single,Single>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static float IBitwiseOperators<float,float,float>.operator | (float left,
float right);
```

Parameters

`left` Single

The value to `or` with `right`.

`right` Single

The value to `or` with `left`.

Returns

Single

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IBitwiseOperators<Single,Single,Single>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static float IBitwiseOperators<float,float,float>.operator ^ (float left,
float right);
```

Parameters

`left` Single

The value to xor with `right`.

`right` Single

The value to xor with `left`.

Returns

Single

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IBitwise Operators<Single,Single,Single>.Ones Complement Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
static float IBitwiseOperators<float,float,float>.operator ~ (float value);
```

Parameters

`value` Single

The value for which to compute the ones-complement.

Returns

Single

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IDecrementOperators<Single>.Decrement(Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static float IDecrementOperators<float>.operator -- (float value);
```

Parameters

`value` Single

The value to decrement.

Returns

Single

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IDivisionOperators<Single,Single,Single>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static float IDivisionOperators<float,float,float>.operator / (float left,
float right);
```

Parameters

`left` Single

The value that `right` divides.

`right` Single

The value that divides `left`.

Returns

Single

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IFloatingPoint<Single>.GetExponentByteCount Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of bytes that will be written as part of TryWriteExponentLittleEndian(Span<Byte>, Int32).

C#

```
int IFloatingPoint<float>.GetExponentByteCount ();
```

Returns

Int32

The number of bytes that will be written as part of TryWriteExponentLittleEndian(Span<Byte>, Int32).

Implements

GetExponentByteCount()

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IFloatingPoint<Single>.GetExponentShortestBitLength Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the length, in bits, of the shortest two's complement representation of the current exponent.

C#

```
int IFloatingPoint<float>.GetExponentShortestBitLength ();
```

Returns

Int32

The length, in bits, of the shortest two's complement representation of the current exponent.

Implements

GetExponentShortestBitLength()

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IFloatingPoint<Single>.TryWriteExponentBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current exponent, in big-endian format, to a given span.

C#

```
bool IFloatingPoint<float>.TryWriteExponentBigEndian (Span<byte>
destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current exponent should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the exponent was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteExponentBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IFloatingPoint<Single>.TryWriteExponentLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current exponent, in little-endian format, to a given span.

C#

```
bool IFloatingPoint<float>.TryWriteExponentLittleEndian (Span<byte>
destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current exponent should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the exponent was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteExponentLittleEndian(Span<Byte>, Int32)

Applies to

Single.IIncrementOperators<Single>.Increment(Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static float IIncrementOperators<float>.operator ++ (float value);
```

Parameters

`value` Single

The value to increment.

Returns

Single

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IModulusOperators<Single,Single,Single>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#
static float IModulusOperators<float,float,float>.operator % (float left,
float right);
```

Parameters

`left` Single

The value that `right` divides.

`right` Single

The value that divides `left`.

Returns

Single

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.IMultiplyOperators<Single,Single,Single>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static float IMultiplyOperators<float,float,float>.operator * (float left,
float right);
```

Parameters

`left` Single

The value that `right` multiplies.

`right` Single

The value that multiplies `left`.

Returns

Single

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.INumberBase<Single>.IsCanonical(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<float>.IsCanonical (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Single.INumberBase<Single>.IsComplexNumber(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<float>.IsComplexNumber (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.INumberBase<Single>.IsImaginaryNumber(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

```
C#
static bool INumberBase<float>.IsImaginaryNumber (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Single.INumberBase<Single>.IsZero(Single) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<float>.IsZero (float value);
```

Parameters

`value` Single

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.INumberBase<Single>.One Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `1` for the type.

```
C#
static float System.Numerics.INumberBase<System.Single>.One { get; }
```

Property Value

Single

Implements

One

Applies to

Product	Versions
.NET	7, 8, 9

Single.INumberBase<Single>.Radix Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the radix, or base, for the type.

C#

```
static int System.Numerics.INumberBase<System.Single>.Radix { get; }
```

Property Value

Int32

Implements

Radix

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.INumberBase<Single>.TryConvertFromChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<float>.TryConvertFromChecked<TOther> (TOther value,
out float result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` Single

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

Single.INumberBase<Single>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<float>.TryConvertToChecked<TOther> (float value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Single

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.INumberBase<Single>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<float>.TryConvertToSaturating<TOther> (float value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Single

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.INumberBase<Single>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<float>.TryConvertToTruncating<TOther> (float value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` Single

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Single.ISubtractionOperators<Single,Single,Single>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static float ISubtractionOperators<float,float,float>.operator - (float
left, float right);
```

Parameters

`left` Single

The value from which `right` is subtracted.

`right` Single

The value that's subtracted from `left`.

Returns

Single

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IUnaryNegationOperators<Single,Single>.UnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static float IUnaryNegationOperators<float,float>.operator - (float value);
```

Parameters

`value` Single

The value for which to compute the unary negation.

Returns

Single

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Single.IUnaryPlusOperators<Single,Single>.UnaryPlus(Single) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static float IUnaryPlusOperators<float,float>.operator + (float value);
```

Parameters

`value` Single

The value for which to compute the unary plus.

Returns

Single

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Span<T>.Enumerator Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides an enumerator for the elements of a Span<T>.

```
C#
public ref struct Span<T>.Enumerator
```

Type Parameters

T

Inheritance Object → ValueType → Span<T>.Enumerator

Remarks

The C# foreach of the C# language and the For Each...Next construct in Visual Basic hides the complexity of enumerators. Instead of directly manipulating the enumerator, using `foreach` or `For Each...Next` is recommended.

Initially, the enumerator is positioned before the first element in the Span<T>. At this position, Current is undefined. You must call MoveNext to advance the enumerator to the first item in the Span<T> before reading the value of Current.

Current returns the same value until MoveNext is called. MoveNext sets Current to the next item in the Span<T>.

If MoveNext passes the end of the Span<T>, MoveNext returns `false`. When the enumerator is at this state, subsequent calls to MoveNext also return `false` and Current is undefined. You cannot set Current to the first item in the Span<T> again; you must create a new enumerator instance instead.

The enumerator does not have exclusive access to the Span<T>. In addition, the underlying data on which the span is based can also be modified. Therefore,

enumerating through a span is intrinsically not a thread-safe procedure. To guarantee thread safety during enumeration, you must implement your own synchronization. For example, the following code has a race condition. It does not ensure that the span will be enumerated before the `ClearContents` method executes. As a result, the underlying array is cleared during enumeration of the span:

C#

```
using System;
using System.Threading.Tasks;

class Program
{
    private static readonly byte[] _array = new byte[5];

    static void Main()
    {
        new Random(42).NextBytes(_array);
        Span<byte> span = _array;

        Task.Run( () => ClearContents() );

       EnumerateSpan(span);
    }

    public static void ClearContents()
    {
        Task.Delay(20).Wait();
        lock (_array)
        {
           Array.Clear(_array, 0, _array.Length);
        }
    }

    public static void EnumerateSpan(Span<byte> span)
    {
        foreach (byte element in span)
        {
            Console.WriteLine(element);
            Task.Delay(10).Wait();
        }
    }
}
// The example displays output like the following:
//     62
//     23
//     186
//     0
//     0
```

If you synchronize access to the array before enumerating the span, as the revised version of the `EnumerateSpan` method does in the following example, the `ClearContents` method doesn't modify underlying span data during enumeration. Note that the example locks the underlying array on which the span is based.

C#

```
public static void EnumerateSpan(Span<byte> span)
{
    lock (_array)
    {
        foreach (byte element in span)
        {
            Console.WriteLine(element);
            Task.Delay(10).Wait();
        }
    }
}
// The example displays the following output:
//    62
//    23
//    186
//    150
//    174
```

Unlike some other enumerator structures in .NET, the Span<T>.Enumerator:

- Does not implement the IEnumerator or IEnumerator<T> interface. This is because Span<T>.Enumerator is a ref struct.
- Does not include a `Reset` method, which can set the enumerator to its initial position before the first element in the span. (The IEnumerator.Reset() method must be implemented as part of the interface, but most implementors either throw an exception or provide no implementation.)

Properties

Expand table

Current	Gets a reference to the item at the current position of the enumerator.

Methods

Expand table

MoveNext()	Advances the enumerator to the next item of the Span<T>.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.Enumerator.Current Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a reference to the item at the current position of the enumerator.

```
C#
public ref T Current { get; }
```

Property Value

T

The element in the Span<T> at the current position of the enumerator.

Remarks

`Current` is undefined under either of the following conditions:

- Immediately after the enumerator is created, the enumerator is positioned before the first element in the span. MoveNext must be called to advance the enumerator to the first element of the span before reading the value of `Current`.
- The last call to MoveNext returned `false`, which indicates the end of the span.

`Current` returns the same value until MoveNext is called. MoveNext sets `Current` to the next item in the span.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

.NET feedback

.NET is an open source project. Select a link to provide feedback:

Span<T>.Enumerator.MoveNext Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Advances the enumerator to the next item of the Span<T>.

```
C#
public bool MoveNext ();
```

Returns

Boolean

`true` if the enumerator successfully advanced to the next item; `false` if the end of the span has been passed.

Remarks

After an enumerator is created, it is positioned before the first element in the span, and the first call to `MoveNext` advances the enumerator to the first item in the span.

If `MoveNext` passes the end of the span, `MoveNext` returns `false`. When the enumerator is at this state, subsequent calls to `MoveNext` also return `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Span<T> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a type-safe and memory-safe representation of a contiguous region of arbitrary memory.

C#

```
[System.Runtime.InteropServices.Marshalling.NativeMarshalling(typeof(System.
Runtime.InteropServices.Marshalling.SpanMarshaller<,>))]
public readonly ref struct Span<T>
```

Type Parameters

T

The type of items in the Span<T>.

Inheritance Object → ValueType → Span<T>

Attributes NativeMarshallingAttribute

Remarks

For more information about this API, see Supplemental API remarks for Span<T>.

Constructors

Expand table

Span<T>(T)	Creates a new Span<T> of length 1 around the specified reference.
Span<T>(T[])	Creates a new Span<T> object over the entirety of a specified array.
Span<T>(T[], Int32, Int32)	Creates a new Span<T> object that includes a specified number of elements of an array starting at a specified index.

Span<T>(Void*, Int32)	Creates a new Span<T> object from a specified number of `T` elements starting at a specified memory address.

Properties

Expand table

Empty	Returns an empty Span<T> object.
IsEmpty	Returns a value that indicates whether the current Span<T> is empty.
Item[Int32]	Gets the element at the specified zero-based index.
Length	Returns the length of the current span.

Methods

Expand table

Clear()	Clears the contents of this Span<T> object.
CopyTo(Span<T>)	Copies the contents of this Span<T> into a destination Span<T>.
Equals(Object)	**Obsolete.** Calls to this method are not supported.
Fill(T)	Fills the elements of this span with a specified value.
GetEnumerator()	Returns an enumerator for this Span<T>.
GetHashCode()	**Obsolete.** Throws a NotSupportedException.
GetPinnable Reference()	Returns a reference to an object of type T that can be used for pinning. This method is intended to support .NET compilers and is not intended to be called by user code.
Slice(Int32)	Forms a slice out of the current span that begins at a specified index.
Slice(Int32, Int32)	Forms a slice out of the current span starting at a specified index for a specified length.
ToArray()	Copies the contents of this span into a new array.

ToString()	Returns the string representation of this Span<T> object.
TryCopyTo(Span<T>)	Attempts to copy the current Span<T> to a destination Span<T> and returns a value that indicates whether the copy operation succeeded.

Operators

Expand table

Equality(Span<T>, Span<T>)	Returns a value that indicates whether two Span<T> objects are equal.
Implicit(ArraySegment<T> to Span<T>)	Defines an implicit conversion of an ArraySegment<T> to a Span<T>.
Implicit(Span<T> to ReadOnlySpan<T>)	Defines an implicit conversion of a Span<T> to a ReadOnlySpan<T>.
Implicit(T[] to Span<T>)	Defines an implicit conversion of an array to a Span<T>.
Inequality(Span<T>, Span<T>)	Returns a value that indicates whether two Span<T> objects are not equal.

Extension Methods

Expand table

ToImmutableArray<T>(Span<T>)	Converts the span to an immutable array.
BinarySearch<T>(Span<T>, IComparable<T>)	Searches an entire sorted Span<T> for a value using the specified IComparable<T> generic interface.
BinarySearch<T,TComparer>(Span<T>, T, TComparer)	Searches an entire sorted Span<T> for a specified value using the specified `TComparer` generic type.
BinarySearch<T,TComparable>(Span<T>, TComparable)	Searches an entire sorted Span<T> for a value using the specified `TComparable` generic type.
CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>)	Finds the length of any common prefix shared between `span` and `other`.
CommonPrefixLength<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Finds the length of any common prefix shared between `span` and `other`.
Contains<T>(Span<T>, T)	Indicates whether a specified value is found in a span. Values are compared using

	IEquatable{T}.Equals(T).
ContainsAny<T>(Span<T>, T, T)	Searches for an occurrence of `value0` or `value1`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, T, T, T)	Searches for an occurrence of `value0`, `value1`, or `value2`, and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, SearchValues<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for an occurrence of any of the specified `values` and returns `true` if found. If not found, returns `false`.
ContainsAnyExcept<T>(Span<T>, T)	Searches for any value other than the specified `value`.
ContainsAnyExcept<T>(Span<T>, T, T)	Searches for any value other than `value0` or `value1`.
ContainsAnyExcept<T>(Span<T>, T, T, T)	Searches for any value other than `value0`, `value1`, or `value2`.
ContainsAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for any value other than the specified `values`.
ContainsAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for any value other than the specified `values`.
ContainsAnyExceptInRange<T>(Span<T>, T, T)	Searches for any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
ContainsAnyInRange<T>(Span<T>, T, T)	Searches for any value in the range between `lowInclusive` and `highInclusive`, inclusive, and returns `true` if found. If not found, returns `false`.
Count<T>(Span<T>, T)	Counts the number of times the specified `value` occurs in the `span`.
Count<T>(Span<T>, ReadOnlySpan<T>)	Counts the number of times the specified `value` occurs in the `span`.
EndsWith<T>(Span<T>, ReadOnlySpan<T>)	Determines whether the specified sequence appears at the end of a span.

IndexOf<T>(Span<T>, T)	Searches for the specified value and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOf<T>(Span<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its first occurrence. Values are compared using IEquatable{T}.Equals(T).
IndexOfAny<T>(Span<T>, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, T, T, T)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAny<T>(Span<T>, SearchValues<T>)	Searches for the first index of any of the specified values.
IndexOfAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for the first index of any of the specified values similar to calling IndexOf several times with the logical OR operator.
IndexOfAnyExcept<T>(Span<T>, T)	Searches for the first index of any value other than the specified `value`.
IndexOfAnyExcept<T>(Span<T>, T, T)	Searches for the first index of any value other than the specified `value0` or `value1`.
IndexOfAnyExcept<T>(Span<T>, T, T, T)	Searches for the first index of any value other than the specified `value0`, `value1`, or `value2`.
IndexOfAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for the first index of any value other than the specified `values`.
IndexOfAnyExceptInRange<T>(Span<T>, T, T)	Searches for the first index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
IndexOfAnyInRange<T>(Span<T>, T, T)	Searches for the first index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOf<T>(Span<T>, T)	Searches for the specified value and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).

LastIndexOf<T>(Span<T>, ReadOnlySpan<T>)	Searches for the specified sequence and returns the index of its last occurrence. Values are compared using IEquatable{T}.Equals(T).
LastIndexOfAny<T>(Span<T>, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, T, T, T)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAny<T>(Span<T>, SearchValues<T>)	Searches for the last index of any of the specified values.
LastIndexOfAny<T>(Span<T>, ReadOnlySpan<T>)	Searches for the last index of any of the specified values similar to calling LastIndexOf several times with the logical OR operator.
LastIndexOfAnyExcept<T>(Span<T>, T)	Searches for the last index of any value other than the specified `value`.
LastIndexOfAnyExcept<T>(Span<T>, T, T)	Searches for the last index of any value other than the specified `value0` or `value1`.
LastIndexOfAnyExcept<T>(Span<T>, T, T, T)	Searches for the last index of any value other than the specified `value0`, `value1`, or `value2`.
LastIndexOfAnyExcept<T>(Span<T>, SearchValues<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExcept<T>(Span<T>, ReadOnlySpan<T>)	Searches for the last index of any value other than the specified `values`.
LastIndexOfAnyExceptInRange<T>(Span<T>, T, T)	Searches for the last index of any value outside of the range between `lowInclusive` and `highInclusive`, inclusive.
LastIndexOfAnyInRange<T>(Span<T>, T, T)	Searches for the last index of any value in the range between `lowInclusive` and `highInclusive`, inclusive.
Overlaps<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a span and a read-only span overlap in memory.
Overlaps<T>(Span<T>, ReadOnlySpan<T>, Int32)	Determines whether a span and a read-only span overlap in memory and outputs the element offset.
Replace<T>(Span<T>, T, T)	Replaces all occurrences of `oldValue` with `newValue`.

Reverse<T>(Span<T>)	Reverses the sequence of the elements in the entire span.
SequenceCompareTo<T>(Span<T>, ReadOnlySpan<T>)	Determines the relative order of a span and a read-only span by comparing the elements using IComparable{T}.CompareTo(T).
SequenceEqual<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a span and a read-only span are equal by comparing the elements using IEquatable{T}.Equals(T).
SequenceEqual<T>(Span<T>, ReadOnlySpan<T>, IEqualityComparer<T>)	Determines whether two sequences are equal by comparing the elements using an IEqualityComparer<T>.
Sort<T>(Span<T>)	Sorts the elements in the entire Span<T> using the IComparable<T> implementation of each element of the Span<T>.
Sort<T>(Span<T>, Comparison<T>)	Sorts the elements in the entire Span<T> using the specified Comparison<T>.
Sort<T,TComparer>(Span<T>, TComparer)	Sorts the elements in the entire Span<T> using the `TComparer`.
Sort<TKey,TValue>(Span<TKey>, Span<TValue>)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the IComparable<T> implementation of each key.
Sort<TKey,TValue>(Span<TKey>, Span<TValue>, Comparison<TKey>)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparison.
Sort<TKey,TValue,TComparer>(Span<TKey>, Span<TValue>, TComparer)	Sorts a pair of spans (one containing the keys and the other containing the corresponding items) based on the keys in the first Span<T> using the specified comparer.
StartsWith<T>(Span<T>, ReadOnlySpan<T>)	Determines whether a specified sequence appears at the start of a span.
Trim<T>(Span<T>, T)	Removes all leading and trailing occurrences of a specified element from a span.
Trim<T>(Span<T>, ReadOnlySpan<T>)	Removes all leading and trailing occurrences of a set of elements specified in a read-only span from a span.

TrimEnd<T>(Span<T>, T)	Removes all trailing occurrences of a specified element from a span.
TrimEnd<T>(Span<T>, ReadOnlySpan<T>)	Removes all trailing occurrences of a set of elements specified in a read-only span from a span.
TrimStart<T>(Span<T>, T)	Removes all leading occurrences of a specified element from the span.
TrimStart<T>(Span<T>, ReadOnlySpan<T>)	Removes all leading occurrences of a set of elements specified in a read-only span from the span.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T> Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Span<T>(T)	Creates a new Span<T> of length 1 around the specified reference.
Span<T>(T[])	Creates a new Span<T> object over the entirety of a specified array.
Span<T>(Void*, Int32)	Creates a new Span<T> object from a specified number of `T` elements starting at a specified memory address.
Span<T>(T[], Int32, Int32)	Creates a new Span<T> object that includes a specified number of elements of an array starting at a specified index.

Span<T>(T)

Creates a new Span<T> of length 1 around the specified reference.

C#

```
public Span (ref T reference);
```

Parameters

`reference` T

A reference to data.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Span<T>(T[])

Creates a new Span<T> object over the entirety of a specified array.

```
C#
public Span (T[]? array);
```

Parameters

`array` T[]

The array from which to create the Span<T> object.

Exceptions

ArrayTypeMismatchException

`T` is a reference type, and `array` is not an array of type `T`.

Remarks

If `array` is `null`, this constructor returns a `null` `Span<T>`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T>(Void*, Int32)

> Important

This API is not CLS-compliant.

Creates a new Span<T> object from a specified number of `T` elements starting at a specified memory address.

```
C#

[System.CLSCompliant(false)]
public Span (void* pointer, int length);
```

Parameters

`pointer` Void*

A pointer to the starting address of a specified number of `T` elements in memory.

`length` Int32

The number of `T` elements to be included in the Span<T>.

Attributes CLSCompliantAttribute

Exceptions

ArgumentException

`T` is a reference type or contains pointers and therefore cannot be stored in unmanaged memory.

ArgumentOutOfRangeException

`length` is negative.

Remarks

This constructor should be used with care, since it creates arbitrarily typed `T`s from a `void*`-typed block of memory, and `length` is not checked. However, if the constructor succeeds in creating a new Span<T> object, all subsequent uses are correct.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T>(T[], Int32, Int32)

Creates a new Span<T> object that includes a specified number of elements of an array starting at a specified index.

```
C#

public Span (T[]? array, int start, int length);
```

Parameters

`array` T[]

The source array.

`start` Int32

The index of the first element to include in the new Span<T>.

`length` Int32

The number of elements to include in the new Span<T>.

Exceptions

ArgumentOutOfRangeException

`array` is `null`, but `start` or `length` is non-zero.

-or-

`start` is outside the bounds of the array.

-or-

`start` and `length` exceeds the number of elements in the array.

ArrayTypeMismatchException

`T` is a reference type, and `array` is not an array of type `T`.

Remarks

This method returns `default` when `array` is `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Span<T>.Empty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an empty Span<T> object.

C#

```
public static Span<T> Empty { get; }
```

Property Value

Span<T>

An empty Span<T> object.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.IsEmpty Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Span<T> is empty.

C#

```
public bool IsEmpty { get; }
```

Property Value

Boolean

`true` if the current span is empty; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the element at the specified zero-based index.

```
C#
public ref T this[int index] { get; }
```

Parameters

`index` Int32

The zero-based index of the element.

Property Value

T

The element at the specified index.

Exceptions

IndexOutOfRangeException

`index` is less than zero or greater than or equal to Length.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T>.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the length of the current span.

C#

```
public int Length { get; }
```

Property Value

Int32

The length of the current span.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.Clear Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clears the contents of this Span<T> object.

C#

```
public void Clear ();
```

Remarks

The `Clear` method sets the items in the Span<T> object to their default values. It does not remove items from the Span<T>.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.CopyTo(Span<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of this Span<T> into a destination Span<T>.

```
C#
public void CopyTo (Span<T> destination);
```

Parameters

`destination` Span<T>

The destination Span<T> object.

Exceptions

ArgumentException

`destination` is shorter than the source Span<T>.

Remarks

This method copies all of `source` to `destination` even if `source` and `destination` overlap.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Equals() on Span will always throw an exception. Use the equality operator instead.

Calls to this method are not supported.

C#

```
[System.Obsolete("Equals() on Span will always throw an exception. Use the equality operator instead.")]
public override bool Equals (object? obj);
```

Parameters

obj Object

Not supported.

Returns

Boolean

Calls to this method are not supported.

Attributes ObsoleteAttribute

Exceptions

NotSupportedException

Calls to this method are not supported.

Remarks

Calls to the Equals method are not supported. Calls to the Equals methods produce either of two results:

- If `obj` is a Span<T>, the method call generates compiler error CS1503: "cannot convert from 'System.Span' to 'object'." This is because Span<T> is a ref struct that cannot be boxed and therefore cannot be converted to an Object.
- If the type of `obj` is not a Span<T>, the method call throws a NotSupportedException.

To compare two Span<T> objects for equality, use the Equality comparison operator.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Standard	*(2.1)*

Collaborate with us on GitHub

Span<T>.Fill(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Fills the elements of this span with a specified value.

C#

```
public void Fill (T value);
```

Parameters

`value` T

The value to assign to each element of the span.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumerator for this Span<T>.

C#

```
public Span<T>.Enumerator GetEnumerator ();
```

Returns

Span<T>.Enumerator

An enumerator for this span.

Remarks

Instead of calling the GetEnumerator method directly, you can use the C# `foreach` statement and the Visual Basic `For Each`...`Next` construct to enumerate a Span<T>.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Span<T>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> GetHashCode() on Span will always throw an exception.

Throws a NotSupportedException.

C#

```
[System.Obsolete("GetHashCode() on Span will always throw an exception.")]
public override int GetHashCode ();
```

Returns

Int32

Calls to this method always throw a NotSupportedException.

Attributes ObsoleteAttribute

Exceptions

NotSupportedException

Calls to this method are not supported.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Standard	*(2.1)*

Span<T>.GetPinnableReference Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a reference to an object of type T that can be used for pinning.

This method is intended to support .NET compilers and is not intended to be called by user code.

C#

```
public ref T GetPinnableReference ();
```

Returns

T

A reference to the element of the span at index 0, or `null` if the span is empty.

Examples

The following example demonstrates creating an integer array, pinning it, and writing each element to the console.

C#

```
using System;

// Note: you must compile this sample using the unsafe flag.
// From the command line, type the following: csc sample.cs /unsafe

public class Example
{
    public static unsafe void Main()
    {
        int[] array = CreateInt32Array();

        // Create a span, pin it, and print its elements.
        Span<int> span = array.AsSpan();
        fixed (int* spanPtr = span)
```

```
        {
            Console.WriteLine($"Span contains {span.Length} elements:");
            for (int i = 0; i < span.Length; i++)
            {
                Console.WriteLine(spanPtr[i]);
            }
            Console.WriteLine();
        }

        // Create a read-only span, pin it, and print its elements.
        ReadOnlySpan<int> readonlyspan = array.AsSpan();
        fixed (int* readonlyspanPtr = readonlyspan)
        {
            Console.WriteLine($"ReadOnlySpan contains {readonlyspan.Length}
elements:");
            for (int i = 0; i < readonlyspan.Length; i++)
            {
                Console.WriteLine(readonlyspanPtr[i]);
            }
            Console.WriteLine();
        }
    }

    private static int[] CreateInt32Array()
    {
        return new int[] { 100, 200, 300, 400, 500 };
    }
}

// The example displays the following output:
//       Span contains 5 elements:
//       100
//       200
//       300
//       400
//       500
//
//       ReadOnlySpan contains 5 elements:
//       100
//       200
//       300
//       400
//       500
```

Remarks

Applications should not directly call `GetPinnableReference`. Instead, callers should use their language's normal pinning syntax, such as C#'s `fixed` statement.

If pinning a `Span<char>`, the resulting `char*` **is not** assumed to be null-terminated. This behavior is different from pinning a `string`, where the resulting `char*` is guaranteed to

be null-terminated.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Span<T>.Slice Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Slice(Int32)	Forms a slice out of the current span that begins at a specified index.
Slice(Int32, Int32)	Forms a slice out of the current span starting at a specified index for a specified length.

Slice(Int32)

Forms a slice out of the current span that begins at a specified index.

C#

```
public Span<T> Slice (int start);
```

Parameters

`start` Int32

The index at which to begin the slice.

Returns

Span<T>

A span that consists of all elements of the current span from `start` to the end of the span.

Exceptions

ArgumentOutOfRangeException

`start` is less than zero or greater than Length.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Slice(Int32, Int32)

Forms a slice out of the current span starting at a specified index for a specified length.

C#

```
public Span<T> Slice (int start, int length);
```

Parameters

`start` Int32

The index at which to begin this slice.

`length` Int32

The desired length for the slice.

Returns

Span<T>

A span that consists of `length` elements from the current span starting at `start`.

Exceptions

ArgumentOutOfRangeException

`start` or `start` + `length` is less than zero or greater than Length.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T>.ToArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of this span into a new array.

C#

```
public T[] ToArray ();
```

Returns

T[]

An array containing the data in the current span.

Remarks

This method performs a heap allocation and therefore should be avoided if possible. Heap allocations are expected in APIs that work with arrays. Using such APIs is unavoidable if an alternative API overload that takes a Span<T> does not exist.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of this Span<T> object.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Span<T> object.

Remarks

For a `Span<Char>`, the `ToString` method returns a String that contains the characters pointed to by the Span<T>. Otherwise, it returns a String with the name of the type and the number of elements that the Span<T> contains.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Span<T>.TryCopyTo(Span<T>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Attempts to copy the current Span<T> to a destination Span<T> and returns a value that indicates whether the copy operation succeeded.

```
C#
public bool TryCopyTo (Span<T> destination);
```

Parameters

destination Span<T>

The target of the copy operation.

Returns

Boolean

`true` if the copy operation succeeded; otherwise, `false`.

Remarks

This method copies all of `source` to `destination` even if `source` and `destination` overlap.

If `destination` is shorter than the source Span<T>, this method returns `false`, and no data is written to `destination`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Span<T>.Equality(Span<T>, Span<T>) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two Span<T> objects are equal.

```
C#
public static bool operator == (Span<T> left, Span<T> right);
```

Parameters

`left` Span<T>

The first span to compare.

`right` Span<T>

The second span to compare.

Returns

Boolean

`true` if the two Span<T> objects are equal; otherwise, `false`.

Remarks

Two Span<T> objects are equal if they have the same length and the corresponding elements of `left` and `right` point to the same memory. Note that the test for equality does *not* attempt to determine whether the contents are equal.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

Span<T>.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(ArraySegment<T> to Span<T>)	Defines an implicit conversion of an ArraySegment<T> to a Span<T>.
Implicit(Span<T> to ReadOnlySpan<T>)	Defines an implicit conversion of a Span<T> to a ReadOnlySpan<T>.
Implicit(T[] to Span<T>)	Defines an implicit conversion of an array to a Span<T>.

Implicit(ArraySegment<T> to Span<T>)

Defines an implicit conversion of an ArraySegment<T> to a Span<T>.

C#

```
public static implicit operator Span<T> (ArraySegment<T> segment);
```

Parameters

`segment` ArraySegment<T>

The array segment to be converted to a Span<T>.

Returns

Span<T>

A span that corresponds to the array segment.

Applies to

▼ .NET 9 and other versions

Product	Versions

.NET Standard	2.1

Implicit(Span<T> to ReadOnlySpan<T>)

Defines an implicit conversion of a Span<T> to a ReadOnlySpan<T>.

C#

```
public static implicit operator ReadOnlySpan<T> (Span<T> span);
```

Parameters

span Span<T>

The object to convert to a ReadOnlySpan<T>.

Returns

ReadOnlySpan<T>

A read-only span that corresponds to the current instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Implicit(T[] to Span<T>)

Defines an implicit conversion of an array to a Span<T>.

```
C#
public static implicit operator Span<T> (T[]? array);
```

Parameters

`array` T[]

The array to convert to a Span<T>.

Returns

Span<T>

The span that corresponds to `array`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Span<T>.Inequality(Span<T>, Span<T>) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether two Span<T> objects are not equal.

C#

```
public static bool operator != (Span<T> left, Span<T> right);
```

Parameters

left Span<T>

The first span to compare.

right Span<T>

The second span to compare.

Returns

Boolean

`true` if the two Span<T> objects are not equal; otherwise, `false`.

Remarks

Two Span<T> objects are not equal if they have different lengths or if the corresponding elements of `left` and `right` do not point to the same memory.

Applies to

StackOverflowException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when the execution stack exceeds the stack size. This class cannot be inherited.

C#

```
public sealed class StackOverflowException : SystemException
```

Inheritance Object → Exception → SystemException → StackOverflowException

Examples

The following example uses a counter to ensure that the number of recursive calls to the `Execute` method do not exceed a maximum defined by the MAX_RECURSIVE_CALLS constant.

C#

```
using System;

public class Example
{
   private const int MAX_RECURSIVE_CALLS = 1000;
   static int ctr = 0;

   public static void Main()
   {
      Example ex = new Example();
      ex.Execute();
      Console.WriteLine("\nThe call counter: {0}", ctr);
   }

   private void Execute()
   {
      ctr++;
      if (ctr % 50 == 0)
         Console.WriteLine("Call number {0} to the Execute method", ctr);
```

```
        if (ctr <= MAX_RECURSIVE_CALLS)
           Execute();

        ctr--;
     }
  }
  // The example displays the following output:
  //       Call number 50 to the Execute method
  //       Call number 100 to the Execute method
  //       Call number 150 to the Execute method
  //       Call number 200 to the Execute method
  //       Call number 250 to the Execute method
  //       Call number 300 to the Execute method
  //       Call number 350 to the Execute method
  //       Call number 400 to the Execute method
  //       Call number 450 to the Execute method
  //       Call number 500 to the Execute method
  //       Call number 550 to the Execute method
  //       Call number 600 to the Execute method
  //       Call number 650 to the Execute method
  //       Call number 700 to the Execute method
  //       Call number 750 to the Execute method
  //       Call number 800 to the Execute method
  //       Call number 850 to the Execute method
  //       Call number 900 to the Execute method
  //       Call number 950 to the Execute method
  //       Call number 1000 to the Execute method
  //
  //       The call counter: 0
```

Remarks

`StackOverflowException` is thrown for execution stack overflow errors, typically in case of a very deep or unbounded recursion. So make sure your code doesn't have an infinite loop or infinite recursion.

`StackOverflowException` uses the HRESULT COR_E_STACKOVERFLOW, which has the value 0x800703E9. The Localloc intermediate language (IL) instruction throws `StackOverflowException`. For a list of initial property values for a `StackOverflowException` object, see the StackOverflowException constructors.

Starting with the .NET Framework 2.0, you can't catch a `StackOverflowException` object with a `try`/`catch` block, and the corresponding process is terminated by default. Consequently, you should write your code to detect and prevent a stack overflow. For example, if your app depends on recursion, use a counter or a state condition to terminate the recursive loop. See the Examples section for an illustration of this technique.

> **Note**
>
> Applying the **HandleProcessCorruptedStateExceptionsAttribute** attribute to a method that throws a `StackOverflowException` has no effect. You still cannot handle the exception from user code.

If your app hosts the common language runtime (CLR), it can specify that the CLR should unload the application domain where the stack overflow exception occurs and let the corresponding process continue. For more information, see ICLRPolicyManager Interface.

Constructors

Expand table

StackOverflowException()	Initializes a new instance of the StackOverflowException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "The requested operation caused a stack overflow." This message takes into account the current system culture.
StackOverflowException(String)	Initializes a new instance of the StackOverflowException class with a specified error message.
StackOverflowException(String, Exception)	Initializes a new instance of the StackOverflowException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)

Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

StackOverflowException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the StackOverflowException class.

Overloads

Expand table

StackOverflowException()	Initializes a new instance of the StackOverflowException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "The requested operation caused a stack overflow." This message takes into account the current system culture.
StackOverflowException(String)	Initializes a new instance of the StackOverflowException class with a specified error message.
StackOverflowException(String, Exception)	Initializes a new instance of the StackOverflowException class with a specified error message and a reference to the inner exception that is the cause of this exception.

StackOverflowException()

Initializes a new instance of the StackOverflowException class, setting the Message property of the new instance to a system-supplied message that describes the error, such as "The requested operation caused a stack overflow." This message takes into account the current system culture.

C#

```
public StackOverflowException ();
```

Remarks

The following table shows the initial property values for an instance of StackOverflowException.

Expand table

Property	Value
InnerException	`null`.
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

StackOverflowException(String)

Initializes a new instance of the StackOverflowException class with a specified error message.

C#

```
public StackOverflowException (string? message);
```

Parameters

`message` String

A String that describes the error. The content of message is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of StackOverflowException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

StackOverflowException(String, Exception)

Initializes a new instance of the StackOverflowException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public StackOverflowException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is

raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of StackOverflowException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

STAThreadAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that the COM threading model for an application is single-threaded apartment (STA).

C#

```
[System.AttributeUsage(System.AttributeTargets.Method)]
public sealed class STAThreadAttribute : Attribute
```

Inheritance Object → Attribute → STAThreadAttribute

Attributes AttributeUsageAttribute

Remarks

Apply this attribute to the entry point method (the `Main()` method in C# and Visual Basic). It has no effect on other methods. To set the apartment state of threads you start in your code, use the Thread.SetApartmentState or Thread.TrySetApartmentState method before starting the thread.

> **Note**
>
> For an overview of COM threading models, see **Understanding and Using COM Threading Models**.

COM threading models only apply to applications that use COM interop. The COM threading model can be set to single-threaded apartment or multithreaded apartment. The application thread is only initialized for COM interop if the thread actually makes a call to a COM component. If COM interop is not used, then the thread is not initialized, and the STAThreadAttribute attribute, if it is present, has no effect.

Starting with the .NET Framework version 2.0, the default threading model for COM interop depends on the language in which you are developing your application, as the following table shows.

Expand table

Language	COM apartment model
C#	Multithreaded apartment
C++	Multithreaded apartment
Visual Basic	Single-threaded apartment

To change these defaults, you use the STAThreadAttribute attribute to set the threading model for the application, or call the Thread.SetApartmentState or Thread.TrySetApartmentState method before starting the thread to set the threading model for a particular thread. In C++, you can also use the /CLRTHREADATTRIBUTE linker option to specify the apartment model.

ASP.NET applications should set the `ASPCompat` attribute of the @ Page directive to `true` to force the page to be serviced by the STA thread pool.

Here are some of the cases in which you'll want to use the STAThreadAttribute attribute to explicitly set the threading model to single-threaded apartment:

- You're developing a Windows Forms app. Windows Forms apps must be single-threaded if they communicate with Windows system components such as the Clipboard or Windows common dialog boxes, or if they use system features such as drag-and-drop functionality. The Windows Forms Application template for C# automatically adds the STAThreadAttribute attribute to C# projects. Because the single-threaded apartment model is the default for Visual Basic, there is no need for the attribute.

- You're developing a C# app that calls a Visual Basic library, which, in turn, relies on COM interop. Because the single-threaded apartment model is the default for Visual Basic, you should change your app's threading model to single-threaded by using the STAThreadAttribute attribute.

- Your application makes calls to COM components that use the single-threaded apartment model.

Constructors

Expand table

STAThreadAttribute()	Initializes a new instance of the STAThreadAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents text as a sequence of UTF-16 code units.

C#

```
public sealed class String : ICloneable, IComparable, IComparable<string>,
IConvertible, IEquatable<string>, IParsable<string>, ISpanParsable<string>,
System.Collections.Generic.IEnumerable<char>
```

Inheritance Object → String

Implements IEnumerable<Char> , IEnumerable , IComparable , IComparable<String> , IConvertible , IEquatable<String> , ICloneable , IParsable<String> , IParsable<TSelf> , ISpanParsable<String>

Remarks

For more information about this API, see Supplemental API remarks for String.

Constructors

Expand table

String(Char*)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of Unicode characters.
String(Char*, Int32, Int32)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of Unicode characters, a starting character position within that array, and a length.
String(Char, Int32)	Initializes a new instance of the String class to the value indicated by a specified Unicode character repeated a specified number of times.

String(Char[])	Initializes a new instance of the String class to the Unicode characters indicated in the specified character array.
String(Char[], Int32, Int32)	Initializes a new instance of the String class to the value indicated by an array of Unicode characters, a starting character position within that array, and a length.
String(ReadOnlySpan<Char>)	Initializes a new instance of the String class to the Unicode characters indicated in the specified read-only span.
String(SByte*)	Initializes a new instance of the String class to the value indicated by a pointer to an array of 8-bit signed integers.
String(SByte*, Int32, Int32)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of 8-bit signed integers, a starting position within that array, and a length.
String(SByte*, Int32, Int32, Encoding)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of 8-bit signed integers, a starting position within that array, a length, and an Encoding object.

Fields

Expand table

Empty	Represents the empty string. This field is read-only.

Properties

Expand table

Chars[Int32]	Gets the Char object at a specified position in the current String object.
Length	Gets the number of characters in the current String object.

Methods

Expand table

Clone()	Returns a reference to this instance of String.
Compare(String, Int32, String, Int32, Int32)	Compares substrings of two specified String objects and returns an integer that indicates their relative

	position in the sort order.
Compare(String, Int32, String, Int32, Int32, Boolean)	Compares substrings of two specified String objects, ignoring or honoring their case, and returns an integer that indicates their relative position in the sort order.
Compare(String, Int32, String, Int32, Int32, Boolean, CultureInfo)	Compares substrings of two specified String objects, ignoring or honoring their case and using culture-specific information to influence the comparison, and returns an integer that indicates their relative position in the sort order.
Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions)	Compares substrings of two specified String objects using the specified comparison options and culture-specific information to influence the comparison, and returns an integer that indicates the relationship of the two substrings to each other in the sort order.
Compare(String, Int32, String, Int32, Int32, StringComparison)	Compares substrings of two specified String objects using the specified rules, and returns an integer that indicates their relative position in the sort order.
Compare(String, String)	Compares two specified String objects and returns an integer that indicates their relative position in the sort order.
Compare(String, String, Boolean)	Compares two specified String objects, ignoring or honoring their case, and returns an integer that indicates their relative position in the sort order.
Compare(String, String, Boolean, Culture Info)	Compares two specified String objects, ignoring or honoring their case, and using culture-specific information to influence the comparison, and returns an integer that indicates their relative position in the sort order.
Compare(String, String, CultureInfo, CompareOptions)	Compares two specified String objects using the specified comparison options and culture-specific information to influence the comparison, and returns an integer that indicates the relationship of the two strings to each other in the sort order.
Compare(String, String, String Comparison)	Compares two specified String objects using the specified rules, and returns an integer that indicates their relative position in the sort order.
CompareOrdinal(String, Int32, String, Int32, Int32)	Compares substrings of two specified String objects by evaluating the numeric values of the corresponding Char objects in each substring.
CompareOrdinal(String, String)	Compares two specified String objects by evaluating the numeric values of the corresponding Char objects

	in each string.
CompareTo(Object)	Compares this instance with a specified Object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Object.
CompareTo(String)	Compares this instance with a specified String object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified string.
Concat(IEnumerable<String>)	Concatenates the members of a constructed IEnumerable<T> collection of type String.
Concat(Object)	Creates the string representation of a specified object.
Concat(Object, Object)	Concatenates the string representations of two specified objects.
Concat(Object, Object, Object)	Concatenates the string representations of three specified objects.
Concat(Object[])	Concatenates the string representations of the elements in a specified Object array.
Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Concatenates the string representations of two specified read-only character spans.
Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Concatenates the string representations of three specified read-only character spans.
Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Concatenates the string representations of four specified read-only character spans.
Concat(String, String)	Concatenates two specified instances of String.
Concat(String, String, String)	Concatenates three specified instances of String.
Concat(String, String, String, String)	Concatenates four specified instances of String.
Concat(String[])	Concatenates the elements of a specified String array.
Concat<T>(IEnumerable<T>)	Concatenates the members of an IEnumerable<T> implementation.
Contains(Char)	Returns a value indicating whether a specified character occurs within this string.
Contains(Char, StringComparison)	Returns a value indicating whether a specified character occurs within this string, using the specified

	comparison rules.
Contains(String)	Returns a value indicating whether a specified substring occurs within this string.
Contains(String, StringComparison)	Returns a value indicating whether a specified string occurs within this string, using the specified comparison rules.
Copy(String)	**Obsolete.** Creates a new instance of String with the same value as a specified String.
CopyTo(Int32, Char[], Int32, Int32)	Copies a specified number of characters from a specified position in this instance to a specified position in an array of Unicode characters.
CopyTo(Span<Char>)	Copies the contents of this string into the destination span.
Create(IFormatProvider, DefaultInterpolatedStringHandler)	Creates a new string by using the specified provider to control the formatting of the specified interpolated string.
Create(IFormatProvider, Span<Char>, DefaultInterpolatedStringHandler)	Creates a new string by using the specified provider to control the formatting of the specified interpolated string.
Create<TState>(Int32, TState, SpanAction<Char,TState>)	Creates a new string with a specific length and initializes it after creation by using the specified callback.
EndsWith(Char)	Determines whether the end of this string instance matches the specified character.
EndsWith(String)	Determines whether the end of this string instance matches the specified string.
EndsWith(String, Boolean, CultureInfo)	Determines whether the end of this string instance matches the specified string when compared using the specified culture.
EndsWith(String, StringComparison)	Determines whether the end of this string instance matches the specified string when compared using the specified comparison option.
EnumerateRunes()	Returns an enumeration of Rune from this string.
Equals(Object)	Determines whether this instance and a specified object, which must also be a String object, have the same value.

Equals(String)	Determines whether this instance and another specified String object have the same value.
Equals(String, String)	Determines whether two specified String objects have the same value.
Equals(String, String, StringComparison)	Determines whether two specified String objects have the same value. A parameter specifies the culture, case, and sort rules used in the comparison.
Equals(String, StringComparison)	Determines whether this string and a specified String object have the same value. A parameter specifies the culture, case, and sort rules used in the comparison.
Format(IFormatProvider, CompositeFormat, Object[])	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format(IFormatProvider, CompositeFormat, ReadOnlySpan<Object>)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format(IFormatProvider, String, Object)	Replaces the format item or items in a specified string with the string representation of the corresponding object. A parameter supplies culture-specific formatting information.
Format(IFormatProvider, String, Object, Object)	Replaces the format items in a string with the string representation of two specified objects. A parameter supplies culture-specific formatting information.
Format(IFormatProvider, String, Object, Object, Object)	Replaces the format items in a string with the string representation of three specified objects. An parameter supplies culture-specific formatting information.
Format(IFormatProvider, String, Object[])	Replaces the format items in a string with the string representations of corresponding objects in a specified array. A parameter supplies culture-specific formatting information.
Format(String, Object)	Replaces one or more format items in a string with the string representation of a specified object.
Format(String, Object, Object)	Replaces the format items in a string with the string representation of two specified objects.
Format(String, Object, Object, Object)	Replaces the format items in a string with the string representation of three specified objects.
Format(String, Object[])	Replaces the format item in a specified string with the string representation of a corresponding object in a

	specified array.
Format<TArg0,TArg1,TArg2>(IFormatProvider, CompositeFormat, TArg0, TArg1, TArg2)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format<TArg0,TArg1>(IFormatProvider, CompositeFormat, TArg0, TArg1)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format<TArg0>(IFormatProvider, CompositeFormat, TArg0)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
GetEnumerator()	Retrieves an object that can iterate through the individual characters in this string.
GetHashCode()	Returns the hash code for this string.
GetHashCode(ReadOnlySpan<Char>)	Returns the hash code for the provided read-only character span.
GetHashCode(ReadOnlySpan<Char>, StringComparison)	Returns the hash code for the provided read-only character span using the specified rules.
GetHashCode(StringComparison)	Returns the hash code for this string using the specified rules.
GetPinnableReference()	Returns a reference to the element of the string at index zero. This method is intended to support .NET compilers and is not intended to be called by user code.
GetType()	Gets the Type of the current instance. (Inherited from Object)
GetTypeCode()	Returns the TypeCode for the String class.
IndexOf(Char)	Reports the zero-based index of the first occurrence of the specified Unicode character in this string.
IndexOf(Char, Int32)	Reports the zero-based index of the first occurrence of the specified Unicode character in this string. The search starts at a specified character position.
IndexOf(Char, Int32, Int32)	Reports the zero-based index of the first occurrence of the specified character in this instance. The search starts at a specified character position and examines a specified number of character positions.
IndexOf(Char, StringComparison)	Reports the zero-based index of the first occurrence of the specified Unicode character in this string. A

	parameter specifies the type of search to use for the specified character.
IndexOf(String)	Reports the zero-based index of the first occurrence of the specified string in this instance.
IndexOf(String, Int32)	Reports the zero-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position.
IndexOf(String, Int32, Int32)	Reports the zero-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position and examines a specified number of character positions.
IndexOf(String, Int32, Int32, StringComparison)	Reports the zero-based index of the first occurrence of the specified string in the current String object. Parameters specify the starting search position in the current string, the number of characters in the current string to search, and the type of search to use for the specified string.
IndexOf(String, Int32, StringComparison)	Reports the zero-based index of the first occurrence of the specified string in the current String object. Parameters specify the starting search position in the current string and the type of search to use for the specified string.
IndexOf(String, StringComparison)	Reports the zero-based index of the first occurrence of the specified string in the current String object. A parameter specifies the type of search to use for the specified string.
IndexOfAny(Char[])	Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters.
IndexOfAny(Char[], Int32)	Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position.
IndexOfAny(Char[], Int32, Int32)	Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position and examines a specified number of character positions.
Insert(Int32, String)	Returns a new string in which a specified string is inserted at a specified index position in this instance.

Intern(String)	Retrieves the system's reference to the specified String.
IsInterned(String)	Retrieves a reference to a specified String.
IsNormalized()	Indicates whether this string is in Unicode normalization form C.
IsNormalized(NormalizationForm)	Indicates whether this string is in the specified Unicode normalization form.
IsNullOrEmpty(String)	Indicates whether the specified string is `null` or an empty string ("").
IsNullOrWhiteSpace(String)	Indicates whether a specified string is `null`, empty, or consists only of white-space characters.
Join(Char, Object[])	Concatenates the string representations of an array of objects, using the specified separator between each member.
Join(Char, String[])	Concatenates an array of strings, using the specified separator between each member.
Join(Char, String[], Int32, Int32)	Concatenates an array of strings, using the specified separator between each member, starting with the element in `value` located at the `startIndex` position, and concatenating up to `count` elements.
Join(String, IEnumerable<String>)	Concatenates the members of a constructed IEnumerable<T> collection of type String, using the specified separator between each member.
Join(String, Object[])	Concatenates the elements of an object array, using the specified separator between each element.
Join(String, String[])	Concatenates all the elements of a string array, using the specified separator between each element.
Join(String, String[], Int32, Int32)	Concatenates the specified elements of a string array, using the specified separator between each element.
Join<T>(Char, IEnumerable<T>)	Concatenates the members of a collection, using the specified separator between each member.
Join<T>(String, IEnumerable<T>)	Concatenates the members of a collection, using the specified separator between each member.
LastIndexOf(Char)	Reports the zero-based index position of the last occurrence of a specified Unicode character within this instance.

LastIndexOf(Char, Int32)	Reports the zero-based index position of the last occurrence of a specified Unicode character within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string.
LastIndexOf(Char, Int32, Int32)	Reports the zero-based index position of the last occurrence of the specified Unicode character in a substring within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.
LastIndexOf(String)	Reports the zero-based index position of the last occurrence of a specified string within this instance.
LastIndexOf(String, Int32)	Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string.
LastIndexOf(String, Int32, Int32)	Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.
LastIndexOf(String, Int32, Int32, StringComparison)	Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for the specified number of character positions. A parameter specifies the type of comparison to perform when searching for the specified string.
LastIndexOf(String, Int32, StringComparison)	Reports the zero-based index of the last occurrence of a specified string within the current String object. The search starts at a specified character position and proceeds backward toward the beginning of the string. A parameter specifies the type of comparison to perform when searching for the specified string.
LastIndexOf(String, StringComparison)	Reports the zero-based index of the last occurrence of a specified string within the current String object. A parameter specifies the type of search to use for the specified string.
LastIndexOfAny(Char[])	Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array.

LastIndexOfAny(Char[], Int32)	Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The search starts at a specified character position and proceeds backward toward the beginning of the string.
LastIndexOfAny(Char[], Int32, Int32)	Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Normalize()	Returns a new string whose textual value is the same as this string, but whose binary representation is in Unicode normalization form C.
Normalize(NormalizationForm)	Returns a new string whose textual value is the same as this string, but whose binary representation is in the specified Unicode normalization form.
PadLeft(Int32)	Returns a new string that right-aligns the characters in this instance by padding them with spaces on the left, for a specified total length.
PadLeft(Int32, Char)	Returns a new string that right-aligns the characters in this instance by padding them on the left with a specified Unicode character, for a specified total length.
PadRight(Int32)	Returns a new string that left-aligns the characters in this string by padding them with spaces on the right, for a specified total length.
PadRight(Int32, Char)	Returns a new string that left-aligns the characters in this string by padding them on the right with a specified Unicode character, for a specified total length.
Remove(Int32)	Returns a new string in which all the characters in the current instance, beginning at a specified position and continuing through the last position, have been deleted.
Remove(Int32, Int32)	Returns a new string in which a specified number of characters in the current instance beginning at a specified position have been deleted.

Replace(Char, Char)	Returns a new string in which all occurrences of a specified Unicode character in this instance are replaced with another specified Unicode character.
Replace(String, String)	Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string.
Replace(String, String, Boolean, CultureInfo)	Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string, using the provided culture and case sensitivity.
Replace(String, String, StringComparison)	Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string, using the provided comparison type.
ReplaceLineEndings()	Replaces all newline sequences in the current string with NewLine.
ReplaceLineEndings(String)	Replaces all newline sequences in the current string with `replacementText`.
Split(Char, Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on a specified delimiting character and, optionally, options. Splits a string into a maximum number of substrings based on the provided character separator, optionally omitting empty substrings from the result.
Split(Char, StringSplitOptions)	Splits a string into substrings based on a specified delimiting character and, optionally, options.
Split(Char[])	Splits a string into substrings based on specified delimiting characters.
Split(Char[], Int32)	Splits a string into a maximum number of substrings based on specified delimiting characters.
Split(Char[], Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on specified delimiting characters and, optionally, options.
Split(Char[], StringSplitOptions)	Splits a string into substrings based on specified delimiting characters and options.
Split(String, Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on a specified delimiting string and, optionally, options.

Split(String, StringSplitOptions)	Splits a string into substrings that are based on the provided string separator.
Split(String[], Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on specified delimiting strings and, optionally, options.
Split(String[], StringSplitOptions)	Splits a string into substrings based on a specified delimiting string and, optionally, options.
StartsWith(Char)	Determines whether this string instance starts with the specified character.
StartsWith(String)	Determines whether the beginning of this string instance matches the specified string.
StartsWith(String, Boolean, CultureInfo)	Determines whether the beginning of this string instance matches the specified string when compared using the specified culture.
StartsWith(String, StringComparison)	Determines whether the beginning of this string instance matches the specified string when compared using the specified comparison option.
Substring(Int32)	Retrieves a substring from this instance. The substring starts at a specified character position and continues to the end of the string.
Substring(Int32, Int32)	Retrieves a substring from this instance. The substring starts at a specified character position and has a specified length.
ToCharArray()	Copies the characters in this instance to a Unicode character array.
ToCharArray(Int32, Int32)	Copies the characters in a specified substring in this instance to a Unicode character array.
ToLower()	Returns a copy of this string converted to lowercase.
ToLower(CultureInfo)	Returns a copy of this string converted to lowercase, using the casing rules of the specified culture.
ToLowerInvariant()	Returns a copy of this String object converted to lowercase using the casing rules of the invariant culture.
ToString()	Returns this instance of String; no actual conversion is performed.
ToString(IFormatProvider)	Returns this instance of String; no actual conversion is performed.

ToUpper()	Returns a copy of this string converted to uppercase.
ToUpper(CultureInfo)	Returns a copy of this string converted to uppercase, using the casing rules of the specified culture.
ToUpperInvariant()	Returns a copy of this String object converted to uppercase using the casing rules of the invariant culture.
Trim()	Removes all leading and trailing white-space characters from the current string.
Trim(Char)	Removes all leading and trailing instances of a character from the current string.
Trim(Char[])	Removes all leading and trailing occurrences of a set of characters specified in an array from the current string.
TrimEnd()	Removes all the trailing white-space characters from the current string.
TrimEnd(Char)	Removes all the trailing occurrences of a character from the current string.
TrimEnd(Char[])	Removes all the trailing occurrences of a set of characters specified in an array from the current string.
TrimStart()	Removes all the leading white-space characters from the current string.
TrimStart(Char)	Removes all the leading occurrences of a specified character from the current string.
TrimStart(Char[])	Removes all the leading occurrences of a set of characters specified in an array from the current string.
TryCopyTo(Span<Char>)	Copies the contents of this string into the destination span.

Operators

Expand table

Equality(String, String)	Determines whether two specified strings have the same value.
Implicit(String to ReadOnlySpan<Char>)	Defines an implicit conversion of a given string to a read-only span of characters.

Inequality(String, String)	Determines whether two specified strings have different values.

Explicit Interface Implementations

Expand table

IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	For a description of this member, see ToDateTime(IFormatProvider).
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).

IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IEnumerable.GetEnumerator()	Returns an enumerator that iterates through the current String object.
IEnumerable<Char>.GetEnumerator()	Returns an enumerator that iterates through the current String object.
IParsable<String>.Parse(String, IFormatProvider)	Parses a string into a value.
IParsable<String>.TryParse(String, IFormatProvider, String)	
ISpanParsable<String>.Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
ISpanParsable<String>.TryParse(ReadOnlySpan<Char>, IFormatProvider, String)	

Extension Methods

Expand table

ToFrozenDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Creates a FrozenDictionary<TKey,TValue> from an IEnumerable<T> according to specified key selector function.
ToFrozenDictionary<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEqualityComparer<TKey>)	Creates a FrozenDictionary<TKey,TValue> from an IEnumerable<T> according to specified key selector and element selector functions.
ToFrozenSet<T>(IEnumerable<T>, IEqualityComparer<T>)	Creates a FrozenSet<T> with the specified values.
ToImmutableArray<TSource>(IEnumerable<TSource>)	Creates an immutable array from the specified collection.
ToImmutableDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Constructs an immutable dictionary from an existing collection of elements, applying a transformation function to the source keys.
ToImmutableDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Constructs an immutable dictionary based on some

	transformation of a sequence.
ToImmutableDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>)	Enumerates and transforms a sequence, and produces an immutable dictionary of its contents.
ToImmutableDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IEqualityComparer<TKey>)	Enumerates and transforms a sequence, and produces an immutable dictionary of its contents by using the specified key comparer.
ToImmutableDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IEqualityComparer<TKey>, IEqualityComparer<TValue>)	Enumerates and transforms a sequence, and produces an immutable dictionary of its contents by using the specified key and value comparers.
ToImmutableHashSet<TSource>(IEnumerable<TSource>)	Enumerates a sequence and produces an immutable hash set of its contents.
ToImmutableHashSet<TSource>(IEnumerable<TSource>, IEqualityComparer<TSource>)	Enumerates a sequence, produces an immutable hash set of its contents, and uses the specified equality comparer for the set type.
ToImmutableList<TSource>(IEnumerable<TSource>)	Enumerates a sequence and produces an immutable list of its contents.
ToImmutableSortedDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>)	Enumerates and transforms a sequence, and produces an immutable sorted dictionary of its contents.
ToImmutableSortedDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IComparer<TKey>)	Enumerates and transforms a sequence, and produces an immutable sorted dictionary of its contents by using the specified key comparer.
ToImmutableSortedDictionary<TSource,TKey,TValue>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TValue>, IComparer<TKey>, IEqualityComparer<TValue>)	Enumerates and transforms a sequence, and produces an immutable sorted dictionary of its contents by using the specified key and value comparers.

ToImmutableSortedSet<TSource>(IEnumerable<TSource>)	Enumerates a sequence and produces an immutable sorted set of its contents.
ToImmutableSortedSet<TSource>(IEnumerable<TSource>, IComparer<TSource>)	Enumerates a sequence, produces an immutable sorted set of its contents, and uses the specified comparer.
CopyToDataTable<T>(IEnumerable<T>)	Returns a DataTable that contains copies of the DataRow objects, given an input IEnumerable<T> object where the generic parameter `T` is DataRow.
CopyToDataTable<T>(IEnumerable<T>, DataTable, LoadOption)	Copies DataRow objects to the specified DataTable, given an input IEnumerable<T> object where the generic parameter `T` is DataRow.
CopyToDataTable<T>(IEnumerable<T>, DataTable, LoadOption, FillErrorEventHandler)	Copies DataRow objects to the specified DataTable, given an input IEnumerable<T> object where the generic parameter `T` is DataRow.
Aggregate<TSource>(IEnumerable<TSource>, Func<TSource,TSource,TSource>)	Applies an accumulator function over a sequence.
Aggregate<TSource,TAccumulate>(IEnumerable<TSource>, TAccumulate, Func<TAccumulate,TSource,TAccumulate>)	Applies an accumulator function over a sequence. The specified seed value is used as the initial accumulator value.
Aggregate<TSource,TAccumulate,TResult>(IEnumerable<TSource>, TAccumulate, Func<TAccumulate,TSource,TAccumulate>, Func<TAccumulate,TResult>)	Applies an accumulator function over a sequence. The specified seed value is used as the initial accumulator value, and the specified function is used to select the result value.
All<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Determines whether all elements of a sequence satisfy a condition.
Any<TSource>(IEnumerable<TSource>)	Determines whether a sequence contains any elements.

Any<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Determines whether any element of a sequence satisfies a condition.
Append<TSource>(IEnumerable<TSource>, TSource)	Appends a value to the end of the sequence.
AsEnumerable<TSource>(IEnumerable<TSource>)	Returns the input typed as IEnumerable<T>.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Computes the average of a sequence of Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Computes the average of a sequence of Double values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Computes the average of a sequence of Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Computes the average of a sequence of Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Computes the average of a sequence of nullable Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Computes the average of a sequence of nullable Double values that are obtained by invoking a transform function

	on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Computes the average of a sequence of nullable Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Computes the average of a sequence of nullable Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Computes the average of a sequence of nullable Single values that are obtained by invoking a transform function on each element of the input sequence.
Average<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Computes the average of a sequence of Single values that are obtained by invoking a transform function on each element of the input sequence.
Cast<TResult>(IEnumerable)	Casts the elements of an IEnumerable to the specified type.
Chunk<TSource>(IEnumerable<TSource>, Int32)	Splits the elements of a sequence into chunks of size at most `size`.
Concat<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Concatenates two sequences.
Contains<TSource>(IEnumerable<TSource>, TSource)	Determines whether a sequence contains a specified element by using the default equality comparer.
Contains<TSource>(IEnumerable<TSource>, TSource, IEqualityComparer<TSource>)	Determines whether a sequence contains a specified element by using a specified IEqualityComparer<T>.

Count<TSource>(IEnumerable<TSource>)	Returns the number of elements in a sequence.
Count<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns a number that represents how many elements in the specified sequence satisfy a condition.
DefaultIfEmpty<TSource>(IEnumerable<TSource>)	Returns the elements of the specified sequence or the type parameter's default value in a singleton collection if the sequence is empty.
DefaultIfEmpty<TSource>(IEnumerable<TSource>, TSource)	Returns the elements of the specified sequence or the specified value in a singleton collection if the sequence is empty.
Distinct<TSource>(IEnumerable<TSource>)	Returns distinct elements from a sequence by using the default equality comparer to compare values.
Distinct<TSource>(IEnumerable<TSource>, IEqualityComparer<TSource>)	Returns distinct elements from a sequence by using a specified IEqualityComparer<T> to compare values.
DistinctBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Returns distinct elements from a sequence according to a specified key selector function.
DistinctBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Returns distinct elements from a sequence according to a specified key selector function and using a specified comparer to compare keys.
ElementAt<TSource>(IEnumerable<TSource>, Index)	Returns the element at a specified index in a sequence.
ElementAt<TSource>(IEnumerable<TSource>, Int32)	Returns the element at a specified index in a sequence.
ElementAtOrDefault<TSource>(IEnumerable<TSource>, Index)	Returns the element at a specified index in a sequence

	or a default value if the index is out of range.
ElementAtOrDefault<TSource>(IEnumerable<TSource>, Int32)	Returns the element at a specified index in a sequence or a default value if the index is out of range.
Except<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Produces the set difference of two sequences by using the default equality comparer to compare values.
Except<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Produces the set difference of two sequences by using the specified IEqualityComparer<T> to compare values.
ExceptBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>)	Produces the set difference of two sequences according to a specified key selector function.
ExceptBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>, IEquality Comparer<TKey>)	Produces the set difference of two sequences according to a specified key selector function.
First<TSource>(IEnumerable<TSource>)	Returns the first element of a sequence.
First<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the first element in a sequence that satisfies a specified condition.
FirstOrDefault<TSource>(IEnumerable<TSource>)	Returns the first element of a sequence, or a default value if the sequence contains no elements.
FirstOrDefault<TSource>(IEnumerable<TSource>, TSource)	Returns the first element of a sequence, or a specified default value if the sequence contains no elements.
FirstOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the first element of the sequence that satisfies a condition or a default value if no such element is found.

FirstOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>, TSource)	Returns the first element of the sequence that satisfies a condition, or a specified default value if no such element is found.
GroupBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Groups the elements of a sequence according to a specified key selector function.
GroupBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Groups the elements of a sequence according to a specified key selector function and compares the keys by using a specified comparer.
GroupBy<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>)	Groups the elements of a sequence according to a specified key selector function and projects the elements for each group by using a specified function.
GroupBy<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEquality Comparer<TKey>)	Groups the elements of a sequence according to a key selector function. The keys are compared by using a comparer and each group's elements are projected by using a specified function.
GroupBy<TSource,TKey,TResult>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TKey,IEnumerable<TSource>,TResult>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key.
GroupBy<TSource,TKey,TResult>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TKey,IEnumerable<TSource>,TResult>, IEquality Comparer<TKey>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key. The keys are compared by using a specified comparer.
GroupBy<TSource,TKey,TElement,TResult> (IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, Func<TKey,IEnumerable<TElement>,TResult>)	Groups the elements of a sequence according to a specified key selector function and creates a result value

	from each group and its key. The elements of each group are projected by using a specified function.
GroupBy<TSource,TKey,TElement,TResult> (IEnumerable<TSource>, Func<TSource, TKey>, Func<TSource,TElement>, Func<TKey,IEnumerable<TElement>, TResult>, IEqualityComparer<TKey>)	Groups the elements of a sequence according to a specified key selector function and creates a result value from each group and its key. Key values are compared by using a specified comparer, and the elements of each group are projected by using a specified function.
GroupJoin<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,IEnumerable<TInner>, TResult>)	Correlates the elements of two sequences based on equality of keys and groups the results. The default equality comparer is used to compare keys.
GroupJoin<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,IEnumerable<TInner>, TResult>, IEquality Comparer<TKey>)	Correlates the elements of two sequences based on key equality and groups the results. A specified IEqualityComparer<T> is used to compare keys.
Intersect<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Produces the set intersection of two sequences by using the default equality comparer to compare values.
Intersect<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Produces the set intersection of two sequences by using the specified IEqualityComparer<T> to compare values.
IntersectBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>)	Produces the set intersection of two sequences according to a specified key selector function.
IntersectBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TKey>, Func<TSource,TKey>, IEquality Comparer<TKey>)	Produces the set intersection of two sequences according to a specified key selector function.

Join<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,TInner,TResult>)	Correlates the elements of two sequences based on matching keys. The default equality comparer is used to compare keys.
Join<TOuter,TInner,TKey,TResult>(IEnumerable<TOuter>, IEnumerable<TInner>, Func<TOuter,TKey>, Func<TInner,TKey>, Func<TOuter,TInner,TResult>, IEqualityComparer<TKey>)	Correlates the elements of two sequences based on matching keys. A specified IEqualityComparer<T> is used to compare keys.
Last<TSource>(IEnumerable<TSource>)	Returns the last element of a sequence.
Last<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the last element of a sequence that satisfies a specified condition.
LastOrDefault<TSource>(IEnumerable<TSource>)	Returns the last element of a sequence, or a default value if the sequence contains no elements.
LastOrDefault<TSource>(IEnumerable<TSource>, TSource)	Returns the last element of a sequence, or a specified default value if the sequence contains no elements.
LastOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the last element of a sequence that satisfies a condition or a default value if no such element is found.
LastOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>, TSource)	Returns the last element of a sequence that satisfies a condition, or a specified default value if no such element is found.
LongCount<TSource>(IEnumerable<TSource>)	Returns an Int64 that represents the total number of elements in a sequence.
LongCount<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns an Int64 that represents how many elements in a sequence satisfy a condition.
Max<TSource>(IEnumerable<TSource>)	Returns the maximum value in a generic sequence.

Max<TSource>(IEnumerable<TSource>, IComparer<TSource>)	Returns the maximum value in a generic sequence.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Invokes a transform function on each element of a sequence and returns the maximum Decimal value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Invokes a transform function on each element of a sequence and returns the maximum Double value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Invokes a transform function on each element of a sequence and returns the maximum Int32 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Invokes a transform function on each element of a sequence and returns the maximum Int64 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Decimal value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Double value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Int32 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Invokes a transform function on each element of a sequence and returns the maximum nullable Int64 value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Invokes a transform function on each element of a sequence and returns the

	maximum nullable Single value.
Max<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Invokes a transform function on each element of a sequence and returns the maximum Single value.
Max<TSource,TResult>(IEnumerable<TSource>, Func<TSource,TResult>)	Invokes a transform function on each element of a generic sequence and returns the maximum resulting value.
MaxBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Returns the maximum value in a generic sequence according to a specified key selector function.
MaxBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Returns the maximum value in a generic sequence according to a specified key selector function and key comparer.
Min<TSource>(IEnumerable<TSource>)	Returns the minimum value in a generic sequence.
Min<TSource>(IEnumerable<TSource>, IComparer<TSource>)	Returns the minimum value in a generic sequence.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Invokes a transform function on each element of a sequence and returns the minimum Decimal value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Invokes a transform function on each element of a sequence and returns the minimum Double value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Invokes a transform function on each element of a sequence and returns the minimum Int32 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Invokes a transform function on each element of a sequence and returns the minimum Int64 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Invokes a transform function on each element of a sequence and returns the

	minimum nullable Decimal value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Double value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Int32 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Int64 value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Invokes a transform function on each element of a sequence and returns the minimum nullable Single value.
Min<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Invokes a transform function on each element of a sequence and returns the minimum Single value.
Min<TSource,TResult>(IEnumerable<TSource>, Func<TSource,TResult>)	Invokes a transform function on each element of a generic sequence and returns the minimum resulting value.
MinBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Returns the minimum value in a generic sequence according to a specified key selector function.
MinBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Returns the minimum value in a generic sequence according to a specified key selector function and key comparer.
OfType<TResult>(IEnumerable)	Filters the elements of an IEnumerable based on a specified type.
Order<T>(IEnumerable<T>)	Sorts the elements of a sequence in ascending order.

Order<T>(IEnumerable<T>, IComparer<T>)	Sorts the elements of a sequence in ascending order.
OrderBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Sorts the elements of a sequence in ascending order according to a key.
OrderBy<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Sorts the elements of a sequence in ascending order by using a specified comparer.
OrderByDescending<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Sorts the elements of a sequence in descending order according to a key.
OrderByDescending<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IComparer<TKey>)	Sorts the elements of a sequence in descending order by using a specified comparer.
OrderDescending<T>(IEnumerable<T>)	Sorts the elements of a sequence in descending order.
OrderDescending<T>(IEnumerable<T>, IComparer<T>)	Sorts the elements of a sequence in descending order.
Prepend<TSource>(IEnumerable<TSource>, TSource)	Adds a value to the beginning of the sequence.
Reverse<TSource>(IEnumerable<TSource>)	Inverts the order of the elements in a sequence.
Select<TSource,TResult>(IEnumerable<TSource>, Func<TSource,TResult>)	Projects each element of a sequence into a new form.
Select<TSource,TResult>(IEnumerable<TSource>, Func<TSource,Int32,TResult>)	Projects each element of a sequence into a new form by incorporating the element's index.
SelectMany<TSource,TResult>(IEnumerable<TSource>, Func<TSource,IEnumerable<TResult>>)	Projects each element of a sequence to an IEnumerable<T> and flattens the resulting sequences into one sequence.
SelectMany<TSource,TResult>(IEnumerable<TSource>, Func<TSource,Int32,IEnumerable<TResult>>)	Projects each element of a sequence to an

	IEnumerable<T>, and flattens the resulting sequences into one sequence. The index of each source element is used in the projected form of that element.
SelectMany<TSource,TCollection,TResult> (IEnumerable<TSource>, Func<TSource,IEnumerable<TCollection>>, Func<TSource,TCollection,TResult>)	Projects each element of a sequence to an IEnumerable<T>, flattens the resulting sequences into one sequence, and invokes a result selector function on each element therein.
SelectMany<TSource,TCollection,TResult> (IEnumerable<TSource>, Func<TSource,Int32,IEnumerable<TCollection>>, Func<TSource,TCollection,TResult>)	Projects each element of a sequence to an IEnumerable<T>, flattens the resulting sequences into one sequence, and invokes a result selector function on each element therein. The index of each source element is used in the intermediate projected form of that element.
SequenceEqual<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Determines whether two sequences are equal by comparing the elements by using the default equality comparer for their type.
SequenceEqual<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Determines whether two sequences are equal by comparing their elements by using a specified IEqualityComparer<T>.
Single<TSource>(IEnumerable<TSource>)	Returns the only element of a sequence, and throws an exception if there is not exactly one element in the sequence.
Single<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the only element of a sequence that satisfies a specified condition, and throws an exception if more than one such element exists.

SingleOrDefault<TSource>(IEnumerable<TSource>)	Returns the only element of a sequence, or a default value if the sequence is empty; this method throws an exception if there is more than one element in the sequence.
SingleOrDefault<TSource>(IEnumerable<TSource>, TSource)	Returns the only element of a sequence, or a specified default value if the sequence is empty; this method throws an exception if there is more than one element in the sequence.
SingleOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns the only element of a sequence that satisfies a specified condition or a default value if no such element exists; this method throws an exception if more than one element satisfies the condition.
SingleOrDefault<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>, TSource)	Returns the only element of a sequence that satisfies a specified condition, or a specified default value if no such element exists; this method throws an exception if more than one element satisfies the condition.
Skip<TSource>(IEnumerable<TSource>, Int32)	Bypasses a specified number of elements in a sequence and then returns the remaining elements.
SkipLast<TSource>(IEnumerable<TSource>, Int32)	Returns a new enumerable collection that contains the elements from `source` with the last `count` elements of the source collection omitted.
SkipWhile<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Bypasses elements in a sequence as long as a specified condition is true and then returns the remaining elements.

SkipWhile<TSource>(IEnumerable<TSource>, Func<TSource,Int32,Boolean>)	Bypasses elements in a sequence as long as a specified condition is true and then returns the remaining elements. The element's index is used in the logic of the predicate function.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Decimal>)	Computes the sum of the sequence of Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Double>)	Computes the sum of the sequence of Double values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Int32>)	Computes the sum of the sequence of Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Int64>)	Computes the sum of the sequence of Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Decimal>>)	Computes the sum of the sequence of nullable Decimal values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Double>>)	Computes the sum of the sequence of nullable Double values that are obtained by invoking a transform function on each element of the input sequence.

Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int32>>)	Computes the sum of the sequence of nullable Int32 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Int64>>)	Computes the sum of the sequence of nullable Int64 values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Nullable<Single>>)	Computes the sum of the sequence of nullable Single values that are obtained by invoking a transform function on each element of the input sequence.
Sum<TSource>(IEnumerable<TSource>, Func<TSource,Single>)	Computes the sum of the sequence of Single values that are obtained by invoking a transform function on each element of the input sequence.
Take<TSource>(IEnumerable<TSource>, Int32)	Returns a specified number of contiguous elements from the start of a sequence.
Take<TSource>(IEnumerable<TSource>, Range)	Returns a specified range of contiguous elements from a sequence.
TakeLast<TSource>(IEnumerable<TSource>, Int32)	Returns a new enumerable collection that contains the last `count` elements from `source`.
TakeWhile<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Returns elements from a sequence as long as a specified condition is true.
TakeWhile<TSource>(IEnumerable<TSource>, Func<TSource,Int32,Boolean>)	Returns elements from a sequence as long as a specified condition is true. The element's index is used in

	the logic of the predicate function.
ToArray<TSource>(IEnumerable<TSource>)	Creates an array from a IEnumerable<T>.
ToDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to a specified key selector function.
ToDictionary<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to a specified key selector function and key comparer.
ToDictionary<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to specified key selector and element selector functions.
ToDictionary<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEqualityComparer<TKey>)	Creates a Dictionary<TKey,TValue> from an IEnumerable<T> according to a specified key selector function, a comparer, and an element selector function.
ToHashSet<TSource>(IEnumerable<TSource>)	Creates a HashSet<T> from an IEnumerable<T>.
ToHashSet<TSource>(IEnumerable<TSource>, IEqualityComparer<TSource>)	Creates a HashSet<T> from an IEnumerable<T> using the `comparer` to compare keys.
ToList<TSource>(IEnumerable<TSource>)	Creates a List<T> from an IEnumerable<T>.
ToLookup<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to a specified key selector function.

ToLookup<TSource,TKey>(IEnumerable<TSource>, Func<TSource,TKey>, IEqualityComparer<TKey>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to a specified key selector function and key comparer.
ToLookup<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to specified key selector and element selector functions.
ToLookup<TSource,TKey,TElement>(IEnumerable<TSource>, Func<TSource,TKey>, Func<TSource,TElement>, IEquality Comparer<TKey>)	Creates a Lookup<TKey,TElement> from an IEnumerable<T> according to a specified key selector function, a comparer and an element selector function.
TryGetNonEnumeratedCount<TSource>(IEnumerable<TSource>, Int32)	Attempts to determine the number of elements in a sequence without forcing an enumeration.
Union<TSource>(IEnumerable<TSource>, IEnumerable<TSource>)	Produces the set union of two sequences by using the default equality comparer.
Union<TSource>(IEnumerable<TSource>, IEnumerable<TSource>, IEqualityComparer<TSource>)	Produces the set union of two sequences by using a specified IEqualityComparer<T>.
UnionBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TSource>, Func<TSource,TKey>)	Produces the set union of two sequences according to a specified key selector function.
UnionBy<TSource,TKey>(IEnumerable<TSource>, IEnumerable<TSource>, Func<TSource,TKey>, IEquality Comparer<TKey>)	Produces the set union of two sequences according to a specified key selector function.
Where<TSource>(IEnumerable<TSource>, Func<TSource,Boolean>)	Filters a sequence of values based on a predicate.
Where<TSource>(IEnumerable<TSource>, Func<TSource,Int32,Boolean>)	Filters a sequence of values based on a predicate. Each

	element's index is used in the logic of the predicate function.
Zip<TFirst,TSecond>(IEnumerable<TFirst>, IEnumerable<TSecond>)	Produces a sequence of tuples with elements from the two specified sequences.
Zip<TFirst,TSecond,TThird>(IEnumerable<TFirst>, IEnumerable<TSecond>, IEnumerable<TThird>)	Produces a sequence of tuples with elements from the three specified sequences.
Zip<TFirst,TSecond,TResult>(IEnumerable<TFirst>, IEnumerable<TSecond>, Func<TFirst,TSecond,TResult>)	Applies a specified function to the corresponding elements of two sequences, producing a sequence of the results.
AsParallel(IEnumerable)	Enables parallelization of a query.
AsParallel<TSource>(IEnumerable<TSource>)	Enables parallelization of a query.
AsQueryable(IEnumerable)	Converts an IEnumerable to an IQueryable.
AsQueryable<TElement>(IEnumerable<TElement>)	Converts a generic IEnumerable<T> to a generic IQueryable<T>.
AsMemory(String)	Creates a new `ReadOnlyMemory<Char>` over the portion of the target string.
AsMemory(String, Index)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified index.
AsMemory(String, Int32)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string starting at a specified character position.
AsMemory(String, Int32, Int32)	Creates a new `ReadOnlyMemory<Char>` over a portion of the target string beginning at a specified position with a length.

AsMemory(String, Range)	Creates a new `ReadOnlyMemory<Char>` over a specified range of the target string.
AsSpan(String)	Creates a new read-only span over a string.
AsSpan(String, Index)	Creates a new ReadOnlySpan<T> over a portion of the target string from a specified position to the end of the string.
AsSpan(String, Int32)	Creates a new read-only span over a portion of the target string from a specified position to the end of the string.
AsSpan(String, Int32, Int32)	Creates a new read-only span over a portion of the target string from a specified position for a specified number of characters.
AsSpan(String, Range)	Creates a new ReadOnlySpan<T> over a portion of a target string using the range start and end indexes.
IsNormalized(String)	Indicates whether the specified string is in Unicode normalization form C.
IsNormalized(String, NormalizationForm)	Indicates whether a string is in a specified Unicode normalization form.
Normalize(String)	Normalizes a string to a Unicode normalization form C.
Normalize(String, NormalizationForm)	Normalizes a string to the specified Unicode normalization form.
Ancestors<T>(IEnumerable<T>)	Returns a collection of elements that contains the

	ancestors of every node in the source collection.
Ancestors<T>(IEnumerable<T>, XName)	Returns a filtered collection of elements that contains the ancestors of every node in the source collection. Only elements that have a matching XName are included in the collection.
DescendantNodes<T>(IEnumerable<T>)	Returns a collection of the descendant nodes of every document and element in the source collection.
Descendants<T>(IEnumerable<T>)	Returns a collection of elements that contains the descendant elements of every element and document in the source collection.
Descendants<T>(IEnumerable<T>, XName)	Returns a filtered collection of elements that contains the descendant elements of every element and document in the source collection. Only elements that have a matching XName are included in the collection.
Elements<T>(IEnumerable<T>)	Returns a collection of the child elements of every element and document in the source collection.
Elements<T>(IEnumerable<T>, XName)	Returns a filtered collection of the child elements of every element and document in the source collection. Only elements that have a matching XName are included in the collection.
InDocumentOrder<T>(IEnumerable<T>)	Returns a collection of nodes that contains all nodes in the source collection, sorted in document order.
Nodes<T>(IEnumerable<T>)	Returns a collection of the child nodes of every

	document and element in the source collection.
Remove<T>(IEnumerable<T>)	Removes every node in the source collection from its parent node.

String Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the String class.

Overloads

Expand table

String(Char*)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of Unicode characters.
String(Char[])	Initializes a new instance of the String class to the Unicode characters indicated in the specified character array.
String(ReadOnlySpan<Char>)	Initializes a new instance of the String class to the Unicode characters indicated in the specified read-only span.
String(SByte*)	Initializes a new instance of the String class to the value indicated by a pointer to an array of 8-bit signed integers.
String(Char, Int32)	Initializes a new instance of the String class to the value indicated by a specified Unicode character repeated a specified number of times.
String(Char*, Int32, Int32)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of Unicode characters, a starting character position within that array, and a length.
String(Char[], Int32, Int32)	Initializes a new instance of the String class to the value indicated by an array of Unicode characters, a starting character position within that array, and a length.
String(SByte*, Int32, Int32)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of 8-bit signed integers, a starting position within that array, and a length.

String(SByte*, Int32, Int32, Encoding)	Initializes a new instance of the String class to the value indicated by a specified pointer to an array of 8-bit signed integers, a starting position within that array, a length, and an Encoding object.

Remarks

For more information about this API, see Supplemental API remarks for String constructor.

String(Char*)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the String class to the value indicated by a specified pointer to an array of Unicode characters.

C#

```
[System.CLSCompliant(false)]
public String (char* value);
```

Parameters

`value` Char*

A pointer to a null-terminated array of Unicode characters.

Attributes CLSCompliantAttribute

Exceptions

ArgumentOutOfRangeException

The current process does not have read access to all the addressed characters.

ArgumentException

`value` specifies an array that contains an invalid Unicode character, or `value` specifies an address less than 64000.

Remarks

> ⓘ **Note**
>
> For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

String(Char[])

Initializes a new instance of the String class to the Unicode characters indicated in the specified character array.

C#

```
public String (char[]? value);
```

Parameters

`value` Char[]

An array of Unicode characters.

Remarks

> ⓘ **Note**

For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

String(ReadOnlySpan<Char>)

Initializes a new instance of the String class to the Unicode characters indicated in the specified read-only span.

C#

```
public String (ReadOnlySpan<char> value);
```

Parameters

`value` ReadOnlySpan<Char>

A read-only span of Unicode characters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

String(SByte*)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the String class to the value indicated by a pointer to an array of 8-bit signed integers.

```
C#

[System.CLSCompliant(false)]
public String (sbyte* value);
```

Parameters

`value` SByte*

A pointer to a null-terminated array of 8-bit signed integers. The integers are interpreted using the current system code page encoding (that is, the encoding specified by Default).

Attributes CLSCompliantAttribute

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

A new instance of String could not be initialized using `value`, assuming `value` is encoded in ANSI.

ArgumentOutOfRangeException

The length of the new string to initialize, which is determined by the null termination character of `value`, is too large to allocate.

AccessViolationException

`value` specifies an invalid address.

Remarks

> ⓘ **Note**
>
> For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

.NET Standard	2.0, 2.1

String(Char, Int32)

Initializes a new instance of the String class to the value indicated by a specified Unicode character repeated a specified number of times.

C#

```
public String (char c, int count);
```

Parameters

c Char

A Unicode character.

count Int32

The number of times `c` occurs.

Exceptions

ArgumentOutOfRangeException

`count` is less than zero.

Remarks

C#

```
[System.CLSCompliant(false)]
public String (char* value, int startIndex, int length);
```

Parameters

`value` Char*

A pointer to an array of Unicode characters.

`startIndex` Int32

The starting position within `value`.

`length` Int32

The number of characters within `value` to use.

Attributes CLSCompliantAttribute

Exceptions

ArgumentOutOfRangeException

`startIndex` or `length` is less than zero, `value` + `startIndex` cause a pointer overflow, or the current process does not have read access to all the addressed characters.

ArgumentException

`value` specifies an array that contains an invalid Unicode character, or `value` + `startIndex` specifies an address less than 64000.

Remarks

> **Note**
>
> For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

String(Char[], Int32, Int32)

Initializes a new instance of the String class to the value indicated by an array of Unicode characters, a starting character position within that array, and a length.

```
C#
public String (char[] value, int startIndex, int length);
```

Parameters

`value` Char[]

An array of Unicode characters.

`startIndex` Int32

The starting position within `value`.

`length` Int32

The number of characters within `value` to use.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` or `length` is less than zero.

-or-

The sum of `startIndex` and `length` is greater than the number of elements in `value`.

Remarks

ⓘ Note

For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UWP	10.0

String(SByte*, Int32, Int32)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the String class to the value indicated by a specified pointer to an array of 8-bit signed integers, a starting position within that array, and a length.

C#

```
[System.CLSCompliant(false)]
public String (sbyte* value, int startIndex, int length);
```

Parameters

`value` SByte*

A pointer to an array of 8-bit signed integers. The integers are interpreted using the current system code page encoding (that is, the encoding specified by Default).

`startIndex` Int32

The starting position within `value`.

`length` Int32

The number of characters within `value` to use.

Attributes CLSCompliantAttribute

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` or `length` is less than zero.

-or-

The address specified by `value` + `startIndex` is too large for the current platform; that is, the address calculation overflowed.

-or-

The length of the new string to initialize is too large to allocate.

ArgumentException

The address specified by `value` + `startIndex` is less than 64K.

-or-

A new instance of String could not be initialized using `value`, assuming `value` is encoded in ANSI.

AccessViolationException

`value`, `startIndex`, and `length` collectively specify an invalid address.

Remarks

> **Note**
>
> For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

String(SByte*, Int32, Int32, Encoding)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the String class to the value indicated by a specified pointer to an array of 8-bit signed integers, a starting position within that array, a length, and an Encoding object.

C#

```
[System.CLSCompliant(false)]
public String (sbyte* value, int startIndex, int length,
System.Text.Encoding enc);
```

Parameters

`value` SByte*

A pointer to an array of 8-bit signed integers.

`startIndex` Int32

The starting position within `value`.

`length` Int32

The number of characters within `value` to use.

`enc` Encoding

An object that specifies how the array referenced by `value` is encoded. If `enc` is `null`, ANSI encoding is assumed.

Attributes CLSCompliantAttribute

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` or `length` is less than zero.

-or-

The address specified by `value` + `startIndex` is too large for the current platform; that is, the address calculation overflowed.

-or-

The length of the new string to initialize is too large to allocate.

ArgumentException

The address specified by `value` + `startIndex` is less than 64K.

-or-

A new instance of String could not be initialized using `value`, assuming `value` is encoded as specified by `enc`.

AccessViolationException

`value`, `startIndex`, and `length` collectively specify an invalid address.

Remarks

> **Note**
>
> For examples and comprehensive usage information about this and other `String` constructor overloads, see the **String** constructor summary.

String.Empty Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the empty string. This field is read-only.

C#

```
public static readonly string Empty;
```

Field Value

String

Remarks

The value of this field is the zero-length string, "".

In application code, this field is most commonly used in assignments to initialize a string variable to an empty string. To test whether the value of a string is either `null` or String.Empty, use the IsNullOrEmpty method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.Chars[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the Char object at a specified position in the current String object.

C#

```
public char this[int index] { get; }
```

Parameters

index Int32

A position in the current string.

Property Value

Char

The object at position `index`.

Exceptions

IndexOutOfRangeException

`index` is greater than or equal to the length of this object or less than zero.

Examples

The following example demonstrates how you can use this indexer in a routine to validate a string.

C#

```
Console.Write("Type a string : ");
string myString = Console.ReadLine();
for (int i = 0; i < myString.Length; i ++)
   if(Uri.IsHexDigit(myString[i]))
```

```
        Console.WriteLine("{0} is a hexadecimal digit.", myString[i]);
    else
        Console.WriteLine("{0} is not a hexadecimal digit.", myString[i]);
// The example produces output like the following:
//    Type a string : 3f5EaZ
//    3 is a hexadecimal digit.
//    f is a hexadecimal digit.
//    5 is a hexadecimal digit.
//    E is a hexadecimal digit.
//    a is a hexadecimal digit.
//    Z is not a hexadecimal digit.
```

Remarks

The `index` parameter is zero-based.

This property returns the Char object at the position specified by the `index` parameter. However, a Unicode character might be represented by more than one Char. Use the System.Globalization.StringInfo class to work with Unicode characters instead of Char objects. For more information, see the "Char Objects and Unicode Characters" section in the String class overview.

In C#, the Chars[] property is an indexer. In Visual Basic, it is the default property of the String class. Each Char object in the string can be accessed by using code such as the following.

C#

```
string str1 = "Test";
for (int ctr = 0; ctr <= str1.Length - 1; ctr++ )
   Console.Write("{0} ", str1[ctr]);
// The example displays the following output:
//      T e s t
```

Applies to

Product	Versions

String.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of characters in the current String object.

C#

```
public int Length { get; }
```

Property Value

Int32

The number of characters in the current string.

Examples

The following example demonstrates the Length property.

C#

```
string str = "abcdefg";
Console.WriteLine("1) The length of '{0}' is {1}", str, str.Length);
Console.WriteLine("2) The length of '{0}' is {1}", "xyz", "xyz".Length);

int length = str.Length;
Console.WriteLine("3) The length of '{0}' is {1}", str, length);

// This example displays the following output:
//    1) The length of 'abcdefg' is 7
//    2) The length of 'xyz' is 3
//    3) The length of 'abcdefg' is 7
```

Remarks

The Length property returns the number of Char objects in this instance, not the number of Unicode characters. The reason is that a Unicode character might be represented by

more than one Char. Use the System.Globalization.StringInfo class to work with each Unicode character instead of each Char.

In some languages, such as C and C++, a null character indicates the end of a string. In .NET, a null character can be embedded in a string. When a string includes one or more null characters, they are included in the length of the total string. For example, in the following string, the substrings "abc" and "def" are separated by a null character. The Length property returns 7, which indicates that it includes the six alphabetic characters as well as the null character.

C#

```
string characters = "abc\u0000def";
Console.WriteLine(characters.Length); // Displays 7
```

Applies to

String.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a reference to this instance of String.

C#

```
public object Clone ();
```

Returns

Object

This instance of String.

Implements

Clone()

Remarks

The return value is not an independent copy of this instance; it is simply another view of the same data. Use the Copy or CopyTo method to create a separate String object with the same value as this instance.

Because the Clone method simply returns the existing string instance, there is little reason to call it directly.

String.Compare Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two specified String objects and returns an integer that indicates their relative position in the sort order.

Overloads

Expand table

Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions)	Compares substrings of two specified String objects using the specified comparison options and culture-specific information to influence the comparison, and returns an integer that indicates the relationship of the two substrings to each other in the sort order.
Compare(String, Int32, String, Int32, Int32, Boolean, CultureInfo)	Compares substrings of two specified String objects, ignoring or honoring their case and using culture-specific information to influence the comparison, and returns an integer that indicates their relative position in the sort order.
Compare(String, Int32, String, Int32, Int32, StringComparison)	Compares substrings of two specified String objects using the specified rules, and returns an integer that indicates their relative position in the sort order.
Compare(String, Int32, String, Int32, Int32, Boolean)	Compares substrings of two specified String objects, ignoring or honoring their case, and returns an integer that indicates their relative position in the sort order.
Compare(String, Int32, String, Int32, Int32)	Compares substrings of two specified String objects and returns an integer that indicates their relative position in the sort order.
Compare(String, String)	Compares two specified String objects and returns an integer that indicates their relative position in the sort order.
Compare(String, String, Boolean, CultureInfo)	Compares two specified String objects, ignoring or honoring their case, and using culture-specific information to influence the comparison, and returns an integer that indicates their relative position in the sort order.

Compare(String, String, StringComparison)	Compares two specified String objects using the specified rules, and returns an integer that indicates their relative position in the sort order.
Compare(String, String, Boolean)	Compares two specified String objects, ignoring or honoring their case, and returns an integer that indicates their relative position in the sort order.
Compare(String, String, CultureInfo, CompareOptions)	Compares two specified String objects using the specified comparison options and culture-specific information to influence the comparison, and returns an integer that indicates the relationship of the two strings to each other in the sort order.

Remarks

All overloads of the Compare method return a 32-bit signed integer indicating the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	The first substring precedes the second substring in the sort order.
Zero	The substrings occur in the same position in the sort order, or `length` is zero.
Greater than zero	The first substring follows the second substring in the sort order.

> ⚠ **Warning**
>
> Whenever possible, you should call an overload of the **Compare** method that includes a **StringComparison** parameter. For more information, see **Best Practices for Using Strings**.

Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions)

Compares substrings of two specified String objects using the specified comparison options and culture-specific information to influence the comparison, and returns an integer that indicates the relationship of the two substrings to each other in the sort order.

```C#
public static int Compare (string? strA, int indexA, string? strB, int indexB, int length, System.Globalization.CultureInfo? culture, System.Globalization.CompareOptions options);
```

Parameters

`strA` String

The first string to use in the comparison.

`indexA` Int32

The starting position of the substring within `strA`.

`strB` String

The second string to use in the comparison.

`indexB` Int32

The starting position of the substring within `strB`.

`length` Int32

The maximum number of characters in the substrings to compare.

`culture` CultureInfo

An object that supplies culture-specific comparison information. If `culture` is `null`, the current culture is used.

`options` CompareOptions

Options to use when performing the comparison (such as ignoring case or symbols).

Returns

Int32

An integer that indicates the lexical relationship between the two substrings, as shown in the following table.

Expand table

Value	Condition
Less than zero	The substring in `strA` precedes the substring in `strB` in the sort order.

Value	Condition
Zero	The substrings occur in the same position in the sort order, or `length` is zero.
Greater than zero	The substring in `strA` follows the substring in `strB` in the sort order.

Exceptions

ArgumentException

`options` is not a CompareOptions value.

ArgumentOutOfRangeException

`indexA` is greater than `strA.Length`.

-or-

`indexB` is greater than `strB.Length`.

-or-

`indexA`, `indexB`, or `length` is negative.

-or-

Either `strA` or `strB` is `null`, and `length` is greater than zero.

Examples

The following example uses the Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions) method to compare the last names of two people. It then lists them in alphabetical order.

C#

```
string name1 = "Jack Smith";
string name2 = "John Doe";

// Get position of character after the space character.
int index1 = name1.IndexOf(" ");
index1 = index1 < 0 ? 0 : ++index1;

int index2 = name2.IndexOf(" ");
index2 = index2 < 0 ? 0 : ++index2;

int length = Math.Max(name1.Length, name2.Length);
```

```
Console.WriteLine("Sorted alphabetically by last name:");
if (String.Compare(name1, index1, name2, index2, length,
                   new CultureInfo("en-US"), CompareOptions.IgnoreCase) <
0)
    Console.WriteLine("{0}\n{1}", name1, name2);
else
    Console.WriteLine("{0}\n{1}", name2, name1);

// The example displays the following output:
//       Sorted alphabetically by last name:
//       John Doe
//       Jack Smith
```

Remarks

The substrings to compare start in `strA` at position `indexA` and in `strB` at position `indexB`. The length of the first substring is the length of `strA` minus `indexA`. The length of the second substring is the length of `strB` minus `indexB`.

The number of characters to compare is the lesser of the lengths of the two substrings, and `length`. The `indexA`, `indexB`, and `length` parameters must be nonnegative.

The comparison uses the `culture` parameter to obtain culture-specific information, such as casing rules and the alphabetical order of individual characters. For example, a particular culture could specify that certain combinations of characters be treated as a single character, that uppercase and lowercase characters be compared in a particular way, or that the sort order of a character depends on the characters that precede or follow it.

> ⊗ **Caution**
>
> The **Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions)** method is designed primarily for use in sorting or alphabetizing operations. It should not be used when the primary purpose of the method call is to determine whether two substrings are equivalent (that is, when the purpose of the method call is to test for a return value of zero). To determine whether two strings are equivalent, call the **Equals** method.

One or both of `strA` and `strB` can be `null`. By definition, any string, including String.Empty, compares greater than a null reference, and two null references compare equal to each other.

The comparison can be further specified by the `options` parameter, which consists of one or more members of the System.Globalization.CompareOptions enumeration. However, because the purpose of this method is to conduct a culture-sensitive string comparison, the CompareOptions.Ordinal and CompareOptions.OrdinalIgnoreCase values have no effect.

The comparison terminates when an inequality is discovered or both substrings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, the string with the remaining characters is considered greater. The return value is the result of the last comparison performed.

Notes to Callers

Character sets include ignorable characters. The Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions) method does not consider these characters when it performs a linguistic or culture-sensitive comparison. To recognize ignorable characters in your comparison, supply a value of Ordinal or OrdinalIgnoreCase for the `options` parameter.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Compare(String, Int32, String, Int32, Int32, Boolean, CultureInfo)

Compares substrings of two specified String objects, ignoring or honoring their case and using culture-specific information to influence the comparison, and returns an

integer that indicates their relative position in the sort order.

```C#
public static int Compare (string? strA, int indexA, string? strB, int indexB, int length, bool ignoreCase, System.Globalization.CultureInfo? culture);
```

Parameters

`strA` String

The first string to use in the comparison.

`indexA` Int32

The position of the substring within `strA`.

`strB` String

The second string to use in the comparison.

`indexB` Int32

The position of the substring within `strB`.

`length` Int32

The maximum number of characters in the substrings to compare.

`ignoreCase` Boolean

`true` to ignore case during the comparison; otherwise, `false`.

`culture` CultureInfo

An object that supplies culture-specific comparison information. If `culture` is `null`, the current culture is used.

Returns

Int32

An integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	The substring in `strA` precedes the substring in `strB` in the sort order.
Zero	The substrings occur in the same position in the sort order, or `length` is zero.
Greater than zero	The substring in `strA` follows the substring in `strB` in the sort order.

Exceptions

ArgumentOutOfRangeException

`indexA` is greater than `strA`.Length.

-or-

`indexB` is greater than `strB`.Length.

-or-

`indexA`, `indexB`, or `length` is negative.

-or-

Either `strA` or `strB` is `null`, and `length` is greater than zero.

Examples

The following example compares two substrings using different cultures and ignoring the case of the substrings. The choice of culture affects how the letter "I" is compared.

C#

```
// Sample for String.Compare(String, Int32, String, Int32, Int32,
Boolean, CultureInfo)
using System;
using System.Globalization;

class Sample5
{
    public static void Main()
    {
        //                  0123456
        String str1 = "MACHINE";
        String str2 = "machine";
        String str;
```

```
        int result;

        Console.WriteLine();
        Console.WriteLine("str1 = '{0}', str2 = '{1}'", str1, str2);
        Console.WriteLine("Ignore case, Turkish culture:");
        result = String.Compare(str1, 4, str2, 4, 2, true, new
CultureInfo("tr-TR"));
        str = ((result < 0) ? "less than" : ((result > 0) ? "greater
than" : "equal to"));
        Console.Write("Substring '{0}' in '{1}' is ", str1.Substring(4,
2), str1);
        Console.Write("{0} ", str);
        Console.WriteLine("substring '{0}' in '{1}'.", str2.Substring(4,
2), str2);

        Console.WriteLine();
        Console.WriteLine("Ignore case, invariant culture:");
        result = String.Compare(str1, 4, str2, 4, 2, true,
CultureInfo.InvariantCulture);
        str = ((result < 0) ? "less than" : ((result > 0) ? "greater
than" : "equal to"));
        Console.Write("Substring '{0}' in '{1}' is ", str1.Substring(4,
2), str1);
        Console.Write("{0} ", str);
        Console.WriteLine("substring '{0}' in '{1}'.", str2.Substring(4,
2), str2);
    }
}
/*
This example produces the following results:

str1 = 'MACHINE', str2 = 'machine'
Ignore case, Turkish culture:
Substring 'IN' in 'MACHINE' is less than substring 'in' in 'machine'.

Ignore case, invariant culture:
Substring 'IN' in 'MACHINE' is equal to substring 'in' in 'machine'.
*/
```

Remarks

The substrings to compare start in `strA` at `indexA`, and in `strB` at `indexB`. Both `indexA` and `indexB` are zero-based; that is, the first character in `strA` and `strB` is at position zero, not position one. The length of the first substring is equal to the length of `strA` minus `indexA` plus one. The length of the second substring is equal to the length of `strB` minus `indexB` plus one.

The number of characters to compare is the lesser of the lengths of the two substrings, and `length`. The `indexA`, `indexB`, and `length` parameters must be

nonnegative.

The comparison uses the `culture` parameter to obtain culture-specific information such as casing rules and the alphabetic order of individual characters. For example, a culture could specify that certain combinations of characters be treated as a single character, or uppercase and lowercase characters be compared in a particular way, or that the sorting order of a character depends on the characters that precede or follow it.

The comparison is performed using word sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

One or both comparands can be `null`. By definition, any string, including the empty string (""), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both substrings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, then the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, Int32, String, Int32, Int32, Boolean, CultureInfo) method does not consider these characters when it performs a linguistic or culture-sensitive comparison. To recognize ignorable characters in your comparison, call the Compare(String, Int32, String, Int32, Int32, CultureInfo, CompareOptions) method and supply a value of Ordinal or OrdinalIgnoreCase for the `options` parameter.

.NET Standard	2.0, 2.1

Compare(String, Int32, String, Int32, Int32, StringComparison)

Compares substrings of two specified String objects using the specified rules, and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, int indexA, string? strB, int
indexB, int length, StringComparison comparisonType);
```

Parameters

`strA` String

The first string to use in the comparison.

`indexA` Int32

The position of the substring within `strA`.

`strB` String

The second string to use in the comparison.

`indexB` Int32

The position of the substring within `strB`.

`length` Int32

The maximum number of characters in the substrings to compare.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules to use in the comparison.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	The substring in `strA` precedes the substring in `strB` in the sort order.
Zero	The substrings occur in the same position in the sort order, or the `length` parameter is zero.
Greater than zero	The substring in `strA` follows the substring in `strB` in the sort order.

Exceptions

ArgumentOutOfRangeException

`indexA` is greater than `strA`.Length.

-or-

`indexB` is greater than `strB`.Length.

-or-

`indexA`, `indexB`, or `length` is negative.

-or-

Either `indexA` or `indexB` is `null`, and `length` is greater than zero.

ArgumentException

`comparisonType` is not a StringComparison value.

Examples

The following example compares two substrings.

C#

```
String str1 = "machine";
String str2 = "device";
String str;
int result;

Console.WriteLine();
Console.WriteLine("str1 = '{0}', str2 = '{1}'", str1, str2);
result = String.Compare(str1, 2, str2, 0, 2);
str = ((result < 0) ? "less than" : ((result > 0) ? "greater than" :
"equal to"));
Console.Write("Substring '{0}' in '{1}' is ", str1.Substring(2, 2),
str1);
Console.Write("{0} ", str);
Console.WriteLine("substring '{0}' in '{1}'.", str2.Substring(0, 2),
str2);

/*
This example produces the following results:

str1 = 'machine', str2 = 'device'
Substring 'ch' in 'machine' is less than substring 'de' in 'device'.
*/
```

Remarks

The substrings to compare start in `strA` at `indexA` and in `strB` at `indexB`. Both `indexA` and `indexB` are zero-based; that is, the first character in `strA` and `strB` is at position zero, not position one. The length of the first substring is equal to the

length of `strA` minus `indexA` plus one. The length of the second substring is equal to the length of `strB` minus `indexB` plus one.

The number of characters to compare is the lesser of the lengths of the two substrings, and `length`. The `indexA`, `indexB`, and `length` parameters must be nonnegative.

The `comparisonType` parameter indicates whether the comparison should use the current or invariant culture, honor or ignore the case of the comparands, or use word (culture-sensitive) or ordinal (culture-insensitive) sort rules.

One or both comparands can be `null`. By definition, any string, including the empty string ("), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both substrings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, Int32, String, Int32, Int32, StringComparison) method does not consider these characters when it performs a linguistic or culture-sensitive comparison. To recognize ignorable characters in your comparison, supply a value of Ordinal or OrdinalIgnoreCase for the `comparisonType` parameter.

UWP	10.0

Compare(String, Int32, String, Int32, Int32, Boolean)

Compares substrings of two specified String objects, ignoring or honoring their case, and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, int indexA, string? strB, int
indexB, int length, bool ignoreCase);
```

Parameters

strA String

The first string to use in the comparison.

`indexA` Int32

The position of the substring within `strA`.

`strB` String

The second string to use in the comparison.

`indexB` Int32

The position of the substring within `strB`.

`length` Int32

The maximum number of characters in the substrings to compare.

`ignoreCase` Boolean

`true` to ignore case during the comparison; otherwise, `false`.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	The substring in `strA` precedes the substring in `strB` in the sort order.
Zero	The substrings occur in the same position in the sort order, or `length` is zero.
Greater than zero	The substring in `strA` follows the substring in `strB` in the sort order.

Exceptions

ArgumentOutOfRangeException

`indexA` is greater than `strA`.Length.

-or-

`indexB` is greater than `strB`.Length.

-or-

`indexA`, `indexB`, or `length` is negative.

-or-

Either `indexA` or `indexB` is `null`, and `length` is greater than zero.

Examples

The following example performs two comparisons of two substrings that only differ in case. The first comparison ignores case and the second comparison considers case.

C#

```
String str1 = "MACHINE";
String str2 = "machine";
String str;
int result;

Console.WriteLine();
Console.WriteLine("str1 = '{0}', str2 = '{1}'", str1, str2);

Console.WriteLine("Ignore case:");
result = String.Compare(str1, 2, str2, 2, 2, true);
str = ((result < 0) ? "less than" : ((result > 0) ? "greater than" :
"equal to"));
Console.Write("Substring '{0}' in '{1}' is ", str1.Substring(2, 2),
str1);
Console.Write("{0} ", str);
Console.WriteLine("substring '{0}' in '{1}'.", str2.Substring(2, 2),
str2);
Console.WriteLine();

Console.WriteLine("Honor case:");
result = String.Compare(str1, 2, str2, 2, 2, false);
str = ((result < 0) ? "less than" : ((result > 0) ? "greater than" :
"equal to"));
Console.Write("Substring '{0}' in '{1}' is ", str1.Substring(2, 2),
str1);
Console.Write("{0} ", str);
Console.WriteLine("substring '{0}' in '{1}'.", str2.Substring(2, 2),
str2);

/*
This example produces the following results:

str1 = 'MACHINE', str2 = 'machine'
```

```
Ignore case:
Substring 'CH' in 'MACHINE' is equal to substring 'ch' in 'machine'.

Honor case:
Substring 'CH' in 'MACHINE' is greater than substring 'ch' in 'machine'.
*/
```

Remarks

The substrings to compare start in `strA` at `indexA`, and in `strB` at `indexB`. Both `indexA` and `indexB` are zero-based; that is, the first character in `strA` and `strB` is at position zero. The length of the first substring is equal to the length of `strA` minus `indexA` plus one. The length of the second substring is equal to the length of `strB` minus `indexB` plus one.

The number of characters to compare is the lesser of the lengths of the two substrings, and `length`. The `indexA`, `indexB`, and `length` parameters must be nonnegative.

The comparison uses the current culture to obtain culture-specific information such as casing rules and the alphabetic order of individual characters. For example, a culture could specify that certain combinations of characters be treated as a single character, or uppercase and lowercase characters be compared in a particular way, or that the sorting order of a character depends on the characters that precede or follow it.

The comparison is performed using word sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

> ⚠ **Warning**
>
> When comparing strings, you should call the **Compare(String, Int32, String, Int32, Int32, StringComparison)** method, which requires that you explicitly specify the type of string comparison that the method uses. For more information, see **Best Practices for Using Strings**.

One or both comparands can be `null`. By definition, any string, including the empty string ("), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both substrings have been compared. However, if the two strings compare equal to the end of one string,

and the other string has characters remaining, then the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

The path name needs to be compared in an invariant manner. The correct code to do this is as follows.

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, Int32, String, Int32, Int32, Boolean) method does not consider these characters when it performs a linguistic or culture-sensitive comparison. To recognize ignorable characters in your comparison, call the Compare(String, Int32, String, Int32, Int32, StringComparison) method and supply a value of Ordinal or OrdinalIgnoreCase for the `comparisonType` parameter.

.NET Standard	2.0, 2.1

Compare(String, Int32, String, Int32, Int32)

Compares substrings of two specified String objects and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, int indexA, string? strB, int
indexB, int length);
```

Parameters

`strA` String

The first string to use in the comparison.

`indexA` Int32

The position of the substring within `strA`.

`strB` String

The second string to use in the comparison.

`indexB` Int32

The position of the substring within `strB`.

`length` Int32

The maximum number of characters in the substrings to compare.

Returns

Int32

A 32-bit signed integer indicating the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	The substring in `strA` precedes the substring in `strB` in the sort order.
Zero	The substrings occur in the same position in the sort order, or `length` is zero.
Greater than zero	The substring in `strA` follows the substring in `strB` in the sort order.

Exceptions

ArgumentOutOfRangeException

`indexA` is greater than `strA`.Length.

-or-

`indexB` is greater than `strB`.Length.

-or-

`indexA`, `indexB`, or `length` is negative.

-or-

Either `indexA` or `indexB` is `null`, and `length` is greater than zero.

Examples

The following example compares two substrings.

C#

```
String str1 = "machine";
String str2 = "device";
String str;
int result;

Console.WriteLine();
Console.WriteLine("str1 = '{0}', str2 = '{1}'", str1, str2);
```

```
result = String.Compare(str1, 2, str2, 0, 2);
str = ((result < 0) ? "less than" : ((result > 0) ? "greater than" :
"equal to"));
Console.Write("Substring '{0}' in '{1}' is ", str1.Substring(2, 2),
str1);
Console.Write("{0} ", str);
Console.WriteLine("substring '{0}' in '{1}'.", str2.Substring(0, 2),
str2);

/*
This example produces the following results:

str1 = 'machine', str2 = 'device'
Substring 'ch' in 'machine' is less than substring 'de' in 'device'.
*/
```

Remarks

The substrings to compare start in `strA` at `indexA` and in `strB` at `indexB`. Both `indexA` and `indexB` are zero-based; that is, the first character in `strA` and `strB` is at position zero. The length of the first substring is equal to the length of `strA` minus `indexA` plus one. The length of the second substring is equal to the length of `strB` minus `indexB` plus one.

The number of characters to compare is the lesser of the lengths of the two substrings, and `length`. The `indexA`, `indexB`, and `length` parameters must be nonnegative.

The comparison uses the current culture to obtain culture-specific information such as casing rules and the alphabetic order of individual characters. For example, a culture could specify that certain combinations of characters be treated as a single character, or uppercase and lowercase characters be compared in a particular way, or that the sorting order of a character depends on the characters that precede or follow it.

The comparison is performed using word sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

> ⚠ **Warning**
>
> When comparing strings, you should call the **Compare(String, Int32, String, Int32, Int32, StringComparison)** method, which requires that you explicitly specify the type of string comparison that the method uses. For more information, see **Best Practices for Using Strings**.

One or both comparands can be `null`. By definition, any string, including the empty string ("), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both substrings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, then the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, Int32, String, Int32, Int32) method does not consider these characters when it performs a linguistic or culture-sensitive comparison. To recognize ignorable characters in your comparison, call the Compare(String, Int32, String, Int32, Int32, StringComparison) method and supply a value of Ordinal or OrdinalIgnoreCase for the `comparisonType` parameter.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Compare(String, String)

Compares two specified String objects and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, string? strB);
```

Parameters

`strA` String

The first string to compare.

`strB` String

The second string to compare.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	`strA` precedes `strB` in the sort order.
Zero	`strA` occurs in the same position as `strB` in the sort order.
Greater than zero	`strA` follows `strB` in the sort order.

Examples

The following example calls the Compare(String, String) method to compare three sets of strings.

C#

```
// Create upper-case characters from their Unicode code units.
String stringUpper = "\x0041\x0042\x0043";

// Create lower-case characters from their Unicode code units.
String stringLower = "\x0061\x0062\x0063";

// Display the strings.
Console.WriteLine("Comparing '{0}' and '{1}':",
                stringUpper, stringLower);

// Compare the uppercased strings; the result is true.
Console.WriteLine("The Strings are equal when capitalized? {0}",
                String.Compare(stringUpper.ToUpper(),
stringLower.ToUpper()) == 0
                               ? "true" : "false");

// The previous method call is equivalent to this Compare method, which
ignores case.
Console.WriteLine("The Strings are equal when case is ignored? {0}",
                String.Compare(stringUpper, stringLower, true) == 0
                               ? "true" : "false" );

// The example displays the following output:
//       Comparing 'ABC' and 'abc':
//       The Strings are equal when capitalized? true
//       The Strings are equal when case is ignored? true
```

In the following example, the `ReverseStringComparer` class demonstrates how you can evaluate two strings with the Compare method.

C#

```
using System;
using System.Text;
using System.Collections;

public class SamplesArrayList
{

    public static void Main()
    {
        // Creates and initializes a new ArrayList.
        ArrayList myAL = new ArrayList();
        myAL.Add("Eric");
        myAL.Add("Mark");
        myAL.Add("Lance");
        myAL.Add("Rob");
        myAL.Add("Kris");
        myAL.Add("Brad");
        myAL.Add("Kit");
        myAL.Add("Bradley");
        myAL.Add("Keith");
        myAL.Add("Susan");

        // Displays the properties and values of    the ArrayList.
        Console.WriteLine("Count: {0}", myAL.Count);

        PrintValues("Unsorted", myAL);
        myAL.Sort();
        PrintValues("Sorted", myAL);
        myAL.Sort(new ReverseStringComparer());
        PrintValues("Reverse", myAL);

        string[] names = (string[])myAL.ToArray(typeof(string));
    }
    public static void PrintValues(string title, IEnumerable myList)
    {
        Console.Write("{0,10}: ", title);
        StringBuilder sb = new StringBuilder();
        foreach (string s in myList)
        {
            sb.AppendFormat("{0}, ", s);
        }
        sb.Remove(sb.Length - 2, 2);
        Console.WriteLine(sb);
    }
}
public class ReverseStringComparer : IComparer
{
    public int Compare(object? x, object? y)
    {
        string? s1 = x as string;
        string? s2 = y as string;
        //negate the return value to get the reverse order
        return -String.Compare(s1, s2);
```

```
    }
}
```

Remarks

The comparison uses the current culture to obtain culture-specific information such as casing rules and the alphabetic order of individual characters. For example, a culture could specify that certain combinations of characters be treated as a single character, or uppercase and lowercase characters be compared in a particular way, or that the sorting order of a character depends on the characters that precede or follow it.

The comparison is performed using word sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

> ⚠ **Warning**
>
> When comparing strings, you should call the **Compare(String, String, StringComparison)** method, which requires that you explicitly specify the type of string comparison that the method uses. For more information, see **Best Practices for Using Strings**.

One or both comparands can be `null`. By definition, any string, including the empty string (""), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both strings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, then the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
```

```
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

```C#
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, String) method does not consider such characters when it performs a culture-sensitive comparison. For example, if the following code is run on the .NET Framework 4 or later, a culture-sensitive comparison of "animal" with "ani-mal" (using a soft hyphen, or U+00AD) indicates that the two strings are equivalent.

```C#
string s1 = "ani\u00ADmal";
string s2 = "animal";

Console.WriteLine("Comparison of '{0}' and '{1}': {2}",
                s1, s2, String.Compare(s1, s2));

// The example displays the following output:
//       Comparison of 'ani-mal' and 'animal': 0
```

To recognize ignorable characters in a string comparison, call the Compare(String, String, StringComparison) method and supply a value of either Ordinal or OrdinalIgnoreCase for the `comparisonType` parameter.

UWP	10.0

Compare(String, String, Boolean, CultureInfo)

Compares two specified String objects, ignoring or honoring their case, and using culture-specific information to influence the comparison, and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, string? strB, bool ignoreCase,
System.Globalization.CultureInfo? culture);
```

Parameters

`strA` String

The first string to compare.

`strB` String

The second string to compare.

`ignoreCase` Boolean

`true` to ignore case during the comparison; otherwise, `false`.

`culture` CultureInfo

An object that supplies culture-specific comparison information. If `culture` is `null`, the current culture is used.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	`strA` precedes `strB` in the sort order.
Zero	`strA` occurs in the same position as `strB` in the sort order.
Greater than zero	`strA` follows `strB` in the sort order.

Examples

The following example demonstrates how culture can affect a comparison. In Czech - Czech Republic culture, "ch" is a single character that is greater than "d". However, in English - United States culture, "ch" consists of two characters, and "c" is less than "d".

C#

```
public static void Main()
{
    String str1 = "change";
    String str2 = "dollar";
    String relation;

    relation = symbol(String.Compare(str1, str2, false, new
CultureInfo("en-US")));
    Console.WriteLine("For en-US: {0} {1} {2}", str1, relation, str2);

    relation = symbol(String.Compare(str1, str2, false, new
CultureInfo("cs-CZ")));
    Console.WriteLine("For cs-CZ: {0} {1} {2}", str1, relation, str2);
}

private static String symbol(int r)
{
    String s = "=";
    if (r < 0) s = "<";
    else if (r > 0) s = ">";
    return s;
}

/*
```

```
This example produces the following results.
For en-US: change < dollar
For cs-CZ: change > dollar
*/
```

Remarks

The comparison uses the `culture` parameter to obtain culture-specific information such as casing rules and the alphabetic order of individual characters. For example, a culture could specify that certain combinations of characters be treated as a single character, or uppercase and lowercase characters be compared in a particular way, or that the sorting order of a character depends on the characters that precede or follow it.

The comparison is performed using word sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

One or both comparands can be `null`. By definition, any string, including the empty string ("), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both strings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, then the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, String, Boolean, CultureInfo) method does not consider such characters when it performs a culture-sensitive comparison. For example, if the following code is run on the .NET Framework 4 or later, a case-insensitive comparison of "animal" with "Ani-mal" (using a soft hyphen, or U+00AD) using the invariant culture indicates that the two strings are equivalent.

C#

```
string s1 = "Ani\u00ADmal";
string s2 = "animal";

Console.WriteLine("Comparison of '{0}' and '{1}': {2}",
                s1, s2, String.Compare(s1, s2, true,
                CultureInfo.InvariantCulture));

// The example displays the following output:
//       Comparison of 'Ani-mal' and 'animal': 0
```

To recognize ignorable characters in a string comparison, call the Compare(String, String, CultureInfo, CompareOptions) method and supply a value of either Ordinal or OrdinalIgnoreCase for the `options` parameter.

.NET Standard	2.0, 2.1

Compare(String, String, StringComparison)

Compares two specified String objects using the specified rules, and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, string? strB, StringComparison
comparisonType);
```

Parameters

`strA` String

The first string to compare.

`strB` String

The second string to compare.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules to use in the comparison.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	`strA` precedes `strB` in the sort order.

Value	Condition
Zero	`strA` is in the same position as `strB` in the sort order.
Greater than zero	`strA` follows `strB` in the sort order.

Exceptions

ArgumentException

`comparisonType` is not a StringComparison value.

NotSupportedException

StringComparison is not supported.

Examples

The following example compares three versions of the letter "I". The results are affected by the choice of culture, whether case is ignored, and whether an ordinal comparison is performed.

C#

```
// This example demonstrates the
// System.String.Compare(String, String, StringComparison) method.

using System;
using System.Threading;

class Sample
{
    public static void Main()
    {
        string intro = "Compare three versions of the letter I using
different " +
                       "values of StringComparison.";

        // Define an array of strings where each element contains a
version of the
        // letter I. (An array of strings is used so you can easily
modify this
        // code example to test additional or different combinations of
strings.)

        string[] threeIs = new string[3];
        // LATIN SMALL LETTER I (U+0069)
        threeIs[0] = "\u0069";
        // LATIN SMALL LETTER DOTLESS I (U+0131)
        threeIs[1] = "\u0131";
```

```
        // LATIN CAPITAL LETTER I (U+0049)
        threeIs[2] = "\u0049";

        string[] unicodeNames =
        {
            "LATIN SMALL LETTER I (U+0069)",
            "LATIN SMALL LETTER DOTLESS I (U+0131)",
            "LATIN CAPITAL LETTER I (U+0049)"
        };

        StringComparison[] scValues =
        {
            StringComparison.CurrentCulture,
            StringComparison.CurrentCultureIgnoreCase,
            StringComparison.InvariantCulture,
            StringComparison.InvariantCultureIgnoreCase,
            StringComparison.Ordinal,
            StringComparison.OrdinalIgnoreCase
        };

        Console.Clear();
        Console.WriteLine(intro);

        // Display the current culture because the culture-specific
comparisons
        // can produce different results with different cultures.
        Console.WriteLine(
            "The current culture is {0}.\n",
Thread.CurrentThread.CurrentCulture.Name);

        // Determine the relative sort order of three versions of the
letter I.
        foreach (StringComparison sc in scValues)
        {
            Console.WriteLine("StringComparison.{0}:", sc);

            // LATIN SMALL LETTER I (U+0069) : LATIN SMALL LETTER DOTLESS
I (U+0131)
            Test(0, 1, sc, threeIs, unicodeNames);

            // LATIN SMALL LETTER I (U+0069) : LATIN CAPITAL LETTER I
(U+0049)
            Test(0, 2, sc, threeIs, unicodeNames);

            // LATIN SMALL LETTER DOTLESS I (U+0131) : LATIN CAPITAL
LETTER I (U+0049)
            Test(1, 2, sc, threeIs, unicodeNames);

            Console.WriteLine();
        }
    }

    protected static void Test(
        int x, int y, StringComparison comparison, string[] testI,
string[] testNames)
```

```
    {
        string resultFmt = "{0} is {1} {2}";
        string result = "equal to";
        int cmpValue = 0;

        cmpValue = String.Compare(testI[x], testI[y], comparison);
        if (cmpValue < 0)
            result = "less than";
        else if (cmpValue > 0)
            result = "greater than";
        Console.WriteLine(resultFmt, testNames[x], result, testNames[y]);
    }
}

/*
This code example produces the following results:

Compare three versions of the letter I using different values of
StringComparison.
The current culture is en-US.

StringComparison.CurrentCulture:
LATIN SMALL LETTER I (U+0069) is less than LATIN SMALL LETTER DOTLESS I
(U+0131)
LATIN SMALL LETTER I (U+0069) is less than LATIN CAPITAL LETTER I
(U+0049)
LATIN SMALL LETTER DOTLESS I (U+0131) is greater than LATIN CAPITAL
LETTER I (U+0049)

StringComparison.CurrentCultureIgnoreCase:
LATIN SMALL LETTER I (U+0069) is less than LATIN SMALL LETTER DOTLESS I
(U+0131)
LATIN SMALL LETTER I (U+0069) is equal to LATIN CAPITAL LETTER I (U+0049)
LATIN SMALL LETTER DOTLESS I (U+0131) is greater than LATIN CAPITAL
LETTER I (U+0049)

StringComparison.InvariantCulture:
LATIN SMALL LETTER I (U+0069) is less than LATIN SMALL LETTER DOTLESS I
(U+0131)
LATIN SMALL LETTER I (U+0069) is less than LATIN CAPITAL LETTER I
(U+0049)
LATIN SMALL LETTER DOTLESS I (U+0131) is greater than LATIN CAPITAL
LETTER I (U+0049)

StringComparison.InvariantCultureIgnoreCase:
LATIN SMALL LETTER I (U+0069) is less than LATIN SMALL LETTER DOTLESS I
(U+0131)
LATIN SMALL LETTER I (U+0069) is equal to LATIN CAPITAL LETTER I (U+0049)
LATIN SMALL LETTER DOTLESS I (U+0131) is greater than LATIN CAPITAL
LETTER I (U+0049)

StringComparison.Ordinal:
LATIN SMALL LETTER I (U+0069) is less than LATIN SMALL LETTER DOTLESS I
(U+0131)
LATIN SMALL LETTER I (U+0069) is greater than LATIN CAPITAL LETTER I
```

```
(U+0049)
LATIN SMALL LETTER DOTLESS I (U+0131) is greater than LATIN CAPITAL
LETTER I (U+0049)

StringComparison.OrdinalIgnoreCase:
LATIN SMALL LETTER I (U+0069) is less than LATIN SMALL LETTER DOTLESS I
(U+0131)
LATIN SMALL LETTER I (U+0069) is equal to LATIN CAPITAL LETTER I (U+0049)
LATIN SMALL LETTER DOTLESS I (U+0131) is greater than LATIN CAPITAL
LETTER I (U+0049)

*/
```

Remarks

The `comparisonType` parameter indicates whether the comparison should use the current or invariant culture, honor or ignore the case of the comparands, or use word (culture-sensitive) or ordinal (culture-insensitive) sort rules.

One or both comparands can be `null`. By definition, any string, including the empty string ("), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both strings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, String, StringComparison) method does not consider such characters when it performs a culture-sensitive comparison. To recognize ignorable characters in your comparison, supply a value of Ordinal or OrdinalIgnoreCase for the `comparisonType` parameter.

UWP	10.0

Compare(String, String, Boolean)

Compares two specified String objects, ignoring or honoring their case, and returns an integer that indicates their relative position in the sort order.

C#

```
public static int Compare (string? strA, string? strB, bool ignoreCase);
```

Parameters

`strA` String

The first string to compare.

`strB` String

The second string to compare.

`ignoreCase` Boolean

`true` to ignore case during the comparison; otherwise, `false`.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	`strA` precedes `strB` in the sort order.
Zero	`strA` occurs in the same position as `strB` in the sort order.
Greater than zero	`strA` follows `strB` in the sort order.

Examples

The following example demonstrates that the Compare(String, String, Boolean) method is equivalent to using ToUpper or ToLower when comparing strings.

C#

```
// Create upper-case characters from their Unicode code units.
String stringUpper = "\x0041\x0042\x0043";

// Create lower-case characters from their Unicode code units.
String stringLower = "\x0061\x0062\x0063";

// Display the strings.
```

```
Console.WriteLine("Comparing '{0}' and '{1}':",
                stringUpper, stringLower);

// Compare the uppercased strings; the result is true.
Console.WriteLine("The Strings are equal when capitalized? {0}",
                String.Compare(stringUpper.ToUpper(),
stringLower.ToUpper()) == 0
                               ? "true" : "false");

// The previous method call is equivalent to this Compare method, which
ignores case.
Console.WriteLine("The Strings are equal when case is ignored? {0}",
                String.Compare(stringUpper, stringLower, true) == 0
                               ? "true" : "false" );

// The example displays the following output:
//       Comparing 'ABC' and 'abc':
//       The Strings are equal when capitalized? true
//       The Strings are equal when case is ignored? true
```

Remarks

The comparison uses the current culture to obtain culture-specific information such as casing rules and the alphabetic order of individual characters. For example, a culture could specify that certain combinations of characters be treated as a single character, or uppercase and lowercase characters be compared in a particular way, or that the sorting order of a character depends on the characters that precede or follow it.

The comparison is performed using word sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

> ⚠ **Warning**
>
> When comparing strings, you should call the **Compare(String, String, StringComparison)** method, which requires that you explicitly specify the type of string comparison that the method uses. For more information, see **Best Practices for Using Strings**.

One or both comparands can be `null`. By definition, any string, including the empty string ("), compares greater than a null reference; and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both strings have been compared. However, if the two strings compare equal to the end of one string,

and the other string has characters remaining, then the string with remaining characters is considered greater. The return value is the result of the last comparison performed.

Unexpected results can occur when comparisons are affected by culture-specific casing rules. For example, in Turkish, the following example yields the wrong results because the file system in Turkish does not use linguistic casing rules for the letter "i" in "file".

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5, true) == 0);
}
```

Compare the path name to "file" using an ordinal comparison. The correct code to do this is as follows:

C#

```
static bool IsFileURI(String path)
{
    return (String.Compare(path, 0, "file:", 0, 5,
StringComparison.OrdinalIgnoreCase) == 0);
}
```

Notes to Callers

Character sets include ignorable characters. The Compare(String, String, Boolean) method does not consider such characters when it performs a culture-sensitive comparison. For example, if the following code is run on the .NET Framework 4 or later, a culture-sensitive, case-insensitive comparison of "animal" with "Ani-mal" (using a soft hyphen, or U+00AD) indicates that the two strings are equivalent.

C#

```
string s1 = "Ani\u00ADmal";
string s2 = "animal";

Console.WriteLine("Comparison of '{0}' and '{1}': {2}",
                s1, s2, String.Compare(s1, s2, true));

// The example displays the following output:
//       Comparison of 'Ani-mal' and 'animal': 0
```

To recognize ignorable characters in a string comparison, call the Compare(String, String, StringComparison) method and supply a value of either Ordinal or OrdinalIgnoreCase for the `comparisonType` parameter.

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Compare(String, String, CultureInfo, CompareOptions)

Compares two specified String objects using the specified comparison options and culture-specific information to influence the comparison, and returns an integer that indicates the relationship of the two strings to each other in the sort order.

C#

```
public static int Compare (string? strA, string? strB,
System.Globalization.CultureInfo? culture,
System.Globalization.CompareOptions options);
```

Parameters

`strA` String

The first string to compare.

`strB` String

The second string to compare.

`culture` CultureInfo

The culture that supplies culture-specific comparison information. If `culture` is `null`, the current culture is used.

`options` CompareOptions

Options to use when performing the comparison (such as ignoring case or symbols).

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between `strA` and `strB`, as shown in the following table

Expand table

Value	Condition
Less than zero	`strA` precedes `strB` in the sort order.
Zero	`strA` occurs in the same position as `strB` in the sort order.
Greater than zero	`strA` follows `strB` in the sort order.

Exceptions

ArgumentException

`options` is not a CompareOptions value.

Examples

The following example compares two strings in three different ways: Use linguistic comparison for the en-US culture; using linguistic case-sensitive comparison for the en-US culture; and using an ordinal comparison. It illustrates how the three methods of comparison produce three different results.

C#

```
using System;
using System.Globalization;

public class Example0
{
    public static void Main()
    {
        string string1 = "brother";
        string string2 = "Brother";
        string relation;
        int result;

        // Cultural (linguistic) comparison.
        result = String.Compare(string1, string2, new CultureInfo("en-
US"),
                                CompareOptions.None);
        if (result > 0)
            relation = "comes after";
        else if (result == 0)
            relation = "is the same as";
        else
            relation = "comes before";

        Console.WriteLine("'{0}' {1} '{2}'.",
                          string1, relation, string2);

        // Cultural (linguistic) case-insensitive comparison.
        result = String.Compare(string1, string2, new CultureInfo("en-
US"),
                                CompareOptions.IgnoreCase);
        if (result > 0)
            relation = "comes after";
        else if (result == 0)
            relation = "is the same as";
        else
            relation = "comes before";

        Console.WriteLine("'{0}' {1} '{2}'.",
                          string1, relation, string2);

        // Culture-insensitive ordinal comparison.
        result = String.CompareOrdinal(string1, string2);
        if (result > 0)
            relation = "comes after";
        else if (result == 0)
            relation = "is the same as";
        else
            relation = "comes before";

        Console.WriteLine("'{0}' {1} '{2}'.",
                          string1, relation, string2);
```

```
        // The example produces the following output:
        //    'brother' comes before 'Brother'.
        //    'brother' is the same as 'Brother'.
        //    'brother' comes after 'Brother'.
    }
}
```

Remarks

The comparison uses the `culture` parameter to obtain culture-specific information, such as casing rules and the alphabetical order of individual characters. For example, a particular culture could specify that certain combinations of characters be treated as a single character, that uppercase and lowercase characters be compared in a particular way, or that the sort order of a character depends on the characters that precede or follow it.

> ⊗ **Caution**
>
> The **Compare(String, String, CultureInfo, CompareOptions)** method is designed primarily for use in sorting or alphabetizing operations. It should not be used when the primary purpose of the method call is to determine whether two strings are equivalent (that is, when the purpose of the method call is to test for a return value of zero). To determine whether two strings are equivalent, call the **Equals** method.

The comparison can be further specified by the `options` parameter, which consists of one or more members of the CompareOptions enumeration. However, because the purpose of this method is to conduct a culture-sensitive string comparison, the CompareOptions.Ordinal and CompareOptions.OrdinalIgnoreCase values have no effect.

Either or both comparands can be `null`. By definition, any string, including String.Empty, compares greater than a null reference, and two null references compare equal to each other.

The comparison terminates when an inequality is discovered or both strings have been compared. However, if the two strings compare equal to the end of one string, and the other string has characters remaining, the string with the remaining characters is considered greater.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. The Compare(String, String, CultureInfo, CompareOptions) method does not consider such characters when it performs a culture-sensitive comparison. To recognize ignorable characters in your comparison, supply a value of Ordinal or OrdinalIgnoreCase for the `options` parameter.

String.CompareOrdinal Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two String objects by evaluating the numeric values of the corresponding Char objects in each string.

Overloads

Expand table

CompareOrdinal(String, String)	Compares two specified String objects by evaluating the numeric values of the corresponding Char objects in each string.
CompareOrdinal(String, Int32, String, Int32, Int32)	Compares substrings of two specified String objects by evaluating the numeric values of the corresponding Char objects in each substring.

CompareOrdinal(String, String)

Compares two specified String objects by evaluating the numeric values of the corresponding Char objects in each string.

C#

```
public static int CompareOrdinal (string? strA, string? strB);
```

Parameters

`strA` String

The first string to compare.

`strB` String

The second string to compare.

Returns

Int32

An integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	`strA` is less than `strB`.
Zero	`strA` and `strB` are equal.
Greater than zero	`strA` is greater than `strB`.

Examples

The following example performs and ordinal comparison of two strings that only differ in case.

C#

```
// Sample for String.CompareOrdinal(String, String)
using System;

class Sample {
    public static void Main() {
    String str1 = "ABCD";
    String str2 = "abcd";
    String str;
    int result;

    Console.WriteLine();
    Console.WriteLine("Compare the numeric values of the corresponding
Char objects in each string.");
    Console.WriteLine("str1 = '{0}', str2 = '{1}'", str1, str2);
    result = String.CompareOrdinal(str1, str2);
    str = ((result < 0) ? "less than" : ((result > 0) ? "greater than" :
"equal to"));
    Console.Write("String '{0}' is ", str1);
    Console.Write("{0} ", str);
    Console.WriteLine("String '{0}'.", str2);
    }
}
/*
This example produces the following results:

Compare the numeric values of the corresponding Char objects in each
string.
str1 = 'ABCD', str2 = 'abcd'
```

```
String 'ABCD' is less than String 'abcd'.
*/
```

Remarks

This method performs a case-sensitive comparison using ordinal sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions. To perform a case-insensitive comparison using ordinal sort rules, call the Compare(String, String, StringComparison) method with the `comparisonType` argument set to StringComparison.OrdinalIgnoreCase.

Because CompareOrdinal(String, String) is a static method, `strA` and `strB` can be `null`. If both values are `null`, the method returns 0 (zero), which indicates that `strA` and `strB` are equal. If only one of the values is `null`, the method considers the non-null value to be greater.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareOrdinal(String, Int32, String, Int32, Int32)

Compares substrings of two specified String objects by evaluating the numeric values of the corresponding Char objects in each substring.

```
C#

public static int CompareOrdinal (string? strA, int indexA, string? strB,
int indexB, int length);
```

Parameters

strA String

The first string to use in the comparison.

indexA Int32

The starting index of the substring in `strA`.

strB String

The second string to use in the comparison.

indexB Int32

The starting index of the substring in `strB`.

length Int32

The maximum number of characters in the substrings to compare.

Returns

Int32

A 32-bit signed integer that indicates the lexical relationship between the two comparands.

Expand table

Value	Condition
Less than zero	The substring in `strA` is less than the substring in `strB`.
Zero	The substrings are equal, or `length` is zero.
Greater than zero	The substring in `strA` is greater than the substring in `strB`.

Exceptions

ArgumentOutOfRangeException

`strA` is not `null` and `indexA` is greater than `strA`.Length.

-or-

`strB` is not `null` and `indexB` is greater than `strB`.Length.

-or-

`indexA`, `indexB`, or `length` is negative.

Examples

This following example demonstrates that CompareOrdinal and Compare use different sort orders.

C#

```
using System;
using System.Globalization;

class Test
{
    public static void Main(String[] args)
    {
    String strLow = "abc";
    String strCap = "ABC";
    String result = "equal to ";
    int x = 0;
    int pos = 1;

// The Unicode codepoint for 'b' is greater than the codepoint for 'B'.
    x = String.CompareOrdinal(strLow, pos, strCap, pos, 1);
    if (x < 0) result = "less than";
    if (x > 0) result = "greater than";
    Console.WriteLine("CompareOrdinal(\"{0}\"[{2}], \"{1}\"[{2}]):",
strLow, strCap, pos);
    Console.WriteLine("   '{0}' is {1} '{2}'", strLow[pos], result,
strCap[pos]);

// In U.S. English culture, 'b' is linguistically less than 'B'.
    x = String.Compare(strLow, pos, strCap, pos, 1, false, new
CultureInfo("en-US"));
    if (x < 0) result = "less than";
    else if (x > 0) result = "greater than";
    Console.WriteLine("Compare(\"{0}\"[{2}], \"{1}\"[{2}]):", strLow,
strCap, pos);
    Console.WriteLine("   '{0}' is {1} '{2}'", strLow[pos], result,
strCap[pos]);
```

```
    }
}
```

Remarks

The `indexA`, `indexB`, and `length` parameters must be nonnegative.

The number of characters compared is the lesser of the length of `strA` less `indexA`, the length of `strB` less `indexB`, and `length`.

This method performs a case-sensitive comparison using ordinal sort rules. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions. To perform a case-insensitive comparison using ordinal sort rules, call the Compare(String, Int32, String, Int32, Int32, StringComparison) method with the `comparisonType` argument set to StringComparison.OrdinalIgnoreCase.

Because CompareOrdinal(String, String) is a static method, `strA` and `strB` can be `null`. If both values are `null`, the method returns 0 (zero), which indicates that `strA` and `strB` are equal. If only one of the values is `null`, the method considers the non-null value to be greater.

String.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance with a specified object or String and returns an integer that indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified object or String.

Overloads

Expand table

CompareTo(String)	Compares this instance with a specified String object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified string.
CompareTo(Object)	Compares this instance with a specified Object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Object.

Remarks

Both overloads of the CompareTo method perform culture-sensitive and case-sensitive comparison. You cannot use this method to perform culture-insensitive or ordinal comparisons. For code clarity, we recommend that you avoid the CompareTo method and call the Compare method instead.

CompareTo(String)

Compares this instance with a specified String object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified string.

```
C#
```

```
public int CompareTo (string? strB);
```

Parameters

`strB` String

The string to compare with this instance.

Returns

Int32

A 32-bit signed integer that indicates whether this instance precedes, follows, or appears in the same position in the sort order as the `strB` parameter.

Expand table

Value	Condition
Less than zero	This instance precedes `strB`.
Zero	This instance has the same position in the sort order as `strB`.
Greater than zero	This instance follows `strB`. -or- `strB` is `null`.

Implements

CompareTo(T)

Examples

The following example uses the CompareTo method to compare the current string instance with another string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
```

```
      string strFirst = "Goodbye";
      string strSecond = "Hello";
      string strThird = "a small string";
      string strFourth = "goodbye";

      // Compare a string to itself.
      Console.WriteLine(CompareStrings(strFirst, strFirst));

      Console.WriteLine(CompareStrings(strFirst, strSecond));
      Console.WriteLine(CompareStrings(strFirst, strThird));

      // Compare a string to another string that varies only by case.
      Console.WriteLine(CompareStrings(strFirst, strFourth));
      Console.WriteLine(CompareStrings(strFourth, strFirst));
   }

   private static string CompareStrings( string str1, string str2 )
   {
      // Compare the values, using the CompareTo method on the first
string.
      int cmpVal = str1.CompareTo(str2);

       if (cmpVal == 0) // The strings are the same.
         return "The strings occur in the same position in the sort
order.";
      else if (cmpVal < 0)
         return "The first string precedes the second in the sort
order.";
      else
         return "The first string follows the second in the sort order.";
    }
}
// The example displays the following output:
//       The strings occur in the same position in the sort order.
//       The first string precedes the second in the sort order.
//       The first string follows the second in the sort order.
//       The first string follows the second in the sort order.
//       The first string precedes the second in the sort order.
```

The following example demonstrates generic and non-generic versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;
```

```
class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);

y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.
```

```
    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method performs a word (case-sensitive and culture-sensitive) comparison using the current culture. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

> ⊗ **Caution**
>
> The **CompareTo** method was designed primarily for use in sorting or alphabetizing operations. It should not be used when the primary purpose of

the method call is to determine whether two strings are equivalent. To determine whether two strings are equivalent, call the **Equals** method.

For more information about the behavior of this method, see the Remarks section of the Compare(String, String) method.

This method implements the System.IComparable<T> interface and performs slightly better than the String.CompareTo(Object) method, because it does not have to determine whether the `strB` argument is a mutable value type that must be boxed, and it does not have to cast its parameter from an Object to a String.

Notes to Callers

Character sets include ignorable characters. The CompareTo(String) method does not consider such characters when it performs a culture-sensitive comparison. For example, if the following code is run on the .NET Framework 4 or later, a comparison of "animal" with "ani-mal" (using a soft hyphen, or U+00AD) indicates that the two strings are equivalent.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string s1 = "ani\u00ADmal";
      string s2 = "animal";

      Console.WriteLine("Comparison of '{0}' and '{1}': {2}",
                        s1, s2, s1.CompareTo(s2));
   }
}
// The example displays the following output:
//       Comparison of 'ani-mal' and 'animal': 0
```

To recognize ignorable characters in a string comparison, call the CompareOrdinal(String, String) method.

UWP	10.0

CompareTo(Object)

Compares this instance with a specified Object and indicates whether this instance precedes, follows, or appears in the same position in the sort order as the specified Object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object that evaluates to a String.

Returns

Int32

A 32-bit signed integer that indicates whether this instance precedes, follows, or appears in the same position in the sort order as the `value` parameter.

Expand table

Value	Condition
Less than zero	This instance precedes `value`.

Value	Condition
Zero	This instance has the same position in the sort order as `value`.
Greater than zero	This instance follows `value`. -or- `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a String.

Examples

The following example uses the CompareTo method with an Object. Because it attempts to compare a String instance to a `TestClass` object, the method throws an ArgumentException.

C#

```
using System;

public class TestClass
{}

public class Example
{
   public static void Main()
   {
      var test = new TestClass();
      Object[] objectsToCompare = { test, test.ToString(), 123,
                                    123.ToString(), "some text",
                                    "Some Text" };
      string s = "some text";
      foreach (var objectToCompare in objectsToCompare) {
         try {
            int i = s.CompareTo(objectToCompare);
            Console.WriteLine("Comparing '{0}' with '{1}': {2}",
                              s, objectToCompare, i);
         }
         catch (ArgumentException) {
```

```
            Console.WriteLine("Bad argument: {0} (type {1})",
                              objectToCompare,
                              objectToCompare.GetType().Name);
        }
    }
  }
}
// The example displays the following output:
//    Bad argument: TestClass (type TestClass)
//    Comparing 'some text' with 'TestClass': -1
//    Bad argument: 123 (type Int32)
//    Comparing 'some text' with '123': 1
//    Comparing 'some text' with 'some text': 0
//    Comparing 'some text' with 'Some Text': -1
```

Remarks

`value` must be a String object.

> ⊗ **Caution**
>
> The **CompareTo** method was designed primarily for use in sorting or alphabetizing operations. It should not be used when the primary purpose of the method call is to determine whether two strings are equivalent. To determine whether two strings are equivalent, call the **Equals** method.

This method performs a word (case-sensitive and culture-sensitive) comparison using the current culture. For more information about word, string, and ordinal sorts, see System.Globalization.CompareOptions.

For more information about the behavior of this method, see the Remarks section of the String.Compare(String, String) method.

Notes to Callers

Character sets include ignorable characters. The CompareTo(Object) method does not consider such characters when it performs a culture-sensitive comparison. For example, if the following code is run on the .NET Framework 4 or later, a comparison of "animal" with "ani-mal" (using a soft hyphen, or U+00AD) indicates that the two strings are equivalent.

```
C#
```

```
using System;

public class Example
{
   public static void Main()
   {
      string s1 = "ani\u00ADmal";
      object o1 = "animal";

      Console.WriteLine("Comparison of '{0}' and '{1}': {2}",
                        s1, o1, s1.CompareTo(o1));
   }
}
// The example displays the following output:
//       Comparison of 'ani-mal' and 'animal': 0
```

To recognize ignorable characters in a string comparison, call the CompareOrdinal(String, String) method.

String.Concat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Concatenates one or more instances of String, or the String representations of the values of one or more instances of Object.

Overloads

Expand table

Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Concatenates the string representations of four specified read-only character spans.
Concat(String, String, String, String)	Concatenates four specified instances of String.
Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Concatenates the string representations of three specified read-only character spans.
Concat(Object, Object, Object)	Concatenates the string representations of three specified objects.
Concat(String, String)	Concatenates two specified instances of String.
Concat(String, String, String)	Concatenates three specified instances of String.
Concat(Object, Object)	Concatenates the string representations of two specified objects.
Concat(String[])	Concatenates the elements of a specified String array.
Concat(Object[])	Concatenates the string representations of the elements in a specified Object array.

Concat(Object)	Creates the string representation of a specified object.
Concat(IEnumerable<String>)	Concatenates the members of a constructed IEnumerable<T> collection of type String.
Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>)	Concatenates the string representations of two specified read-only character spans.
Concat<T>(IEnumerable<T>)	Concatenates the members of an IEnumerable<T> implementation.

Remarks

> **Note**
>
> You can also use your language's string concatenation operator, such as `+` in C# and F#, or `&` and `+` in Visual Basic, to concatenate strings. Both compilers translate the concatenation operator into a call to one of the overloads of `String.Concat`.

Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Concatenates the string representations of four specified read-only character spans.

C#

```
public static string Concat (ReadOnlySpan<char> str0, ReadOnlySpan<char>
str1, ReadOnlySpan<char> str2, ReadOnlySpan<char> str3);
```

Parameters

str0 ReadOnlySpan<Char>

The first read-only character span to concatenate.

str1 ReadOnlySpan<Char>

The second read-only character span to concatenate.

`str2` ReadOnlySpan<Char>

The third read-only character span to concatenate.

`str3` ReadOnlySpan<Char>

The fourth read-only character span to concatenate.

Returns

String

The concatenated string representations of the values of `str0`, `str1`, `str2` and `str3`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Concat(String, String, String, String)

Concatenates four specified instances of String.

C#

```
public static string Concat (string? str0, string? str1, string? str2,
string? str3);
```

Parameters

`str0` String

The first string to concatenate.

`str1` String

The second string to concatenate.

`str2` String

The third string to concatenate.

`str3` String

The fourth string to concatenate.

Returns

String

The concatenation of `str0`, `str1`, `str2`, and `str3`.

Examples

The following example defines an array of four-letter words and stores their individual letters to a string array in order to scramble them. It then calls the Concat(String, String, String, String) method to reassemble the scrambled words.

C#

```
using System;
using System.Collections;

public class Example
{
   public static void Main()
   {
      const int WORD_SIZE = 4;

      // Define some 4-letter words to be scrambled.
      string[] words = { "home", "food", "game", "rest" };
      // Define two arrays equal to the number of letters in each word.
      double[] keys = new double[WORD_SIZE];
      string[] letters = new string[WORD_SIZE];
      // Initialize the random number generator.
      Random rnd = new Random();

      // Scramble each word.
      foreach (string word in words)
      {
         for (int ctr = 0; ctr < word.Length; ctr++)
         {
            // Populate the array of keys with random numbers.
            keys[ctr] = rnd.NextDouble();
            // Assign a letter to the array of letters.
            letters[ctr] = word[ctr].ToString();
         }
         // Sort the array.
         Array.Sort(keys, letters, 0, WORD_SIZE, Comparer.Default);
         // Display the scrambled word.
         string scrambledWord = String.Concat(letters[0], letters[1],
                                              letters[2], letters[3]);
         Console.WriteLine("{0} --> {1}", word, scrambledWord);
      }
   }
```

```
}
// The example displays output like the following:
//       home --> mheo
//       food --> oodf
//       game --> aemg
//       rest --> trse
```

Remarks

The method concatenates `str0`, `str1`, `str2`, and `str3`; it does not add any delimiters.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Concatenates the string representations of three specified read-only character spans.

C#

```
public static string Concat (ReadOnlySpan<char> str0, ReadOnlySpan<char>
str1, ReadOnlySpan<char> str2);
```

Parameters

`str0` ReadOnlySpan<Char>

The first read-only character span to concatenate.

`str1` ReadOnlySpan<Char>

The second read-only character span to concatenate.

`str2` ReadOnlySpan<Char>

The third read-only character span to concatenate.

Returns

String

The concatenated string representations of the values of `str0`, `str1` and `str2`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Concat(Object, Object, Object)

Concatenates the string representations of three specified objects.

C#

```
public static string Concat (object? arg0, object? arg1, object? arg2);
```

Parameters

`arg0` Object

The first object to concatenate.

`arg1` Object

The second object to concatenate.

`arg2` Object

The third object to concatenate.

Returns

String

The concatenated string representations of the values of `arg0`, `arg1`, and `arg2`.

Examples

The following example demonstrates the Concat method.

C#

```
using System;

class stringConcat5 {
    public static void Main() {
    int i = -123;
    Object o = i;
    Object[] objs = new Object[] {-123, -456, -789};

    Console.WriteLine("Concatenate 1, 2, and 3 objects:");
    Console.WriteLine("1) {0}", String.Concat(o));
    Console.WriteLine("2) {0}", String.Concat(o, o));
    Console.WriteLine("3) {0}", String.Concat(o, o, o));

    Console.WriteLine("\nConcatenate 4 objects and a variable length
parameter list:");
    Console.WriteLine("4) {0}", String.Concat(o, o, o, o));
    Console.WriteLine("5) {0}", String.Concat(o, o, o, o, o));

    Console.WriteLine("\nConcatenate a 3-element object array:");
    Console.WriteLine("6) {0}", String.Concat(objs));
    }
}
// The example displays the following output:
//    Concatenate 1, 2, and 3 objects:
//    1) -123
//    2) -123-123
//    3) -123-123-123
//
//    Concatenate 4 objects and a variable length parameter list:
//    4) -123-123-123-123
//    5) -123-123-123-123-123
//
//    Concatenate a 3-element object array:
//    6) -123-456-789
```

Remarks

The method concatenates `arg0`, `arg1`, and `arg2` by calling the parameterless `ToString` method of each object; it does not add any delimiters.

String.Empty is used in place of any null argument.

UWP	10.0

Concat(String, String)

Concatenates two specified instances of String.

C#

```
public static string Concat (string? str0, string? str1);
```

Parameters

`str0` String

The first string to concatenate.

`str1` String

The second string to concatenate.

Returns

String

The concatenation of `str0` and `str1`.

Examples

The following example concatenates a person's first, middle, and last name.

C#

```
using System;

public class ConcatTest {
    public static void Main() {

        // we want to simply quickly add this person's name together
        string fName = "Simon";
        string mName = "Jake";
        string lName = "Harrows";

        // because we want a name to appear with a space in between each
name,
        // put a space on the front of the middle, and last name,
allowing for
        // the fact that a space may already be there
        mName = " " + mName.Trim();
        lName = " " + lName.Trim();

        // this line simply concatenates the two strings
        Console.WriteLine("Welcome to this page, '{0}'!", string.Concat(
string.Concat(fName, mName), lName ) );
    }
}
// The example displays the following output:
//        Welcome to this page, 'Simon Jake Harrows'!
```

Remarks

The method concatenates `str0` and `str1`; it does not add any delimiters.

An Empty string is used in place of any null argument.

UWP	10.0

Concat(String, String, String)

Concatenates three specified instances of String.

C#

```
public static string Concat (string? str0, string? str1, string? str2);
```

Parameters

`str0` String

The first string to concatenate.

`str1` String

The second string to concatenate.

`str2` String

The third string to concatenate.

Returns

String

The concatenation of `str0`, `str1`, and `str2`.

Examples

The following example uses the Concat method to concatenate three strings and displays the result.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String s1 = "We went to a bookstore, ";
      String s2 = "a movie, ";
      String s3 = "and a restaurant.";

      var s = String.Concat(s1, s2, s3);
      Console.WriteLine(s);
   }
}
// The example displays the following output:
//      We went to a bookstore, a movie, and a restaurant.
```

Remarks

The method concatenates `str0`, `str1`, and `str2`; it does not add any delimiters.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Concat(Object, Object)

Concatenates the string representations of two specified objects.

C#

```
public static string Concat (object? arg0, object? arg1);
```

Parameters

`arg0` Object

The first object to concatenate.

`arg1` Object

The second object to concatenate.

Returns

String

The concatenated string representations of the values of `arg0` and `arg1`.

Examples

The following example demonstrates the Concat method.

C#

```
using System;

class stringConcat5 {
    public static void Main() {
    int i = -123;
    Object o = i;
    Object[] objs = new Object[] {-123, -456, -789};

    Console.WriteLine("Concatenate 1, 2, and 3 objects:");
    Console.WriteLine("1) {0}", String.Concat(o));
    Console.WriteLine("2) {0}", String.Concat(o, o));
    Console.WriteLine("3) {0}", String.Concat(o, o, o));
```

```
    Console.WriteLine("\nConcatenate 4 objects and a variable length
parameter list:");
    Console.WriteLine("4) {0}", String.Concat(o, o, o, o));
    Console.WriteLine("5) {0}", String.Concat(o, o, o, o, o));

    Console.WriteLine("\nConcatenate a 3-element object array:");
    Console.WriteLine("6) {0}", String.Concat(objs));
    }
}
// The example displays the following output:
//    Concatenate 1, 2, and 3 objects:
//    1) -123
//    2) -123-123
//    3) -123-123-123
//
//    Concatenate 4 objects and a variable length parameter list:
//    4) -123-123-123-123
//    5) -123-123-123-123-123
//
//    Concatenate a 3-element object array:
//    6) -123-456-789
```

Remarks

The method concatenates `arg0` and `arg1` by calling the parameterless `ToString` method of `arg0` and `arg1`; it does not add any delimiters.

String.Empty is used in place of any null argument.

If either of the arguments is an array reference, the method concatenates a string representing that array, instead of its members (for example, "System.String[]").

UWP	10.0

Concat(String[])

> Important
>
> This API is not CLS-compliant.

Concatenates the elements of a specified String array.

C#

```
public static string Concat (params string?[] values);
```

Parameters

`values` String[]

An array of string instances.

Returns

String

The concatenated elements of `values`.

Exceptions

ArgumentNullException

`values` is `null`.

OutOfMemoryException

Out of memory.

Examples

The following example demonstrates the use of the Concat method with a String array.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        // Make an array of strings. Note that we have included spaces.
        string [] s = { "hello ", "and ", "welcome ", "to ",
                        "this ", "demo! " };

        // Put all the strings together.
        Console.WriteLine(string.Concat(s));

        // Sort the strings, and put them together.
        Array.Sort(s);
        Console.WriteLine(string.Concat(s));
    }
}
// The example displays the following output:
//       hello and welcome to this demo!
//       and demo! hello this to welcome
```

Remarks

The method concatenates each object in `values`; it does not add any delimiters.

An Empty string is used in place of any null object in the array.

.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Concat(Object[])

Concatenates the string representations of the elements in a specified Object array.

```
C#
public static string Concat (params object?[] args);
```

Parameters

`args` Object[]

An object array that contains the elements to concatenate.

Returns

String

The concatenated string representations of the values of the elements in `args`.

Exceptions

ArgumentNullException

`args` is `null`.

OutOfMemoryException

Out of memory.

Examples

The following example demonstrates the use of the Concat method with an Object array.

```
C#
```

```
using System;

public class ConcatTest {
    public static void Main() {
        // Create a group of objects.
        Test1 t1 = new Test1();
        Test2 t2 = new Test2();
        int i = 16;
        string s = "Demonstration";

        // Place the objects in an array.
        object [] o = { t1, i, t2, s };

        // Concatenate the objects together as a string. To do this,
        // the ToString method of each of the objects is called.
        Console.WriteLine(string.Concat(o));
    }
}

// Create two empty test classes.
class Test1 {
}

class Test2 {
}
// The example displays the following output:
//       Test116Test2Demonstration
```

Remarks

The method concatenates each object in `args` by calling the parameterless `ToString` method of that object; it does not add any delimiters.

String.Empty is used in place of any null object in the array.

Notes to Callers

This method is not called by C++ code. The C++ compiler resolves calls to Concat that have four or more object parameters as a call to Concat(Object, Object, Object, Object).

Concat(Object)

Creates the string representation of a specified object.

C#

```
public static string Concat (object? arg0);
```

Parameters

`arg0` Object

The object to represent, or `null`.

Returns

String

The string representation of the value of `arg0`, or Empty if `arg0` is `null`.

Examples

The following example demonstrates the Concat method.

C#

```
using System;

class stringConcat5 {
```

```
    public static void Main() {
    int i = -123;
    Object o = i;
    Object[] objs = new Object[] {-123, -456, -789};

    Console.WriteLine("Concatenate 1, 2, and 3 objects:");
    Console.WriteLine("1) {0}", String.Concat(o));
    Console.WriteLine("2) {0}", String.Concat(o, o));
    Console.WriteLine("3) {0}", String.Concat(o, o, o));

    Console.WriteLine("\nConcatenate 4 objects and a variable length
parameter list:");
    Console.WriteLine("4) {0}", String.Concat(o, o, o, o));
    Console.WriteLine("5) {0}", String.Concat(o, o, o, o, o));

    Console.WriteLine("\nConcatenate a 3-element object array:");
    Console.WriteLine("6) {0}", String.Concat(objs));
    }
}
// The example displays the following output:
//    Concatenate 1, 2, and 3 objects:
//    1) -123
//    2) -123-123
//    3) -123-123-123
//
//    Concatenate 4 objects and a variable length parameter list:
//    4) -123-123-123-123
//    5) -123-123-123-123-123
//
//    Concatenate a 3-element object array:
//    6) -123-456-789
```

Remarks

The Concat(Object) method represents `arg0` as a string by calling its parameterless `ToString` method.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Concat(IEnumerable<String>)

Concatenates the members of a constructed IEnumerable<T> collection of type String.

C#

```
public static string Concat
(System.Collections.Generic.IEnumerable<string?> values);
```

Parameters

values IEnumerable<String>

A collection object that implements IEnumerable<T> and whose generic type argument is String.

Returns

String

The concatenated strings in `values`, or Empty if `values` is an empty `IEnumerable(Of String)`.

Exceptions

ArgumentNullException

`values` is `null`.

Examples

The following example uses the Sieve of Eratosthenes algorithm to calculate the prime numbers that are less than or equal to 100. It assigns the result to a List<T> object of type String, which it then passes to the Concat(IEnumerable<String>) method.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      int maxPrime = 100;
      IEnumerable<String> primeList = GetPrimes(maxPrime);
      Console.WriteLine("Primes less than {0}:", maxPrime);
      Console.WriteLine("   {0}", String.Concat(primeList));
   }

   private static IEnumerable<String> GetPrimes(int maxPrime)
   {
      Array values = Array.CreateInstance(typeof(int),
                                 new int[] { maxPrime - 1}, new int[] { 2
});
      // Use Sieve of Erathsthenes to determine prime numbers.
      for (int ctr = values.GetLowerBound(0); ctr <= (int)
Math.Ceiling(Math.Sqrt(values.GetUpperBound(0))); ctr++)
      {

         if ((int) values.GetValue(ctr) == 1) continue;

         for (int multiplier = ctr; multiplier <=  maxPrime / 2;
multiplier++)
            if (ctr * multiplier <= maxPrime)
               values.SetValue(1, ctr * multiplier);
      }

      List<String> primes = new List<String>();
      for (int ctr = values.GetLowerBound(0); ctr <=
values.GetUpperBound(0); ctr++)
         if ((int) values.GetValue(ctr) == 0)
            primes.Add(ctr.ToString() + " ");
      return primes;
   }
}
// The example displays the following output:
//    Primes less than 100:
//       2 3 5 7 11 13 17 19 23 29 31 37 41 43 47 53 59 61 67 71 73 79 83
89 97
```

Remarks

The method concatenates each object in `values`; it does not add any delimiters. To specify a delimiter between each member of `values`, call the Join(String, IEnumerable<String>) method.

An Empty string is used in place of any null element in `values`.

If `values` is an empty `IEnumerable(Of String)`, the method returns String.Empty. If `values` is `null`, the method throws an ArgumentNullException exception.

Concat(IEnumerable<String>) is a convenience method that lets you concatenate each element in an `IEnumerable(Of String)` collection without first converting the elements to a string array. It is particularly useful with Language-Integrated Query (LINQ) query expressions. The following example passes a `List(Of String)` object that contains either the uppercase or lowercase letters of the alphabet to a lambda expression that selects letters that are equal to or greater than a particular letter (which, in the example, is "M"). The `IEnumerable(Of String)` collection that is returned by the Enumerable.Where method is passed to the Concat(IEnumerable<String>) method to display the result as a single string.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Example
{
   public static void Main()
   {
      string output = String.Concat( GetAlphabet(true).Where( letter =>
                      letter.CompareTo("M") >= 0));
      Console.WriteLine(output);
   }

   private static List<string> GetAlphabet(bool upper)
   {
      List<string> alphabet = new List<string>();
      int charValue = upper ? 65 : 97;
      for (int ctr = 0; ctr <= 25; ctr++)
         alphabet.Add(((char)(charValue + ctr)).ToString());
      return alphabet;
   }
}
// The example displays the following output:
//      MNOPQRSTUVWXYZ
```

Applies to

UWP	10.0

Concat(ReadOnlySpan<Char>, ReadOnlySpan<Char>)

Concatenates the string representations of two specified read-only character spans.

C#

```
public static string Concat (ReadOnlySpan<char> str0, ReadOnlySpan<char>
str1);
```

Parameters

`str0` ReadOnlySpan<Char>

The first read-only character span to concatenate.

`str1` ReadOnlySpan<Char>

The second read-only character span to concatenate.

Returns

String

The concatenated string representations of the values of `str0` and `str1`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Concat<T>(IEnumerable<T>)

Concatenates the members of an IEnumerable<T> implementation.

```
C#

public static string Concat<T> (System.Collections.Generic.IEnumerable<T>
values);
```

Type Parameters

T

The type of the members of `values`.

Parameters

values IEnumerable<T>

A collection object that implements the IEnumerable<T> interface.

Returns

String

The concatenated members in `values`.

Exceptions

ArgumentNullException

`values` is `null`.

Examples

The following example defines a very simple `Animal` class that contains the name of an animal and the order to which it belongs. It then defines a List<T> object to contain a number of `Animal` objects. The Enumerable.Where extension method is called to extract the `Animal` objects whose `Order` property equals "Rodent". The

result is passed to the Concat<T>(IEnumerable<T>) method and displayed to the console.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Animal
{
   public string Kind;
   public string Order;

   public Animal(string kind, string order)
   {
      this.Kind = kind;
      this.Order = order;
   }

   public override string ToString()
   {
      return this.Kind;
   }
}

public class Example
{
   public static void Main()
   {
      List<Animal> animals = new List<Animal>();
      animals.Add(new Animal("Squirrel", "Rodent"));
      animals.Add(new Animal("Gray Wolf", "Carnivora"));
      animals.Add(new Animal("Capybara", "Rodent"));
      string output = String.Concat(animals.Where( animal =>
                      (animal.Order == "Rodent")));
      Console.WriteLine(output);
   }
}
// The example displays the following output:
//      SquirrelCapybara
```

Remarks

The method concatenates each object in `values`; it does not add any delimiters.

An Empty string is used in place of any null argument.

Concat<T>(IEnumerable<T>) is a convenience method that lets you concatenate each element in an IEnumerable<T> collection without first converting the elements

to strings. It is particularly useful with Language-Integrated Query (LINQ) query expressions, as the example illustrates. The string representation of each object in the IEnumerable<T> collection is derived by calling that object's `ToString` method.

String.Contains Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Contains(Char)	Returns a value indicating whether a specified character occurs within this string.
Contains(String)	Returns a value indicating whether a specified substring occurs within this string.
Contains(Char, StringComparison)	Returns a value indicating whether a specified character occurs within this string, using the specified comparison rules.
Contains(String, StringComparison)	Returns a value indicating whether a specified string occurs within this string, using the specified comparison rules.

Contains(Char)

Returns a value indicating whether a specified character occurs within this string.

C#

```
public bool Contains (char value);
```

Parameters

`value` Char

The character to seek.

Returns

Boolean

`true` if the `value` parameter occurs within this string; otherwise, `false`.

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Contains(String)

Returns a value indicating whether a specified substring occurs within this string.

C#

```
public bool Contains (string value);
```

Parameters

`value` String

The string to seek.

Returns

Boolean

`true` if the `value` parameter occurs within this string, or if `value` is the empty string (""); otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example determines whether the string "fox" is a substring of a familiar quotation. If "fox" is found in the string, it also displays its starting position.

C#

```
string s1 = "The quick brown fox jumps over the lazy dog";
string s2 = "fox";
bool b = s1.Contains(s2);
Console.WriteLine("'{0}' is in the string '{1}': {2}",
                s2, s1, b);
if (b) {
    int index = s1.IndexOf(s2);
    if (index >= 0)
        Console.WriteLine("'{0} begins at character position {1}",
                      s2, index + 1);
}
// This example displays the following output:
//    'fox' is in the string 'The quick brown fox jumps over the lazy
dog': True
//    'fox begins at character position 17
```

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison. The search begins at the first character position of this string and continues through the last character position.

To perform a culture-sensitive or ordinal case-insensitive comparison:

- On .NET Core 2.1 and later versions: Call the Contains(String, StringComparison) overload instead.
- On .NET Framework: Create a custom method. The following example illustrates one such approach. It defines a String extension method that includes a StringComparison parameter and indicates whether a string contains a substring when using the specified form of string comparison.

C#

```
using System;

public static class StringExtensions
{
   public static bool Contains(this String str, String substring,
                               StringComparison comp)
   {
```

```
        if (substring == null)
            throw new ArgumentNullException("substring",
                                            "substring cannot be null.");
        else if (! Enum.IsDefined(typeof(StringComparison), comp))
            throw new ArgumentException("comp is not a member of
StringComparison",
                                        "comp");

        return str.IndexOf(substring, comp) >= 0;
    }
}
```

C#

```
String s = "This is a string.";
String sub1 = "this";
Console.WriteLine("Does '{0}' contain '{1}'?", s, sub1);
StringComparison comp = StringComparison.Ordinal;
Console.WriteLine("   {0:G}: {1}", comp, s.Contains(sub1, comp));

comp = StringComparison.OrdinalIgnoreCase;
Console.WriteLine("   {0:G}: {1}", comp, s.Contains(sub1, comp));

// The example displays the following output:
//       Does 'This is a string.' contain 'this'?
//          Ordinal: False
//          OrdinalIgnoreCase: True
```

If you are interested in the position of the substring `value` in the current instance, you can call the IndexOf method to get the starting position of its first occurrence, or you can call the LastIndexOf method to get the starting position of its last occurrence. The example includes a call to the IndexOf(String) method if a substring is found in a string instance.

Contains(Char, StringComparison)

Returns a value indicating whether a specified character occurs within this string, using the specified comparison rules.

C#

```
public bool Contains (char value, StringComparison comparisonType);
```

Parameters

`value` Char

The character to seek.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules to use in the comparison.

Returns

Boolean

`true` if the `value` parameter occurs within this string; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.Copy(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API should not be used to create mutable strings. See **https://go.microsoft.com/fwlink/?linkid=2084035** for alternatives.

Creates a new instance of String with the same value as a specified String.

C#

```
[System.Obsolete("This API should not be used to create mutable strings. See https://go.microsoft.com/fwlink/?linkid=2084035 for alternatives.")]
public static string Copy (string str);
```

Parameters

`str` String

The string to copy.

Returns

String

A new string with the same value as `str`.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`str` is `null`.

Remarks

The `Copy` method returns a String object that has the same value as the original string but represents a different object reference. It differs from an assignment operation, which assigns an existing string reference to an additional object variable.

> **ⓘ Important**
>
> Starting with .NET Core 3.0, this method is obsolete. However, we do not recommend its use in any .NET implementation. In particular, because of changes in string interning in .NET Core 3.0, in some cases the `Copy` method will not create a new string but will simply return a reference to an existing interned string.

Depending on Why you want to call the `Copy` method, there are a number of alternatives:

- If you want a different string instance to use in an operation that modifies the string, use the original string instance. Because strings are immutable, the string operation creates a new string instance, and the original string remains unaffected. In this case, you should not assign the new string reference to the original string variable. The following example provides an illustration.

  C#

  ```
  var original = "This is a sentence. This is a second sentence.";
  var sentence1 = original.Substring(0, original.IndexOf(".") + 1);
  Console.WriteLine(original);
  Console.WriteLine(sentence1);
  // The example displays the following output:
  //    This is a sentence. This is a second sentence.
  //    This is a sentence.
  ```

  In this case, calling the `Copy` method to create a new string before calling the Substring method unnecessarily creates a new string instance.

- If you want to create a mutable buffer with the same contents as the original string, call the String.ToCharArray or StringBuilder.StringBuilder(String) constructor. For example:

  C#

  ```
  private static void UseMutableBuffer()
  {
      var original = "This is a sentence. This is a second sentence.";
  ```

```
    var chars = original.ToCharArray();
    var span = new Span<char>(chars);
    var slice = span.Slice(span.IndexOf('.'), 3);
    slice = MergeSentence(slice);
    Console.WriteLine($"Original string: {original}");
    Console.WriteLine($"Modified string: {span.ToString()}");

    static Span<char> MergeSentence(Span<char> span)
    {
        if (span.Length == 0) return Span<char>.Empty;

        span[0] = ';';
        span[2] = Char.ToLower(span[2]);
        return span;
    }
}
// The example displays the following output:
//    Original string: This is a sentence. This is a second sentence.
//    Modified string: This is a sentence; this is a second sentence.
```

- If you want to create a mutable copy of the string so that you can use unsafe code to modify the string contents, use Marshal.StringToHGlobalUni method. The following example uses the Marshal.StringToHGlobalUni method to get a pointer to the location of an copied string in unmanaged memory, increments the Unicode code point of each character in the string by one, and copies the resulting string back to a managed string.

C#

```
private static void UseUnmanaged()
{
    var original = "This is a single sentence.";
    var len = original.Length;
    var ptr = Marshal.StringToHGlobalUni(original);
    string? result;
    unsafe
    {
        char *ch = (char *) ptr.ToPointer();
        while (len-- > 0)
        {
            char c = Convert.ToChar(Convert.ToUInt16(*ch) + 1);
            *ch++ = c;
        }
        result = Marshal.PtrToStringUni(ptr);
        Marshal.FreeHGlobal(ptr);
    }
    Console.WriteLine($"Original string: {original}");
    Console.WriteLine($"String from interop: '{result}'");
}
// The example displays the following output:
```

```
//    Original string: This is a single sentence.
//    String from interop: 'Uijt!jt!b!tjohmf!tfoufodf/'
```

Applies to

String.CopyTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CopyTo(Span<Char>)	Copies the contents of this string into the destination span.
CopyTo(Int32, Char[], Int32, Int32)	Copies a specified number of characters from a specified position in this instance to a specified position in an array of Unicode characters.

CopyTo(Span<Char>)

Copies the contents of this string into the destination span.

C#

```
public void CopyTo (Span<char> destination);
```

Parameters

`destination` Span<Char>

The span into which to copy this string's contents.

Exceptions

ArgumentException

The destination span is shorter than the source string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

CopyTo(Int32, Char[], Int32, Int32)

Copies a specified number of characters from a specified position in this instance to a specified position in an array of Unicode characters.

```
C#

public void CopyTo (int sourceIndex, char[] destination, int
destinationIndex, int count);
```

Parameters

`sourceIndex` Int32

The index of the first character in this instance to copy.

`destination` Char[]

An array of Unicode characters to which characters in this instance are copied.

`destinationIndex` Int32

The index in `destination` at which the copy operation begins.

`count` Int32

The number of characters in this instance to copy to `destination`.

Exceptions

ArgumentNullException

`destination` is `null`.

ArgumentOutOfRangeException

`sourceIndex`, `destinationIndex`, or `count` is negative

-or-

`sourceIndex` does not identify a position in the current instance.

-or-

`destinationIndex` does not identify a valid index in the `destination` array.

-or-

`count` is greater than the length of the substring from `sourceIndex` to the end of this instance

-or-

`count` is greater than the length of the subarray from `destinationIndex` to the end of the `destination` array.

Examples

The following example demonstrates the CopyTo method.

C#

```
using System;

public class CopyToTest {
    public static void Main() {

        // Embed an array of characters in a string
        string strSource = "changed";
    char [] destination = { 'T', 'h', 'e', ' ', 'i', 'n', 'i', 't', 'i',
'a', 'l', ' ',
                'a', 'r', 'r', 'a', 'y' };

        // Print the char array
        Console.WriteLine( destination );

        // Embed the source string in the destination string
        strSource.CopyTo ( 0, destination, 4, strSource.Length );

        // Print the resulting array
        Console.WriteLine( destination );

        strSource = "A different string";

        // Embed only a section of the source string in the destination
        strSource.CopyTo ( 2, destination, 3, 9 );

        // Print the resulting array
        Console.WriteLine( destination );
    }
}
// The example displays the following output:
//       The initial array
```

```
//        The changed array
//        Thedifferentarray
```

Remarks

This method copies `count` characters from the `sourceIndex` position of this instance to the `destinationIndex` position of `destination` character array. This method does not resize the `destination` character array; it must have a sufficient number of elements to accommodate the copied characters or the method throws an ArgumentOutOfRangeException.

`sourceIndex` and `destinationIndex` are zero-based.

String.Create Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Create(IFormatProvider, Span<Char>, DefaultInterpolatedStringHandler)	Creates a new string by using the specified provider to control the formatting of the specified interpolated string.
Create(IFormatProvider, DefaultInterpolatedStringHandler)	Creates a new string by using the specified provider to control the formatting of the specified interpolated string.
Create<TState>(Int32, TState, SpanAction<Char,TState>)	Creates a new string with a specific length and initializes it after creation by using the specified callback.

Create(IFormatProvider, Span<Char>, DefaultInterpolatedStringHandler)

Creates a new string by using the specified provider to control the formatting of the specified interpolated string.

C#

```
public static string Create (IFormatProvider? provider, Span<char>
initialBuffer, ref
System.Runtime.CompilerServices.DefaultInterpolatedStringHandler
handler);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

`initialBuffer` Span<Char>

The initial buffer that may be used as temporary space as part of the formatting operation. The contents of this buffer may be overwritten.

`handler` DefaultInterpolatedStringHandler

The interpolated string, passed by reference.

Returns

String

The string that results for formatting the interpolated string using the specified format provider.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Create(IFormatProvider, DefaultInterpolatedStringHandler)

Creates a new string by using the specified provider to control the formatting of the specified interpolated string.

C#

```
public static string Create (IFormatProvider? provider, ref
System.Runtime.CompilerServices.DefaultInterpolatedStringHandler
handler);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`handler` DefaultInterpolatedStringHandler

The interpolated string, passed by reference.

Returns

String

The string that results for formatting the interpolated string using the specified format provider.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Create<TState>(Int32, TState, SpanAction<Char,TState>)

Creates a new string with a specific length and initializes it after creation by using the specified callback.

C#

```
public static string Create<TState> (int length, TState state,
System.Buffers.SpanAction<char,TState> action);
```

Type Parameters

`TState`

The type of the element to pass to `action`.

Parameters

`length` Int32

The length of the string to create.

`state` TState

The element to pass to `action`.

`action` SpanAction<Char,TState>

A callback to initialize the string.

Returns

String

The created string.

Remarks

The initial content of the destination span passed to `action` is undefined. Therefore, it is the delegate's responsibility to ensure that every element of the span is assigned. Otherwise, the resulting string could contain random characters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

String.EndsWith Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the end of this string instance matches a specified string.

Overloads

Expand table

EndsWith(Char)	Determines whether the end of this string instance matches the specified character.
EndsWith(String)	Determines whether the end of this string instance matches the specified string.
EndsWith(String, StringComparison)	Determines whether the end of this string instance matches the specified string when compared using the specified comparison option.
EndsWith(String, Boolean, CultureInfo)	Determines whether the end of this string instance matches the specified string when compared using the specified culture.

EndsWith(Char)

Determines whether the end of this string instance matches the specified character.

C#

```
public bool EndsWith (char value);
```

Parameters

`value` Char

The character to compare to the character at the end of this instance.

Returns

Boolean

`true` if `value` matches the end of this instance; otherwise, `false`.

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

EndsWith(String)

Determines whether the end of this string instance matches the specified string.

C#

```
public bool EndsWith (string value);
```

Parameters

`value` String

The string to compare to the substring at the end of this instance.

Returns

Boolean

`true` if `value` matches the end of this instance; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example indicates whether each string in an array ends with a period (".").

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String[] strings = { "This is a string.", "Hello!", "Nothing.",
                           "Yes.", "randomize" };
      foreach (var value in strings) {
         bool endsInPeriod = value.EndsWith(".");
         Console.WriteLine("'{0}' ends in a period: {1}",
                           value, endsInPeriod);
      }
   }
}
// The example displays the following output:
//       'This is a string.' ends in a period: True
//       'Hello!' ends in a period: False
//       'Nothing.' ends in a period: True
//       'Yes.' ends in a period: True
//       'randomize' ends in a period: False
```

The following example defines a `StripEndTags` method that uses the EndsWith(String) method to remove HTML end tags from the end of a line. Note that the `StripEndTags` method is called recursively to ensure that multiple HTML end tags at the end of the line are removed.

C#

```
using System;

public class EndsWithTest {
    public static void Main() {

        // process an input file that contains html tags.
        // this sample checks for multiple tags at the end of the line,
rather than simply
        // removing the last one.
        // note: HTML markup tags always end in a greater than symbol
(>).

        string [] strSource = { "<b>This is bold text</b>", "<H1>This is
large Text</H1>",
```

```
                "<b><i><font color=green>This has multiple tags</font>
</i></b>",
                "<b>This has <i>embedded</i> tags.</b>",
                "This line simply ends with a greater than symbol, it
should not be modified>" };

        Console.WriteLine("The following lists the items before the ends
have been stripped:");
        Console.WriteLine("-----------------------------------------------
-------------------");

        // print out the initial array of strings
        foreach ( string s in strSource )
            Console.WriteLine( s );

        Console.WriteLine();

        Console.WriteLine("The following lists the items after the ends
have been stripped:");
        Console.WriteLine("-----------------------------------------------
------------------");

        // print out the array of strings
        foreach (var s in strSource)
            Console.WriteLine(StripEndTags(s));
    }

    private static string StripEndTags( string item ) {

        bool found = false;

        // try to find a tag at the end of the line using EndsWith
        if (item.Trim().EndsWith(">")) {

            // now search for the opening tag...
            int lastLocation = item.LastIndexOf( "</" );

            // remove the identified section, if it is a valid region
            if ( lastLocation >= 0 ) {
                found = true;
                item =  item.Substring( 0, lastLocation );
            }
        }

        if (found)
           item = StripEndTags(item);

        return item;
    }
}
// The example displays the following output:
//    The following lists the items before the ends have been stripped:
//    ----------------------------------------------------------------
//    <b>This is bold text</b>
//    <H1>This is large Text</H1>
```

```
//    <b><i><font color=green>This has multiple tags</font></i></b>
//    <b>This has <i>embedded</i> tags.</b>
//    This line simply ends with a greater than symbol, it should not be
modified>
//
//    The following lists the items after the ends have been stripped:
//    ---------------------------------------------------------------
//    <b>This is bold text
//    <H1>This is large Text
//    <b><i><font color=green>This has multiple tags
//    <b>This has <i>embedded</i> tags.
//    This line simply ends with a greater than symbol, it should not be
modified>
```

Remarks

This method compares `value` to the substring at the end of this instance that is the same length as `value`, and returns an indication whether they are equal. To be equal, `value` must be a reference to this same instance or match the end of this instance.

This method performs a word (case-sensitive and culture-sensitive) comparison using the current culture.

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To determine whether a string ends with a particular substring by using the string comparison rules of the current culture, signal your intention explicitly by calling the EndsWith(String, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

UWP	10.0

EndsWith(String, StringComparison)

Determines whether the end of this string instance matches the specified string when compared using the specified comparison option.

C#

```
public bool EndsWith (string value, StringComparison comparisonType);
```

Parameters

`value` String

The string to compare to the substring at the end of this instance.

`comparisonType` StringComparison

One of the enumeration values that determines how this string and `value` are compared.

Returns

Boolean

`true` if the `value` parameter matches the end of this string; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`comparisonType` is not a StringComparison value.

Examples

The following example determines whether a string ends with a particular substring. The results are affected by the choice of culture, whether case is ignored, and whether an ordinal comparison is performed.

C#

```
// This example demonstrates the
// System.String.EndsWith(String, StringComparison) method.

using System;
using System.Threading;

class Sample
{
    public static void Main()
    {
        string intro = "Determine whether a string ends with another
string, " +
                   "using\n  different values of StringComparison.";

        StringComparison[] scValues = {
            StringComparison.CurrentCulture,
            StringComparison.CurrentCultureIgnoreCase,
            StringComparison.InvariantCulture,
            StringComparison.InvariantCultureIgnoreCase,
            StringComparison.Ordinal,
            StringComparison.OrdinalIgnoreCase };

        Console.WriteLine(intro);

        // Display the current culture because the culture-specific
comparisons
        // can produce different results with different cultures.
        Console.WriteLine("The current culture is {0}.\n",
                       Thread.CurrentThread.CurrentCulture.Name);

        // Determine whether three versions of the letter I are equal to
each other.
        foreach (StringComparison sc in scValues)
        {
            Console.WriteLine("StringComparison.{0}:", sc);
            Test("abcXYZ", "XYZ", sc);
            Test("abcXYZ", "xyz", sc);
            Console.WriteLine();
        }
    }

    protected static void Test(string x, string y, StringComparison
```

```
comparison)
    {
        string resultFmt = "\"{0}\" {1} with \"{2}\".";
        string result = "does not end";

        if (x.EndsWith(y, comparison))
            result = "ends";
        Console.WriteLine(resultFmt, x, result, y);
    }
}

/*
This code example produces the following results:

Determine whether a string ends with another string, using
  different values of StringComparison.
The current culture is en-US.

StringComparison.CurrentCulture:
"abcXYZ" ends with "XYZ".
"abcXYZ" does not end with "xyz".

StringComparison.CurrentCultureIgnoreCase:
"abcXYZ" ends with "XYZ".
"abcXYZ" ends with "xyz".

StringComparison.InvariantCulture:
"abcXYZ" ends with "XYZ".
"abcXYZ" does not end with "xyz".

StringComparison.InvariantCultureIgnoreCase:
"abcXYZ" ends with "XYZ".
"abcXYZ" ends with "xyz".

StringComparison.Ordinal:
"abcXYZ" ends with "XYZ".
"abcXYZ" does not end with "xyz".

StringComparison.OrdinalIgnoreCase:
"abcXYZ" ends with "XYZ".
"abcXYZ" ends with "xyz".

*/
```

Remarks

The EndsWith method compares the `value` parameter to the substring at the end of this string and returns a value that indicates whether they are equal. To be equal, `value` must be a reference to this same string, must be the empty string ("""), or must match the end of this string. The type of comparison performed by the EndsWith method depends on the value of the `comparisonType` parameter.

UWP	10.0

EndsWith(String, Boolean, CultureInfo)

Determines whether the end of this string instance matches the specified string when compared using the specified culture.

C#

```
public bool EndsWith (string value, bool ignoreCase,
System.Globalization.CultureInfo? culture);
```

Parameters

`value` String

The string to compare to the substring at the end of this instance.

`ignoreCase` Boolean

`true` to ignore case during the comparison; otherwise, `false`.

`culture` CultureInfo

Cultural information that determines how this instance and `value` are compared. If `culture` is `null`, the current culture is used.

Returns

Boolean

`true` if the `value` parameter matches the end of this string; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example determines whether a string occurs at the end of another string. The EndsWith method is called several times using case sensitivity, case insensitivity, and different cultures that influence the results of the search.

C#

```
// This code example demonstrates the
// System.String.EndsWith(String, ..., CultureInfo) method.

using System;
using System.Threading;
using System.Globalization;

class Sample
{
    public static void Main()
    {
        string msg1 = "Search for the target string \"{0}\" in the string
\"{1}\".\n";
        string msg2 = "Using the {0} - \"{1}\" culture:";
        string msg3 = "  The string to search ends with the target
string: {0}";
        bool result = false;
        CultureInfo ci;

        // Define a target string to search for.
        // U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
        string capitalARing = "\u00c5";

        // Define a string to search.
        // The result of combining the characters LATIN SMALL LETTER A
and COMBINING
        // RING ABOVE (U+0061, U+030a) is linguistically equivalent to
the character
        // LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
        string xyzARing = "xyz" + "\u0061\u030a";
```

```
        // Display the string to search for and the string to search.
        Console.WriteLine(msg1, capitalARing, xyzARing);

        // Search using English-United States culture.
        ci = new CultureInfo("en-US");
        Console.WriteLine(msg2, ci.DisplayName, ci.Name);

        Console.WriteLine("Case sensitive:");
        result = xyzARing.EndsWith(capitalARing, false, ci);
        Console.WriteLine(msg3, result);

        Console.WriteLine("Case insensitive:");
        result = xyzARing.EndsWith(capitalARing, true, ci);
        Console.WriteLine(msg3, result);
        Console.WriteLine();

        // Search using Swedish-Sweden culture.
        ci = new CultureInfo("sv-SE");
        Console.WriteLine(msg2, ci.DisplayName, ci.Name);

        Console.WriteLine("Case sensitive:");
        result = xyzARing.EndsWith(capitalARing, false, ci);
        Console.WriteLine(msg3, result);

        Console.WriteLine("Case insensitive:");
        result = xyzARing.EndsWith(capitalARing, true, ci);
        Console.WriteLine(msg3, result);
    }
}

/*
This code example produces the following results (for en-us culture):

Search for the target string "Å" in the string "xyza°".

Using the English (United States) - "en-US" culture:
Case sensitive:
  The string to search ends with the target string: False
Case insensitive:
  The string to search ends with the target string: True

Using the Swedish (Sweden) - "sv-SE" culture:
Case sensitive:
  The string to search ends with the target string: False
Case insensitive:
  The string to search ends with the target string: False

*/
```

Remarks

This method compares the `value` parameter to the substring at the end of this string that is the same length as `value`, and returns a value that indicates whether they are equal. To be equal, `value` must be a reference to this same instance or match the end of this string.

This method performs a word (culture-sensitive) comparison using the specified casing and culture.

String.EnumerateRunes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumeration of Rune from this string.

C#

```
public System.Text.StringRuneEnumerator EnumerateRunes ();
```

Returns

StringRuneEnumerator

A string rune enumerator.

Remarks

Invalid sequences are represented in the enumeration by Rune.ReplacementChar.

Applies to

String.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two String objects have the same value.

Overloads

Expand table

Equals(Object)	Determines whether this instance and a specified object, which must also be a String object, have the same value.
Equals(String)	Determines whether this instance and another specified String object have the same value.
Equals(String, String)	Determines whether two specified String objects have the same value.
Equals(String, StringComparison)	Determines whether this string and a specified String object have the same value. A parameter specifies the culture, case, and sort rules used in the comparison.
Equals(String, String, StringComparison)	Determines whether two specified String objects have the same value. A parameter specifies the culture, case, and sort rules used in the comparison.

Equals(Object)

Determines whether this instance and a specified object, which must also be a String object, have the same value.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The string to compare to this instance.

Returns

Boolean

`true` if `obj` is a String and its value is the same as this instance; otherwise, `false`. If `obj` is `null`, the method returns `false`.

Examples

The following example demonstrates the Equals method.

C#

```
// Sample for String.Equals(Object)
//            String.Equals(String)
//            String.Equals(String, String)
using System;
using System.Text;

class Sample1
{
    public static void Main()
    {
        StringBuilder sb = new StringBuilder("abcd");
        String str1 = "abcd";
        String str2 = null;
        Object o2 = null;

        Console.WriteLine();
        Console.WriteLine(" *  The value of String str1 is '{0}'.",
str1);
        Console.WriteLine(" *  The value of StringBuilder sb is '{0}'.",
sb.ToString());

        Console.WriteLine();
        Console.WriteLine("1a) String.Equals(Object). Object is a
StringBuilder, not a String.");
        Console.WriteLine("    Is str1 equal to sb?: {0}",
str1.Equals(sb));

        Console.WriteLine();
        Console.WriteLine("1b) String.Equals(Object). Object is a
String.");
        str2 = sb.ToString();
        o2 = str2;
        Console.WriteLine(" *  The value of Object o2 is '{0}'.", o2);
        Console.WriteLine("    Is str1 equal to o2?: {0}",
```

```
str1.Equals(o2));

        Console.WriteLine();
        Console.WriteLine(" 2) String.Equals(String)");
        Console.WriteLine(" *  The value of String str2 is '{0}'.",
str2);
        Console.WriteLine("    Is str1 equal to str2?: {0}",
str1.Equals(str2));

        Console.WriteLine();
        Console.WriteLine(" 3) String.Equals(String, String)");
        Console.WriteLine("    Is str1 equal to str2?: {0}",
String.Equals(str1, str2));
    }
}
/*
This example produces the following results:

 *  The value of String str1 is 'abcd'.
 *  The value of StringBuilder sb is 'abcd'.

1a) String.Equals(Object). Object is a StringBuilder, not a String.
    Is str1 equal to sb?: False

1b) String.Equals(Object). Object is a String.
 *  The value of Object o2 is 'abcd'.
    Is str1 equal to o2?: True

 2) String.Equals(String)
 *  The value of String str2 is 'abcd'.
    Is str1 equal to str2?: True

 3) String.Equals(String, String)
    Is str1 equal to str2?: True
*/
```

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison.

Equals(String)

Determines whether this instance and another specified String object have the same value.

```
C#

public bool Equals (string? value);
```

Parameters

`value` String

The string to compare to this instance.

Returns

Boolean

`true` if the value of the `value` parameter is the same as the value of this instance; otherwise, `false`. If `value` is `null`, the method returns `false`.

Implements

Equals(T)

Examples

The following example demonstrates the Equals method. It compares the title-cased word "File" with an equivalent word, its lowercase equivalent, its uppercase equivalent, and a word that contains LATIN SMALL LETTER DOTLESS I (U+0131)

instead of LATIN SMALL LETTER I (U+0069). Because the Equals(String) method performs an ordinal comparison, only the comparison with an identical word returns `true`.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        Console.OutputEncoding = System.Text.Encoding.UTF8;
        string word = "File";
        string[] others = { word.ToLower(), word, word.ToUpper(), "Fıle"
};
        foreach (string other in others)
        {
            if (word.Equals(other))
                Console.WriteLine("{0} = {1}", word, other);
            else
                Console.WriteLine("{0} {1} {2}", word, '\u2260', other);
        }
    }
}
// The example displays the following output:
//       File ≠ file
//       File = File
//       File ≠ FILE
//       File ≠ Fıle
```

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison.

UWP	10.0

Equals(String, String)

Determines whether two specified String objects have the same value.

```
C#

public static bool Equals (string? a, string? b);
```

Parameters

a String

The first string to compare, or `null`.

b String

The second string to compare, or `null`.

Returns

Boolean

`true` if the value of `a` is the same as the value of `b`; otherwise, `false`. If both `a` and `b` are `null`, the method returns `true`.

Examples

The following example demonstrates the Equals method.

```
C#

// Sample for String.Equals(Object)
//            String.Equals(String)
//            String.Equals(String, String)
using System;
using System.Text;
```

```
class Sample1
{
    public static void Main()
    {
        StringBuilder sb = new StringBuilder("abcd");
        String str1 = "abcd";
        String str2 = null;
        Object o2 = null;

        Console.WriteLine();
        Console.WriteLine(" *  The value of String str1 is '{0}'.",
str1);
        Console.WriteLine(" *  The value of StringBuilder sb is '{0}'.",
sb.ToString());

        Console.WriteLine();
        Console.WriteLine("1a) String.Equals(Object). Object is a
StringBuilder, not a String.");
        Console.WriteLine("    Is str1 equal to sb?: {0}",
str1.Equals(sb));

        Console.WriteLine();
        Console.WriteLine("1b) String.Equals(Object). Object is a
String.");
        str2 = sb.ToString();
        o2 = str2;
        Console.WriteLine(" *  The value of Object o2 is '{0}'.", o2);
        Console.WriteLine("    Is str1 equal to o2?: {0}",
str1.Equals(o2));

        Console.WriteLine();
        Console.WriteLine(" 2) String.Equals(String)");
        Console.WriteLine(" *  The value of String str2 is '{0}'.",
str2);
        Console.WriteLine("    Is str1 equal to str2?: {0}",
str1.Equals(str2));

        Console.WriteLine();
        Console.WriteLine(" 3) String.Equals(String, String)");
        Console.WriteLine("    Is str1 equal to str2?: {0}",
String.Equals(str1, str2));
    }
}
/*
This example produces the following results:

 *  The value of String str1 is 'abcd'.
 *  The value of StringBuilder sb is 'abcd'.

1a) String.Equals(Object). Object is a StringBuilder, not a String.
    Is str1 equal to sb?: False

1b) String.Equals(Object). Object is a String.
 *  The value of Object o2 is 'abcd'.
```

```
    Is str1 equal to o2?: True

 2) String.Equals(String)
 *  The value of String str2 is 'abcd'.
    Is str1 equal to str2?: True

 3) String.Equals(String, String)
    Is str1 equal to str2?: True
*/
```

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison.

Equals(String, StringComparison)

Determines whether this string and a specified String object have the same value. A parameter specifies the culture, case, and sort rules used in the comparison.

C#

```
public bool Equals (string? value, StringComparison comparisonType);
```

Parameters

`value` String

The string to compare to this instance.

`comparisonType` StringComparison

One of the enumeration values that specifies how the strings will be compared.

Returns

Boolean

`true` if the value of the `value` parameter is the same as this string; otherwise, `false`.

Exceptions

ArgumentException

`comparisonType` is not a StringComparison value.

Examples

The following example creates a string array that consists of an uppercase "I", a lowercase "i", and a dotless "ı". It then calls the Equals(String, StringComparison) method to compare them by using each possible StringComparison enumeration value.

C#

```
using System;

class Sample
{
   public static void Main()
   {
      // Define a string array with the following three "I" characters:
      //      U+0069, U+0131, and U+0049.
      string[] threeIs = { "i", "ı", "I" };
      // Define Type object representing StringComparison type.
      Type scType = typeof(StringComparison);

      // Show the current culture (for culture-sensitive string
comparisons).
      Console.WriteLine("The current culture is {0}.\n",

System.Globalization.CultureInfo.CurrentCulture.Name);

      // Perform comparisons using each StringComparison member.
```

```
      foreach (string scName in Enum.GetNames(scType))
      {
         StringComparison sc = (StringComparison) Enum.Parse(scType,
scName);
         Console.WriteLine("Comparisons using {0}:", sc);
         // Compare each character in character array.
         for (int ctr = 0; ctr <= 1; ctr++)
         {
            string instanceChar = threeIs[ctr];
            for (int innerCtr = ctr + 1; innerCtr <=
threeIs.GetUpperBound(0); innerCtr++)
            {
               string otherChar = threeIs[innerCtr];
               Console.WriteLine("{0} (U+{1}) = {2} (U+{3}): {4}",
                                 instanceChar,
Convert.ToInt16(Char.Parse(instanceChar)).ToString("X4"),
                                 otherChar,
Convert.ToInt16(Char.Parse(otherChar)).ToString("X4"),
                                 instanceChar.Equals(otherChar, sc));
            }
            Console.WriteLine();
         }
      }
   }
}
// The example displays the following output:
//       The current culture is en-US.
//
//       Comparisons using CurrentCulture:
//       i (U+0069) = ı (U+0131): False
//       i (U+0069) = I (U+0049): False
//
//       ı (U+0131) = I (U+0049): False
//
//       Comparisons using CurrentCultureIgnoreCase:
//       i (U+0069) = ı (U+0131): False
//       i (U+0069) = I (U+0049): True
//
//       ı (U+0131) = I (U+0049): False
//
//       Comparisons using InvariantCulture:
//       i (U+0069) = ı (U+0131): False
//       i (U+0069) = I (U+0049): False
//
//       ı (U+0131) = I (U+0049): False
//
//       Comparisons using InvariantCultureIgnoreCase:
//       i (U+0069) = ı (U+0131): False
//       i (U+0069) = I (U+0049): True
//
//       ı (U+0131) = I (U+0049): False
//
//       Comparisons using Ordinal:
//       i (U+0069) = ı (U+0131): False
//       i (U+0069) = I (U+0049): False
```

```
//
//       ı (U+0131) = I (U+0049): False
//
//       Comparisons using OrdinalIgnoreCase:
//       i (U+0069) = ı (U+0131): False
//       i (U+0069) = I (U+0049): True
//
//       ı (U+0131) = I (U+0049): False
```

Remarks

The `comparisonType` parameter indicates whether the comparison should use the current or invariant culture, honor or ignore the case of the two strings being compared, or use word or ordinal sort rules.

Equals(String, String, StringComparison)

Determines whether two specified String objects have the same value. A parameter specifies the culture, case, and sort rules used in the comparison.

C#

```
public static bool Equals (string? a, string? b, StringComparison
```

```
comparisonType);
```

Parameters

a String

The first string to compare, or `null`.

b String

The second string to compare, or `null`.

comparisonType StringComparison

One of the enumeration values that specifies the rules for the comparison.

Returns

Boolean

`true` if the value of the `a` parameter is equal to the value of the `b` parameter; otherwise, `false`.

Exceptions

ArgumentException

`comparisonType` is not a StringComparison value.

Examples

The following example compares three sets of strings by using each member of the StringComparison enumeration. The comparisons use the conventions of the English (United States), Thai (Thailand) and Turkish (Turkey) cultures. Note that the strings "a" and "a-" are considered equivalent in the "th-TH" culture but not in the others, while "i" and "İ" are considered equivalent in the "tr-TR" culture when case is ignored but not in the other cultures.

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example3
{
    public static void Main()
```

```
    {
        String[] cultureNames = { "en-US", "th-TH", "tr-TR" };
        String[] strings1 = { "a", "i", "case", };
        String[] strings2 = { "a-", "\u0130", "Case" };
        StringComparison[] comparisons =
(StringComparison[])Enum.GetValues(typeof(StringComparison));

        foreach (var cultureName in cultureNames)
        {
            Thread.CurrentThread.CurrentCulture =
CultureInfo.CreateSpecificCulture(cultureName);
            Console.WriteLine("Current Culture: {0}",
CultureInfo.CurrentCulture.Name);
            for (int ctr = 0; ctr <= strings1.GetUpperBound(0); ctr++)
            {
                foreach (var comparison in comparisons)
                    Console.WriteLine("   {0} = {1} ({2}): {3}",
strings1[ctr],
                                      strings2[ctr], comparison,
                                      String.Equals(strings1[ctr],
strings2[ctr], comparison));

                Console.WriteLine();
            }
            Console.WriteLine();
        }
    }
}
// The example displays the following output:
//    Current Culture: en-US
//       a = a- (CurrentCulture): False
//       a = a- (CurrentCultureIgnoreCase): False
//       a = a- (InvariantCulture): False
//       a = a- (InvariantCultureIgnoreCase): False
//       a = a- (Ordinal): False
//       a = a- (OrdinalIgnoreCase): False
//
//       i = İ (CurrentCulture): False
//       i = İ (CurrentCultureIgnoreCase): False
//       i = İ (InvariantCulture): False
//       i = İ (InvariantCultureIgnoreCase): False
//       i = İ (Ordinal): False
//       i = İ (OrdinalIgnoreCase): False
//
//       case = Case (CurrentCulture): False
//       case = Case (CurrentCultureIgnoreCase): True
//       case = Case (InvariantCulture): False
//       case = Case (InvariantCultureIgnoreCase): True
//       case = Case (Ordinal): False
//       case = Case (OrdinalIgnoreCase): True
//
//
//    Current Culture: th-TH
//       a = a- (CurrentCulture): True
//       a = a- (CurrentCultureIgnoreCase): True
```

```
//       a = a- (InvariantCulture): False
//       a = a- (InvariantCultureIgnoreCase): False
//       a = a- (Ordinal): False
//       a = a- (OrdinalIgnoreCase): False
//
//       i = İ (CurrentCulture): False
//       i = İ (CurrentCultureIgnoreCase): False
//       i = İ (InvariantCulture): False
//       i = İ (InvariantCultureIgnoreCase): False
//       i = İ (Ordinal): False
//       i = İ (OrdinalIgnoreCase): False
//
//       case = Case (CurrentCulture): False
//       case = Case (CurrentCultureIgnoreCase): True
//       case = Case (InvariantCulture): False
//       case = Case (InvariantCultureIgnoreCase): True
//       case = Case (Ordinal): False
//       case = Case (OrdinalIgnoreCase): True
//
//
//    Current Culture: tr-TR
//       a = a- (CurrentCulture): False
//       a = a- (CurrentCultureIgnoreCase): False
//       a = a- (InvariantCulture): False
//       a = a- (InvariantCultureIgnoreCase): False
//       a = a- (Ordinal): False
//       a = a- (OrdinalIgnoreCase): False
//
//       i = İ (CurrentCulture): False
//       i = İ (CurrentCultureIgnoreCase): True
//       i = İ (InvariantCulture): False
//       i = İ (InvariantCultureIgnoreCase): False
//       i = İ (Ordinal): False
//       i = İ (OrdinalIgnoreCase): False
//
//       case = Case (CurrentCulture): False
//       case = Case (CurrentCultureIgnoreCase): True
//       case = Case (InvariantCulture): False
//       case = Case (InvariantCultureIgnoreCase): True
//       case = Case (Ordinal): False
//       case = Case (OrdinalIgnoreCase): True
```

Remarks

The `comparisonType` parameter indicates whether the comparison should use the current or invariant culture, honor or ignore the case of the two strings being compared, or use word or ordinal sort rules.

String.Format Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of objects to strings based on the formats specified and inserts them into another string.

If you are new to the `String.Format` method, see Get started with the String.Format method for a quick overview.

Overloads

Expand table

Format(IFormatProvider, String, Object, Object, Object)	Replaces the format items in a string with the string representation of three specified objects. An parameter supplies culture-specific formatting information.
Format(String, Object, Object, Object)	Replaces the format items in a string with the string representation of three specified objects.
Format(IFormatProvider, String, Object, Object)	Replaces the format items in a string with the string representation of two specified objects. A parameter supplies culture-specific formatting information.
Format(String, Object, Object)	Replaces the format items in a string with the string representation of two specified objects.
Format(IFormatProvider, CompositeFormat, ReadOnlySpan<Object>)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format(IFormatProvider, String, Object)	Replaces the format item or items in a specified string with the string representation of the corresponding object. A parameter supplies culture-specific formatting information.
Format(IFormatProvider, String, Object[])	Replaces the format items in a string with the string representations of corresponding objects in a

	specified array. A parameter supplies culture-specific formatting information.
Format(String, Object[])	Replaces the format item in a specified string with the string representation of a corresponding object in a specified array.
Format(String, Object)	Replaces one or more format items in a string with the string representation of a specified object.
Format(IFormatProvider, CompositeFormat, Object[])	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format<TArg0,TArg1,TArg2>(IFormatProvider, CompositeFormat, TArg0, TArg1, TArg2)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format<TArg0,TArg1>(IFormatProvider, CompositeFormat, TArg0, TArg1)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.
Format<TArg0>(IFormatProvider, CompositeFormat, TArg0)	Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.

Remarks

For more information about this API, see Supplemental API remarks for String.Format.

Format(IFormatProvider, String, Object, Object, Object)

Replaces the format items in a string with the string representation of three specified objects. An parameter supplies culture-specific formatting information.

C#

```
public static string Format (IFormatProvider? provider, string format,
object? arg0, object? arg1, object? arg2);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

`format` String

A composite format string.

`arg0` Object

The first object to format.

`arg1` Object

The second object to format.

`arg2` Object

The third object to format.

Returns

String

A copy of `format` in which the format items have been replaced by the string representations of `arg0`, `arg1`, and `arg2`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

`format` is invalid.

-or-

The index of a format item is less than zero, or greater than two.

Remarks

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result

string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert three expressions to their string representations and to embed those representations in a string. In performing the conversion, the method uses culture-sensitive formatting or a custom formatter. The method converts each Object argument to its string representation by calling its **ToString(IFormatProvider)** method or, if the object's corresponding format item includes a format string, by calling its **ToString(String,IFormatProvider)** method. If these methods don't exist, it calls the object's parameterless **ToString** method.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with an object that provides culture-sensitive or custom formatting and a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

Format(String, Object, Object, Object)

Replaces the format items in a string with the string representation of three specified objects.

```
C#

public static string Format (string format, object? arg0, object? arg1,
object? arg2);
```

Parameters

`format` String

A composite format string.

`arg0` Object

The first object to format.

`arg1` Object

The second object to format.

`arg2` Object

The third object to format.

Returns

String

A copy of `format` in which the format items have been replaced by the string representations of `arg0`, `arg1`, and `arg2`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

`format` is invalid.

-or-

The index of a format item is less than zero, or greater than two.

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert the value of three expressions to their string representations and to embed those representations in a string.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

Example: Format three arguments

This example uses the Format(String, Object, Object, Object) method to create a string that illustrates the result of a Boolean `And` operation with two integer values. Note that the format string includes six format items, but the method has only three items in its parameter list, because each item is formatted in two different ways.

C#

```
string formatString = "    {0,10} ({0,8:X8})\n" +
                      "And {1,10} ({1,8:X8})\n" +
                      "  = {2,10} ({2,8:X8})";
int value1 = 16932;
int value2 = 15421;
string result = String.Format(formatString,
                              value1, value2, value1 & value2);
Console.WriteLine(result);
```

```
// The example displays the following output:
//                16932 (00004224)
//       And      15421 (00003C3D)
//         =         36 (00000024)
```

Format(IFormatProvider, String, Object, Object)

Replaces the format items in a string with the string representation of two specified objects. A parameter supplies culture-specific formatting information.

C#

```
public static string Format (IFormatProvider? provider, string format,
object? arg0, object? arg1);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

format String

A composite format string.

`arg0` Object

The first object to format.

`arg1` Object

The second object to format.

Returns

String

A copy of `format` in which format items are replaced by the string representations of `arg0` and `arg1`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

`format` is invalid.

-or-

The index of a format item is not zero or one.

Remarks

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert two expressions to their string representations and to embed those representations in a string. In performing the conversion, the method uses culture-sensitive formatting or a custom formatter. The method converts each Object argument to its string representation by calling its **ToString(IFormatProvider)** method or, if the object's

corresponding format item includes a format string, by calling its **ToString(String,IFormatProvider)** method. If these methods don't exist, it calls the object's parameterless **ToString** method.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with an object that provides culture-sensitive or custom formatting and a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

This method uses the composite formatting feature to convert the value of two expressions to their string representations and to embed those representations in a string.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

Example: Format two arguments

This example uses the Format(String, Object, Object) method to display time and temperature data stored in a generic Dictionary<TKey,TValue> object. Note that the format string has three format items, although there are only two objects to format. This is because the first object in the list (a date and time value) is used by two format items: The first format item displays the time, and the second displays the date.

C#

```
Dictionary<DateTime, Double> temperatureInfo = new Dictionary<DateTime,
Double>();
temperatureInfo.Add(new DateTime(2010, 6, 1, 14, 0, 0), 87.46);
temperatureInfo.Add(new DateTime(2010, 12, 1, 10, 0, 0), 36.81);

Console.WriteLine("Temperature Information:\n");
string output;
foreach (var item in temperatureInfo)
{
   output = String.Format("Temperature at {0,8:t} on {0,9:d}:
{1,5:N1}°F",
                          item.Key, item.Value);
   Console.WriteLine(output);
}
// The example displays output like the following:
//       Temperature Information:
//
```

```
//       Temperature at  2:00 PM on  6/1/2010:  87.5°F
//       Temperature at 10:00 AM on 12/1/2010:  36.8°F
```

Format(IFormatProvider, CompositeFormat, ReadOnlySpan<Object>)

Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.

C#

```
public static string Format (IFormatProvider? provider,
System.Text.CompositeFormat format, ReadOnlySpan<object?> args);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`args` ReadOnlySpan<Object>

A span of objects to format.

Returns

String

The formatted string.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Format(IFormatProvider, String, Object)

Replaces the format item or items in a specified string with the string representation of the corresponding object. A parameter supplies culture-specific formatting information.

```
C#
```

```
public static string Format (IFormatProvider? provider, string format,
object? arg0);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` String

A composite format string.

`arg0` Object

The object to format.

Returns

String

A copy of `format` in which the format item or items have been replaced by the string representation of `arg0`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

`format` is invalid.

-or-

The index of a format item is not zero.

Remarks

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result

string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert the value of an expression to its string representation and to embed that representation in a string. In performing the conversion, the method uses culture-sensitive formatting or a custom formatter. The method converts `arg0` to its string representation by calling its **ToString(IFormatProvider)** method or, if the object's corresponding format item includes a format string, by calling its **ToString(String,IFormatProvider)** method. If these methods don't exist, it calls the object's parameterless **ToString** method.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with an object that provides culture-sensitive or custom formatting and a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

UWP	10.0

Format(IFormatProvider, String, Object[])

Replaces the format items in a string with the string representations of corresponding objects in a specified array. A parameter supplies culture-specific formatting information.

```
C#

public static string Format (IFormatProvider? provider, string format,
params object?[] args);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` String

A composite format string.

`args` Object[]

An object array that contains zero or more objects to format.

Returns

String

A copy of `format` in which the format items have been replaced by the string representation of the corresponding objects in `args`.

Exceptions

ArgumentNullException

`format` or `args` is `null`.

FormatException

`format` is invalid.

-or-

The index of a format item is less than zero, or greater than or equal to the length of the `args` array.

Remarks

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert four or more expressions to their string representations and to embed those representations in a string. In performing the conversion, the method uses culture-sensitive formatting or a custom formatter. The method converts each Object argument to its string representation by calling its **ToString(IFormatProvider)** method or, if the object's corresponding format item includes a format string, by calling its **ToString(String,IFormatProvider)** method. If these methods don't exist, it calls the object's parameterless **ToString** method.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with an object that provides culture-sensitive or custom formatting and a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

Example: Culture-sensitive formatting

This example uses the Format(IFormatProvider, String, Object[]) method to display the string representation of some date and time values and numeric values by using several different cultures.

C#

```
string[] cultureNames = { "en-US", "fr-FR", "de-DE", "es-ES" };

DateTime dateToDisplay = new DateTime(2009, 9, 1, 18, 32, 0);
```

```
double value = 9164.32;

Console.WriteLine("Culture     Date
Value\n");
foreach (string cultureName in cultureNames)
{
   System.Globalization.CultureInfo culture = new
System.Globalization.CultureInfo(cultureName);
   string output = String.Format(culture, "{0,-11} {1,-35:D} {2:N}",
                                 culture.Name, dateToDisplay, value);
   Console.WriteLine(output);
}
// The example displays the following output:
//    Culture     Date                                Value
//
//    en-US       Tuesday, September 01, 2009         9,164.32
//    fr-FR       mardi 1 septembre 2009              9 164,32
//    de-DE       Dienstag, 1. September 2009         9.164,32
//    es-ES       martes, 01 de septiembre de 2009    9.164,32
```

UWP	10.0

Format(String, Object[])

Replaces the format item in a specified string with the string representation of a corresponding object in a specified array.

C#

```
public static string Format (string format, params object?[] args);
```

Parameters

`format` String

A composite format string.

`args` Object[]

An object array that contains zero or more objects to format.

Returns

String

A copy of `format` in which the format items have been replaced by the string representation of the corresponding objects in `args`.

Exceptions

ArgumentNullException

`format` or `args` is `null`.

FormatException

`format` is invalid.

-or-

The index of a format item is less than zero, or greater than or equal to the length of the `args` array.

Remarks

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert the value of four or more expressions to their string representations and to embed those representations in a string. Since the `args` parameter is marked with the System.ParamArrayAttribute attribute, you can pass the objects to the method as individual arguments or as an Object array.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

Example: Format more than three arguments

This example creates a string that contains data on the high and low temperature on a particular date. The composite format string has five format items in the C# example and six in the Visual Basic example. Two of the format items define the width of their corresponding value's string representation, and the first format item also includes a standard date and time format string.

C#

```
DateTime date1 = new DateTime(2009, 7, 1);
TimeSpan hiTime = new TimeSpan(14, 17, 32);
decimal hiTemp = 62.1m;
TimeSpan loTime = new TimeSpan(3, 16, 10);
decimal loTemp = 54.8m;

string result1 = String.Format("Temperature on {0:d}:\n{1,11}: {2}
degrees (hi)\n{3,11}: {4} degrees (lo)",
                               date1, hiTime, hiTemp, loTime, loTemp);
Console.WriteLine(result1);
Console.WriteLine();

string result2 = String.Format("Temperature on {0:d}:\n{1,11}: {2}
degrees (hi)\n{3,11}: {4} degrees (lo)",
                               new object[] { date1, hiTime, hiTemp,
loTime, loTemp });
Console.WriteLine(result2);
// The example displays output like the following:
//       Temperature on 7/1/2009:
//          14:17:32: 62.1 degrees (hi)
//          03:16:10: 54.8 degrees (lo)
//       Temperature on 7/1/2009:
//          14:17:32: 62.1 degrees (hi)
//          03:16:10: 54.8 degrees (lo)
```

You can also pass the objects to be formatted as an array rather than as an argument list.

C#

```
using System;

public class CityInfo
{
   public CityInfo(String name, int population, Decimal area, int year)
   {
      this.Name = name;
      this.Population = population;
      this.Area = area;
      this.Year = year;
   }

   public readonly String Name;
   public readonly int Population;
   public readonly Decimal Area;
   public readonly int Year;
}

public class Example
{
```

```
    public static void Main()
    {
        CityInfo nyc2010 = new CityInfo("New York", 8175133, 302.64m,
2010);
        ShowPopulationData(nyc2010);
        CityInfo sea2010 = new CityInfo("Seattle", 608660, 83.94m, 2010);
        ShowPopulationData(sea2010);
    }

    private static void ShowPopulationData(CityInfo city)
    {
        object[] args = { city.Name, city.Year, city.Population, city.Area
};
        String result = String.Format("{0} in {1}: Population {2:N0}, Area
{3:N1} sq. feet",
                                      args);
        Console.WriteLine(result);
    }
}
// The example displays the following output:
//       New York in 2010: Population 8,175,133, Area 302.6 sq. feet
//       Seattle in 2010: Population 608,660, Area 83.9 sq. feet
```

Format(String, Object)

Replaces one or more format items in a string with the string representation of a specified object.

```
C#
public static string Format (string format, object? arg0);
```

Parameters

`format` String

A composite format string.

`arg0` Object

The object to format.

Returns

String

A copy of `format` in which any format items are replaced by the string representation of `arg0`.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The format item in `format` is invalid.

-or-

The index of a format item is not zero.

Remarks

> **Important**
>
> Instead of calling the **String.Format** method or using **composite format strings**, you can use *interpolated strings* if your language supports them. An interpolated string is a string that contains *interpolated expressions*. Each interpolated expression is resolved with the expression's value and included in the result string when the string is assigned. For more information, see **String interpolation (C# Reference)** and **Interpolated Strings (Visual Basic Reference)**.

This method uses the composite formatting feature to convert the value of an expression to its string representation and to embed that representation in a string.

However, when calling the `String.Format` method, it's not necessary to focus on the particular overload that you want to call. Instead, you can call the method with a composite format string that includes one or more format items. You assign each format item a numeric index; the first index starts at 0. In addition to the initial string, your method call should have as many additional arguments as it has index values. For example, a string whose format items have indexes of 0 and 1 should have 2 arguments; one with indexes 0 through 5 should have 6 arguments. The language compiler will then resolve your method call to a particular overload of the `String.Format` method.

For more detailed documentation on using the `String.Format` method, see Get started with the String.Format method and Which method do I call?.

Example: Formatting a single argument

The following example uses the Format(String, Object) method to embed an individual's age in the middle of a string.

C#

```
DateTime birthdate = new DateTime(1993, 7, 28);
DateTime[] dates = { new DateTime(1993, 8, 16),
                     new DateTime(1994, 7, 28),
                     new DateTime(2000, 10, 16),
                     new DateTime(2003, 7, 27),
                     new DateTime(2007, 5, 27) };

foreach (DateTime dateValue in dates)
{
```

```
    TimeSpan interval = dateValue - birthdate;
    // Get the approximate number of years, without accounting for leap
 years.
    int years = ((int) interval.TotalDays) / 365;
    // See if adding the number of years exceeds dateValue.
    string output;
    if (birthdate.AddYears(years) <= dateValue) {
       output = String.Format("You are now {0} years old.", years);
       Console.WriteLine(output);
    }
    else {
       output = String.Format("You are now {0} years old.", years - 1);
       Console.WriteLine(output);
    }
 }
 // The example displays the following output:
 //       You are now 0 years old.
 //       You are now 1 years old.
 //       You are now 7 years old.
 //       You are now 9 years old.
 //       You are now 13 years old.
```

Format(IFormatProvider, CompositeFormat, Object[])

Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.

C#

```
public static string Format (IFormatProvider? provider,
System.Text.CompositeFormat format, params object?[] args);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`args` Object[]

An array of objects to format.

Returns

String

The formatted string.

Exceptions

ArgumentNullException

`format` or `args` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Format<TArg0,TArg1,TArg2>(IFormatProvider, CompositeFormat, TArg0, TArg1, TArg2)

Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.

C#

```
public static string Format<TArg0,TArg1,TArg2> (IFormatProvider?
provider, System.Text.CompositeFormat format, TArg0 arg0, TArg1 arg1,
TArg2 arg2);
```

Type Parameters

`TArg0`

The type of the first object to format.

`TArg1`

The type of the second object to format.

`TArg2`

The type of the third object to format.

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`arg0` TArg0

The first object to format.

`arg1` TArg1

The second object to format.

`arg2` TArg2

The third object to format.

Returns

String

The formatted string.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Format<TArg0,TArg1>(IFormatProvider, CompositeFormat, TArg0, TArg1)

Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.

C#

```
public static string Format<TArg0,TArg1> (IFormatProvider? provider,
System.Text.CompositeFormat format, TArg0 arg0, TArg1 arg1);
```

Type Parameters

`TArg0`

The type of the first object to format.

`TArg1`

The type of the second object to format.

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`arg0` TArg0

The first object to format.

`arg1` TArg1

The second object to format.

Returns

String

The formatted string.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Format<TArg0>(IFormatProvider, CompositeFormat, TArg0)

Replaces the format item or items in a CompositeFormat with the string representation of the corresponding objects in the specified format.

C#

```
public static string Format<TArg0> (IFormatProvider? provider,
System.Text.CompositeFormat format, TArg0 arg0);
```

Type Parameters

`TArg0`

The type of the first object to format.

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

`format` CompositeFormat

A CompositeFormat.

`arg0` TArg0

The first object to format.

Returns

String

The formatted string.

Exceptions

ArgumentNullException

`format` is `null`.

FormatException

The index of a format item is greater than or equal to the number of supplied arguments.

Applies to

String.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves an object that can iterate through the individual characters in this string.

C#

```
public CharEnumerator GetEnumerator ();
```

Returns

CharEnumerator

An enumerator object.

Examples

The following example iterates the characters in several strings and displays information about their individual characters. It uses the language iteration construct rather than a call to the GetEnumerator method.

C#

```
using System;

class Example
{
   public static void Main()
   {
      EnumerateAndDisplay("Test Case");
      EnumerateAndDisplay("This is a sentence.");
      EnumerateAndDisplay("Has\ttwo\ttabs" );
      EnumerateAndDisplay("Two\nnew\nlines");
   }

   static void EnumerateAndDisplay(String phrase)
   {
      Console.WriteLine("The characters in the string \"{0}\" are:",
                        phrase);
```

```
      int CharCount = 0;
      int controlChars = 0;
      int alphanumeric = 0;
      int punctuation = 0;

      foreach (var ch in phrase) {
         Console.Write(Char.IsControl(ch) ? $"{ch}" : $"0x{(ushort)ch:X4}");

         if (Char.IsLetterOrDigit(ch))
            alphanumeric++;
         else if (Char.IsControl(ch))
            controlChars++;
         else if (Char.IsPunctuation(ch))
            punctuation++;
         CharCount++;
      }

      Console.WriteLine("\n   Total characters:        {0,3}", CharCount);
      Console.WriteLine("   Alphanumeric characters: {0,3}", alphanumeric);
      Console.WriteLine("   Punctuation characters:  {0,3}", punctuation);
      Console.WriteLine("   Control Characters:      {0,3}\n",
controlChars);
   }
}
// The example displays the following output:
//    The characters in the string "Test Case" are:
//    'T' 'e' 's' 't' ' ' 'C' 'a' 's' 'e'
//       Total characters:          9
//       Alphanumeric characters:   8
//       Punctuation characters:    0
//       Control Characters:        0
//
//    The characters in the string "This is a sentence." are:
//    'T' 'h' 'i' 's' ' ' 'i' 's' ' ' 'a' ' ' 's' 'e' 'n' 't' 'e' 'n' 'c'
'e' '.'
//       Total characters:         19
//       Alphanumeric characters:  15
//       Punctuation characters:    1
//       Control Characters:        0
//
//    The characters in the string "Has       two     tabs" are:
//    'H' 'a' 's' '0x0009' 't' 'w' 'o' '0x0009' 't' 'a' 'b' 's'
//       Total characters:         12
//       Alphanumeric characters:  10
//       Punctuation characters:    0
//       Control Characters:        2
//
//    The characters in the string "Two
//    new
//    lines" are:
//    'T' 'w' 'o' '0x000A' 'n' 'e' 'w' '0x000A' 'l' 'i' 'n' 'e' 's'
//       Total characters:         13
//       Alphanumeric characters:  11
```

```
//       Punctuation characters:    0
//       Control Characters:        2
```

Remarks

> **Tip**
>
> Rather than calling the **GetEnumerator** method to retrieve a **CharEnumerator** object that you then use to enumerate a string, you should instead use your language's iteration construct (in C#, in F#, in C++/CLR, and in Visual Basic). **foreach** in C#, **for..in** in F#, **for each** in C++/CLR, and **For Each** in Visual Basic).

This method enables you to iterate the individual characters in a string. For example, the Visual Basic `For Each`, the F# `for..in` expression, and C# `foreach` statements invoke this method to return a CharEnumerator object that can provide read-only access to the characters in this string instance.

String.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetHashCode(ReadOnlySpan<Char>, StringComparison)	Returns the hash code for the provided read-only character span using the specified rules.
GetHashCode(StringComparison)	Returns the hash code for this string using the specified rules.
GetHashCode()	Returns the hash code for this string.
GetHashCode(ReadOnlySpan<Char>)	Returns the hash code for the provided read-only character span.

GetHashCode(ReadOnlySpan<Char>, StringComparison)

Returns the hash code for the provided read-only character span using the specified rules.

C#

```
public static int GetHashCode (ReadOnlySpan<char> value, StringComparison
comparisonType);
```

Parameters

`value` ReadOnlySpan<Char>

A read-only character span.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules to use in the comparison.

Returns

Int32

A 32-bit signed integer hash code.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

GetHashCode(StringComparison)

Returns the hash code for this string using the specified rules.

C#

```
public int GetHashCode (StringComparison comparisonType);
```

Parameters

`comparisonType` StringComparison

One of the enumeration values that specifies the rules to use in the comparison.

Returns

Int32

A 32-bit signed integer hash code.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Standard	2.1

GetHashCode()

Returns the hash code for this string.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Examples

The following example demonstrates the GetHashCode method using various input strings.

C#

```
using System;

class GetHashCode
{
    public static void Main()
    {
        DisplayHashCode( "" );
        DisplayHashCode( "a" );
        DisplayHashCode( "ab" );
        DisplayHashCode( "abc" );
        DisplayHashCode( "abd" );
        DisplayHashCode( "abe" );
        DisplayHashCode( "abcdef" );
        DisplayHashCode( "abcdeg" );
        DisplayHashCode( "abcdeh" );
        DisplayHashCode( "abcdei" );
        DisplayHashCode( "Abcdeg" );
        DisplayHashCode( "Abcdeh" );
        DisplayHashCode( "Abcdei" );
    }

    static void DisplayHashCode( String Operand )
```

```
    {
        int     HashCode = Operand.GetHashCode( );
        Console.WriteLine("The hash code for \"{0}\" is: 0x{1:X8}, {1}",
                          Operand, HashCode );
    }
}
/*
      This example displays output like the following:
      The hash code for "" is: 0x2D2816FE, 757602046
      The hash code for "a" is: 0xCDCAB7BF, -842352705
      The hash code for "ab" is: 0xCDE8B7BF, -840386625
      The hash code for "abc" is: 0x2001D81A, 536991770
      The hash code for "abd" is: 0xC2A94CB5, -1029092171
      The hash code for "abe" is: 0x6550C150, 1699791184
      The hash code for "abcdef" is: 0x1762906D, 392335469
      The hash code for "abcdeg" is: 0x1763906D, 392401005
      The hash code for "abcdeh" is: 0x175C906D, 391942253
      The hash code for "abcdei" is: 0x175D906D, 392007789
      The hash code for "Abcdeg" is: 0x1763954D, 392402253
      The hash code for "Abcdeh" is: 0x175C954D, 391943501
      The hash code for "Abcdei" is: 0x175D954D, 392009037
*/
```

Remarks

The behavior of GetHashCode is dependent on its implementation, which might change from one version of the common language runtime to another. A reason why this might happen is to improve the performance of GetHashCode.

> **Important**
>
> If two string objects are equal, the **GetHashCode** method returns identical values. However, there is not a unique hash code value for each unique string value. Different strings can return the same hash code.
>
> The hash code itself is not guaranteed to be stable. Hash codes for identical strings can differ across .NET implementations, across .NET versions, and across .NET platforms (such as 32-bit and 64-bit) for a single version of .NET. In some cases, they can even differ by application domain. This implies that two subsequent runs of the same program may return different hash codes.
>
> As a result, hash codes should never be used outside of the application domain in which they were created, they should never be used as key fields in a collection, and they should never be persisted.
>
> Finally, don't use the hash code instead of a value returned by a cryptographic hashing function if you need a cryptographically strong hash. For cryptographic

hashes, use a class derived from the **System.Security.Cryptography.HashAlgorithm** or **System.Security.Cryptography.KeyedHashAlgorithm** class.

For more information about hash codes, see **Object.GetHashCode**.

In .NET Framework desktop apps, you can use the <UseRandomizedStringHashAlgorithm> element to generate unique hash codes on a per-application domain basis. This can reduce the number of collisions and improve the overall performance of insertions and lookups that use hash tables. The following example shows how to use the <UseRandomizedStringHashAlgorithm> element. It defines a `DisplayString` class that includes a private string constant, `s`, whose value is "This is a string." It also includes a `ShowStringHashCode` method that displays the string value and its hash code along with the name of the application domain in which the method is executing.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Show hash code in current domain.
      DisplayString display = new DisplayString();
      display.ShowStringHashCode();

      // Create a new app domain and show string hash code.
      AppDomain domain = AppDomain.CreateDomain("NewDomain");
      var display2 = (DisplayString)
domain.CreateInstanceAndUnwrap(typeof(Example).Assembly.FullName,

"DisplayString");
      display2.ShowStringHashCode();
   }
}

public class DisplayString : MarshalByRefObject
{
   private String s = "This is a string.";

   public override bool Equals(Object obj)
   {
      String s2 = obj as String;
      if (s2 == null)
         return false;
      else
         return s == s2;
```

```
    }

    public bool Equals(String str)
    {
       return s == str;
    }

    public override int GetHashCode()
    {
       return s.GetHashCode();
    }

    public override String ToString()
    {
       return s;
    }

    public void ShowStringHashCode()
    {
       Console.WriteLine("String '{0}' in domain '{1}': {2:X8}",
                         s, AppDomain.CurrentDomain.FriendlyName,
                         s.GetHashCode());
    }
 }
```

When you run the example without supplying a configuration file, it displays output similar to the following. Note that the hash codes for the string are identical in the two application domains.

```
String 'This is a string.' in domain 'PerDomain.exe': 941BCEAC
String 'This is a string.' in domain 'NewDomain': 941BCEAC
```

However, if you add the following configuration file to the example's directory and then run the example, the hash codes for the same string will differ by application domain.

XML

```
<?xml version ="1.0"?>
<configuration>
   <runtime>
      <UseRandomizedStringHashAlgorithm enabled="1" />
   </runtime>
</configuration>
```

When the configuration file is present, the example displays the following output:

```
String 'This is a string.' in domain 'PerDomain.exe': 5435776D
String 'This is a string.' in domain 'NewDomain': 75CC8236
```

> **Important**
>
> Hash codes are used to insert and retrieve keyed objects from hash tables efficiently. However, hash codes don't uniquely identify strings. Identical strings have equal hash codes, but the common language runtime can also assign the same hash code to different strings. In addition, hash codes can vary by version of .NET, by platform within a single version, and by application domain. Because of this, you should not serialize or persist hash code values, nor should you use them as keys in a hash table or dictionary.

For additional information about the use of hash codes and the `GetHashCode` method, see Object.GetHashCode.

Notes to Callers

The value returned by GetHashCode() is platform-dependent. It differs on the 32-bit and 64-bit versions of .NET Framework. It also can differ between versions of .NET Framework and .NET Core.

GetHashCode(ReadOnlySpan<Char>)

Returns the hash code for the provided read-only character span.

```
C#
public static int GetHashCode (ReadOnlySpan<char> value);
```

Parameters

`value` ReadOnlySpan<Char>

A read-only character span.

Returns

Int32

A 32-bit signed integer hash code.

Applies to

▼ .NET 9 and other versions

Product	Versions

String.GetPinnableReference Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a reference to the element of the string at index zero.

This method is intended to support .NET compilers and is not intended to be called by user code.

```
C#
public ref readonly char GetPinnableReference ();
```

Returns

Char

A reference to the first character in the string, or a reference to the string's null terminator if the string is empty.

Exceptions

NullReferenceException

The string is null.

Remarks

The `GetPinnableReference` method returns a character that can be used for pinning a String in memory. It is required to support the use of a String within a fixed statement.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for the String class.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, String.

Implements

GetTypeCode()

Examples

The following example displays the TypeCode enumerated constant for the String type.

C#

```
// Sample for String.GetTypeCode()
using System;

class Sample
{
    public static void Main()
    {
    String str = "abc";
    TypeCode tc = str.GetTypeCode();
    Console.WriteLine("The type code for '{0}' is {1}, which represents
{2}.",
                          str, tc.ToString("D"), tc.ToString("F"));
    }
}
```

```
/*
This example produces the following results:
The type code for 'abc' is 18, which represents String.
*/
```

Applies to

Product	Versions

String.IndexOf Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reports the zero-based index of the first occurrence of a specified Unicode character or string within this instance. The method returns -1 if the character or string is not found in this instance.

Overloads

Expand table

IndexOf(String, Int32, Int32)	Reports the zero-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position and examines a specified number of character positions.
IndexOf(String, Int32, Int32, StringComparison)	Reports the zero-based index of the first occurrence of the specified string in the current String object. Parameters specify the starting search position in the current string, the number of characters in the current string to search, and the type of search to use for the specified string.
IndexOf(String, Int32, StringComparison)	Reports the zero-based index of the first occurrence of the specified string in the current String object. Parameters specify the starting search position in the current string and the type of search to use for the specified string.
IndexOf(String, StringComparison)	Reports the zero-based index of the first occurrence of the specified string in the current String object. A parameter specifies the type of search to use for the specified string.
IndexOf(Char, Int32, Int32)	Reports the zero-based index of the first occurrence of the specified character in this instance. The search starts at a specified character position and examines a specified number of character positions.
IndexOf(Char, StringComparison)	Reports the zero-based index of the first occurrence of the specified Unicode character in this string. A parameter specifies the type of search to use for the specified character.
IndexOf(Char, Int32)	Reports the zero-based index of the first occurrence of the specified Unicode character in this string. The search starts at a specified

	character position.
IndexOf(String)	Reports the zero-based index of the first occurrence of the specified string in this instance.
IndexOf(Char)	Reports the zero-based index of the first occurrence of the specified Unicode character in this string.
IndexOf(String, Int32)	Reports the zero-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position.

IndexOf(String, Int32, Int32)

Reports the zero-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position and examines a specified number of character positions.

C#

```
public int IndexOf (string value, int startIndex, int count);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position.

`count` Int32

The number of character positions to examine.

Returns

Int32

The zero-based index position of `value` from the start of the current instance if that string is found, or -1 if it is not. If `value` is Empty, the return value is `startIndex`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`count` or `startIndex` is negative.

-or-

`startIndex` is greater than the length of this string.

-or-

`count` is greater than the length of this string minus `startIndex`.

Examples

The following example finds the index of all occurrences of the string "he" within a substring of another string. Note that the number of characters to be searched must be recalculated for each search iteration.

C#

```
string br1 = "0----+----1----+----2----+----3----+----4----+----5----+---
-6----+---";
string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456789012345678";
string str = "Now is the time for all good men to come to the aid of
their country.";
int start;
int at;
int end;
int count;

end = str.Length;
start = end/2;
Console.WriteLine();
Console.WriteLine("All occurrences of 'he' from position {0} to {1}.",
start, end-1);
Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1, br2,
str);
Console.Write("The string 'he' occurs at position(s): ");

count = 0;
at = 0;
while((start <= end) && (at > -1))
{
    // start+count must be a position within -str-.
    count = end - start;
    at = str.IndexOf("he", start, count);
    if (at == -1) break;
    Console.Write("{0} ", at);
```

```
    start = at+1;
}
Console.WriteLine();

/*
This example produces the following results:

All occurrences of 'he' from position 34 to 68.
0----+----1----+----2----+----3----+----4----+----5----+----6----+---
0123456789012345678901234567890123456789012345678901234567890123456789012345678
Now is the time for all good men to come to the aid of their country.

The string 'he' occurs at position(s): 45 56

*/
```

Remarks

Index numbering starts from 0 (zero). The `startIndex` parameter can range from 0 to the length of the string instance.

This method performs a word (case-sensitive and culture-sensitive) search using the current culture. The search begins at `startIndex` and continues to `startIndex` + `count` -1. The character at `startIndex` + `count` is not included in the search.

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search, if `value` contains an ignorable character, the result is equivalent to searching with that character removed. If `value` consists only of one or more ignorable characters, the IndexOf(String, Int32, Int32) method always returns `startIndex`, which is the character position at which the search begins. In the following example, the IndexOf(String, Int32, Int32) method is used to find the position of a soft hyphen (U+00AD) followed by an "m" starting in the third through sixth character positions in two strings. Only one of the strings contains the required substring. If the example is run on the .NET Framework 4 or later, in both cases, because the soft hyphen is an ignorable character, the method returns the index of "m" in the string when it performs a culture-sensitive comparison. Note that in the case of the first string, which includes the soft hyphen followed by an "m", the method fails to return the index of the soft hyphen but instead returns the index of the "m".

C#

```
using System;
```

```
public class Example
{
    public static void Main()
    {
        string searchString = "\u00ADm";
        string s1 = "ani\u00ADmal" ;
        string s2 = "animal";

        Console.WriteLine(s1.IndexOf(searchString, 2, 4));
        Console.WriteLine(s2.IndexOf(searchString, 2, 4));

        // The example displays the following output:
        //       4
        //       3
    }
}
```

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To use the comparison rules of the current culture to perform this operation, signal your intention explicitly by calling the IndexOf(String, Int32, Int32, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

IndexOf(String, Int32, Int32, StringComparison)

Reports the zero-based index of the first occurrence of the specified string in the current String object. Parameters specify the starting search position in the current string, the number of characters in the current string to search, and the type of search to use for the specified string.

C#

```
public int IndexOf (string value, int startIndex, int count,
StringComparison comparisonType);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position.

`count` Int32

The number of character positions to examine.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules for the search.

Returns

Int32

The zero-based index position of the `value` parameter from the start of the current instance if that string is found, or -1 if it is not. If `value` is Empty, the return value is `startIndex`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`count` or `startIndex` is negative.

-or-

`startIndex` is greater than the length of this instance.

-or-

`count` is greater than the length of this string minus `startIndex`.

ArgumentException

`comparisonType` is not a valid StringComparison value.

Examples

The following example demonstrates three overloads of the IndexOf method that find the first occurrence of a string within another string using different values of the StringComparison enumeration.

C#

```
// This code example demonstrates the
// System.String.IndexOf(String, ..., StringComparison) methods.

using System;
using System.Threading;
using System.Globalization;

class Sample
{
    public static void Main()
    {
    string intro = "Find the first occurrence of a character using
different " +
                   "values of StringComparison.";
    string resultFmt = "Comparison: {0,-28} Location: {1,3}";

// Define a string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
    string CapitalAWithRing = "\u00c5";

// Define a string to search.
```

```
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string cat = "A Cheshire c" + "\u0061\u030a" + "t";

    int loc = 0;
    StringComparison[] scValues = {
        StringComparison.CurrentCulture,
        StringComparison.CurrentCultureIgnoreCase,
        StringComparison.InvariantCulture,
        StringComparison.InvariantCultureIgnoreCase,
        StringComparison.Ordinal,
        StringComparison.OrdinalIgnoreCase };

// Clear the screen and display an introduction.
    Console.Clear();
    Console.WriteLine(intro);

// Display the current culture because culture affects the result. For
example,
// try this code example with the "sv-SE" (Swedish-Sweden) culture.

    Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
    Console.WriteLine("The current culture is \"{0}\" - {1}.",
                      Thread.CurrentThread.CurrentCulture.Name,
                      Thread.CurrentThread.CurrentCulture.DisplayName);

// Display the string to search for and the string to search.
    Console.WriteLine("Search for the string \"{0}\" in the string \"
{1}\"",
                      CapitalAWithRing, cat);
    Console.WriteLine();

// Note that in each of the following searches, we look for
// LATIN CAPITAL LETTER A WITH RING ABOVE in a string that contains
// LATIN SMALL LETTER A WITH RING ABOVE. A result value of -1 indicates
// the string was not found.
// Search using different values of StringComparison. Specify the start
// index and count.

    Console.WriteLine("Part 1: Start index and count are specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, 0, cat.Length, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparison. Specify the
// start index.
    Console.WriteLine("\nPart 2: Start index is specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, 0, sc);
```

```
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparison.
    Console.WriteLine("\nPart 3: Neither start index nor count is
specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }
    }
}

/*
Note: This code example was executed on a console whose user interface
culture is "en-US" (English-United States).

This code example produces the following results:

Find the first occurrence of a character using different values of
StringComparison.
The current culture is "en-US" - English (United States).
Search for the string "Å" in the string "A Cheshire ca°t"

Part 1: Start index and count are specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

Part 2: Start index is specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

Part 3: Neither start index nor count is specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

*/
```

Remarks

Index numbering starts from 0 (zero). The `startIndex` parameter can range from 0 to the length of the string instance.

The search begins at `startIndex` and continues to `startIndex` + `count` -1. The character at `startIndex` + `count` is not included in the search.

The `comparisonType` parameter specifies to search for the `value` parameter using the current or invariant culture, using a case-sensitive or case-insensitive search, and using word or ordinal comparison rules.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search (that is, if `comparisonType` is not Ordinal or OrdinalIgnoreCase), if `value` contains an ignorable character, the result is equivalent to searching with that character removed. If `value` consists only of one or more ignorable characters, the IndexOf(String, Int32, Int32, StringComparison) method always returns `startIndex`, which is the character position at which the search begins.

In the following example, the IndexOf(String, Int32, Int32, StringComparison) method is used to find the position of a soft hyphen (U+00AD) followed by an "m" starting in the third through sixth character positions in two strings. Only one of the strings contains the required substring. If the example is run on the .NET Framework 4 or later, in both cases, because the soft hyphen is an ignorable character, the method returns the index of "m" in the string when it performs a culture-sensitive comparison. When it performs an ordinal comparison, however, it finds the substring only in the first string. Note that in the case of the first string, which includes the soft hyphen followed by an "m", the method fails to return the index of the soft hyphen but instead returns the index of the "m" when it performs a culture-sensitive comparison. The method returns the index of the soft hyphen in the first string only when it performs an ordinal comparison.

C#

```
using System;

public class Example
{
    public static void Main()
    {
```

```
        string searchString = "\u00ADm";
        string s1 = "ani\u00ADmal" ;
        string s2 = "animal";

        Console.WriteLine(s1.IndexOf(searchString, 2, 4,
StringComparison.CurrentCulture));
        Console.WriteLine(s1.IndexOf(searchString, 2, 4,
StringComparison.Ordinal));
        Console.WriteLine(s2.IndexOf(searchString, 2, 4,
StringComparison.CurrentCulture));
        Console.WriteLine(s2.IndexOf(searchString, 2, 4,
StringComparison.Ordinal));

        // The example displays the following output:
        //       4
        //       3
        //       3
        //       -1
    }
}
```

IndexOf(String, Int32, StringComparison)

Reports the zero-based index of the first occurrence of the specified string in the current String object. Parameters specify the starting search position in the current string and the type of search to use for the specified string.

C#

```
public int IndexOf (string value, int startIndex, StringComparison
comparisonType);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules for the search.

Returns

Int32

The zero-based index position of the `value` parameter from the start of the current instance if that string is found, or -1 if it is not. If `value` is Empty, the return value is `startIndex`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than 0 (zero) or greater than the length of this string.

ArgumentException

`comparisonType` is not a valid StringComparison value.

Examples

The following example demonstrates three overloads of the IndexOf method that find the first occurrence of a string within another string using different values of the StringComparison enumeration.

C#

```
// This code example demonstrates the
// System.String.IndexOf(String, ..., StringComparison) methods.

using System;
using System.Threading;
```

```
using System.Globalization;

class Sample
{
    public static void Main()
    {
    string intro = "Find the first occurrence of a character using
different " +
                   "values of StringComparison.";
    string resultFmt = "Comparison: {0,-28} Location: {1,3}";

// Define a string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
    string CapitalAWithRing = "\u00c5";

// Define a string to search.
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string cat = "A Cheshire c" + "\u0061\u030a" + "t";

    int loc = 0;
    StringComparison[] scValues = {
        StringComparison.CurrentCulture,
        StringComparison.CurrentCultureIgnoreCase,
        StringComparison.InvariantCulture,
        StringComparison.InvariantCultureIgnoreCase,
        StringComparison.Ordinal,
        StringComparison.OrdinalIgnoreCase };

// Clear the screen and display an introduction.
    Console.Clear();
    Console.WriteLine(intro);

// Display the current culture because culture affects the result. For
example,
// try this code example with the "sv-SE" (Swedish-Sweden) culture.

    Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
    Console.WriteLine("The current culture is \"{0}\" - {1}.",
                      Thread.CurrentThread.CurrentCulture.Name,
                      Thread.CurrentThread.CurrentCulture.DisplayName);

// Display the string to search for and the string to search.
    Console.WriteLine("Search for the string \"{0}\" in the string \"
{1}\"",
                      CapitalAWithRing, cat);
    Console.WriteLine();

// Note that in each of the following searches, we look for
// LATIN CAPITAL LETTER A WITH RING ABOVE in a string that contains
// LATIN SMALL LETTER A WITH RING ABOVE. A result value of -1 indicates
// the string was not found.
```

```
// Search using different values of StringComparison. Specify the start
// index and count.

    Console.WriteLine("Part 1: Start index and count are specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, 0, cat.Length, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparison. Specify the
// start index.
    Console.WriteLine("\nPart 2: Start index is specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, 0, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparison.
    Console.WriteLine("\nPart 3: Neither start index nor count is
specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }
    }
}

/*
Note: This code example was executed on a console whose user interface
culture is "en-US" (English-United States).

This code example produces the following results:

Find the first occurrence of a character using different values of
StringComparison.
The current culture is "en-US" - English (United States).
Search for the string "Å" in the string "A Cheshire ca°t"

Part 1: Start index and count are specified.
Comparison: CurrentCulture               Location:  -1

Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

*/
```

Remarks

Index numbering starts from 0. The `startIndex` parameter can range from 0 to the length of the string instance. If `startIndex` equals the length of the string instance, the method returns -1.

The `comparisonType` parameter specifies to search for the `value` parameter using the current or invariant culture, using a case-sensitive or case-insensitive search, and using word or ordinal comparison rules.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search (that is, if `comparisonType` is not Ordinal or OrdinalIgnoreCase), if `value` contains an ignorable character, the result is equivalent to searching with that character removed. If `value` consists only of one or more ignorable characters, the IndexOf(String, Int32, StringComparison) method always returns `startIndex`, which is the character position at which the search begins.

In the following example, the IndexOf(String, Int32, StringComparison) method is used to find the position of a soft hyphen (U+00AD) followed by an "m" starting with the third character position in two strings. Only one of the strings contains the required substring. If the example is run on the .NET Framework 4 or later, in both cases, because the soft hyphen is an ignorable character, the method returns the index of "m" in the string when it performs a culture-sensitive comparison. Note that in the case of the first string, which includes the soft hyphen followed by an "m", the method fails to return the index of the soft hyphen but instead returns the index of the "m". The method returns the index of the soft hyphen in the first string only when it performs an ordinal comparison.

C#

```
using System;

public class Example
{
    public static void Main()
    {

        string searchString = "\u00ADm";
        string s1 = "ani\u00ADmal" ;
        string s2 = "animal";

        Console.WriteLine(s1.IndexOf(searchString, 2,
StringComparison.CurrentCulture));
        Console.WriteLine(s1.IndexOf(searchString, 2,
StringComparison.Ordinal));
        Console.WriteLine(s2.IndexOf(searchString, 2,
StringComparison.CurrentCulture));
        Console.WriteLine(s2.IndexOf(searchString, 2,
StringComparison.Ordinal));

        // The example displays the following output:
        //       4
        //       3
        //       3
        //       -1
    }
}
```

IndexOf(String, StringComparison)

Reports the zero-based index of the first occurrence of the specified string in the current String object. A parameter specifies the type of search to use for the specified string.

```
C#

public int IndexOf (string value, StringComparison comparisonType);
```

Parameters

`value` String

The string to seek.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules for the search.

Returns

Int32

The index position of the `value` parameter if that string is found, or -1 if it is not. If `value` is Empty, the return value is 0.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`comparisonType` is not a valid StringComparison value.

Examples

The following example demonstrates three overloads of the IndexOf method that find the first occurrence of a string within another string using different values of the StringComparison enumeration.

```
C#

// This code example demonstrates the
// System.String.IndexOf(String, ..., StringComparison) methods.

using System;
```

```
using System.Threading;
using System.Globalization;

class Sample
{
    public static void Main()
    {
    string intro = "Find the first occurrence of a character using
different " +
                   "values of StringComparison.";
    string resultFmt = "Comparison: {0,-28} Location: {1,3}";

// Define a string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
    string CapitalAWithRing = "\u00c5";

// Define a string to search.
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string cat = "A Cheshire c" + "\u0061\u030a" + "t";

    int loc = 0;
    StringComparison[] scValues = {
        StringComparison.CurrentCulture,
        StringComparison.CurrentCultureIgnoreCase,
        StringComparison.InvariantCulture,
        StringComparison.InvariantCultureIgnoreCase,
        StringComparison.Ordinal,
        StringComparison.OrdinalIgnoreCase };

// Clear the screen and display an introduction.
    Console.Clear();
    Console.WriteLine(intro);

// Display the current culture because culture affects the result. For
example,
// try this code example with the "sv-SE" (Swedish-Sweden) culture.

    Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
    Console.WriteLine("The current culture is \"{0}\" - {1}.",
                      Thread.CurrentThread.CurrentCulture.Name,
                      Thread.CurrentThread.CurrentCulture.DisplayName);

// Display the string to search for and the string to search.
    Console.WriteLine("Search for the string \"{0}\" in the string \"
{1}\"",
                      CapitalAWithRing, cat);
    Console.WriteLine();

// Note that in each of the following searches, we look for
// LATIN CAPITAL LETTER A WITH RING ABOVE in a string that contains
// LATIN SMALL LETTER A WITH RING ABOVE. A result value of -1 indicates
```

```
// the string was not found.
// Search using different values of StringComparison. Specify the start
// index and count.

    Console.WriteLine("Part 1: Start index and count are specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, 0, cat.Length, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparison. Specify the
// start index.
    Console.WriteLine("\nPart 2: Start index is specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, 0, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparison.
    Console.WriteLine("\nPart 3: Neither start index nor count is
specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.IndexOf(CapitalAWithRing, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }
    }
}

/*
Note: This code example was executed on a console whose user interface
culture is "en-US" (English-United States).

This code example produces the following results:

Find the first occurrence of a character using different values of
StringComparison.
The current culture is "en-US" - English (United States).
Search for the string "Å" in the string "A Cheshire caºt"

Part 1: Start index and count are specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

Part 2: Start index is specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
```

```
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

Part 3: Neither start index nor count is specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

*/
```

Remarks

Index numbering starts from zero.

The `comparisonType` parameter specifies to search for the `value` parameter using the current or invariant culture, using a case-sensitive or case-insensitive search, and using word or ordinal comparison rules.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search (that is, if `comparisonType` is not Ordinal or OrdinalIgnoreCase), if `value` contains an ignorable character, the result is equivalent to searching with that character removed. If `value` consists only of one or more ignorable characters, the IndexOf(String, StringComparison) method always returns 0 (zero) to indicate that the match is found at the beginning of the current instance.

In the following example, the IndexOf(String, StringComparison) method is used to find three substrings (a soft hyphen (U+00AD), a soft hyphen followed by "n", and a soft hyphen followed by "m") in two strings. Only one of the strings contains a soft hyphen. If the example is run on the .NET Framework 4 or later, because the soft hyphen is an ignorable character, a culture-sensitive search returns the same value that it would return if the soft hyphen were not included in the search string. An ordinal search, however, successfully finds the soft hyphen in one string and reports that it is absent from the second string.

C#

```
using System;
```

```
public class Example
{
    public static void Main()
    {
        string s1 = "ani\u00ADmal";
        string s2 = "animal";

        Console.WriteLine("Culture-sensitive comparison:");
        // Use culture-sensitive comparison to find the soft hyphen.
        Console.WriteLine(s1.IndexOf("\u00AD",
StringComparison.CurrentCulture));
        Console.WriteLine(s2.IndexOf("\u00AD",
StringComparison.CurrentCulture));

        // Use culture-sensitive comparison to find the soft hyphen
followed by "n".
        Console.WriteLine(s1.IndexOf("\u00ADn",
StringComparison.CurrentCulture));
        Console.WriteLine(s2.IndexOf("\u00ADn",
StringComparison.CurrentCulture));

        // Use culture-sensitive comparison to find the soft hyphen
followed by "m".
        Console.WriteLine(s1.IndexOf("\u00ADm",
StringComparison.CurrentCulture));
        Console.WriteLine(s2.IndexOf("\u00ADm",
StringComparison.CurrentCulture));

        Console.WriteLine("Ordinal comparison:");
        // Use ordinal comparison to find the soft hyphen.
        Console.WriteLine(s1.IndexOf("\u00AD",
StringComparison.Ordinal));
        Console.WriteLine(s2.IndexOf("\u00AD",
StringComparison.Ordinal));

        // Use ordinal comparison to find the soft hyphen followed by
"n".
        Console.WriteLine(s1.IndexOf("\u00ADn",
StringComparison.Ordinal));
        Console.WriteLine(s2.IndexOf("\u00ADn",
StringComparison.Ordinal));

        // Use ordinal comparison to find the soft hyphen followed by
"m".
        Console.WriteLine(s1.IndexOf("\u00ADm",
StringComparison.Ordinal));
        Console.WriteLine(s2.IndexOf("\u00ADm",
StringComparison.Ordinal));

        // The example displays the following output:
        //       Culture-sensitive comparison:
        //       0
        //       0
        //       1
        //       1
```

```
        //      4
        //      3
        //      Ordinal comparison:
        //      3
        //      -1
        //      -1
        //      -1
        //      3
        //      -1
    }
}
```

UWP	10.0

IndexOf(Char, Int32, Int32)

Reports the zero-based index of the first occurrence of the specified character in this instance. The search starts at a specified character position and examines a specified number of character positions.

C#

```
public int IndexOf (char value, int startIndex, int count);
```

Parameters

`value` Char

A Unicode character to seek.

`startIndex` Int32

The search starting position.

`count` Int32

The number of character positions to examine.

Returns

Int32

The zero-based index position of `value` from the start of the string if that character is found, or -1 if it is not.

Exceptions

ArgumentOutOfRangeException

`count` or `startIndex` is negative.

-or-

`startIndex` is greater than the length of this string.

-or-

`count` is greater than the length of this string minus `startIndex`.

Examples

The following example demonstrates the IndexOf method.

C#

```
// Example for the String.IndexOf( char, int, int ) method.
using System;

class IndexOfCII
{
    public static void Main()
    {
        string br1 =
            "0----+----1----+----2----+----3----+----" +
            "4----+----5----+----6----+----7";
        string br2 =
            "0123456789012345678901234567890123456789" +
            "0123456789012345678901234567890";
        string str =
            "ABCDEFGHI abcdefghi ABCDEFGHI abcdefghi " +
            "ABCDEFGHI abcdefghi ABCDEFGHI";
```

```
        Console.WriteLine(
            "This example of String.IndexOf( char, int, int )\n" +
            "generates the following output." );
        Console.WriteLine(
            "{0}{1}{0}{2}{0}{3}{0}",
            Environment.NewLine, br1, br2, str );

        FindAllChar( 'A', str );
        FindAllChar( 'a', str );
        FindAllChar( 'I', str );
        FindAllChar( 'i', str );
        FindAllChar( '@', str );
        FindAllChar( ' ', str );
    }

    static void FindAllChar( Char target, String searched )
    {
        Console.Write(
            "The character '{0}' occurs at position(s): ",
            target );

        int     startIndex = -1;
        int     hitCount = 0;

        // Search for all occurrences of the target.
        while( true )
        {
            startIndex = searched.IndexOf(
                target, startIndex + 1,
                searched.Length - startIndex - 1 );

            // Exit the loop if the target is not found.
            if( startIndex < 0 )
                break;

            Console.Write( "{0}, ", startIndex );
            hitCount++;
        }

        Console.WriteLine( "occurrences: {0}", hitCount );
    }
}

/*
This example of String.IndexOf( char, int, int )
generates the following output.

0----+----1----+----2----+----3----+----4----+----5----+----6----+----7
01234567890123456789012345678901234567890123456789012345678901234567890
ABCDEFGHI abcdefghi ABCDEFGHI abcdefghi ABCDEFGHI abcdefghi ABCDEFGHI

The character 'A' occurs at position(s): 0, 20, 40, 60, occurrences: 4
The character 'a' occurs at position(s): 10, 30, 50, occurrences: 3
The character 'I' occurs at position(s): 8, 28, 48, 68, occurrences: 4
```

```
The character 'i' occurs at position(s): 18, 38, 58, occurrences: 3
The character '@' occurs at position(s): occurrences: 0
The character ' ' occurs at position(s): 9, 19, 29, 39, 49, 59,
occurrences: 6
*/
```

Remarks

The search begins at `startIndex` and continues to `startIndex` + `count` -1. The character at `startIndex` + `count` is not included in the search.

Index numbering starts from 0 (zero). The `startIndex` parameter can range from 0 to the length of the string instance.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.IndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

IndexOf(Char, StringComparison)

Reports the zero-based index of the first occurrence of the specified Unicode character in this string. A parameter specifies the type of search to use for the specified character.

C#

```
public int IndexOf (char value, StringComparison comparisonType);
```

Parameters

`value` Char

The character to seek.

`comparisonType` StringComparison

An enumeration value that specifies the rules for the search.

Returns

Int32

The zero-based index of `value` if that character is found, or -1 if it is not.

Exceptions

ArgumentException

`comparisonType` is not a valid StringComparison value.

Remarks

Index numbering starts from zero.

The `comparisonType` parameter is a StringComparison enumeration member that specifies whether the search for the `value` argument uses the current or invariant culture, is case-sensitive or case-insensitive, or uses word or ordinal comparison rules.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

IndexOf(Char, Int32)

Reports the zero-based index of the first occurrence of the specified Unicode character in this string. The search starts at a specified character position.

```
C#

public int IndexOf (char value, int startIndex);
```

Parameters

`value` Char

A Unicode character to seek.

`startIndex` Int32

The search starting position.

Returns

Int32

The zero-based index position of `value` from the start of the string if that character is found, or -1 if it is not.

Exceptions

ArgumentOutOfRangeException

`startIndex` is less than 0 (zero) or greater than the length of the string.

Examples

The following example demonstrates the IndexOf method.

```C#
string br1 = "0----+----1----+----2----+----3----+----4----+----5----+---
-6----+---";
string br2 =
"01234567890123456789012345678901234567890123456789012345678901234567890123456789012345678";
string str = "Now is the time for all good men to come to the aid of
their country.";
int start;
int at;

Console.WriteLine();
Console.WriteLine("All occurrences of 't' from position 0 to {0}.",
str.Length-1);
Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1, br2,
str);
Console.Write("The letter 't' occurs at position(s): ");

at = 0;
start = 0;
while((start < str.Length) && (at > -1))
{
    at = str.IndexOf('t', start);
    if (at == -1) break;
    Console.Write("{0} ", at);
    start = at+1;
}
Console.WriteLine();

/*
This example produces the following results:

All occurrences of 't' from position 0 to 68.
0----+----1----+----2----+----3----+----4----+----5----+----6----+---
01234567890123456789012345678901234567890123456789012345678901234567890123456789012345678
Now is the time for all good men to come to the aid of their country.

The letter 't' occurs at position(s): 7 11 33 41 44 55 65

*/
```

Remarks

Index numbering starts from 0. The `startIndex` parameter can range from 0 to the length of the string instance. If `startIndex` equals the length of the string instance, the method returns -1.

The search ranges from `startIndex` to the end of the string.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.IndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

IndexOf(String)

Reports the zero-based index of the first occurrence of the specified string in this instance.

C#

```
public int IndexOf (string value);
```

Parameters

`value` String

The string to seek.

Returns

Int32

The zero-based index position of `value` if that string is found, or -1 if it is not. If `value` is Empty, the return value is 0.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example searches for the "n" in "animal". Because string indexes begin at zero rather than one, the IndexOf(String) method indicates that the "n" is at position 1.

C#

```
String str = "animal";
String toFind = "n";
int index = str.IndexOf("n");
Console.WriteLine("Found '{0}' in '{1}' at position {2}",
                toFind, str, index);

// The example displays the following output:
//        Found 'n' in 'animal' at position 1
```

The following example uses the IndexOf method to determine the starting position of an animal name in a sentence. It then uses this position to insert an adjective that describes the animal into the sentence.

C#

```
using System;

public class Example {
    public static void Main()
    {
        string animal1 = "fox";
        string animal2 = "dog";
```

```
        string strTarget = String.Format("The {0} jumps over the {1}.",
                                         animal1, animal2);

        Console.WriteLine("The original string is:{0}{1}{0}",
                          Environment.NewLine, strTarget);

        Console.Write("Enter an adjective (or group of adjectives) " +
                      "to describe the {0}: ==> ", animal1);
        string adj1 = Console.ReadLine();

        Console.Write("Enter an adjective (or group of adjectives) " +
                      "to describe the {0}: ==> ", animal2);
        string adj2 = Console.ReadLine();

        adj1 = adj1.Trim() + " ";
        adj2 = adj2.Trim() + " ";

        strTarget = strTarget.Insert(strTarget.IndexOf(animal1), adj1);
        strTarget = strTarget.Insert(strTarget.IndexOf(animal2), adj2);

        Console.WriteLine("{0}The final string is:{0}{1}",
                          Environment.NewLine, strTarget);
    }
}
// Output from the example might appear as follows:
//       The original string is:
//       The fox jumps over the dog.
//
//       Enter an adjective (or group of adjectives) to describe the fox:
==> bold
//       Enter an adjective (or group of adjectives) to describe the dog:
==> lazy
//
//       The final string is:
//       The bold fox jumps over the lazy dog.
```

Remarks

Index numbering starts from zero.

This method performs a word (case-sensitive and culture-sensitive) search using the current culture. The search begins at the first character position of this instance and continues until the last character position.

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search, if `value` contains an ignorable character, the result is equivalent to searching with that character removed. If `value` consists only of one or more ignorable characters, the IndexOf(String) method always returns 0 (zero) to

indicate that the match is found at the beginning of the current instance. In the following example, the IndexOf(String) method is used to find three substrings (a soft hyphen (U+00AD), a soft hyphen followed by "n", and a soft hyphen followed by "m") in two strings. Only one of the strings contains a soft hyphen. If the example is run on the .NET Framework 4 or later, in each case, because the soft hyphen is an ignorable character, the result is the same as if the soft hyphen had not been included in `value`. When searching for a soft hyphen only, the method returns 0 (zero) to indicate that it has found a match at the beginning of the string.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        string s1 = "ani\u00ADmal";
        string s2 = "animal";

        // Find the index of the soft hyphen.
        Console.WriteLine(s1.IndexOf("\u00AD"));
        Console.WriteLine(s2.IndexOf("\u00AD"));

        // Find the index of the soft hyphen followed by "n".
        Console.WriteLine(s1.IndexOf("\u00ADn"));
        Console.WriteLine(s2.IndexOf("\u00ADn"));

        // Find the index of the soft hyphen followed by "m".
        Console.WriteLine(s1.IndexOf("\u00ADm"));
        Console.WriteLine(s2.IndexOf("\u00ADm"));

        // The example displays the following output
        // if run under the .NET Framework 4 or later:
        //       0
        //       0
        //       1
        //       1
        //       4
        //       3
    }
}
```

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To find the first index of a

substring within a string instance by using the comparison rules of the current culture, signal your intention explicitly by calling the IndexOf(String, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IndexOf(Char)

Reports the zero-based index of the first occurrence of the specified Unicode character in this string.

C#

```
public int IndexOf (char value);
```

Parameters

`value` Char

A Unicode character to seek.

Returns

Int32

The zero-based index position of `value` if that character is found, or -1 if it is not.

Examples

The following example demonstrates how you can search a String for a character using the IndexOf method.

C#

```
// Create a Unicode string with 5 Greek Alpha characters.
String szGreekAlpha = new String('\u0391',5);

// Create a Unicode string with 3 Greek Omega characters.
String szGreekOmega = "\u03A9\u03A9\u03A9";

String szGreekLetters = String.Concat(szGreekOmega, szGreekAlpha,
                                      szGreekOmega.Clone());

// Display the entire string.
Console.WriteLine("The string: {0}", szGreekLetters);

// The first index of Alpha.
int ialpha = szGreekLetters.IndexOf('\u0391');
// The first index of Omega.
int iomega = szGreekLetters.IndexOf('\u03A9');

Console.WriteLine("First occurrence of the Greek letter Alpha: Index
{0}",
                ialpha);
Console.WriteLine("First occurrence of the Greek letter Omega: Index
{0}",
                iomega);

// The example displays the following output:
//    The string: ΩΩΩΑΑΑΑΑΩΩΩ
//    First occurrence of the Greek letter Alpha: Index 3
//    First occurrence of the Greek letter Omega: Index 0
```

Remarks

Index numbering starts from zero.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.IndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

IndexOf(String, Int32)

Reports the zero-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position.

C#

```
public int IndexOf (string value, int startIndex);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position.

Returns

Int32

The zero-based index position of `value` from the start of the current instance if that string is found, or -1 if it is not. If `value` is Empty, the return value is `startIndex`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is less than 0 (zero) or greater than the length of this string.

Examples

The following example searches for all occurrences of a specified string within a target string.

C#

```
using System;

public class IndexOfTest {
    public static void Main() {

        string strSource = "This is the string which we will perform the search on";

        Console.WriteLine("The search string is:{0}\"{1}\"{0}", Environment.NewLine, strSource);

        string strTarget = "";
        int found = 0;
        int totFinds = 0;

        do {
            Console.Write("Please enter a search value to look for in the above string (hit Enter to exit) ==> ");
```

```
            strTarget = Console.ReadLine();

            if (strTarget != "") {

                for (int i = 0; i < strSource.Length; i++) {

                    found = strSource.IndexOf(strTarget, i);

                    if (found >= 0) {
                        totFinds++;
                        i = found;
                    }
                    else
                    {
                        break;
                    }
                }
            }
            else
            {
                return;
            }

            Console.WriteLine("{0}The search parameter '{1}' was found
{2} times.{0}",
                    Environment.NewLine, strTarget, totFinds);

            totFinds = 0;
        } while ( true );
    }
}
```

Remarks

Index numbering starts from 0. The `startIndex` parameter can range from 0 to the length of the string instance. If `startIndex` equals the length of the string instance, the method returns -1.

This method performs a word (case-sensitive and culture-sensitive) search using the current culture. The search begins at the `startIndex` character position of this instance and continues until the last character position.

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search, if `value` contains an ignorable character, the result is equivalent to searching with that character removed. If `value` consists only of one or more ignorable characters, the IndexOf(String, Int32) method always returns

`startIndex`, which is the character position at which the search begins. In the following example, the IndexOf(String, Int32) method is used to find the position of a soft hyphen (U+00AD) followed by an "m" in two strings. Only one of the strings contains the required substring. If the example is run on the .NET Framework 4 or later, in both cases, because the soft hyphen is an ignorable character, the method returns the index of "m" in the string. Note that in the case of the first string, which includes the soft hyphen followed by an "m", the method fails to return the index of the soft hyphen but instead returns the index of the "m".

C#

```
using System;

public class Example
{
    public static void Main()
    {
        string searchString = "\u00ADm";
        string s1 = "ani\u00ADmal" ;
        string s2 = "animal";

        Console.WriteLine(s1.IndexOf(searchString, 2));
        Console.WriteLine(s2.IndexOf(searchString, 2));

        // The example displays the following output:
        //       4
        //       3
    }
}
```

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To find the first index of a substring that occurs after a particular character position by using the comparison rules of the current culture, signal your intention explicitly by calling the IndexOf(String, Int32, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

String.IndexOfAny Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reports the index of the first occurrence in this instance of any character in a specified array of Unicode characters. The method returns -1 if the characters in the array are not found in this instance.

Overloads

Expand table

IndexOfAny(Char[])	Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters.
IndexOfAny(Char[], Int32)	Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position.
IndexOfAny(Char[], Int32, Int32)	Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position and examines a specified number of character positions.

IndexOfAny(Char[])

Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters.

C#

```
public int IndexOfAny (char[] anyOf);
```

Parameters

anyOf Char[]

A Unicode character array containing one or more characters to seek.

Returns

Int32

The zero-based index position of the first occurrence in this instance where any character in `anyOf` was found; -1 if no character in `anyOf` was found.

Exceptions

ArgumentNullException

`anyOf` is `null`.

Examples

The following example finds the first vowel in a string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      char[] chars = { 'a', 'e', 'i', 'o', 'u', 'y',
                       'A', 'E', 'I', 'O', 'U', 'Y' };
      String s = "The long and winding road...";
      Console.WriteLine("The first vowel in \n   {0}\nis found at
position {1}",
                        s, s.IndexOfAny(chars) + 1);
   }
}
// The example displays the following output:
//       The first vowel in
//          The long and winding road...
//       is found at position 3
```

Remarks

Index numbering starts from zero.

The search for `anyOf` is case-sensitive. If `anyOf` is an empty array, the method finds a match at the beginning of the string (that is, at index zero).

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.IndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

IndexOfAny(Char[], Int32)

Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position.

C#

```
public int IndexOfAny (char[] anyOf, int startIndex);
```

Parameters

`anyOf` Char[]

A Unicode character array containing one or more characters to seek.

`startIndex` Int32

The search starting position.

Returns

Int32

The zero-based index position of the first occurrence in this instance where any character in `anyOf` was found; -1 if no character in `anyOf` was found.

Exceptions

ArgumentNullException

`anyOf` is `null`.

ArgumentOutOfRangeException

`startIndex` is negative.

-or-

`startIndex` is greater than the number of characters in this instance.

Examples

The following example finds the index of the occurrence of any character of the string "is" within a substring of another string.

C#

```
// Sample for String.IndexOfAny(Char[], Int32)
using System;

class Sample {
    public static void Main()
    {
    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
```

```
    string target = "is";
    char[] anyOf = target.ToCharArray();

    start = str.Length/2;
    Console.WriteLine();
    Console.WriteLine("The first character occurrence from position {0}
to {1}.",
                            start, str.Length-1);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("A character in '{0}' occurs at position: ", target);

    at = str.IndexOfAny(anyOf, start);
    if (at > -1)
        Console.Write(at);
    else
        Console.Write("(not found)");
    Console.WriteLine();
    }
}
/*

The first character occurrence from position 33 to 66.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

A character in 'is' occurs at position: 49

*/
```

Remarks

Index numbering starts from zero. The `startIndex` parameter can range from 0 to one less than the length of the string instance.

The search ranges from `startIndex` to the end of the string.

The search for `anyOf` is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar value are the same. To perform a culture-sensitive search, use the CompareInfo.IndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

IndexOfAny(Char[], Int32, Int32)

Reports the zero-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position and examines a specified number of character positions.

C#

```
public int IndexOfAny (char[] anyOf, int startIndex, int count);
```

Parameters

anyOf Char[]

A Unicode character array containing one or more characters to seek.

startIndex Int32

The search starting position.

`count` Int32

The number of character positions to examine.

Returns

Int32

The zero-based index position of the first occurrence in this instance where any character in `anyOf` was found; -1 if no character in `anyOf` was found.

Exceptions

ArgumentNullException

`anyOf` is `null`.

ArgumentOutOfRangeException

`count` or `startIndex` is negative.

-or-

`count` + `startIndex` is greater than the number of characters in this instance.

Examples

The following example finds the index of the occurrence of any character of the string "aid" within a substring of another string.

C#

```
// Sample for String.IndexOfAny(Char[], Int32, Int32)
using System;

class Sample {
    public static void Main()
    {
    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
    int count;
    string target = "aid";
    char[] anyOf = target.ToCharArray();
```

```
    start = (str.Length-1)/3;
    count = (str.Length-1)/4;
    Console.WriteLine();
    Console.WriteLine("The first character occurrence from position {0}
for {1} characters.", start, count);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("A character in '{0}' occurs at position: ", target);

    at = str.IndexOfAny(anyOf, start, count);
    if (at > -1)
        Console.Write(at);
    else
        Console.Write("(not found)");
    Console.WriteLine();
    }
}
/*

The first character occurrence from position 22 for 16 characters.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

A character in 'aid' occurs at position: 27

*/
```

Remarks

The search begins at `startIndex` and continues to `startIndex` + `count` -1. The character at `startIndex` + `count` is not included in the search.

Index numbering starts from zero. The `startIndex` parameter can range from 0 to one less than the length of the string instance.

The search for `anyOf` is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar value are the same. To perform a culture-sensitive search, use the CompareInfo.IndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

String.Insert(Int32, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string in which a specified string is inserted at a specified index position in this instance.

```
C#
public string Insert (int startIndex, string value);
```

Parameters

`startIndex` Int32

The zero-based index position of the insertion.

`value` String

The string to insert.

Returns

String

A new string that is equivalent to this instance, but with `value` inserted at position `startIndex`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` is negative or greater than the length of this instance.

Examples

The following example inserts a space character in the fourth character position (the character at index 3) of a string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String original = "aaabbb";
      Console.WriteLine("The original string: '{0}'", original);
      String modified = original.Insert(3, " ");
      Console.WriteLine("The modified string: '{0}'", modified);
   }
}
// The example displays the following output:
//     The original string: 'aaabbb'
//     The modified string: 'aaa bbb'
```

The following console application prompts the users to enter one or more adjectives to describe two animals. It then calls the Insert method to insert the text entered by the user into a string.

C#

```
using System;

public class Example {
    public static void Main()
    {
        string animal1 = "fox";
        string animal2 = "dog";
