        Console.Write("Enter an adjective (or group of adjectives) " +
                      "to describe the {0}: ==> ", animal1);
        string adj1 = Console.ReadLine();

        Console.Write("Enter an adjective (or group of adjectives) " +
                      "to describe the {0}: ==> ", animal2);
        string adj2 = Console.ReadLine();

        adj1 = adj1.Trim() + " ";
        adj2 = adj2.Trim() + " ";
```

```
        strTarget = strTarget.Insert(strTarget.IndexOf(animal1), adj1);
        strTarget = strTarget.Insert(strTarget.IndexOf(animal2), adj2);

        Console.WriteLine("{0}The final string is:{0}{1}",
                          Environment.NewLine, strTarget);
    }
}
// Output from the example might appear as follows:
//       The original string is:
//       The fox jumps over the dog.
//
//       Enter an adjective (or group of adjectives) to describe the fox:
==> bold
//       Enter an adjective (or group of adjectives) to describe the dog:
==> lazy
//
//       The final string is:
//       The bold fox jumps over the lazy dog.
```

Remarks

If `startIndex` is equal to the length of this instance, `value` is appended to the end of this instance.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which `value` is inserted into the current instance.

For example, the return value of `"abc".Insert(2, "XYZ")` is "abXYZc".

String.Intern(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves the system's reference to the specified String.

C#

```
public static string Intern (string str);
```

Parameters

`str` String

A string to search for in the intern pool.

Returns

String

The system's reference to `str`, if it is interned; otherwise, a new reference to a string with the value of `str`.

Exceptions

ArgumentNullException

`str` is `null`.

Examples

The following example uses three strings that are equal in value to determine whether a newly created string and an interned string are equal.

C#

```
// Sample for String.Intern(String)
using System;
using System.Text;
```

```
class Sample
{
    public static void Main()
    {
        string s1 = "MyTest";
        string s2 = new
StringBuilder().Append("My").Append("Test").ToString();
        string s3 = String.Intern(s2);
        Console.WriteLine($"s1 == {s1}");
        Console.WriteLine($"s2 == {s2}");
        Console.WriteLine($"s3 == {s3}");
        Console.WriteLine($"Is s2 the same reference as s1?: {(Object)s2 ==
(Object)s1}");
        Console.WriteLine($"Is s3 the same reference as s1?: {(Object)s3 ==
(Object)s1}");
    }
}
/*
This example produces the following results:
s1 == MyTest
s2 == MyTest
s3 == MyTest
Is s2 the same reference as s1?: False
Is s3 the same reference as s1?: True
*/
```

Remarks

For more information about this API, see Supplemental API remarks for String.Intern.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.IsInterned(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves a reference to a specified String.

C#

```
public static string? IsInterned (string str);
```

Parameters

`str` String

The string to search for in the intern pool.

Returns

String

A reference to `str` if it is in the common language runtime intern pool; otherwise, `null`.

Exceptions

ArgumentNullException

`str` is `null`.

Examples

The following example demonstrates that literal strings are interned automatically by the compiler.

C#

```
// Sample for String.IsInterned(String)
using System;
using System.Text;
using System.Runtime.CompilerServices;
```

```
// In the .NET Framework 2.0 the following attribute declaration allows you
to
// avoid the use of the interning when you use NGEN.exe to compile an
assembly
// to the native image cache.
[assembly: CompilationRelaxations(CompilationRelaxations.NoStringInterning)]
class Sample
{
    public static void Main()
    {
        // String str1 is known at compile time, and is automatically
interned.
        String str1 = "abcd";

        // Constructed string, str2, is not explicitly or automatically
interned.
        String str2 = new
StringBuilder().Append("wx").Append("yz").ToString();
        Console.WriteLine();
        Test(1, str1);
        Test(2, str2);
    }

    public static void Test(int sequence, String str)
    {
        Console.Write("{0}) The string, '", sequence);
        String strInterned = String.IsInterned(str);
        if (strInterned == null)
            Console.WriteLine("{0}', is not interned.", str);
        else
            Console.WriteLine("{0}', is interned.", strInterned);
    }
}

//This example produces the following results:

//1) The string, 'abcd', is interned.
//2) The string, 'wxyz', is not interned.

//If you use NGEN.exe to compile the assembly to the native image cache,
this
//example produces the following results:

//1) The string, 'abcd', is not interned.
//2) The string, 'wxyz', is not interned.
```

Remarks

The common language runtime automatically maintains a table, called the intern pool, which contains a single instance of each unique literal string constant declared in a

program, as well as any unique instance of String you add programmatically by calling the Intern method.

The intern pool conserves string storage. If you assign a literal string constant to several variables, each variable is set to reference the same constant in the intern pool instead of referencing several different instances of String that have identical values.

This method looks up `str` in the intern pool. If `str` has already been interned, a reference to that instance is returned; otherwise, `null` is returned.

Compare this method to the Intern method.

This method does not return a Boolean value. If you call the method because you want a Boolean value that indicates whether a particular string is interned, you can use code such as the following.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string str1 = "a";
      string str2 = str1 + "b";
      string str3 = str2 + "c";
      string[] strings = { "value", "part1" + "_" + "part2", str3,
                           String.Empty, null };
      foreach (var value in strings) {
         if (value == null) continue;

         bool interned = String.IsInterned(value) != null;
         if (interned)
            Console.WriteLine("'{0}' is in the string intern pool.",
                              value);
         else
            Console.WriteLine("'{0}' is not in the string intern pool.",
                              value);
      }
   }
}
// The example displays the following output:
//       'value' is in the string intern pool.
//       'part1_part2' is in the string intern pool.
//       'abc' is not in the string intern pool.
//       '' is in the string intern pool.
```

Note

You can override the use of the intern pool when you use **Ngen.exe (Native Image Generator)** to install an assembly to the native image cache on a local computer. For more information, see Performance Considerations in the Remarks section for the **Intern** property.

String.IsNormalized Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether this string is in a particular Unicode normalization form.

Overloads

Expand table

IsNormalized(NormalizationForm)	Indicates whether this string is in the specified Unicode normalization form.
IsNormalized()	Indicates whether this string is in Unicode normalization form C.

Examples

The following example determines whether a string is successfully normalized to various normalization forms.

C#

```
using System;
using System.Text;

class Example
{
    public static void Main()
    {
       // Character c; combining characters acute and cedilla; character 3/4
       string s1 = new String( new char[] {'\u0063', '\u0301', '\u0327',
'\u00BE'});
       string s2 = null;
       string divider = new String('-', 80);
       divider = String.Concat(Environment.NewLine, divider,
Environment.NewLine);

       Show("s1", s1);
       Console.WriteLine();
```

```
        Console.WriteLine("U+0063 = LATIN SMALL LETTER C");
        Console.WriteLine("U+0301 = COMBINING ACUTE ACCENT");
        Console.WriteLine("U+0327 = COMBINING CEDILLA");
        Console.WriteLine("U+00BE = VULGAR FRACTION THREE QUARTERS");
        Console.WriteLine(divider);

        Console.WriteLine("A1) Is s1 normalized to the default form (Form
C)?: {0}",
                                    s1.IsNormalized());
        Console.WriteLine("A2) Is s1 normalized to Form C?:  {0}",

s1.IsNormalized(NormalizationForm.FormC));
        Console.WriteLine("A3) Is s1 normalized to Form D?:  {0}",

s1.IsNormalized(NormalizationForm.FormD));
        Console.WriteLine("A4) Is s1 normalized to Form KC?: {0}",

s1.IsNormalized(NormalizationForm.FormKC));
        Console.WriteLine("A5) Is s1 normalized to Form KD?: {0}",

s1.IsNormalized(NormalizationForm.FormKD));

        Console.WriteLine(divider);

        Console.WriteLine("Set string s2 to each normalized form of string
s1.");
        Console.WriteLine();
        Console.WriteLine("U+1E09 = LATIN SMALL LETTER C WITH CEDILLA AND
ACUTE");
        Console.WriteLine("U+0033 = DIGIT THREE");
        Console.WriteLine("U+2044 = FRACTION SLASH");
        Console.WriteLine("U+0034 = DIGIT FOUR");
        Console.WriteLine(divider);

        s2 = s1.Normalize();
        Console.Write("B1) Is s2 normalized to the default form (Form C)?:
");
        Console.WriteLine(s2.IsNormalized());
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormC);
        Console.Write("B2) Is s2 normalized to Form C?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormC));
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormD);
        Console.Write("B3) Is s2 normalized to Form D?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormD));
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormKC);
        Console.Write("B4) Is s2 normalized to Form KC?: ");
```

```
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormKC));
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormKD);
        Console.Write("B5) Is s2 normalized to Form KD?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormKD));
        Show("s2", s2);
        Console.WriteLine();
    }

    private static void Show(string title, string s)
    {
        Console.Write("Characters in string {0} = ", title);
        foreach(short x in s) {
            Console.Write("{0:X4} ", x);
        }
        Console.WriteLine();
    }
}
/*
This example produces the following results:

Characters in string s1 = 0063 0301 0327 00BE

U+0063 = LATIN SMALL LETTER C
U+0301 = COMBINING ACUTE ACCENT
U+0327 = COMBINING CEDILLA
U+00BE = VULGAR FRACTION THREE QUARTERS

--------------------------------------------------------------------------
----

A1) Is s1 normalized to the default form (Form C)?: False
A2) Is s1 normalized to Form C?:  False
A3) Is s1 normalized to Form D?:  False
A4) Is s1 normalized to Form KC?: False
A5) Is s1 normalized to Form KD?: False

--------------------------------------------------------------------------
----

Set string s2 to each normalized form of string s1.

U+1E09 = LATIN SMALL LETTER C WITH CEDILLA AND ACUTE
U+0033 = DIGIT THREE
U+2044 = FRACTION SLASH
U+0034 = DIGIT FOUR

--------------------------------------------------------------------------
----

B1) Is s2 normalized to the default form (Form C)?: True
Characters in string s2 = 1E09 00BE
```

```
B2) Is s2 normalized to Form C?: True
Characters in string s2 = 1E09 00BE

B3) Is s2 normalized to Form D?: True
Characters in string s2 = 0063 0327 0301 00BE

B4) Is s2 normalized to Form KC?: True
Characters in string s2 = 1E09 0033 2044 0034

B5) Is s2 normalized to Form KD?: True
Characters in string s2 = 0063 0327 0301 0033 2044 0034

*/
```

IsNormalized(NormalizationForm)

Indicates whether this string is in the specified Unicode normalization form.

```
C#

public bool IsNormalized (System.Text.NormalizationForm
normalizationForm);
```

Parameters

`normalizationForm` NormalizationForm

A Unicode normalization form.

Returns

Boolean

`true` if this string is in the normalization form specified by the `normalizationForm` parameter; otherwise, `false`.

Exceptions

ArgumentException

The current instance contains invalid Unicode characters.

Remarks

Some Unicode characters have multiple equivalent binary representations consisting of sets of combining and/or composite Unicode characters. The existence of multiple

representations for a single character complicates searching, sorting, matching, and other operations.

The Unicode standard defines a process called normalization that returns one binary representation when given any of the equivalent binary representations of a character. Normalization can be performed with several algorithms, called normalization forms, that obey different rules. .NET currently supports normalization forms C, D, KC, and KD.

For a description of supported Unicode normalization forms, see System.Text.NormalizationForm.

Notes to Callers

The IsNormalized method returns `false` as soon as it encounters the first non-normalized character in a string. Therefore, if a string contains non-normalized characters followed by invalid Unicode characters, the Normalize method will throw an ArgumentException although IsNormalized returns `false`.

.NET Standard	2.0, 2.1

IsNormalized()

Indicates whether this string is in Unicode normalization form C.

C#

```
public bool IsNormalized ();
```

Returns

Boolean

`true` if this string is in normalization form C; otherwise, `false`.

Exceptions

ArgumentException

The current instance contains invalid Unicode characters.

Remarks

Some Unicode characters have multiple equivalent binary representations consisting of sets of combining and/or composite Unicode characters. The existence of multiple representations for a single character complicates searching, sorting, matching, and other operations.

The Unicode standard defines a process called normalization that returns one binary representation when given any of the equivalent binary representations of a character. Normalization can be performed with several algorithms, called normalization forms, that obey different rules. .NET currently supports normalization forms C, D, KC, and KD.

For a description of supported Unicode normalization forms, see System.Text.NormalizationForm.

Notes to Callers

The IsNormalized method returns `false` as soon as it encounters the first non-normalized character in a string. Therefore, if a string contains non-normalized characters followed by invalid Unicode characters, the Normalize method will throw an ArgumentException although IsNormalized returns `false`.

String.IsNullOrEmpty(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the specified string is `null` or an empty string ("").

C#

```
public static bool IsNullOrEmpty (string? value);
```

Parameters

`value` String

The string to test.

Returns

Boolean

`true` if the `value` parameter is `null` or an empty string (""); otherwise, `false`.

Examples

The following example examines three strings and determines whether each string has a value, is an empty string, or is `null`.

C#

```
string s1 = "abcd";
string s2 = "";
string s3 = null;

Console.WriteLine("String s1 {0}.", Test(s1));
Console.WriteLine("String s2 {0}.", Test(s2));
Console.WriteLine("String s3 {0}.", Test(s3));

String Test(string s)
{
if (String.IsNullOrEmpty(s))
```

```
    return "is null or empty";
else
    return String.Format("(\"{0}\") is neither null nor empty", s);
}

// The example displays the following output:
//       String s1 ("abcd") is neither null nor empty.
//       String s2 is null or empty.
//       String s3 is null or empty.
```

Remarks

For more information about this API, see Supplemental API remarks for String.IsNullOrEmpty.

String.IsNullOrWhiteSpace(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified string is `null`, empty, or consists only of white-space characters.

```
C#

public static bool IsNullOrWhiteSpace (string? value);
```

Parameters

`value` String

The string to test.

Returns

Boolean

`true` if the `value` parameter is `null` or Empty, or if `value` consists exclusively of white-space characters.

Examples

The following example creates a string array, and then passes each element of the array to the IsNullOrWhiteSpace method.

```
C#

using System;

public class Example
{
   public static void Main()
   {
```

```
        string[] values = { null, String.Empty, "ABCDE",
                            new String(' ', 20), "  \t   ",
                            new String('\u2000', 10) };
        foreach (string value in values)
           Console.WriteLine(String.IsNullOrWhiteSpace(value));
    }
}
// The example displays the following output:
//       True
//       True
//       False
//       True
//       True
//       True
```

Remarks

IsNullOrWhiteSpace is a convenience method that is similar to the following code, except that it offers superior performance:

```
C#

return String.IsNullOrEmpty(value) || value.Trim().Length == 0;
```

White-space characters are defined by the Unicode standard. The IsNullOrWhiteSpace method interprets any character that returns a value of `true` when it is passed to the Char.IsWhiteSpace method as a white-space character.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

String.Join Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Concatenates the elements of a specified array or the members of a collection, using the specified separator between each element or member.

Overloads

Expand table

Join(Char, Object[])	Concatenates the string representations of an array of objects, using the specified separator between each member.
Join(Char, String[])	Concatenates an array of strings, using the specified separator between each member.
Join(String, IEnumerable<String>)	Concatenates the members of a constructed IEnumerable<T> collection of type String, using the specified separator between each member.
Join(String, Object[])	Concatenates the elements of an object array, using the specified separator between each element.
Join(String, String[])	Concatenates all the elements of a string array, using the specified separator between each element.
Join(Char, String[], Int32, Int32)	Concatenates an array of strings, using the specified separator between each member, starting with the element in `value` located at the `startIndex` position, and concatenating up to `count` elements.
Join(String, String[], Int32, Int32)	Concatenates the specified elements of a string array, using the specified separator between each element.
Join<T>(Char, IEnumerable<T>)	Concatenates the members of a collection, using the specified separator between each member.
Join<T>(String, IEnumerable<T>)	Concatenates the members of a collection, using the specified separator between each member.

Join(Char, Object[])

Concatenates the string representations of an array of objects, using the specified separator between each member.

```
C#
public static string Join (char separator, params object?[] values);
```

Parameters

`separator` Char

The character to use as a separator. `separator` is included in the returned string only if `value` has more than one element.

`values` Object[]

An array of objects whose string representations will be concatenated.

Returns

String

A string that consists of the elements of `values` delimited by the `separator` character.

-or-

Empty if `values` has zero elements.

Exceptions

ArgumentNullException

`value` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Join(Char, String[])

Concatenates an array of strings, using the specified separator between each member.

```
C#
public static string Join (char separator, params string?[] value);
```

Parameters

`separator` Char

The character to use as a separator. `separator` is included in the returned string only if `value` has more than one element.

`value` String[]

An array of strings to concatenate.

Returns

String

A string that consists of the elements of `value` delimited by the `separator` character.

-or-

Empty if `value` has zero elements.

Exceptions

ArgumentNullException

`value` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Join(String, IEnumerable<String>)

Concatenates the members of a constructed IEnumerable<T> collection of type String, using the specified separator between each member.

C#

```
public static string Join (string? separator,
System.Collections.Generic.IEnumerable<string?> values);
```

Parameters

`separator` String

The string to use as a separator. `separator` is included in the returned string only if `values` has more than one element.

`values` IEnumerable<String>

A collection that contains the strings to concatenate.

Returns

String

A string that consists of the elements of `values` delimited by the `separator` string.

-or-

Empty if `values` has zero elements.

Exceptions

ArgumentNullException

`values` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Examples

The following example uses the Sieve of Eratosthenes algorithm to calculate the prime numbers that are less than or equal to 100. It assigns the result to a List<T> object of type String, which it then passes to the Join(String, IEnumerable<String>) method.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      int maxPrime = 100;
      List<int> primes = GetPrimes(maxPrime);
      Console.WriteLine("Primes less than {0}:", maxPrime);
      Console.WriteLine("   {0}", String.Join(" ", primes));
   }

   private static List<int> GetPrimes(int maxPrime)
   {
      Array values = Array.CreateInstance(typeof(int),
                              new int[] { maxPrime - 1}, new int[] { 2
});
      // Use Sieve of Eratosthenes to determine prime numbers.
      for (int ctr = values.GetLowerBound(0); ctr <= (int)
Math.Ceiling(Math.Sqrt(values.GetUpperBound(0))); ctr++)
      {

         if ((int) values.GetValue(ctr) == 1) continue;

         for (int multiplier = ctr; multiplier <=  maxPrime / 2;
multiplier++)
            if (ctr * multiplier <= maxPrime)
               values.SetValue(1, ctr * multiplier);
      }

      List<int> primes = new List<int>();
      for (int ctr = values.GetLowerBound(0); ctr <=
values.GetUpperBound(0); ctr++)
         if ((int) values.GetValue(ctr) == 0)
```

```
            primes.Add(ctr);
        return primes;
    }
}
// The example displays the following output:
//    Primes less than 100:
//       2 3 5 7 11 13 17 19 23 29 31 37 41 43 47 53 59 61 67 71 73 79 83
89 97
```

Remarks

If `separator` is `null`, an empty string (String.Empty) is used instead. If any member of `values` is `null`, an empty string is used instead.

Join(String, IEnumerable<String>) is a convenience method that lets you concatenate each element in an `IEnumerable(Of String)` collection without first converting the elements to a string array. It is particularly useful with Language-Integrated Query (LINQ) query expressions. The following example passes a `List(Of String)` object that contains either the uppercase or lowercase letters of the alphabet to a lambda expression that selects letters that are equal to or greater than a particular letter (which, in the example, is "M"). The `IEnumerable(Of String)` collection returned by the Enumerable.Where method is passed to the Join(String, IEnumerable<String>) method to display the result as a single string.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Example
{
   public static void Main()
   {
      string output = String.Join(" ", GetAlphabet(true).Where( letter =>
                      letter.CompareTo("M") >= 0));
      Console.WriteLine(output);
   }

   private static List<string> GetAlphabet(bool upper)
   {
      List<string> alphabet = new List<string>();
      int charValue = upper ? 65 : 97;
      for (int ctr = 0; ctr <= 25; ctr++)
         alphabet.Add(((char)(charValue + ctr)).ToString());
      return alphabet;
   }
}
```

```
// The example displays the following output:
//      M N O P Q R S T U V W X Y Z
```

UWP	10.0

Join(String, Object[])

Concatenates the elements of an object array, using the specified separator between each element.

C#

```
public static string Join (string? separator, params object?[] values);
```

Parameters

`separator` String

The string to use as a separator. `separator` is included in the returned string only if `values` has more than one element.

`values` Object[]

An array that contains the elements to concatenate.

Returns

String

A string that consists of the elements of `values` delimited by the `separator` string.

-or-

Empty if `values` has zero elements.

-or-

.NET Framework only: Empty if the first element of `values` is `null`.

Exceptions

ArgumentNullException

`values` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Examples

The following example uses the Sieve of Eratosthenes algorithm to calculate the prime numbers that are less than or equal to 100. It assigns the result to a integer array, which it then passes to the Join(String, Object[]) method.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      int maxPrime = 100;
      int[] primes = GetPrimes(maxPrime);
      Console.WriteLine("Primes less than {0}:", maxPrime);
      Console.WriteLine("   {0}", String.Join(" ", primes));
   }

   private static int[] GetPrimes(int maxPrime)
   {
      Array values = Array.CreateInstance(typeof(int),
                                          new int[] { maxPrime - 1}, new int[] { 2
```

```
});
      // Use Sieve of Eratosthenes to determine prime numbers.
      for (int ctr = values.GetLowerBound(0); ctr <= (int)
Math.Ceiling(Math.Sqrt(values.GetUpperBound(0))); ctr++)
      {

         if ((int) values.GetValue(ctr) == 1) continue;

         for (int multiplier = ctr; multiplier <=  maxPrime / 2;
multiplier++)
            if (ctr * multiplier <= maxPrime)
               values.SetValue(1, ctr * multiplier);
      }

      List<int> primes = new List<int>();
      for (int ctr = values.GetLowerBound(0); ctr <=
values.GetUpperBound(0); ctr++)
         if ((int) values.GetValue(ctr) == 0)
            primes.Add(ctr);
      return primes.ToArray();
   }
}
// The example displays the following output:
//    Primes less than 100:
//       2 3 5 7 11 13 17 19 23 29 31 37 41 43 47 53 59 61 67 71 73 79 83
89 97
```

Remarks

If `separator` is `null` or if any element of `values` other than the first element is `null`, an empty string (String.Empty) is used instead. See the Notes for Callers section if the first element of `values` is `null`.

Join(String, Object[]) is a convenience method that lets you concatenate each element in an object array without explicitly converting its elements to strings. The string representation of each object in the array is derived by calling that object's `ToString` method.

Notes to Callers

.NET Framework only: If the first element of `values` is `null`, the Join(String, Object[]) method does not concatenate the elements in `values` but instead returns Empty. A number of workarounds for this issue are available. The easiest is to assign a value of Empty to the first element of the array, as the following example shows.

```
C#
```

```
object[] values = { null, "Cobb", 4189, 11434, .366 };
if (values[0] == null) values[0] = String.Empty;
Console.WriteLine(String.Join("|", values));

// The example displays the following output:
//       |Cobb|4189|11434|0.366
```

UWP	10.0

Join(String, String[])

Concatenates all the elements of a string array, using the specified separator between each element.

C#

```
public static string Join (string? separator, params string?[] value);
```

Parameters

`separator` String

The string to use as a separator. `separator` is included in the returned string only if `value` has more than one element.

`value` String[]

An array that contains the elements to concatenate.

Returns

String

A string that consists of the elements in `value` delimited by the `separator` string.

-or-

Empty if `values` has zero elements.

Exceptions

ArgumentNullException

`value` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Examples

The following example demonstrates the Join method.

C#

```
using System;

public class JoinTest
{
    public static void Main()
    {
        Console.WriteLine(MakeLine(0, 5, ", "));
        Console.WriteLine(MakeLine(1, 6, "  "));
        Console.WriteLine(MakeLine(9, 9, ": "));
        Console.WriteLine(MakeLine(4, 7, "< "));
    }

    private static string MakeLine(int initVal, int multVal, string sep)
    {
        string [] sArr = new string [10];

        for (int i = initVal; i < initVal + 10; i++)
            sArr[i - initVal] = String.Format("{0,-3}", i * multVal);
```

```
        return String.Join(sep, sArr);
    }
}
// The example displays the following output:
//       0  , 5  , 10 , 15 , 20 , 25 , 30 , 35 , 40 , 45
//       6    12   18   24   30   36   42   48   54   60
//       81 : 90 : 99 : 108: 117: 126: 135: 144: 153: 162
//       28 < 35 < 42 < 49 < 56 < 63 < 70 < 77 < 84 < 91
```

Remarks

For example, if `separator` is ", " and the elements of `value` are "apple", "orange", "grape", and "pear", `Join(separator, value)` returns "apple, orange, grape, pear".

If `separator` is `null`, an empty string (String.Empty) is used instead. If any element in `value` is `null`, an empty string is used instead.

Join(Char, String[], Int32, Int32)

Concatenates an array of strings, using the specified separator between each member, starting with the element in `value` located at the `startIndex` position, and concatenating up to `count` elements.

```
C#

public static string Join (char separator, string?[] value, int
startIndex, int count);
```

Parameters

separator Char

Concatenates an array of strings, using the specified separator between each member, starting with the element located at the specified index and including a specified number of elements.

value String[]

An array of strings to concatenate.

startIndex Int32

The first item in `value` to concatenate.

count Int32

The number of elements from `value` to concatenate, starting with the element in the `startIndex` position.

Returns

String

A string that consists of `count` elements of `value` starting at `startIndex` delimited by the `separator` character.

-or-

Empty if `count` is zero.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` or `count` are negative.

-or-

`startIndex` is greater than the length of `value` - `count`.

OutOfMemoryException
The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Join(String, String[], Int32, Int32)

Concatenates the specified elements of a string array, using the specified separator between each element.

C#

```
public static string Join (string? separator, string?[] value, int
startIndex, int count);
```

Parameters

`separator` String

The string to use as a separator. `separator` is included in the returned string only if `value` has more than one element.

`value` String[]

An array that contains the elements to concatenate.

`startIndex` Int32

The first element in `value` to use.

`count` Int32

The number of elements of `value` to use.

Returns

String

A string that consists of `count` elements of `value` starting at `startIndex` delimited by the `separator` character.

-or-

Empty if `count` is zero.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`startIndex` or `count` is less than 0.

-or-

`startIndex` plus `count` is greater than the number of elements in `value`.

OutOfMemoryException

Out of memory.

Examples

The following example concatenates two elements from an array of names of fruit.

C#

```
String[] val = {"apple", "orange", "grape", "pear"};
String sep   = ", ";
String result;

Console.WriteLine("sep = '{0}'", sep);
Console.WriteLine("val[] = {{'{0}' '{1}' '{2}' '{3}'}}", val[0], val[1],
val[2], val[3]);
result = String.Join(sep, val, 1, 2);
Console.WriteLine("String.Join(sep, val, 1, 2) = '{0}'", result);

// This example produces the following results:
// sep = ', '
// val[] = {'apple' 'orange' 'grape' 'pear'}
// String.Join(sep, val, 1, 2) = 'orange, grape'
```

Remarks

For example, if `separator` is ", " and the elements of `value` are "apple", "orange", "grape", and "pear", `Join(separator, value, 1, 2)` returns "orange, grape".

If `separator` is `null`, an empty string (String.Empty) is used instead. If any element in `value` is `null`, an empty string is used instead.

Join<T>(Char, IEnumerable<T>)

Concatenates the members of a collection, using the specified separator between each member.

C#

```
public static string Join<T> (char separator,
System.Collections.Generic.IEnumerable<T> values);
```

Type Parameters

T

The type of the members of `values`.

Parameters

`separator` Char

The character to use as a separator. `separator` is included in the returned string only if `values` has more than one element.

`values` IEnumerable<T>

A collection that contains the objects to concatenate.

Returns

String

A string that consists of the members of `values` delimited by the `separator` character.

-or-

Empty if `values` has no elements.

Exceptions

ArgumentNullException

`values` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Applies to

Join<T>(String, IEnumerable<T>)

Concatenates the members of a collection, using the specified separator between each member.

```
C#

public static string Join<T> (string? separator,
System.Collections.Generic.IEnumerable<T> values);
```

Type Parameters

T

The type of the members of `values`.

Parameters

separator String

The string to use as a separator. `separator` is included in the returned string only if `values` has more than one element.

values IEnumerable<T>

A collection that contains the objects to concatenate.

Returns

String

A string that consists of the elements of `values` delimited by the `separator` string.

-or-

Empty if `values` has no elements.

Exceptions

ArgumentNullException

`values` is `null`.

OutOfMemoryException

The length of the resulting string overflows the maximum allowed length (Int32.MaxValue).

Examples

The following example uses the Sieve of Eratosthenes algorithm to calculate the prime numbers that are less than or equal to 100. It assigns the result to a List<T> object of type integer, which it then passes to the Join<T>(String, IEnumerable<T>) method.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      int maxPrime = 100;
      List<int> primes = GetPrimes(maxPrime);
      Console.WriteLine("Primes less than {0}:", maxPrime);
      Console.WriteLine("   {0}", String.Join(" ", primes));
   }

   private static List<int> GetPrimes(int maxPrime)
   {
      Array values = Array.CreateInstance(typeof(int),
                              new int[] { maxPrime - 1}, new int[] { 2
});
      // Use Sieve of Eratosthenes to determine prime numbers.
      for (int ctr = values.GetLowerBound(0); ctr <= (int)
Math.Ceiling(Math.Sqrt(values.GetUpperBound(0))); ctr++)
      {

         if ((int) values.GetValue(ctr) == 1) continue;

         for (int multiplier = ctr; multiplier <=  maxPrime / 2;
multiplier++)
            if (ctr * multiplier <= maxPrime)
               values.SetValue(1, ctr * multiplier);
      }

      List<int> primes = new List<int>();
      for (int ctr = values.GetLowerBound(0); ctr <=
values.GetUpperBound(0); ctr++)
         if ((int) values.GetValue(ctr) == 0)
            primes.Add(ctr);
      return primes;
   }
}
// The example displays the following output:
//    Primes less than 100:
//       2 3 5 7 11 13 17 19 23 29 31 37 41 43 47 53 59 61 67 71 73 79 83
89 97
```

Remarks

If `separator` is `null`, an empty string (String.Empty) is used instead. If any member of `values` is `null`, an empty string is used instead.

Join<T>(String, IEnumerable<T>) is a convenience method that lets you concatenate each member of an IEnumerable<T> collection without first converting them to strings. The string representation of each object in the IEnumerable<T> collection is derived by calling that object's `ToString` method.

This method is particular useful with Language-Integrated Query (LINQ) query expressions. For example, the following code defines a very simple `Animal` class that contains the name of an animal and the order to which it belongs. It then defines a List<T> object that contains a number of `Animal` objects. The Enumerable.Where extension method is called to extract the `Animal` objects whose `Order` property equals "Rodent". The result is passed to the Join<T>(String, IEnumerable<T>) method.

C#

```
using System;
using System.Collections.Generic;
using System.Linq;

public class Animal
{
   public string Kind;
   public string Order;

   public Animal(string kind, string order)
   {
      this.Kind = kind;
      this.Order = order;
   }

   public override string ToString()
   {
      return this.Kind;
   }
}

public class Example
{
   public static void Main()
   {
      List<Animal> animals = new List<Animal>();
      animals.Add(new Animal("Squirrel", "Rodent"));
      animals.Add(new Animal("Gray Wolf", "Carnivora"));
      animals.Add(new Animal("Capybara", "Rodent"));
```

```
        string output = String.Join(" ", animals.Where( animal =>
                                (animal.Order == "Rodent")));
        Console.WriteLine(output);
    }
}
// The example displays the following output:
//      Squirrel Capybara
```

String.LastIndexOf Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reports the zero-based index position of the last occurrence of a specified Unicode character or string within this instance. The method returns -1 if the character or string is not found in this instance.

Overloads

Expand table

LastIndexOf(String, Int32, Int32, StringComparison)	Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for the specified number of character positions. A parameter specifies the type of comparison to perform when searching for the specified string.
LastIndexOf(String, Int32, StringComparison)	Reports the zero-based index of the last occurrence of a specified string within the current String object. The search starts at a specified character position and proceeds backward toward the beginning of the string. A parameter specifies the type of comparison to perform when searching for the specified string.
LastIndexOf(String, Int32, Int32)	Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.
LastIndexOf(Char, Int32, Int32)	Reports the zero-based index position of the last occurrence of the specified Unicode character in a substring within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.
LastIndexOf(String, Int32)	Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string.

LastIndexOf(Char, Int32)	Reports the zero-based index position of the last occurrence of a specified Unicode character within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string.
LastIndexOf(String)	Reports the zero-based index position of the last occurrence of a specified string within this instance.
LastIndexOf(Char)	Reports the zero-based index position of the last occurrence of a specified Unicode character within this instance.
LastIndexOf(String, StringComparison)	Reports the zero-based index of the last occurrence of a specified string within the current String object. A parameter specifies the type of search to use for the specified string.

LastIndexOf(String, Int32, Int32, StringComparison)

Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for the specified number of character positions. A parameter specifies the type of comparison to perform when searching for the specified string.

C#

```
public int LastIndexOf (string value, int startIndex, int count,
StringComparison comparisonType);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position. The search proceeds from `startIndex` toward the beginning of this instance.

`count` Int32

The number of character positions to examine.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules for the search.

Returns

Int32

The zero-based starting index position of the `value` parameter if that string is found, or -1 if it is not found or if the current instance equals Empty.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`count` is negative.

-or-

The current instance does not equal Empty, and `startIndex` is negative.

-or-

The current instance does not equal Empty, and `startIndex` is greater than the length of this instance.

-or-

The current instance does not equal Empty, and `startIndex` + 1 - `count` specifies a position that is not within this instance.

-or-

The current instance equals Empty and `start` is less than -1 or greater than zero.

-or-

The current instance equals Empty and `count` is greater than 1.

ArgumentException

`comparisonType` is not a valid StringComparison value.

Examples

The following example demonstrates three overloads of the LastIndexOf method that find the last occurrence of a string within another string using different values of the StringComparison enumeration.

C#

```
// This code example demonstrates the
// System.String.LastIndexOf(String, ..., StringComparison) methods.

using System;
using System.Threading;
using System.Globalization;

class Sample
{
    public static void Main()
    {
    string intro = "Find the last occurrence of a character using
different " +
                   "values of StringComparison.";
    string resultFmt = "Comparison: {0,-28} Location: {1,3}";

// Define a string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
    string CapitalAWithRing = "\u00c5";

// Define a string to search.
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string cat = "A Cheshire c" + "\u0061\u030a" + "t";
    int loc = 0;
    StringComparison[] scValues = {
        StringComparison.CurrentCulture,
        StringComparison.CurrentCultureIgnoreCase,
        StringComparison.InvariantCulture,
        StringComparison.InvariantCultureIgnoreCase,
        StringComparison.Ordinal,
        StringComparison.OrdinalIgnoreCase };

// Clear the screen and display an introduction.
    Console.Clear();
    Console.WriteLine(intro);

// Display the current culture because culture affects the result. For
example,
// try this code example with the "sv-SE" (Swedish-Sweden) culture.

    Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
    Console.WriteLine("The current culture is \"{0}\" - {1}.",
                      Thread.CurrentThread.CurrentCulture.Name,
```

```
                        Thread.CurrentThread.CurrentCulture.DisplayName);

// Display the string to search for and the string to search.
    Console.WriteLine("Search for the string \"{0}\" in the string \"
{1}\"",
                        CapitalAWithRing, cat);
    Console.WriteLine();

// Note that in each of the following searches, we look for
// LATIN CAPITAL LETTER A WITH RING ABOVE in a string that contains
// LATIN SMALL LETTER A WITH RING ABOVE. A result value of -1 indicates
// the string was not found.
// Search using different values of StringComparsion. Specify the start
// index and count.

    Console.WriteLine("Part 1: Start index and count are specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.LastIndexOf(CapitalAWithRing, cat.Length-1, cat.Length,
sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparsion. Specify the
// start index.
    Console.WriteLine("\nPart 2: Start index is specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.LastIndexOf(CapitalAWithRing, cat.Length-1, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparsion.
    Console.WriteLine("\nPart 3: Neither start index nor count is
specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.LastIndexOf(CapitalAWithRing, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }
    }
}

/*
Note: This code example was executed on a console whose user interface
culture is "en-US" (English-United States).

This code example produces the following results:

Find the last occurrence of a character using different values of
StringComparison.
The current culture is "en-US" - English (United States).
Search for the string "Å" in the string "A Cheshire ca°t"

Part 1: Start index and count are specified.
```

```
Comparison: CurrentCulture                Location:  -1
Comparison: CurrentCultureIgnoreCase      Location:  12
Comparison: InvariantCulture              Location:  -1
Comparison: InvariantCultureIgnoreCase    Location:  12
Comparison: Ordinal                       Location:  -1
Comparison: OrdinalIgnoreCase             Location:  -1

Part 2: Start index is specified.
Comparison: CurrentCulture                Location:  -1
Comparison: CurrentCultureIgnoreCase      Location:  12
Comparison: InvariantCulture              Location:  -1
Comparison: InvariantCultureIgnoreCase    Location:  12
Comparison: Ordinal                       Location:  -1
Comparison: OrdinalIgnoreCase             Location:  -1

Part 3: Neither start index nor count is specified.
Comparison: CurrentCulture                Location:  -1
Comparison: CurrentCultureIgnoreCase      Location:  12
Comparison: InvariantCulture              Location:  -1
Comparison: InvariantCultureIgnoreCase    Location:  12
Comparison: Ordinal                       Location:  -1
Comparison: OrdinalIgnoreCase             Location:  -1

*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

The search begins at the `startIndex` character position and proceeds backward until either `value` is found or `count` character positions have been examined. For example, if `startIndex` is Length - 1, the method searches backward `count` characters from the last character in the string.

The `comparisonType` parameter specifies to search for the `value` parameter using:

- The current or invariant culture.
- A case-sensitive or case-insensitive search.
- Word or ordinal comparison rules.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search (that is, if `comparisonType` is not Ordinal or

OrdinalIgnoreCase), if `value` contains an ignorable character, the result is equivalent to searching with that character removed.

In the following example, the LastIndexOf(String, Int32, Int32, StringComparison) method is used to find the position of a soft hyphen (U+00AD) followed by an "m" in all but the first character position before the final "m" in two strings. Only one of the strings contains the required substring. If the example is run on .NET Framework 4 or later, in both cases, because the soft hyphen is an ignorable character, the method returns the index of "m" in the string when it performs a culture-sensitive comparison. When it performs an ordinal comparison, however, it finds the substring only in the first string. Note that in the case of the first string, which includes the soft hyphen followed by an "m", the method returns the index of the "m" when it performs a culture-sensitive comparison. The method returns the index of the soft hyphen in the first string only when it performs an ordinal comparison.

C#

```
string searchString = "\u00ADm";

string s1 = "ani\u00ADmal";
string s2 = "animal";

int position;

position = s1.LastIndexOf('m');
if (position >= 1)
{
    Console.WriteLine(s1.LastIndexOf(searchString, position, position,
StringComparison.CurrentCulture));
    Console.WriteLine(s1.LastIndexOf(searchString, position, position,
StringComparison.Ordinal));
}

position = s2.LastIndexOf('m');
if (position >= 1)
{
    Console.WriteLine(s2.LastIndexOf(searchString, position, position,
StringComparison.CurrentCulture));
    Console.WriteLine(s2.LastIndexOf(searchString, position, position,
StringComparison.Ordinal));
}

// The example displays the following output:
//
// 4
// 3
// 3
// -1
```

LastIndexOf(String, Int32, StringComparison)

Reports the zero-based index of the last occurrence of a specified string within the current String object. The search starts at a specified character position and proceeds backward toward the beginning of the string. A parameter specifies the type of comparison to perform when searching for the specified string.

C#

```
public int LastIndexOf (string value, int startIndex, StringComparison
comparisonType);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position. The search proceeds from `startIndex` toward the beginning of this instance.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules for the search.

Returns

Int32

The zero-based starting index position of the `value` parameter if that string is found, or -1 if it is not found or if the current instance equals Empty.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

The current instance does not equal Empty, and `startIndex` is less than zero or greater than the length of the current instance.

-or-

The current instance equals Empty, and `startIndex` is less than -1 or greater than zero.

ArgumentException

`comparisonType` is not a valid StringComparison value.

Examples

The following example demonstrates three overloads of the LastIndexOf method that find the last occurrence of a string within another string using different values of the StringComparison enumeration.

C#

```
// This code example demonstrates the
// System.String.LastIndexOf(String, ..., StringComparison) methods.

using System;
using System.Threading;
using System.Globalization;

    string intro = "Find the last occurrence of a character using
different " +
                   "values of StringComparison.";
    string resultFmt = "Comparison: {0,-28} Location: {1,3}";

// Define a string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
```

```
    string CapitalAWithRing = "\u00c5";

// Define a string to search.
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string cat = "A Cheshire c" + "\u0061\u030a" + "t";
    int loc = 0;
    StringComparison[] scValues = {
        StringComparison.CurrentCulture,
        StringComparison.CurrentCultureIgnoreCase,
        StringComparison.InvariantCulture,
        StringComparison.InvariantCultureIgnoreCase,
        StringComparison.Ordinal,
        StringComparison.OrdinalIgnoreCase };

// Clear the screen and display an introduction.
    Console.Clear();
    Console.WriteLine(intro);

// Display the current culture because culture affects the result. For
example,
// try this code example with the "sv-SE" (Swedish-Sweden) culture.

    Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
    Console.WriteLine("The current culture is \"{0}\" - {1}.",
                      Thread.CurrentThread.CurrentCulture.Name,
                      Thread.CurrentThread.CurrentCulture.DisplayName);

// Display the string to search for and the string to search.
    Console.WriteLine("Search for the string \"{0}\" in the string \"
{1}\"",
                      CapitalAWithRing, cat);
    Console.WriteLine();

*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

The search begins at the `startIndex` character position and proceeds backward until either `value` is found or the first character position has been examined. For example, if `startIndex` is Length - 1, the method searches every character from the last character in the string to the beginning.

The `comparisonType` parameter specifies to search for the `value` parameter using the current or invariant culture, using a case-sensitive or case-insensitive search, and using word or ordinal comparison rules.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search (that is, if `comparisonType` is not Ordinal or OrdinalIgnoreCase), if `value` contains an ignorable character, the result is equivalent to searching with that character removed.

In the following example, the LastIndexOf(String, Int32, StringComparison) method is used to find the position of a soft hyphen (U+00AD) followed by an "m", starting with the final "m" in two strings. Only one of the strings contains the required substring. If the example is run on .NET Framework 4 or later, in both cases, because the soft hyphen is an ignorable character, the method returns the index of "m" in the string when it performs a culture-sensitive comparison. Note that in the case of the first string, which includes the soft hyphen followed by an "m", the method returns the index of the "m" and not the index of the soft hyphen. The method returns the index of the soft hyphen in the first string only when it performs an ordinal comparison.

C#

```
string searchString = "\u00ADm";

string s1 = "ani\u00ADmal";
string s2 = "animal";

int position;

position = s1.LastIndexOf('m');
if (position >= 0)
```

```
{
    Console.WriteLine(s1.LastIndexOf(searchString, position,
StringComparison.CurrentCulture));
    Console.WriteLine(s1.LastIndexOf(searchString, position,
StringComparison.Ordinal));
}

position = s2.LastIndexOf('m');
if (position >= 0)
{
    Console.WriteLine(s2.LastIndexOf(searchString, position,
StringComparison.CurrentCulture));
    Console.WriteLine(s2.LastIndexOf(searchString, position,
StringComparison.Ordinal));
}

// The example displays the following output:
//
// 4
// 3
// 3
// -1
```

LastIndexOf(String, Int32, Int32)

Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.

```
C#
```

```
public int LastIndexOf (string value, int startIndex, int count);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position. The search proceeds from `startIndex` toward the beginning of this instance.

`count` Int32

The number of character positions to examine.

Returns

Int32

The zero-based starting index position of `value` if that string is found, or -1 if it is not found or if the current instance equals Empty.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

`count` is negative.

-or-

The current instance does not equal Empty, and `startIndex` is negative.

-or-

The current instance does not equal Empty, and `startIndex` is greater than the length of this instance.

-or-

The current instance does not equal Empty, and `startIndex` - `count` + 1 specifies a position that is not within this instance.

-or-

The current instance equals Empty and `start` is less than -1 or greater than zero.

-or-

The current instance equals Empty and `count` is greater than 1.

Examples

The following example finds the index of all occurrences of a string in substring, working from the end of the substring to the start of the substring.

C#

```
// Sample for String.LastIndexOf(String, Int32, Int32)
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
    int count;
    int end;

    start = str.Length-1;
    end = start/2 - 1;
    Console.WriteLine("All occurrences of 'he' from position {0} to
{1}.", start, end);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("The string 'he' occurs at position(s): ");

    count = 0;
    at = 0;
    while((start > -1) && (at > -1))
        {
        count = start - end; //Count must be within the substring.
        at = str.LastIndexOf("he", start, count);
        if (at > -1)
            {
            Console.Write("{0} ", at);
            start = at - 1;
            }
```

```
        }
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
}
/*
This example produces the following results:
All occurrences of 'he' from position 66 to 32.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

The string 'he' occurs at position(s): 56 45
*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

The search begins at the `startIndex` character position of this instance and proceeds backward toward the beginning until either `value` is found or `count` character positions have been examined. For example, if `startIndex` is Length - 1, the method searches backward `count` characters from the last character in the string.

This method performs a word (case-sensitive and culture-sensitive) search using the current culture.

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search, if `value` contains an ignorable character, the result is equivalent to searching with that character removed.

In the following example, the LastIndexOf method is used to find the position of a soft hyphen (U+00AD) followed by an "m" or "n" in two strings. Only one of the strings contains a soft hyphen. In the case of the string that includes the soft hyphen followed by an "m", `LastIndexOf` returns the index of the "m" when searching for the soft hyphen followed by "m".

C#

```
int position = 0;
string s1 = "ani\u00ADmal";
string s2 = "animal";

// Find the index of the soft hyphen followed by "n".
position = s1.LastIndexOf("m");
```

```
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s1.LastIndexOf("\u00ADn", position, position + 1));

position = s2.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s2.LastIndexOf("\u00ADn", position, position + 1));

// Find the index of the soft hyphen followed by "m".
position = s1.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s1.LastIndexOf("\u00ADm", position, position + 1));

position = s2.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s2.LastIndexOf("\u00ADm", position, position + 1));

// The example displays the following output:
//
// 'm' at position 4
// 1
// 'm' at position 3
// 1
// 'm' at position 4
// 4
// 'm' at position 3
// 3
```

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To perform this operation by using the comparison rules of the current culture, signal your intention explicitly by calling the LastIndexOf(String, Int32, Int32, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

UWP	10.0

LastIndexOf(Char, Int32, Int32)

Reports the zero-based index position of the last occurrence of the specified Unicode character in a substring within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.

C#

```
public int LastIndexOf (char value, int startIndex, int count);
```

Parameters

`value` Char

The Unicode character to seek.

`startIndex` Int32

The starting position of the search. The search proceeds from `startIndex` toward the beginning of this instance.

`count` Int32

The number of character positions to examine.

Returns

Int32

The zero-based index position of `value` if that character is found, or -1 if it is not found or if the current instance equals Empty.

Exceptions

ArgumentOutOfRangeException

The current instance does not equal Empty, and `startIndex` is less than zero or greater than or equal to the length of this instance.

-or-

The current instance does not equal Empty, and `startIndex` - `count` + 1 is less than zero.

Examples

The following example finds the index of all occurrences of a character in a substring, working from the end of the substring to the start of the substring.

C#

```
// Sample for String.LastIndexOf(Char, Int32, Int32)
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
    int count;
    int end;

    start = str.Length-1;
    end = start/2 - 1;
    Console.WriteLine("All occurrences of 't' from position {0} to {1}.",
start, end);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("The letter 't' occurs at position(s): ");
```

```
    count = 0;
    at = 0;
    while((start > -1) && (at > -1))
        {
        count = start - end; //Count must be within the substring.
        at = str.LastIndexOf('t', start, count);
        if (at > -1)
            {
            Console.Write("{0} ", at);
            start = at - 1;
            }
        }
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
}
/*
This example produces the following results:
All occurrences of 't' from position 66 to 32.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

The letter 't' occurs at position(s): 64 55 44 41 33

*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

This method begins searching at the `startIndex` character position and proceeds backward toward the beginning of this instance until either `value` is found or `count` character positions have been examined. For example, if `startIndex` is Length - 1, the method searches backward `count` characters from the last character in the string. The search is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar value are the same. To perform a culture-sensitive search, use the CompareInfo.LastIndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

LastIndexOf(String, Int32)

Reports the zero-based index position of the last occurrence of a specified string within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string.

C#

```
public int LastIndexOf (string value, int startIndex);
```

Parameters

`value` String

The string to seek.

`startIndex` Int32

The search starting position. The search proceeds from `startIndex` toward the beginning of this instance.

Returns

Int32

The zero-based starting index position of `value` if that string is found, or -1 if it is not found or if the current instance equals Empty.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentOutOfRangeException

The current instance does not equal Empty, and `startIndex` is less than zero or greater than the length of the current instance.

-or-

The current instance equals Empty, and `startIndex` is less than -1 or greater than zero.

Examples

The following example finds the index of all occurrences of a string in target string, working from the end of the target string to the start of the target string.

C#

```
// Sample for String.LastIndexOf(String, Int32)
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;

    start = str.Length-1;
    Console.WriteLine("All occurrences of 'he' from position {0} to 0.",
start);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
```

```
    Console.Write("The string 'he' occurs at position(s): ");

    at = 0;
    while((start > -1) && (at > -1))
        {
        at = str.LastIndexOf("he", start);
        if (at > -1)
            {
            Console.Write("{0} ", at);
            start = at - 1;
            }
        }
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
}
/*
This example produces the following results:
All occurrences of 'he' from position 66 to 0.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

The string 'he' occurs at position(s): 56 45 8

*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

The search begins at the `startIndex` character position of this instance and proceeds backward toward the beginning until either `value` is found or the first character position has been examined. For example, if `startIndex` is Length - 1, the method searches every character from the last character in the string to the beginning.

This method performs a word (case-sensitive and culture-sensitive) search using the current culture.

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search, if `value` contains an ignorable character, the result is equivalent to searching with that character removed. In the following example, the LastIndexOf(String, Int32) method is used to find a substring that includes a soft hyphen (U+00AD) and that precedes or includes the final "m" in a string. If the example is run on .NET Framework 4 or later, because the soft hyphen in the search

string is ignored, calling the method to find a substring that consists of the soft hyphen and "m" returns the position of the "m" in the string, whereas calling it to find a substring that consists of the soft hyphen and "n" returns the position of the "n".

C#

```
int position = 0;
string s1 = "ani\u00ADmal";
string s2 = "animal";

// Find the index of the soft hyphen followed by "n".
position = s1.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s1.LastIndexOf("\u00ADn", position));

position = s2.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s2.LastIndexOf("\u00ADn", position));

// Find the index of the soft hyphen followed by "m".
position = s1.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s1.LastIndexOf("\u00ADm", position));

position = s2.LastIndexOf("m");
Console.WriteLine($"'m' at position {position}");

if (position >= 0)
    Console.WriteLine(s2.LastIndexOf("\u00ADm", position));

// The example displays the following output:
//
// 'm' at position 4
// 1
// 'm' at position 3
// 1
// 'm' at position 4
// 4
// 'm' at position 3
// 3
```

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To find the index of a substring that precedes a particular character position by using the comparison rules of the current culture, signal your intention explicitly by calling the LastIndexOf(String, Int32, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

LastIndexOf(Char, Int32)

Reports the zero-based index position of the last occurrence of a specified Unicode character within this instance. The search starts at a specified character position and proceeds backward toward the beginning of the string.

C#

```
public int LastIndexOf (char value, int startIndex);
```

Parameters

`value` Char

The Unicode character to seek.

`startIndex` Int32

The starting position of the search. The search proceeds from `startIndex` toward the beginning of this instance.

Returns

Int32

The zero-based index position of `value` if that character is found, or -1 if it is not found or if the current instance equals Empty.

Exceptions

ArgumentOutOfRangeException

The current instance does not equal Empty, and `startIndex` is less than zero or greater than or equal to the length of this instance.

Examples

The following example finds the index of all occurrences of a character in a string, working from the end of the string to the start of the string.

C#

```
// Sample for String.LastIndexOf(Char, Int32)
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;

    start = str.Length-1;
    Console.WriteLine("All occurrences of 't' from position {0} to 0.",
start);
```

```
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("The letter 't' occurs at position(s): ");

    at = 0;
    while((start > -1) && (at > -1))
        {
        at = str.LastIndexOf('t', start);
        if (at > -1)
            {
            Console.Write("{0} ", at);
            start = at - 1;
            }
        }
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
}
/*
This example produces the following results:
All occurrences of 't' from position 66 to 0.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

The letter 't' occurs at position(s): 64 55 44 41 33 11 7
*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1. This method begins searching at the `startIndex` character position of this instance and proceeds backward toward the beginning of the current instance until either `value` is found or the first character position has been examined. For example, if `startIndex` is Length - 1, the method searches every character from the last character in the string to the beginning. The search is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.LastIndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

LastIndexOf(String)

Reports the zero-based index position of the last occurrence of a specified string within this instance.

C#

```
public int LastIndexOf (string value);
```

Parameters

`value` String

The string to seek.

Returns

Int32

The zero-based starting index position of `value` if that string is found, or -1 if it is not.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example removes opening and closing HTML tags from a string if the tags begin and end the string. If a string ends with a closing bracket character (">"), the example uses the LastIndexOf method to locate the start of the end tag.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] strSource = { "<b>This is bold text</b>", "<H1>This is
large Text</H1>",
                "<b><i><font color=green>This has multiple tags</font></i>
</b>",
                "<b>This has <i>embedded</i> tags.</b>",
                "This line ends with a greater than symbol and should not
be modified>" };

      // Strip HTML start and end tags from each string if they are
present.
      foreach (string s in strSource)
      {
         Console.WriteLine("Before: " + s);
         string item = s;
         // Use EndsWith to find a tag at the end of the line.
         if (item.Trim().EndsWith(">"))
         {
            // Locate the opening tag.
            int endTagStartPosition = item.LastIndexOf("</");
            // Remove the identified section, if it is valid.
            if (endTagStartPosition >= 0 )
               item = item.Substring(0, endTagStartPosition);

            // Use StartsWith to find the opening tag.
            if (item.Trim().StartsWith("<"))
            {
               // Locate the end of opening tab.
               int openTagEndPosition = item.IndexOf(">");
               // Remove the identified section, if it is valid.
               if (openTagEndPosition >= 0)
                  item = item.Substring(openTagEndPosition + 1);
            }
         }
```

```
            // Display the trimmed string.
            Console.WriteLine("After: " + item);
            Console.WriteLine();
        }
    }
}
// The example displays the following output:
//    Before: <b>This is bold text</b>
//    After: This is bold text
//
//    Before: <H1>This is large Text</H1>
//    After: This is large Text
//
//    Before: <b><i><font color=green>This has multiple tags</font></i>
</b>
//    After: <i><font color=green>This has multiple tags</font></i>
//
//    Before: <b>This has <i>embedded</i> tags.</b>
//    After: This has <i>embedded</i> tags.
//
//    Before: This line ends with a greater than symbol and should not be
modified>
//    After: This line ends with a greater than symbol and should not be
modified>
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

The search begins at the last character position of this instance and proceeds backward toward the beginning until either `value` is found or the first character position has been examined.

This method performs a word (case-sensitive and culture-sensitive) search using the current culture.

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search, if `value` contains an ignorable character, the result is equivalent to searching with that character removed.

In the following example, the LastIndexOf(String) method is used to find two substrings (a soft hyphen followed by "n" and a soft hyphen followed by "m") in two strings. Only one of the strings contains a soft hyphen. If the example is run on .NET Framework 4 or later, in each case, because the soft hyphen is an ignorable

character, the result is the same as if the soft hyphen had not been included in `value`.

```
C#

string s1 = "ani\u00ADmal";
string s2 = "animal";

// Find the index of the last soft hyphen followed by "n".
Console.WriteLine(s1.LastIndexOf("\u00ADn"));
Console.WriteLine(s2.LastIndexOf("\u00ADn"));

// Find the index of the last soft hyphen followed by "m".
Console.WriteLine(s1.LastIndexOf("\u00ADm"));
Console.WriteLine(s2.LastIndexOf("\u00ADm"));

// The example displays the following output:
//
// 1
// 1
// 4
// 3
```

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To find the last index of a substring within a string instance by using the comparison rules of the current culture, signal your intention explicitly by calling the LastIndexOf(String, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

UWP	10.0

LastIndexOf(Char)

Reports the zero-based index position of the last occurrence of a specified Unicode character within this instance.

C#

```
public int LastIndexOf (char value);
```

Parameters

`value` Char

The Unicode character to seek.

Returns

Int32

The zero-based index position of `value` if that character is found, or -1 if it is not.

Examples

The following example defines an `ExtractFilename` method that uses the LastIndexOf(Char) method to find the last directory separator character in a string and to extract the string's file name. If the file exists, the method returns the file name without its path.

C#

```
using System;
using System.IO;
```

```
public class TestLastIndexOf
{
   public static void Main()
   {
      string filename;

      filename = ExtractFilename(@"C:\temp\");
      Console.WriteLine("{0}", String.IsNullOrEmpty(filename) ? "<none>"
: filename);

      filename = ExtractFilename(@"C:\temp\delegate.txt");
      Console.WriteLine("{0}", String.IsNullOrEmpty(filename) ? "<none>"
: filename);

      filename = ExtractFilename("delegate.txt");
      Console.WriteLine("{0}", String.IsNullOrEmpty(filename) ? "<none>"
: filename);

      filename = ExtractFilename(@"C:\temp\notafile.txt");
      Console.WriteLine("{0}", String.IsNullOrEmpty(filename) ? "<none>"
: filename);
   }

   public static string ExtractFilename(string filepath)
   {
      // If path ends with a "\", it's a path only so return
String.Empty.
      if (filepath.Trim().EndsWith(@"\"))
         return String.Empty;

      // Determine where last backslash is.
      int position = filepath.LastIndexOf('\\');
      // If there is no backslash, assume that this is a filename.
      if (position == -1)
      {
         // Determine whether file exists in the current directory.
         if (File.Exists(Environment.CurrentDirectory +
Path.DirectorySeparatorChar + filepath))
            return filepath;
         else
            return String.Empty;
      }
      else
      {
         // Determine whether file exists using filepath.
         if (File.Exists(filepath))
            // Return filename without file path.
            return filepath.Substring(position + 1);
         else
            return String.Empty;
      }
   }
}
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

This method begins searching at the last character position of this instance and proceeds backward toward the beginning until either `value` is found or the first character position has been examined. The search is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.LastIndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

LastIndexOf(String, StringComparison)

Reports the zero-based index of the last occurrence of a specified string within the current String object. A parameter specifies the type of search to use for the specified string.

```
C#

public int LastIndexOf (string value, StringComparison comparisonType);
```

Parameters

`value` String

The string to seek.

`comparisonType` StringComparison

One of the enumeration values that specifies the rules for the search.

Returns

Int32

The zero-based starting index position of the `value` parameter if that string is found, or -1 if it is not.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`comparisonType` is not a valid StringComparison value.

Examples

The following example demonstrates three overloads of the LastIndexOf method that find the last occurrence of a string within another string using different values of the StringComparison enumeration.

```
C#

// This code example demonstrates the
// System.String.LastIndexOf(String, ..., StringComparison) methods.

using System;
```

```
using System.Threading;
using System.Globalization;

class Sample
{
    public static void Main()
    {
    string intro = "Find the last occurrence of a character using
different " +
                   "values of StringComparison.";
    string resultFmt = "Comparison: {0,-28} Location: {1,3}";

// Define a string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
    string CapitalAWithRing = "\u00c5";

// Define a string to search.
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string cat = "A Cheshire c" + "\u0061\u030a" + "t";
    int loc = 0;
    StringComparison[] scValues = {
        StringComparison.CurrentCulture,
        StringComparison.CurrentCultureIgnoreCase,
        StringComparison.InvariantCulture,
        StringComparison.InvariantCultureIgnoreCase,
        StringComparison.Ordinal,
        StringComparison.OrdinalIgnoreCase };

// Clear the screen and display an introduction.
    Console.Clear();
    Console.WriteLine(intro);

// Display the current culture because culture affects the result. For
example,
// try this code example with the "sv-SE" (Swedish-Sweden) culture.

    Thread.CurrentThread.CurrentCulture = new CultureInfo("en-US");
    Console.WriteLine("The current culture is \"{0}\" - {1}.",
                      Thread.CurrentThread.CurrentCulture.Name,
                      Thread.CurrentThread.CurrentCulture.DisplayName);

// Display the string to search for and the string to search.
    Console.WriteLine("Search for the string \"{0}\" in the string \"
{1}\"",
                      CapitalAWithRing, cat);
    Console.WriteLine();

// Note that in each of the following searches, we look for
// LATIN CAPITAL LETTER A WITH RING ABOVE in a string that contains
// LATIN SMALL LETTER A WITH RING ABOVE. A result value of -1 indicates
// the string was not found.
```

```
// Search using different values of StringComparsion. Specify the start
// index and count.

    Console.WriteLine("Part 1: Start index and count are specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.LastIndexOf(CapitalAWithRing, cat.Length-1, cat.Length,
sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparsion. Specify the
// start index.
    Console.WriteLine("\nPart 2: Start index is specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.LastIndexOf(CapitalAWithRing, cat.Length-1, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }

// Search using different values of StringComparsion.
    Console.WriteLine("\nPart 3: Neither start index nor count is
specified.");
    foreach (StringComparison sc in scValues)
        {
        loc = cat.LastIndexOf(CapitalAWithRing, sc);
        Console.WriteLine(resultFmt, sc, loc);
        }
    }
}

/*
Note: This code example was executed on a console whose user interface
culture is "en-US" (English-United States).

This code example produces the following results:

Find the last occurrence of a character using different values of
StringComparison.
The current culture is "en-US" - English (United States).
Search for the string "Å" in the string "A Cheshire ca°t"

Part 1: Start index and count are specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

Part 2: Start index is specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
```

```
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

Part 3: Neither start index nor count is specified.
Comparison: CurrentCulture               Location:  -1
Comparison: CurrentCultureIgnoreCase     Location:  12
Comparison: InvariantCulture             Location:  -1
Comparison: InvariantCultureIgnoreCase   Location:  12
Comparison: Ordinal                      Location:  -1
Comparison: OrdinalIgnoreCase            Location:  -1

*/
```

Remarks

Index numbering starts from zero. That is, the first character in the string is at index zero and the last is at Length - 1.

The `comparisonType` parameter specifies to search for the `value` parameter using:

- The current or invariant culture.
- A case-sensitive or case-insensitive search.
- Word or ordinal comparison rules.

The search begins at the last character position of this instance and proceeds backward toward the beginning until either `value` is found or the first character position has been examined.

Notes to Callers

Character sets include ignorable characters, which are characters that are not considered when performing a linguistic or culture-sensitive comparison. In a culture-sensitive search (that is, if `options` is not Ordinal or OrdinalIgnoreCase), if `value` contains an ignorable character, the result is equivalent to searching with that character removed.

In the following example, the LastIndexOf(String, StringComparison) method is used to find two substrings (a soft hyphen followed by "n", and a soft hyphen followed by "m") in two strings. Only one of the strings contains a soft hyphen. If the example is run on .NET Framework 4 or later, because the soft hyphen is an ignorable character, a culture-sensitive search returns the same value that it would return if the soft hyphen were not included in the search string. An ordinal search, however, successfully finds the soft hyphen in one string and reports that it is absent from the second string.

C#

```
string s1 = "ani\u00ADmal";
string s2 = "animal";

Console.WriteLine("Culture-sensitive comparison:");

// Use culture-sensitive comparison to find the last soft hyphen followed
by "n".
Console.WriteLine(s1.LastIndexOf("\u00ADn",
StringComparison.CurrentCulture));
Console.WriteLine(s2.LastIndexOf("\u00ADn",
StringComparison.CurrentCulture));

// Use culture-sensitive comparison to find the last soft hyphen followed
by "m".
Console.WriteLine(s1.LastIndexOf("\u00ADm",
StringComparison.CurrentCulture));
Console.WriteLine(s2.LastIndexOf("\u00ADm",
StringComparison.CurrentCulture));

Console.WriteLine("Ordinal comparison:");

// Use ordinal comparison to find the last soft hyphen followed by "n".
Console.WriteLine(s1.LastIndexOf("\u00ADn", StringComparison.Ordinal));
Console.WriteLine(s2.LastIndexOf("\u00ADn", StringComparison.Ordinal));

// Use ordinal comparison to find the last soft hyphen followed by "m".
Console.WriteLine(s1.LastIndexOf("\u00ADm", StringComparison.Ordinal));
Console.WriteLine(s2.LastIndexOf("\u00ADm", StringComparison.Ordinal));

// The example displays the following output:
//
// Culture-sensitive comparison:
// 1
// 1
// 4
// 3
// Ordinal comparison:
// -1
// -1
// 3
// -1
```

String.LastIndexOfAny Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The method returns -1 if the characters in the array are not found in this instance.

Overloads

Expand table

LastIndexOfAny(Char[])	Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array.
LastIndexOfAny(Char[], Int32)	Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The search starts at a specified character position and proceeds backward toward the beginning of the string.
LastIndexOfAny(Char[], Int32, Int32)	Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.

LastIndexOfAny(Char[])

Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array.

C#

```
public int LastIndexOfAny (char[] anyOf);
```

Parameters

anyOf Char[]

A Unicode character array containing one or more characters to seek.

Returns

Int32

The index position of the last occurrence in this instance where any character in `anyOf` was found; -1 if no character in `anyOf` was found.

Exceptions

ArgumentNullException

`anyOf` is `null`.

Examples

The following example finds the index of the last occurrence of any character in the string "is" within another string.

C#

```
// Sample for String.LastIndexOfAny(Char[])
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
    string target = "is";
    char[] anyOf = target.ToCharArray();

    start = str.Length-1;
    Console.WriteLine("The last character occurrence  from position {0}
to 0.", start);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("A character in '{0}' occurs at position: ", target);

    at = str.LastIndexOfAny(anyOf);
    if (at > -1)
```

```
        Console.Write(at);
    else
        Console.Write("(not found)");
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
}
/*
This example produces the following results:
The last character occurrence  from position 66 to 0.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

A character in 'is' occurs at position: 58

*/
```

Remarks

Index numbering starts from zero.

This method begins searching at the last character position of this instance and proceeds backward toward the beginning until either a character in `anyOf` is found or the first character position has been examined. The search is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. To perform a culture-sensitive search, use the CompareInfo.LastIndexOf method, where a Unicode scalar value representing a precomposed character, such as the ligature "Æ" (U+00C6), might be considered equivalent to any occurrence of the character's components in the correct sequence, such as "AE" (U+0041, U+0045), depending on the culture.

UWP	10.0

LastIndexOfAny(Char[], Int32)

Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The search starts at a specified character position and proceeds backward toward the beginning of the string.

C#

```
public int LastIndexOfAny (char[] anyOf, int startIndex);
```

Parameters

`anyOf` Char[]

A Unicode character array containing one or more characters to seek.

`startIndex` Int32

The search starting position. The search proceeds from `startIndex` toward the beginning of this instance.

Returns

Int32

The index position of the last occurrence in this instance where any character in `anyOf` was found; -1 if no character in `anyOf` was found or if the current instance equals Empty.

Exceptions

ArgumentNullException

`anyOf` is `null`.

ArgumentOutOfRangeException

The current instance does not equal Empty, and `startIndex` specifies a position that is not within this instance.

Examples

The following example finds the index of the last occurrence of any character in the string "is" within a substring of another string.

C#

```
// Sample for String.LastIndexOfAny(Char[], Int32)
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
    string target = "is";
    char[] anyOf = target.ToCharArray();

    start = (str.Length-1)/2;
    Console.WriteLine("The last character occurrence  from position {0}
to 0.", start);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("A character in '{0}' occurs at position: ", target);

    at = str.LastIndexOfAny(anyOf, start);
    if (at > -1)
        Console.Write(at);
    else
        Console.Write("(not found)");
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
}
/*
This example produces the following results:
The last character occurrence  from position 33 to 0.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
```

```
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

A character in 'is' occurs at position: 12

*/
```

Remarks

Index numbering starts from zero.

This method begins searching at the `startIndex` character position of this instance and proceeds backward toward the beginning until either a character in `anyOf` is found or the first character position has been examined. The search is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. LastIndexOfAny(Char[], Int32, Int32)

Reports the zero-based index position of the last occurrence in this instance of one or more characters specified in a Unicode array. The search starts at a specified character position and proceeds backward toward the beginning of the string for a specified number of character positions.

C#

```
public int LastIndexOfAny (char[] anyOf, int startIndex, int count);
```

Parameters

`anyOf` Char[]

A Unicode character array containing one or more characters to seek.

`startIndex` Int32

The search starting position. The search proceeds from `startIndex` toward the beginning of this instance.

`count` Int32

The number of character positions to examine.

Returns

Int32

The index position of the last occurrence in this instance where any character in `anyOf` was found; -1 if no character in `anyOf` was found or if the current instance equals Empty.

Exceptions

ArgumentNullException

`anyOf` is `null`.

ArgumentOutOfRangeException

The current instance does not equal Empty, and `count` or `startIndex` is negative.

-or-

The current instance does not equal Empty, and `startIndex` minus `count` + 1 is less than zero.

Examples

The following example finds the index of the last occurrence of any character in the string "aid" within a substring of another string.

C#

```
// Sample for String.LastIndexOfAny(Char[], Int32, Int32)
using System;

class Sample {
    public static void Main() {

    string br1 = "0----+----1----+----2----+----3----+----4----+----5----
+----6----+-";
    string br2 =
"0123456789012345678901234567890123456789012345678901234567890123456";
    string str = "Now is the time for all good men to come to the aid of
their party.";
    int start;
    int at;
    int count;
    string target = "aid";
    char[] anyOf = target.ToCharArray();

    start = ((str.Length-1)*2)/3;
    count = (str.Length-1)/3;
    Console.WriteLine("The last character occurrence from position {0}
for {1} characters.", start, count);
    Console.WriteLine("{1}{0}{2}{0}{3}{0}", Environment.NewLine, br1,
br2, str);
    Console.Write("A character in '{0}' occurs at position: ", target);

    at = str.LastIndexOfAny(anyOf, start, count);
    if (at > -1)
        Console.Write(at);
    else
        Console.Write("(not found)");
    Console.Write("{0}{0}{0}", Environment.NewLine);
    }
```

```
}
/*
This example produces the following results:
The last character occurrence from position 44 for 22 characters.
0----+----1----+----2----+----3----+----4----+----5----+----6----+-
0123456789012345678901234567890123456789012345678901234567890123456
Now is the time for all good men to come to the aid of their party.

A character in 'aid' occurs at position: 27
*/
```

Remarks

Index numbering starts from zero.

This method begins searching at the `startIndex` character position of this instance and proceeds backward toward the beginning until either a character in `anyOf` is found or `count` character positions have been examined. The search is case-sensitive.

This method performs an ordinal (culture-insensitive) search, where a character is considered equivalent to another character only if their Unicode scalar values are the same. String.Normalize Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string whose binary representation is in a particular Unicode normalization form.

Overloads

Expand table

Normalize(NormalizationForm)	Returns a new string whose textual value is the same as this string, but whose binary representation is in the specified Unicode normalization form.
Normalize()	Returns a new string whose textual value is the same as this string, but whose binary representation is in Unicode normalization form C.

Examples

The following example normalizes a string to each of four normalization forms, confirms the string was normalized to the specified normalization form, then lists the code points in the normalized string.

C#

```
using System;
using System.Text;

class Example
{
    public static void Main()
    {
       // Character c; combining characters acute and cedilla; character 3/4
       string s1 = new String( new char[] {'\u0063', '\u0301', '\u0327',
'\u00BE'});
       string s2 = null;
       string divider = new String('-', 80);
```

```
        divider = String.Concat(Environment.NewLine, divider,
Environment.NewLine);

        Show("s1", s1);
        Console.WriteLine();
        Console.WriteLine("U+0063 = LATIN SMALL LETTER C");
        Console.WriteLine("U+0301 = COMBINING ACUTE ACCENT");
        Console.WriteLine("U+0327 = COMBINING CEDILLA");
        Console.WriteLine("U+00BE = VULGAR FRACTION THREE QUARTERS");
        Console.WriteLine(divider);

        Console.WriteLine("A1) Is s1 normalized to the default form (Form
C)?: {0}",
                                    s1.IsNormalized());
        Console.WriteLine("A2) Is s1 normalized to Form C?:  {0}",

s1.IsNormalized(NormalizationForm.FormC));
        Console.WriteLine("A3) Is s1 normalized to Form D?:  {0}",

s1.IsNormalized(NormalizationForm.FormD));
        Console.WriteLine("A4) Is s1 normalized to Form KC?: {0}",

s1.IsNormalized(NormalizationForm.FormKC));
        Console.WriteLine("A5) Is s1 normalized to Form KD?: {0}",

s1.IsNormalized(NormalizationForm.FormKD));

        Console.WriteLine(divider);

        Console.WriteLine("Set string s2 to each normalized form of string
s1.");
        Console.WriteLine();
        Console.WriteLine("U+1E09 = LATIN SMALL LETTER C WITH CEDILLA AND
ACUTE");
        Console.WriteLine("U+0033 = DIGIT THREE");
        Console.WriteLine("U+2044 = FRACTION SLASH");
        Console.WriteLine("U+0034 = DIGIT FOUR");
        Console.WriteLine(divider);

        s2 = s1.Normalize();
        Console.Write("B1) Is s2 normalized to the default form (Form C)?:
");
        Console.WriteLine(s2.IsNormalized());
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormC);
        Console.Write("B2) Is s2 normalized to Form C?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormC));
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormD);
        Console.Write("B3) Is s2 normalized to Form D?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormD));
```

```
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormKC);
        Console.Write("B4) Is s2 normalized to Form KC?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormKC));
        Show("s2", s2);
        Console.WriteLine();

        s2 = s1.Normalize(NormalizationForm.FormKD);
        Console.Write("B5) Is s2 normalized to Form KD?: ");
        Console.WriteLine(s2.IsNormalized(NormalizationForm.FormKD));
        Show("s2", s2);
        Console.WriteLine();
    }

    private static void Show(string title, string s)
    {
        Console.Write("Characters in string {0} = ", title);
        foreach(short x in s) {
            Console.Write("{0:X4} ", x);
        }
        Console.WriteLine();
    }
}
/*
This example produces the following results:

Characters in string s1 = 0063 0301 0327 00BE

U+0063 = LATIN SMALL LETTER C
U+0301 = COMBINING ACUTE ACCENT
U+0327 = COMBINING CEDILLA
U+00BE = VULGAR FRACTION THREE QUARTERS

--------------------------------------------------------------------------
----

A1) Is s1 normalized to the default form (Form C)?: False
A2) Is s1 normalized to Form C?:  False

Characters in string s2 = 1E09 0033 2044 0034

B5) Is s2 normalized to Form KD?: True
Characters in string s2 = 0063 0327 0301 0033 2044 0034

*/
```

Normalize(NormalizationForm)

Returns a new string whose textual value is the same as this string, but whose binary representation is in the specified Unicode normalization form.

```
C#

public string Normalize (System.Text.NormalizationForm
normalizationForm);
```

Parameters

`normalizationForm` NormalizationForm

A Unicode normalization form.

Returns

String

A new string whose textual value is the same as this string, but whose binary representation is in the normalization form specified by the `normalizationForm` parameter.

Exceptions

ArgumentException

The current instance contains invalid Unicode characters.

Remarks

Some Unicode characters have multiple equivalent binary representations consisting of sets of combining and/or composite Unicode characters. The existence of multiple representations for a single character complicates searching, sorting, matching, and other operations.

The Unicode standard defines a process called normalization that returns one binary representation when given any of the equivalent binary representations of a character. Normalization can be performed with several algorithms, called normalization forms, that obey different rules. .NET supports the four normalization forms (C, D, KC, and KD) that are defined by the Unicode standard. When two strings are represented in the same normalization form, they can be compared by using ordinal comparison.

To normalize and compare two strings, do the following:

1. Obtain the strings to be compared from an input source, such as a file or a user input device.

2. Call the Normalize(NormalizationForm) method to normalize the strings to a specified normalization form.

3. To compare two strings, call a method that supports ordinal string comparison, such as the Compare(String, String, StringComparison) method, and supply a value of StringComparison.Ordinal or StringComparison.OrdinalIgnoreCase as the StringComparison argument. To sort an array of normalized strings, pass a `comparer` value of StringComparer.Ordinal or StringComparer.OrdinalIgnoreCase to an appropriate overload of Array.Sort.

4. Emit the strings in the sorted output based on the order indicated by the previous step.

For a description of supported Unicode normalization forms, see System.Text.NormalizationForm.

Notes to Callers

The IsNormalized method returns `false` as soon as it encounters the first non-normalized character in a string. Therefore, if a string contains non-normalized

characters followed by invalid Unicode characters, the Normalize method may throw an ArgumentException although IsNormalized returns `false`.

.NET Standard	2.0, 2.1

Normalize()

Returns a new string whose textual value is the same as this string, but whose binary representation is in Unicode normalization form C.

C#

```
public string Normalize ();
```

Returns

String

A new, normalized string whose textual value is the same as this string, but whose binary representation is in normalization form C.

Exceptions

ArgumentException

The current instance contains invalid Unicode characters.

Remarks

Some Unicode characters have multiple equivalent binary representations consisting of sets of combining and/or composite Unicode characters. For example, any of the following code points can represent the letter "ắ":

- U+1EAF
- U+0103 U+0301
- U+0061 U+0306 U+0301

The existence of multiple representations for a single character complicates searching, sorting, matching, and other operations.

The Unicode standard defines a process called normalization that returns one binary representation when given any of the equivalent binary representations of a character. Normalization can be performed with several algorithms, called normalization forms, that obey different rules. .NET supports the four normalization forms (C, D, KC, and KD) that are defined by the Unicode standard. When two strings are represented in the same normalization form, they can be compared by using ordinal comparison.

To normalize and compare two strings, do the following:

1. Obtain the strings to be compared from an input source, such as a file or a user input device.
2. Call the Normalize() method to normalize the strings to normalization form C.
3. To compare two strings, call a method that supports ordinal string comparison, such as the Compare(String, String, StringComparison) method, and supply a value of StringComparison.Ordinal or StringComparison.OrdinalIgnoreCase as the StringComparison argument. To sort an array of normalized strings, pass a `comparer` value of StringComparer.Ordinal or StringComparer.OrdinalIgnoreCase to an appropriate overload of Array.Sort.
4. Emit the strings in the sorted output based on the order indicated by the previous step.

For a description of supported Unicode normalization forms, see System.Text.NormalizationForm.

Notes to Callers

The IsNormalized method returns `false` as soon as it encounters the first non-normalized character in a string. Therefore, if a string contains non-normalized characters followed by invalid Unicode characters, the Normalize method will throw an ArgumentException although IsNormalized returns `false`.

String.PadLeft Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string of a specified length in which the beginning of the current string is padded with spaces or with a specified Unicode character.

Overloads

Expand table

PadLeft(Int32)	Returns a new string that right-aligns the characters in this instance by padding them with spaces on the left, for a specified total length.
PadLeft(Int32, Char)	Returns a new string that right-aligns the characters in this instance by padding them on the left with a specified Unicode character, for a specified total length.

PadLeft(Int32)

Returns a new string that right-aligns the characters in this instance by padding them with spaces on the left, for a specified total length.

C#

```
public string PadLeft (int totalWidth);
```

Parameters

`totalWidth` Int32

The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.

Returns

String

A new string that is equivalent to this instance, but right-aligned and padded on the left with as many spaces as needed to create a length of `totalWidth`. However, if `totalWidth` is less than the length of this instance, the method returns a reference to the existing instance. If `totalWidth` is equal to the length of this instance, the method returns a new string that is identical to this instance.

Exceptions

ArgumentOutOfRangeException

`totalWidth` is less than zero.

Examples

The following example demonstrates the PadLeft method.

C#

```
string str = "BBQ and Slaw";
Console.WriteLine(str.PadLeft(15));  // Displays "   BBQ and Slaw".
Console.WriteLine(str.PadLeft(5));   // Displays "BBQ and Slaw".
```

Remarks

A Unicode space is defined as hexadecimal 0x0020.

The PadLeft(Int32) method pads the beginning of the returned string. This means that, when used with right-to-left languages, it pads the right portion of the string.

> **Note**
>
> If the **PadLeft** method pads the current instance with white-space characters, this method does not modify the value of the current instance. Instead, it returns a new string that is padded with leading white space so that its total length is `totalWidth` characters.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

PadLeft(Int32, Char)

Returns a new string that right-aligns the characters in this instance by padding them on the left with a specified Unicode character, for a specified total length.

C#

```
public string PadLeft (int totalWidth, char paddingChar);
```

Parameters

`totalWidth` Int32

The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.

`paddingChar` Char

A Unicode padding character.

Returns

String

A new string that is equivalent to this instance, but right-aligned and padded on the left with as many `paddingChar` characters as needed to create a length of `totalWidth`. However, if `totalWidth` is less than the length of this instance, the

method returns a reference to the existing instance. If `totalWidth` is equal to the length of this instance, the method returns a new string that is identical to this instance.

Exceptions

ArgumentOutOfRangeException

`totalWidth` is less than zero.

Examples

The following example demonstrates the PadLeft method.

C#

```
using System;

class Sample
{
   public static void Main()
   {
   string str = "forty-two";
   char pad = '.';

   Console.WriteLine(str.PadLeft(15, pad));
   Console.WriteLine(str.PadLeft(2, pad));
   }
}
// The example displays the following output:
//       ......forty-two
//       forty-two
```

Remarks

The PadLeft(Int32, Char) method pads the beginning of the returned string. This means that, when used with right-to-left languages, it pads the right portion of the string.

> **Note**
>
> If the **PadLeft** method pads the current instance with white-space characters, this method does not modify the value of the current instance. Instead, it returns a new string that is padded with leading `paddingChar` characters so that its total length is `totalWidth` characters.

String.PadRight Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string of a specified length in which the end of the current string is padded with spaces or with a specified Unicode character.

Overloads

Expand table

PadRight(Int32)	Returns a new string that left-aligns the characters in this string by padding them with spaces on the right, for a specified total length.
PadRight(Int32, Char)	Returns a new string that left-aligns the characters in this string by padding them on the right with a specified Unicode character, for a specified total length.

PadRight(Int32)

Returns a new string that left-aligns the characters in this string by padding them with spaces on the right, for a specified total length.

C#

```
public string PadRight (int totalWidth);
```

Parameters

`totalWidth` Int32

The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.

Returns

String

A new string that is equivalent to this instance, but left-aligned and padded on the right with as many spaces as needed to create a length of `totalWidth`. However, if `totalWidth` is less than the length of this instance, the method returns a reference to the existing instance. If `totalWidth` is equal to the length of this instance, the method returns a new string that is identical to this instance.

Exceptions

ArgumentOutOfRangeException

`totalWidth` is less than zero.

Examples

The following example demonstrates the PadRight method.

C#

```
string str;
str = "BBQ and Slaw";

Console.Write("|");
Console.Write(str.PadRight(15));
Console.WriteLine("|");       // Displays "|BBQ and Slaw   |".

Console.Write("|");
Console.Write(str.PadRight(5));
Console.WriteLine("|");       // Displays "|BBQ and Slaw|".
```

Remarks

A Unicode space is defined as hexadecimal 0x0020.

The PadRight(Int32) method pads the end of the returned string. This means that, when used with right-to-left languages, it pads the left portion of the string.

> **Note**
>
> If the **PadRight** method pads the current instance with white-space characters, this method does not modify the value of the current instance. Instead, it returns a new string that is padded with trailing white space so that its total length is `totalWidth` characters.

UWP	10.0

PadRight(Int32, Char)

Returns a new string that left-aligns the characters in this string by padding them on the right with a specified Unicode character, for a specified total length.

C#

```
public string PadRight (int totalWidth, char paddingChar);
```

Parameters

`totalWidth` Int32

The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.

`paddingChar` Char

A Unicode padding character.

Returns

String

A new string that is equivalent to this instance, but left-aligned and padded on the right with as many `paddingChar` characters as needed to create a length of `totalWidth`. However, if `totalWidth` is less than the length of this instance, the method returns a reference to the existing instance. If `totalWidth` is equal to the length of this instance, the method returns a new string that is identical to this instance.

Exceptions

ArgumentOutOfRangeException

`totalWidth` is less than zero.

Examples

The following example demonstrates the PadRight method.

C#

```
string str = "forty-two";
char pad = '.';

Console.WriteLine(str.PadRight(15, pad));    // Displays "forty-
two......".
Console.WriteLine(str.PadRight(2,  pad));    // Displays "forty-two".
```

Remarks

The PadRight(Int32, Char) method pads the end of the returned string. This means that, when used with right-to-left languages, it pads the left portion of the string.

> **Note**
>
> If the **PadRight** method pads the current instance with white-space characters, this method does not modify the value of the current instance. Instead, it returns a new string that is padded with trailing `paddingChar` characters so that its total length is `totalWidth` characters.

String.Remove Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string in which a specified number of characters from the current string are deleted.

Overloads

Expand table

Remove(Int32)	Returns a new string in which all the characters in the current instance, beginning at a specified position and continuing through the last position, have been deleted.
Remove(Int32, Int32)	Returns a new string in which a specified number of characters in the current instance beginning at a specified position have been deleted.

Remove(Int32)

Returns a new string in which all the characters in the current instance, beginning at a specified position and continuing through the last position, have been deleted.

C#

```
public string Remove (int startIndex);
```

Parameters

`startIndex` Int32

The zero-based position to begin deleting characters.

Returns

String

A new string that is equivalent to this string except for the removed characters.

Exceptions

ArgumentOutOfRangeException

`startIndex` is less than zero.

-or-

`startIndex` specifies a position that is not within this string.

Examples

The following example demonstrates the Remove method. The next-to-last case removes all text starting from the specified index through the end of the string. The last case removes three characters starting from the specified index.

C#

```
// This example demonstrates the String.Remove() method.
using System;

class Sample
{
    public static void Main()
    {
        string s = "abc---def";

        Console.WriteLine("Index: 012345678");
        Console.WriteLine("1)     {0}", s);
        Console.WriteLine("2)     {0}", s.Remove(3));
        Console.WriteLine("3)     {0}", s.Remove(3, 3));
    }
}
/*
This example produces the following results:

Index: 012345678
1)     abc---def
2)     abc
3)     abcdef

*/
```

Remarks

In the .NET Framework, strings are zero-based. The value of the `startIndex` parameter can range from zero to one less than the length of the string instance.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters from position `startIndex` to the end of the original string have been removed.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Remove(Int32, Int32)

Returns a new string in which a specified number of characters in the current instance beginning at a specified position have been deleted.

```C#
public string Remove (int startIndex, int count);
```

Parameters

`startIndex` Int32

The zero-based position to begin deleting characters.

`count` Int32

The number of characters to delete.

Returns

String

A new string that is equivalent to this instance except for the removed characters.

Exceptions

ArgumentOutOfRangeException

Either `startIndex` or `count` is less than zero.

-or-

`startIndex` plus `count` specify a position outside this instance.

Examples

The following example demonstrates how you can remove the middle name from a complete name.

```C#
using System;

public class RemoveTest
{
    public static void Main()
    {

        string name = "Michelle Violet Banks";

        Console.WriteLine("The entire name is '{0}'", name);
```

```
        // Remove the middle name, identified by finding the spaces in
the name.
        int foundS1 = name.IndexOf(" ");
        int foundS2 = name.IndexOf(" ", foundS1 + 1);

        if (foundS1 != foundS2 && foundS1 >= 0)
        {
            name = name.Remove(foundS1 + 1, foundS2 - foundS1);

            Console.WriteLine("After removing the middle name, we are
left with '{0}'", name);
        }
    }
}
// The example displays the following output:
//       The entire name is 'Michelle Violet Banks'
//       After removing the middle name, we are left with 'Michelle
Banks'
```

Remarks

In the .NET Framework, strings are zero-based. The value of the `startIndex` parameter can range from zero to one less than the length of the string instance.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which the number of characters specified by the `count` parameter have been removed. The characters are removed at the position specified by `startIndex`.

String.Replace Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string in which all occurrences of a specified Unicode character or String in the current string are replaced with another specified Unicode character or String.

Overloads

Expand table

Replace(Char, Char)	Returns a new string in which all occurrences of a specified Unicode character in this instance are replaced with another specified Unicode character.
Replace(String, String)	Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string.
Replace(String, String, StringComparison)	Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string, using the provided comparison type.
Replace(String, String, Boolean, CultureInfo)	Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string, using the provided culture and case sensitivity.

Replace(Char, Char)

Returns a new string in which all occurrences of a specified Unicode character in this instance are replaced with another specified Unicode character.

C#

```
public string Replace (char oldChar, char newChar);
```

Parameters

`oldChar` Char

The Unicode character to be replaced.

`newChar` Char

The Unicode character to replace all occurrences of `oldChar`.

Returns

String

A string that is equivalent to this instance except that all instances of `oldChar` are replaced with `newChar`. If `oldChar` is not found in the current instance, the method returns the current instance unchanged.

Examples

The following example creates a comma separated value list by substituting commas for the blanks between a series of numbers.

C#

```
String str = "1 2 3 4 5 6 7 8 9";
Console.WriteLine("Original string: \"{0}\"", str);
Console.WriteLine("CSV string:      \"{0}\"", str.Replace(' ', ','));

// This example produces the following output:
// Original string: "1 2 3 4 5 6 7 8 9"
// CSV string:      "1,2,3,4,5,6,7,8,9"
```

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) search to find `oldChar`.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all occurrences of `oldChar` are replaced by `newChar`.

Because this method returns the modified string, you can chain together successive calls to the Replace method to perform multiple replacements on the original string.

Method calls are executed from left to right. The following example provides an illustration.

```C#
String s = new String('a', 3);
Console.WriteLine("The initial string: '{0}'", s);
s = s.Replace('a', 'b').Replace('b', 'c').Replace('c', 'd');
Console.WriteLine("The final string: '{0}'", s);

// The example displays the following output:
//       The initial string: 'aaa'
//       The final string: 'ddd'
```

See also

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Replace(String, String)

Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string.

```
C#

public string Replace (string oldValue, string? newValue);
```

Parameters

`oldValue` String

The string to be replaced.

`newValue` String

The string to replace all occurrences of `oldValue`.

Returns

String

A string that is equivalent to the current string except that all instances of `oldValue` are replaced with `newValue`. If `oldValue` is not found in the current instance, the method returns the current instance unchanged.

Exceptions

ArgumentNullException

`oldValue` is `null`.

ArgumentException

`oldValue` is the empty string ("").

Examples

The following example demonstrates how you can use the Replace method to correct a spelling error.

```
C#

string errString = "This docment uses 3 other docments to docment the
docmentation";

Console.WriteLine("The original string is:{0}'{1}'{0}",
Environment.NewLine, errString);
```

```
// Correct the spelling of "document".

string correctString = errString.Replace("docment", "document");

Console.WriteLine("After correcting the string, the result is:{0}'{1}'",
        Environment.NewLine, correctString);

// This code example produces the following output:
//
// The original string is:
// 'This docment uses 3 other docments to docment the docmentation'
//
// After correcting the string, the result is:
// 'This document uses 3 other documents to document the documentation'
//
```

Remarks

If `newValue` is `null`, all occurrences of `oldValue` are removed.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all occurrences of `oldValue` are replaced by `newValue`.

This method performs an ordinal (case-sensitive and culture-insensitive) search to find `oldValue`.

Because this method returns the modified string, you can chain together successive calls to the Replace method to perform multiple replacements on the original string. Method calls are executed from left to right. The following example provides an illustration.

C#

```
String s = "aaa";
Console.WriteLine("The initial string: '{0}'", s);
s = s.Replace("a", "b").Replace("b", "c").Replace("c", "d");
Console.WriteLine("The final string: '{0}'", s);

// The example displays the following output:
//       The initial string: 'aaa'
//       The final string: 'ddd'
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Replace(String, String, StringComparison)

Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string, using the provided comparison type.

C#

```
public string Replace (string oldValue, string? newValue,
StringComparison comparisonType);
```

Parameters

`oldValue` String

The string to be replaced.

`newValue` String

The string to replace all occurrences of `oldValue`.

`comparisonType` StringComparison

One of the enumeration values that determines how `oldValue` is searched within this instance.

Returns

String

A string that is equivalent to the current string except that all instances of `oldValue` are replaced with `newValue`. If `oldValue` is not found in the current instance, the method returns the current instance unchanged.

Exceptions

ArgumentNullException

`oldValue` is `null`.

ArgumentException

`oldValue` is the empty string ("").

Remarks

If `newValue` is `null`, all occurrences of `oldValue` are removed.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all occurrences of `oldValue` are replaced by `newValue`.

This method performs a search to find `oldValue` using the culture and case sensitivity described by `comparisonType`.

Because this method returns the modified string, you can chain together successive calls to the Replace method to perform multiple replacements on the original string. Method calls are executed from left to right. The following example provides an illustration.

```
C#
```

```
String s = "aaa";
Console.WriteLine("The initial string: '{0}'", s);
s = s.Replace("a", "b").Replace("b", "c").Replace("c", "d");
Console.WriteLine("The final string: '{0}'", s);

// The example displays the following output:
//       The initial string: 'aaa'
//       The final string: 'ddd'
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Replace(String, String, Boolean, CultureInfo)

Returns a new string in which all occurrences of a specified string in the current instance are replaced with another specified string, using the provided culture and case sensitivity.

C#

```
public string Replace (string oldValue, string? newValue, bool
ignoreCase, System.Globalization.CultureInfo? culture);
```

Parameters

`oldValue` String

The string to be replaced.

`newValue` String

The string to replace all occurrences of `oldValue`.

`ignoreCase` Boolean

`true` to ignore casing when comparing; `false` otherwise.

`culture` CultureInfo

The culture to use when comparing. If `culture` is `null`, the current culture is used.

Returns

String

A string that is equivalent to the current string except that all instances of `oldValue` are replaced with `newValue`. If `oldValue` is not found in the current instance, the method returns the current instance unchanged.

Exceptions

ArgumentNullException

`oldValue` is `null`.

ArgumentException

`oldValue` is the empty string ("").

Remarks

If `newValue` is `null`, all occurrences of `oldValue` are removed.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all occurrences of `oldValue` are replaced by `newValue`.

This method performs a search to find `oldValue` using the provided `culture` and `ignoreCase` case sensitivity.

Because this method returns the modified string, you can chain together successive calls to the Replace method to perform multiple replacements on the original string. Method calls are executed from left to right. The following example provides an illustration.

C#

```
String s = "aaa";
Console.WriteLine("The initial string: '{0}'", s);
s = s.Replace("a", "b").Replace("b", "c").Replace("c", "d");
```

```
Console.WriteLine("The final string: '{0}'", s);

// The example displays the following output:
//       The initial string: 'aaa'
//       The final string: 'ddd'
```

String.ReplaceLineEndings Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ReplaceLineEndings(String)	Replaces all newline sequences in the current string with `replacementText`.
ReplaceLineEndings()	Replaces all newline sequences in the current string with NewLine.

ReplaceLineEndings(String)

Replaces all newline sequences in the current string with `replacementText`.

C#

```
public string ReplaceLineEndings (string replacementText);
```

Parameters

`replacementText` String

The text to use as replacement.

Returns

String

A string whose contents match the current string, but with all newline sequences replaced with `replacementText`.

Remarks

This method searches for all newline sequences within the string and canonicalizes them to the newline sequence provided by `replacementText`. If `replacementText` is Empty, all newline sequences within the string will be removed.

It is not recommended that protocol parsers utilize this API. Protocol specifications often mandate specific newline sequences. For example, HTTP/1.1 (RFC 8615) mandates that the request line, status line, and headers lines end with CRLF. Since this API operates over a wide range of newline sequences, a protocol parser utilizing this API could exhibit behaviors unintended by the protocol's authors.

The list of recognized newline sequences is CR (U+000D), LF (U+000A), CRLF (U+000D U+000A), NEL (U+0085), LS (U+2028), FF (U+000C), and PS (U+2029). This list is given by the Unicode Standard, Sec. 5.8, Recommendation R4 and Table 5-2.

This method is guaranteed O(n * r) complexity, where *n* is the length of the input string, and where *r* is the length of `replacementText`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ReplaceLineEndings()

Replaces all newline sequences in the current string with NewLine.

C#

```
public string ReplaceLineEndings ();
```

Returns

String

A string whose contents match the current string, but with all newline sequences replaced with NewLine.

Remarks

This method searches for all newline sequences within the string and canonicalizes them to match the newline sequence for the current environment. For example, when running on Windows, all occurrences of non-Windows newline sequences will be replaced with the sequence CRLF. When running on Unix, all occurrences of non-Unix newline sequences will be replaced with a single LF character.

It is not recommended that protocol parsers utilize this API. Protocol specifications often mandate specific newline sequences. For example, HTTP/1.1 (RFC 8615) mandates that the request line, status line, and headers lines end with CRLF. Since this API operates over a wide range of newline sequences, a protocol parser utilizing this API could exhibit behaviors unintended by the protocol's authors.

This overload is equivalent to calling ReplaceLineEndings(String), passing NewLine as the *replacementText* parameter.

This method is guaranteed O(n) complexity, where *n* is the length of the input string.

Applies to

String.Split Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string array that contains the substrings in this instance that are delimited by elements of a specified string or Unicode character array.

Overloads

Expand table

Split(Char[])	Splits a string into substrings based on specified delimiting characters.
Split(Char, StringSplitOptions)	Splits a string into substrings based on a specified delimiting character and, optionally, options.
Split(Char[], Int32)	Splits a string into a maximum number of substrings based on specified delimiting characters.
Split(Char[], StringSplitOptions)	Splits a string into substrings based on specified delimiting characters and options.
Split(String, StringSplitOptions)	Splits a string into substrings that are based on the provided string separator.
Split(String[], StringSplitOptions)	Splits a string into substrings based on a specified delimiting string and, optionally, options.
Split(Char, Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on a specified delimiting character and, optionally, options. Splits a string into a maximum number of substrings based on the provided character separator, optionally omitting empty substrings from the result.
Split(Char[], Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on specified delimiting characters and, optionally, options.
Split(String, Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on a specified delimiting string and, optionally, options.
Split(String[], Int32, StringSplitOptions)	Splits a string into a maximum number of substrings based on specified delimiting strings and, optionally, options.

Remarks

Split is used to break a delimited string into substrings. You can use either a character array or a string array to specify zero or more delimiting characters or strings. If no delimiting characters are specified, the string is split at white-space characters.

Overloads of the Split method allow you to limit the number of substrings returned by the method (the Split(Char[], Int32) method), to specify whether to include empty strings and/or trim substrings in the result (the Split(Char[], StringSplitOptions) and Split(String[], StringSplitOptions) methods), or to do both (the Split(Char[], Int32, StringSplitOptions) and Split(String[], Int32, StringSplitOptions) methods).

> **Tip**
>
> The **Split** method is not always the best way to break a delimited string into substrings. If you don't want to extract all of the substrings of a delimited string, or if you want to parse a string based on a pattern instead of a set of delimiter characters, consider using regular expressions, or combine one of the search methods that returns the index of a character with the **Substring** method. For more information, see **Extract substrings from a string**.

Example

The following examples show three different overloads of `String.Split()`. The first example calls the Split(Char[]) overload and passes in a single delimiter.

C#

```
string s = "You win some. You lose some.";

string[] subs = s.Split(' ');

foreach (var sub in subs)
{
    Console.WriteLine($"Substring: {sub}");
}

// This example produces the following output:
//
// Substring: You
// Substring: win
// Substring: some.
// Substring: You
```

```
// Substring: lose
// Substring: some.
```

As you can see, the period characters (`.`) are included in two of the substrings. If you want to exclude the period characters, you can add the period character as an additional delimiting character. The next example shows how to do this.

C#

```
string s = "You win some. You lose some.";

string[] subs = s.Split(' ', '.');

foreach (var sub in subs)
{
    Console.WriteLine($"Substring: {sub}");
}

// This example produces the following output:
//
// Substring: You
// Substring: win
// Substring: some
// Substring:
// Substring: You
// Substring: lose
// Substring: some
// Substring:
```

The periods are gone from the substrings, but now two extra empty substrings have been included. These empty substring represent the substring between a word and the period that follows it. To omit empty substrings from the resulting array, you can call the Split(Char[], StringSplitOptions) overload and specify StringSplitOptions.RemoveEmptyEntries for the `options` parameter.

C#

```
string s = "You win some. You lose some.";
char[] separators = new char[] { ' ', '.' };

string[] subs = s.Split(separators, StringSplitOptions.RemoveEmptyEntries);

foreach (var sub in subs)
{
    Console.WriteLine($"Substring: {sub}");
}

// This example produces the following output:
//
```

```
// Substring: You
// Substring: win
// Substring: some
// Substring: You
// Substring: lose
// Substring: some
```

The sections for the individual overloads of `String.Split()` contain further examples.

Split(Char[])

Splits a string into substrings based on specified delimiting characters.

```
C#

public string[] Split (params char[]? separator);
```

Parameters

`separator` Char[]

An array of delimiting characters, an empty array that contains no delimiters, or `null`.

Returns

String[]

An array whose elements contain the substrings from this instance that are delimited by one or more characters in `separator`. For more information, see the Remarks section.

Examples

The following example demonstrates how to extract individual words from a block of text by treating the space character ( ) and tab character (`\t`) as delimiters. The string being split includes both of these characters.

```
C#

string s = "Today\tI'm going to school";
string[] subs = s.Split(' ', '\t');

foreach (var sub in subs)
```

```
{
    Console.WriteLine($"Substring: {sub}");
}

// This example produces the following output:
//
// Substring: Today
// Substring: I'm
// Substring: going
// Substring: to
// Substring: school
```

Remarks

When a string is delimited by a known set of characters, you can use the Split(Char[]) method to separate it into substrings.

Delimiter characters are not included in the elements of the returned array. For example, if the separator array includes the character "-" and the value of the current string instance is "aa-bb-cc", the method returns an array that contains three elements: "aa", "bb", and "cc".

If this instance does not contain any of the characters in `separator`, the returned array consists of a single element that contains this instance.

Each element of `separator` defines a separate delimiter character. If two delimiters are adjacent, or a delimiter is found at the beginning or end of this instance, the corresponding element in the returned array contains Empty.

The following table shows some examples.

Expand table

Language	String value	Separator	Returned array
C#	"42, 12, 19"	new Char[] {',', ' '}	{"42", "", "12", "", "19"}
Visual Basic	"42, 12, 19"	Char() = {","c, " "c})	{"42", "", "12", "", "19"}
C#	"42..12..19."	new Char[] {'.'}	{"42", "", "12", "", "19", ""}
Visual Basic	"42..12..19."	Char() = {"."c}	{"42", "", "12", "", "19", ""}
C#	"Banana"	new Char[] {'.'}	{"Banana"}
Visual Basic	"Banana"	Char() = {"."c}	{"Banana"}
C#	"Darb\nSmarba"	new Char[] {}	{"Darb", "Smarba"}

Language	String value	Separator	Returned array
Visual Basic	"Darb" & vbLf & "Smarba"	Char() = {}	{"Darb", "Smarba"}
C#	"Darb\nSmarba"	null	{"Darb", "Smarba"}
Visual Basic	"Darb" & vbLf & "Smarba"	Nothing	{"Darb", "Smarba"}

The separator array

Each element of separator defines a separate delimiter that consists of a single character.

If the `separator` argument is `null` or contains no characters, the method treats white-space characters as the delimiters. White-space characters are defined by the Unicode standard, and the Char.IsWhiteSpace method returns `true` if a white-space character is passed to it.

String.Split(Char[]) and compiler overload resolution

Although the single parameter for this overload of String.Split is a character array, you can call it with a single character, as the following example shows.

C#

```
string value = "This is a short string.";
char delimiter = 's';
string[] substrings = value.Split(delimiter);
foreach (var substring in substrings)
    Console.WriteLine(substring);

// The example displays the following output:
//     Thi
//      i
//      a
//     hort
//     tring.
```

Because the `separator` parameter is decorated with the ParamArrayAttribute attribute, compilers will interpret a single character as a single-element character array. This is not the case for other String.Split overloads that include a `separator` parameter; you must explicitly pass these overloads a character array as the `separator` argument.

Comparison details

The Split(Char[]) method extracts the substrings in this string that are delimited by one or more of the characters in the `separator` array, and returns those substrings as elements of an array.

The Split(Char[]) method looks for delimiters by performing comparisons using case-sensitive ordinal sort rules. For more information about word, string, and ordinal sorts, see the System.Globalization.CompareOptions enumeration.

Performance considerations

The Split methods allocate memory for the returned array object and a String object for each array element. If your application requires optimal performance or if managing memory allocation is critical in your application, consider using the IndexOf or IndexOfAny method. You also have the option of using the Compare method to locate a substring within a string.

To split a string at a separator character, use the IndexOf or IndexOfAny method to locate a separator character in the string. To split a string at a separator string, use the IndexOf or IndexOfAny method to locate the first character of the separator string. Then use the Compare method to determine whether the characters after that first character are equal to the remaining characters of the separator string.

In addition, if the same set of characters is used to split strings in multiple Split method calls, consider creating a single array and referencing it in each method call. This significantly reduces the additional overhead of each method call.

Notes to Callers

In .NET Framework 3.5 and earlier versions, if the Split(Char[]) method is passed a `separator` that is `null` or contains no characters, the method uses a slightly different set of white-space characters to split the string than the Trim(Char[]) method does to trim the string. Starting with .NET Framework 4, both methods use an identical set of Unicode white-space characters.

Split(Char, StringSplitOptions)

Splits a string into substrings based on a specified delimiting character and, optionally, options.

C#

```
public string[] Split (char separator, StringSplitOptions options =
System.StringSplitOptions.None);
```

Parameters

`separator` Char

A character that delimits the substrings in this string.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array whose elements contain the substrings from this instance that are delimited by `separator`.

Applies to

Split(Char[], Int32)

Splits a string into a maximum number of substrings based on specified delimiting characters.

```
C#

public string[] Split (char[]? separator, int count);
```

Parameters

`separator` Char[]

An array of characters that delimit the substrings in this string, an empty array that contains no delimiters, or `null`.

`count` Int32

The maximum number of substrings to return.

Returns

String[]

An array whose elements contain the substrings in this instance that are delimited by one or more characters in `separator`. For more information, see the Remarks section.

Exceptions

ArgumentOutOfRangeException

`count` is negative.

Examples

The following example demonstrates how `count` can be used to limit the number of strings returned by Split.

C#

```
string name = "Alex Johnson III";

string[] subs = name.Split(null, 2);

string firstName = subs[0];
string lastName;
if (subs.Length > 1)
{
    lastName = subs[1];
}

// firstName = "Alex"
// lastName = "Johnson III"
```

Remarks

Delimiter characters are not included in the elements of the returned array.

If this instance does not contain any of the characters in `separator`, the returned array consists of a single element that contains this instance. If `count` is zero, an empty array is returned.

If the `separator` parameter is `null` or contains no characters, white-space characters are assumed to be the delimiters. White-space characters are defined by the Unicode standard and the Char.IsWhiteSpace method returns `true` if they are passed to it.

Each element of `separator` defines a separate delimiter character. If two delimiters are adjacent, or a delimiter is found at the beginning or end of this instance, the corresponding array element contains Empty.

If there are more than `count` substrings in this instance, the first `count - 1` substrings are returned in the first `count - 1` elements of the return value, and the remaining characters in this instance are returned in the last element of the return value.

If `count` is greater than the number of substrings, the available substrings are returned and no exception is thrown.

The following table shows some examples.

Expand table

Language	String value	Separator	Returned array
C#	"42, 12, 19"	new Char[] {',', ' '}	{"42", "", "12", "", "19"}
Visual Basic	"42, 12, 19"	Char() = {","c, " "c})	{"42", "", "12", "", "19"}
C#	"42..12..19."	new Char[] {'.'}	{"42", "", "12", "", "19", ""}
Visual Basic	"42..12..19."	Char() = {"."c}	{"42", "", "12", "", "19", ""}
C#	"Banana"	new Char[] {'.'}	{"Banana"}
Visual Basic	"Banana"	Char() = {"."c}	{"Banana"}
C#	"Darb\nSmarba"	new Char[] {}	{"Darb", "Smarba"}
Visual Basic	"Darb" & vbLf & "Smarba"	Char() = {}	{"Darb", "Smarba"}
C#	"Darb\nSmarba"	null	{"Darb", "Smarba"}
Visual Basic	"Darb" & vbLf & "Smarba"	Nothing	{"Darb", "Smarba"}

Performance considerations

The Split methods allocate memory for the returned array object and a String object for each array element. If your application requires optimal performance or if managing memory allocation is critical in your application, consider using the IndexOf or IndexOfAny method, and optionally the Compare method, to locate a substring within a string.

If you are splitting a string at a separator character, use the IndexOf or IndexOfAny method to locate a separator character in the string. If you are splitting a string at a separator string, use the IndexOf or IndexOfAny method to locate the first character of the separator string. Then use the Compare method to determine whether the characters after that first character are equal to the remaining characters of the separator string.

In addition, if the same set of characters is used to split strings in multiple Split method calls, consider creating a single array and referencing it in each method call. This significantly reduces the additional overhead of each method call.

Notes to Callers

In .NET Framework 3.5 and earlier versions, if the Split(Char[]) method is passed a `separator` that is `null` or contains no characters, the method uses a slightly different set of white-space characters to split the string than the Trim(Char[]) method does to trim the string. Starting with .NET Framework 4, both methods use an identical set of Unicode white-space characters.

Split(Char[], StringSplitOptions)

Splits a string into substrings based on specified delimiting characters and options.

```
C#
```

```
public string[] Split (char[]? separator, StringSplitOptions options);
```

Parameters

`separator` Char[]

An array of characters that delimit the substrings in this string, an empty array that contains no delimiters, or `null`.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array whose elements contain the substrings in this string that are delimited by one or more characters in `separator`. For more information, see the Remarks section.

Exceptions

ArgumentException

`options` is not one of the StringSplitOptions values.

Examples

The following example uses the StringSplitOptions enumeration to include or exclude substrings generated by the Split method.

C#

```
// This example demonstrates the String.Split() methods that use
// the StringSplitOptions enumeration.
string s1 = ",ONE,,TWO,,,THREE,,";
string s2 = "[stop]" +
            "ONE[stop][stop]" +
            "TWO[stop][stop][stop]" +
            "THREE[stop][stop]";
char[] charSeparators = new char[] { ',' };
string[] stringSeparators = new string[] { "[stop]" };
string[] result;
// ----------------------------------------------------------------------
--------
// Split a string delimited by characters.
```

```
// ----------------------------------------------------------------------
--------
Console.WriteLine("1) Split a string delimited by characters:\n");

// Display the original string and delimiter characters.
Console.WriteLine($"1a) The original string is \"{s1}\".");
Console.WriteLine($"The delimiter character is
'{charSeparators[0]}'.\n");

// Split a string delimited by characters and return all elements.
Console.WriteLine("1b) Split a string delimited by characters and " +
                  "return all elements:");
result = s1.Split(charSeparators, StringSplitOptions.None);
Show(result);

// Split a string delimited by characters and return all non-empty
elements.
Console.WriteLine("1c) Split a string delimited by characters and " +
                  "return all non-empty elements:");
result = s1.Split(charSeparators, StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the string and empty string before the
// delimiter and the remainder of the original string after the
delimiter.
Console.WriteLine("1d) Split a string delimited by characters and " +
                  "return 2 elements:");
result = s1.Split(charSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
// remainder of the original string after the delimiter.
Console.WriteLine("1e) Split a string delimited by characters and " +
                  "return 2 non-empty elements:");
result = s1.Split(charSeparators, 2,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// ----------------------------------------------------------------------
--------
// Split a string delimited by another string.
// ----------------------------------------------------------------------
--------
Console.WriteLine("2) Split a string delimited by another string:\n");

// Display the original string and delimiter string.
Console.WriteLine($"2a) The original string is \"{s2}\".");
Console.WriteLine($"The delimiter string is \"
{stringSeparators[0]}\".\n");

// Split a string delimited by another string and return all elements.
Console.WriteLine("2b) Split a string delimited by another string and " +
                  "return all elements:");
result = s2.Split(stringSeparators, StringSplitOptions.None);
Show(result);
```

```
// Split the original string at the delimiter and return all non-empty
elements.
Console.WriteLine("2c) Split a string delimited by another string and " +
                  "return all non-empty elements:");
result = s2.Split(stringSeparators,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the empty string before the
// delimiter and the remainder of the original string after the
delimiter.
Console.WriteLine("2d) Split a string delimited by another string and " +
                  "return 2 elements:");
result = s2.Split(stringSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
// remainder of the original string after the delimiter.
Console.WriteLine("2e) Split a string delimited by another string and " +
                  "return 2 non-empty elements:");
result = s2.Split(stringSeparators, 2,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Display the array of separated strings using a local function
void Show(string[] entries)
{
    Console.WriteLine($"The return value contains these {entries.Length}
elements:");
    foreach (string entry in entries)
    {
        Console.Write($"<{entry}>");
    }
    Console.Write("\n\n");
}

/*
This example produces the following results:

1) Split a string delimited by characters:

1a) The original string is ",ONE,,TWO,,,THREE,,".
The delimiter character is ',',

1b) Split a string delimited by characters and return all elements:
The return value contains these 9 elements:
<><ONE><><TWO><><><THREE><><>

1c) Split a string delimited by characters and return all non-empty
elements:
The return value contains these 3 elements:
<ONE><TWO><THREE>

1d) Split a string delimited by characters and return 2 elements:
```

```
The return value contains these 2 elements:
<><ONE,,TWO,,,THREE,,>

1e) Split a string delimited by characters and return 2 non-empty
elements:
The return value contains these 2 elements:
<ONE><TWO,,,THREE,,>

2) Split a string delimited by another string:

2a) The original string is "[stop]ONE[stop][stop]TWO[stop][stop]
[stop]THREE[stop][stop]".
The delimiter string is "[stop]".

2b) Split a string delimited by another string and return all elements:
The return value contains these 9 elements:
<><ONE><><TWO><><><THREE><><>

2c) Split a string delimited by another string and return all non-empty
elements:
The return value contains these 3 elements:
<ONE><TWO><THREE>

2d) Split a string delimited by another string and return 2 elements:
The return value contains these 2 elements:
<><ONE[stop][stop]TWO[stop][stop][stop]THREE[stop][stop]>

2e) Split a string delimited by another string and return 2 non-empty
elements:
The return value contains these 2 elements:
<ONE><TWO[stop][stop][stop]THREE[stop][stop]>

*/
```

Remarks

Delimiter characters (the characters in the `separator` array) are not included in the elements of the returned array. For example, if the `separator` array includes the character "-" and the value of the current string instance is "aa-bb-cc", the method returns an array that contains three elements: "aa", "bb", and "cc".

If this instance does not contain any of the characters in `separator`, the returned array consists of a single element that contains this instance.

If the `options` parameter is RemoveEmptyEntries and the length of this instance is zero, the method returns an empty array.

Each element of `separator` defines a separate delimiter that consists of a single character. If the `options` argument is None, and two delimiters are adjacent or a

delimiter is found at the beginning or end of this instance, the corresponding array element contains String.Empty. For example, if `separator` includes two elements, `'-'` and `'_'`, the value of the string instance is "-_aa-_", and the value of the `options` argument is None, the method returns a string array with the following five elements:

1. String.Empty, which represents the empty string that precedes the "-" character at index 0.
2. String.Empty, which represents the empty string between the "-" character at index 0 and the "_" character at index 1.
3. "aa".
4. String.Empty, which represents the empty string that follows the "-" character at index 4.
5. String.Empty, which represents the empty string that follows the "_" character at index 5.

The separator array

If the `separator` parameter is `null` or contains no characters, white-space characters are assumed to be the delimiters. White-space characters are defined by the Unicode standard and the Char.IsWhiteSpace method returns `true` if they are passed to it.

To pass `null` for the `char[] separator` parameter, you must indicate the type of the `null` to disambiguate the call from some other overloads, such as Split(String[], StringSplitOptions). The following example shows several ways to unambiguously identify this overload.

C#

```
string phrase = "The quick  brown fox";

_ = phrase.Split(default(char[]), StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split((char[]?)null, StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split(null as char[], StringSplitOptions.RemoveEmptyEntries);
```

Comparison details

The Split method extracts the substrings in this string that are delimited by one or more of the characters in the `separator` parameter, and returns those substrings as elements of an array.

The Split method looks for delimiters by performing comparisons using case-sensitive ordinal sort rules. For more information about word, string, and ordinal sorts, see the System.Globalization.CompareOptions enumeration.

Performance considerations

The Split methods allocate memory for the returned array object and a String object for each array element. If your application requires optimal performance or if managing memory allocation is critical in your application, consider using the IndexOf or IndexOfAny method, and optionally the Compare method, to locate a substring within a string.

If you are splitting a string at a separator character, use the IndexOf or IndexOfAny method to locate a separator character in the string. If you are splitting a string at a separator string, use the IndexOf or IndexOfAny method to locate the first character of the separator string. Then use the Compare method to determine whether the characters after that first character are equal to the remaining characters of the separator string.

In addition, if the same set of characters is used to split strings in multiple Split method calls, consider creating a single array and referencing it in each method call. This significantly reduces the additional overhead of each method call.

Notes to Callers

In .NET Framework 3.5 and earlier versions, if the Split(Char[]) method is passed a `separator` that is `null` or contains no characters, the method uses a slightly different set of white-space characters to split the string than the Trim(Char[]) method does to trim the string. Starting with .NET Framework 4, both methods use an identical set of Unicode white-space characters.

UWP	10.0

Split(String, StringSplitOptions)

Splits a string into substrings that are based on the provided string separator.

C#

```
public string[] Split (string? separator, StringSplitOptions options =
System.StringSplitOptions.None);
```

Parameters

`separator` String

A string that delimits the substrings in this string.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array whose elements contain the substrings from this instance that are delimited by `separator`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Split(String[], StringSplitOptions)

Splits a string into substrings based on a specified delimiting string and, optionally, options.

C#

```
public string[] Split (string[]? separator, StringSplitOptions options);
```

Parameters

`separator` String[]

An array of strings that delimit the substrings in this string, an empty array that contains no delimiters, or `null`.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array whose elements contain the substrings in this string that are delimited by one or more strings in `separator`. For more information, see the Remarks section.

Exceptions

ArgumentException

`options` is not one of the StringSplitOptions values.

Examples

The following example illustrates the difference in the arrays returned by calling a string's String.Split(String[], StringSplitOptions) method with its `options` parameter

equal to StringSplitOptions.None and StringSplitOptions.RemoveEmptyEntries.

C#

```
string source = "[stop]ONE[stop][stop]TWO[stop][stop][stop]THREE[stop]
[stop]";
string[] stringSeparators = new string[] { "[stop]" };
string[] result;

// Display the original string and delimiter string.
Console.WriteLine($"Splitting the string:\n   \"{source}\".");
Console.WriteLine();
Console.WriteLine($"Using the delimiter string:\n   \"
{stringSeparators[0]}\"");
Console.WriteLine();

// Split a string delimited by another string and return all elements.
result = source.Split(stringSeparators, StringSplitOptions.None);
Console.WriteLine($"Result including all elements ({result.Length}
elements):");
Console.Write("   ");
foreach (string s in result)
{
    Console.Write("'{0}' ", String.IsNullOrEmpty(s) ? "<>" : s);
}
Console.WriteLine();
Console.WriteLine();

// Split delimited by another string and return all non-empty elements.
result = source.Split(stringSeparators,
StringSplitOptions.RemoveEmptyEntries);
Console.WriteLine($"Result including non-empty elements ({result.Length}
elements):");
Console.Write("   ");
foreach (string s in result)
{
    Console.Write("'{0}' ", String.IsNullOrEmpty(s) ? "<>" : s);
}
Console.WriteLine();

// The example displays the following output:
//    Splitting the string:
//       "[stop]ONE[stop][stop]TWO[stop][stop][stop]THREE[stop][stop]".
//
//    Using the delimiter string:
//       "[stop]"
//
//    Result including all elements (9 elements):
//       '<>' 'ONE' '<>' 'TWO' '<>' '<>' 'THREE' '<>' '<>'
//
//    Result including non-empty elements (3 elements):
//       'ONE' 'TWO' 'THREE'
```

The following example defines an array of separators that include punctuation and white-space characters. Passing this array along with a value of StringSplitOptions.RemoveEmptyEntries to the Split(String[], StringSplitOptions) method returns an array that consists of the individual words from the string.

C#

```
string[] separators = { ",", ".", "!", "?", ";", ":", " " };
string value = "The handsome, energetic, young dog was playing with his
smaller, more lethargic litter mate.";
string[] words = value.Split(separators,
StringSplitOptions.RemoveEmptyEntries);
foreach (var word in words)
    Console.WriteLine(word);

// The example displays the following output:
//       The
//       handsome
//       energetic
//       young
//       dog
//       was
//       playing
//       with
//       his
//       smaller
//       more
//       lethargic
//       litter
//       mate
```

Note that the method is called with the `options` argument set to StringSplitOptions.RemoveEmptyEntries. This prevents the returned array from including String.Empty values that represent empty substring matches between punctuation marks and white-space characters.

Remarks

When a string is delimited by a known set of strings, you can use the Split method to separate it into substrings.

Delimiter strings are not included in the elements of the returned array. For example, if the `separator` array includes the string "--" and the value of the current string instance is "aa--bb--cc", the method returns an array that contains three elements: "aa", "bb", and "cc".

If this instance does not contain any of the strings in `separator`, the returned array consists of a single element that contains this instance.

If the `options` parameter is RemoveEmptyEntries and the length of this instance is zero, the method returns an empty array.

Each element of `separator` defines a separate delimiter that consists of one or more characters. If the `options` argument is None, and two delimiters are adjacent or a delimiter is found at the beginning or end of this instance, the corresponding array element contains String.Empty. For example, if `separator` includes two elements, "-" and "_", the value of the string instance is "-_aa-_", and the value of the `options` argument is None, the method returns a string array with the following five elements:

1. String.Empty, which represents the empty string that precedes the "-" substring at index 0.

2. String.Empty, which represents the empty string between the "-" substring at index 0 and the "_" substring at index 1.

3. "aa".

4. String.Empty, which represents the empty string that follows the "-" substring at index 4.

5. String.Empty, which represents the empty string that follows the "_" substring at index 5.

The separator array

If any of the elements in `separator` consists of multiple characters, the entire substring is considered a delimiter. For example, if one of the elements in `separator` is "10", attempting to split the string "This10is10a10string." returns the following four-element array: { "This", "is", "a", "string." }.

If the `separator` parameter is `null` or contains no non-empty strings, white-space characters are assumed to be the delimiters. White-space characters are defined by the Unicode standard and the Char.IsWhiteSpace method returns `true` if they are passed to it.

To pass `null` for the `string[] separator` parameter, you must indicate the type of the `null` to disambiguate the call from some other overloads, such as Split(Char[],

StringSplitOptions). The following example shows several ways to unambiguously identify this overload.

```
C#

string phrase = "The quick  brown fox";

_ = phrase.Split(default(string[]),
StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split((string[]?)null, StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split(null as string[],
StringSplitOptions.RemoveEmptyEntries);
```

Comparison details

The Split method extracts the substrings in this string that are delimited by one or more of the strings in the `separator` parameter, and returns those substrings as elements of an array.

The Split method looks for delimiters by performing comparisons using case-sensitive ordinal sort rules. For more information about word, string, and ordinal sorts, see the System.Globalization.CompareOptions enumeration.

The Split method ignores any element of `separator` whose value is `null` or the empty string ("").

To avoid ambiguous results when strings in `separator` have characters in common, the Split operation proceeds from the beginning to the end of the value of the instance, and matches the first element in `separator` that is equal to a delimiter in the instance. The order in which substrings are encountered in the instance takes precedence over the order of elements in `separator`.

For example, consider an instance whose value is "abcdef". If the first element in `separator` was "ef" and the second element was "bcde", the result of the split operation would be a string array that contains two elements, "a" and "f". This is because the substring in the instance, "bcde", is encountered and matches an element in `separator` before the substring "f" is encountered.

However, if the first element of `separator` was "bcd" and the second element was "bc", the result of the split operation would be a string array that contains two elements, "a" and "ef". This is because "bcd" is the first delimiter in `separator` that matches a delimiter in the instance. If the order of the separators was reversed so the

first element was "bc" and the second element was "bcd", the result would be a string array that contains two elements, "a" and "def".

Performance considerations

The Split methods allocate memory for the returned array object and a String object for each array element. If your application requires optimal performance or if managing memory allocation is critical in your application, consider using the IndexOf or IndexOfAny method, and optionally the Compare method, to locate a substring within a string.

If you are splitting a string at a separator character, use the IndexOf or IndexOfAny method to locate a separator character in the string. If you are splitting a string at a separator string, use the IndexOf or IndexOfAny method to locate the first character of the separator string. Then use the Compare method to determine whether the characters after that first character are equal to the remaining characters of the separator string.

In addition, if the same set of characters is used to split strings in multiple Split method calls, consider creating a single array and referencing it in each method call. This significantly reduces the additional overhead of each method call.

Notes to Callers

In .NET Framework 3.5 and earlier versions, if the Split(Char[]) method is passed a `separator` that is `null` or contains no characters, the method uses a slightly different set of white-space characters to split the string than the Trim(Char[]) method does to trim the string. Starting with .NET Framework 4, both methods use an identical set of Unicode white-space characters.

Split(Char, Int32, StringSplitOptions)

Splits a string into a maximum number of substrings based on a specified delimiting character and, optionally, options. Splits a string into a maximum number of substrings based on the provided character separator, optionally omitting empty substrings from the result.

C#

```
public string[] Split (char separator, int count, StringSplitOptions
options = System.StringSplitOptions.None);
```

Parameters

`separator` Char

A character that delimits the substrings in this instance.

`count` Int32

The maximum number of elements expected in the array.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array that contains at most `count` substrings from this instance that are delimited by `separator`.

Remarks

If the string has already been split `count` - 1 times, but the end of the string has not been reached, then the last string in the returned array will contain this instance's remaining trailing substring, untouched.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Split(Char[], Int32, StringSplitOptions)

Splits a string into a maximum number of substrings based on specified delimiting characters and, optionally, options.

```
C#

public string[] Split (char[]? separator, int count, StringSplitOptions
options);
```

Parameters

`separator` Char[]

An array of characters that delimit the substrings in this string, an empty array that contains no delimiters, or `null`.

`count` Int32

The maximum number of substrings to return.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array that contains the substrings in this string that are delimited by one or more characters in `separator`. For more information, see the Remarks section.

Exceptions

ArgumentOutOfRangeException

`count` is negative.

ArgumentException

`options` is not one of the StringSplitOptions values.

Examples

The following example uses the StringSplitOptions enumeration to include or exclude substrings generated by the Split method.

C#

```
// This example demonstrates the String.Split() methods that use
// the StringSplitOptions enumeration.
string s1 = ",ONE,,TWO,,,THREE,,";
string s2 = "[stop]" +
            "ONE[stop][stop]" +
            "TWO[stop][stop][stop]" +
            "THREE[stop][stop]";
char[] charSeparators = new char[] { ',' };
string[] stringSeparators = new string[] { "[stop]" };
string[] result;
// ----------------------------------------------------------------------
--------
// Split a string delimited by characters.
// ----------------------------------------------------------------------
--------
Console.WriteLine("1) Split a string delimited by characters:\n");

// Display the original string and delimiter characters.
Console.WriteLine($"1a) The original string is \"{s1}\".");
Console.WriteLine($"The delimiter character is
'{charSeparators[0]}'.\n");

// Split a string delimited by characters and return all elements.
Console.WriteLine("1b) Split a string delimited by characters and " +
                  "return all elements:");
result = s1.Split(charSeparators, StringSplitOptions.None);
Show(result);

// Split a string delimited by characters and return all non-empty
elements.
Console.WriteLine("1c) Split a string delimited by characters and " +
                  "return all non-empty elements:");
result = s1.Split(charSeparators, StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the string and empty string before the
// delimiter and the remainder of the original string after the
```

```
delimiter.
Console.WriteLine("1d) Split a string delimited by characters and " +
                  "return 2 elements:");
result = s1.Split(charSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
// remainder of the original string after the delimiter.
Console.WriteLine("1e) Split a string delimited by characters and " +
                  "return 2 non-empty elements:");
result = s1.Split(charSeparators, 2,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// ---------------------------------------------------------------------
--------
// Split a string delimited by another string.
// ---------------------------------------------------------------------
--------
Console.WriteLine("2) Split a string delimited by another string:\n");

// Display the original string and delimiter string.
Console.WriteLine($"2a) The original string is \"{s2}\".");

Show(result);
```

```
// Display the array of separated strings using a local function
void Show(string[] entries)
{
    Console.WriteLine($"The return value contains these {entries.Length}
elements:");
    foreach (string entry in entries)
    {
        Console.Write($"<{entry}>");
    }
    Console.Write("\n\n");
}

/*
This example produces the following results:

1) Split a string delimited by characters:

1a) The original string is ",ONE,,TWO,,,THREE,,".
The delimiter character is ',',

1b) Split a string delimited by characters and return all elements:
The return value contains these 9 elements:
<><ONE><><TWO><><><THREE><><>

1c) Split a string delimited by characters and return all non-empty
elements:
The return value contains these 3 elements:
<ONE><TWO><THREE>

1d) Split a string delimited by characters and return 2 elements:
The return value contains these 2 elements:
<><ONE,,TWO,,,THREE,,>

1e) Split a string delimited by characters and return 2 non-empty
elements:
The return value contains these 2 elements:
<ONE><TWO,,,THREE,,>

2) Split a string delimited by another string:

2a) The original string is "[stop]ONE[stop][stop]TWO[stop][stop]
[stop]THREE[stop][stop]".
The delimiter string is "[stop]".

2b) Split a string delimited by another string and return all elements:
The return value contains these 9 elements:
<><ONE><><TWO><><><THREE><><>

2c) Split a string delimited by another string and return all non-empty
elements:
The return value contains these 3 elements:
<ONE><TWO><THREE>

2d) Split a string delimited by another string and return 2 elements:
```

```
The return value contains these 2 elements:
<><ONE[stop][stop]TWO[stop][stop][stop]THREE[stop][stop]>

2e) Split a string delimited by another string and return 2 non-empty
elements:
The return value contains these 2 elements:
<ONE><TWO[stop][stop][stop]THREE[stop][stop]>

*/
```

Remarks

Delimiter characters are not included in the elements of the returned array.

If this instance does not contain any of the characters in `separator`, or the `count` parameter is 1, the returned array consists of a single element that contains this instance.

If the `separator` parameter is `null` or contains no characters, white-space characters are assumed to be the delimiters. White-space characters are defined by the Unicode standard and the Char.IsWhiteSpace method returns `true` if they are passed to it.

To pass `null` for the `char[] separator` parameter, you must indicate the type of the `null` to disambiguate the call from some other overloads, such as Split(String[], Int32, StringSplitOptions). The following example shows several ways to unambiguously identify this overload.

C#

```
string phrase = "The quick  brown fox";

_ = phrase.Split(default(char[]), 3,
StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split((char[]?)null, 3,
StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split(null as char[], 3,
StringSplitOptions.RemoveEmptyEntries);
```

If the `count` parameter is zero, or the `options` parameter is RemoveEmptyEntries and the length of this instance is zero, an empty array is returned.

Each element of `separator` defines a separate delimiter character. If the `options` parameter is None, and two delimiters are adjacent or a delimiter is found at the beginning or end of this instance, the corresponding array element contains Empty.

If there are more than `count` substrings in this instance, the first `count` minus 1 substrings are returned in the first `count` minus 1 elements of the return value, and the remaining characters in this instance are returned in the last element of the return value.

If `count` is greater than the number of substrings, the available substrings are returned and no exception is thrown.

Performance considerations

The Split methods allocate memory for the returned array object and a String object for each array element. If your application requires optimal performance or if managing memory allocation is critical in your application, consider using the IndexOf or IndexOfAny method, and optionally the Compare method, to locate a substring within a string.

If you are splitting a string at a separator character, use the IndexOf or IndexOfAny method to locate a separator character in the string. If you are splitting a string at a separator string, use the IndexOf or IndexOfAny method to locate the first character of the separator string. Then use the Compare method to determine whether the characters after that first character are equal to the remaining characters of the separator string.

In addition, if the same set of characters is used to split strings in multiple Split method calls, consider creating a single array and referencing it in each method call. This significantly reduces the additional overhead of each method call.

Notes to Callers

In .NET Framework 3.5 and earlier versions, if the Split(Char[]) method is passed a `separator` that is `null` or contains no characters, the method uses a slightly different set of white-space characters to split the string than the Trim(Char[]) method does to trim the string. Starting with .NET Framework 4, both methods use an identical set of Unicode white-space characters.

UWP	10.0

Split(String, Int32, StringSplitOptions)

Splits a string into a maximum number of substrings based on a specified delimiting string and, optionally, options.

C#

```
public string[] Split (string? separator, int count, StringSplitOptions
options = System.StringSplitOptions.None);
```

Parameters

`separator` String

A string that delimits the substrings in this instance.

`count` Int32

The maximum number of elements expected in the array.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array that contains at most `count` substrings from this instance that are delimited by `separator`.

Remarks

If the string has already been split `count` - 1 times, but the end of the string has not been reached, then the last string in the returned array will contain this instance's remaining trailing substring, untouched.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Split(String[], Int32, StringSplitOptions)

Splits a string into a maximum number of substrings based on specified delimiting strings and, optionally, options.

C#

```
public string[] Split (string[]? separator, int count, StringSplitOptions
options);
```

Parameters

`separator` String[]

The strings that delimit the substrings in this string, an empty array that contains no delimiters, or `null`.

`count` Int32

The maximum number of substrings to return.

`options` StringSplitOptions

A bitwise combination of the enumeration values that specifies whether to trim substrings and include empty substrings.

Returns

String[]

An array whose elements contain the substrings in this string that are delimited by one or more strings in `separator`. For more information, see the Remarks section.

Exceptions

ArgumentOutOfRangeException

`count` is negative.

ArgumentException

`options` is not one of the StringSplitOptions values.

Examples

The following example uses the StringSplitOptions enumeration to include or exclude substrings generated by the Split method.

C#

```
// This example demonstrates the String.Split() methods that use
// the StringSplitOptions enumeration.
string s1 = ",ONE,,TWO,,,THREE,,";
string s2 = "[stop]" +
            "ONE[stop][stop]" +
            "TWO[stop][stop][stop]" +
            "THREE[stop][stop]";
char[] charSeparators = new char[] { ',' };
string[] stringSeparators = new string[] { "[stop]" };
string[] result;
// ----------------------------------------------------------------------
--------
// Split a string delimited by characters.
// ----------------------------------------------------------------------
--------
Console.WriteLine("1) Split a string delimited by characters:\n");

// Display the original string and delimiter characters.
Console.WriteLine($"1a) The original string is \"{s1}\".");
Console.WriteLine($"The delimiter character is
'{charSeparators[0]}'.\n");

// Split a string delimited by characters and return all elements.
Console.WriteLine("1b) Split a string delimited by characters and " +
                  "return all elements:");
result = s1.Split(charSeparators, StringSplitOptions.None);
Show(result);

// Split a string delimited by characters and return all non-empty
elements.
Console.WriteLine("1c) Split a string delimited by characters and " +
```

```
                  "return all non-empty elements:");
result = s1.Split(charSeparators, StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the string and empty string before the
// delimiter and the remainder of the original string after the
delimiter.
Console.WriteLine("1d) Split a string delimited by characters and " +
                  "return 2 elements:");
result = s1.Split(charSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
// remainder of the original string after the delimiter.
Console.WriteLine("1e) Split a string delimited by characters and " +
                  "return 2 non-empty elements:");
result = s1.Split(charSeparators, 2,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// ---------------------------------------------------------------------
--------
// Split a string delimited by another string.
// ---------------------------------------------------------------------
--------
Console.WriteLine("2) Split a string delimited by another string:\n");

// Display the original string and delimiter string.
Console.WriteLine($"2a) The original string is \"{s2}\".");
Console.WriteLine($"The delimiter string is \"
{stringSeparators[0]}\".\n");

// Split a string delimited by another string and return all elements.
Console.WriteLine("2b) Split a string delimited by another string and " +
                  "return all elements:");
result = s2.Split(stringSeparators, StringSplitOptions.None);
Show(result);

// Split the original string at the delimiter and return all non-empty
elements.
Console.WriteLine("2c) Split a string delimited by another string and " +
                  "return all non-empty elements:");
result = s2.Split(stringSeparators,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the empty string before the
// delimiter and the remainder of the original string after the
delimiter.
Console.WriteLine("2d) Split a string delimited by another string and " +
                  "return 2 elements:");
result = s2.Split(stringSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
```

```
// remainder of the original string after the delimiter.
Console.WriteLine("2e) Split a string delimited by another string and " +
                  "return 2 non-empty elements:");
result = s2.Split(stringSeparators, 2,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Display the array of separated strings using a local function
void Show(string[] entries)
{
    Console.WriteLine($"The return value contains these {entries.Length}
elements:");
    foreach (string entry in entries)
    {
        Console.Write($"<{entry}>");
    }
    Console.Write("\n\n");
}

/*
This example produces the following results:

1) Split a string delimited by characters:

1a) The original string is ",ONE,,TWO,,,THREE,,".
The delimiter character is ',',

1b) Split a string delimited by characters and return all elements:
The return value contains these 9 elements:

2e) Split a string delimited by another string and return 2 non-empty
elements:
The return value contains these 2 elements:
<ONE><TWO[stop][stop][stop]THREE[stop][stop]>

*/
```

Remarks

Delimiter strings are not included in the elements of the returned array.

If this instance does not contain any of the strings in `separator`, or the `count` parameter is 1, the returned array consists of a single element that contains this instance.

If the `separator` parameter is `null` or contains no characters, white-space characters are assumed to be the delimiters. White-space characters are defined by the Unicode standard and the Char.IsWhiteSpace method returns `true` if they are passed to it.

To pass `null` for the `string[] separator` parameter, you must indicate the type of the `null` to disambiguate the call from some other overloads, such as Split(Char[], Int32, StringSplitOptions). The following example shows several ways to unambiguously identify this overload.

C#

```
string phrase = "The quick  brown fox";

_ = phrase.Split(default(string[]), 3,
StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split((string[]?)null, 3,
StringSplitOptions.RemoveEmptyEntries);

_ = phrase.Split(null as string[], 3,
StringSplitOptions.RemoveEmptyEntries);
```

If the `count` parameter is zero, or the `options` parameter is RemoveEmptyEntries and the length of this instance is zero, an empty array is returned.

Each element of `separator` defines a separate delimiter that consists of one or more characters. If the `options` parameter is None, and two delimiters are adjacent or a delimiter is found at the beginning or end of this instance, the corresponding array element contains Empty.

If there are more than `count` substrings in this instance, the first `count` minus 1 substrings are returned in the first `count` minus 1 elements of the return value, and the remaining characters in this instance are returned in the last element of the return value.

If `count` is greater than the number of substrings, the available substrings are returned and no exception is thrown.

The separator array

If any of the elements in `separator` consists of multiple characters, the entire substring is considered a delimiter. For example, if one of the elements in `separator` is "10", attempting to split the string "This10is10a10string." returns this four-element array: { "This", "is", "a", "string." }.

Comparison details

The Split method extracts the substrings in this string that are delimited by one or more of the strings in the `separator` parameter, and returns those substrings as elements of an array.

The Split method looks for delimiters by performing comparisons using case-sensitive ordinal sort rules. For more information about word, string, and ordinal sorts, see the System.Globalization.CompareOptions enumeration.

The Split method ignores any element of `separator` whose value is `null` or the empty string ("").

To avoid ambiguous results when strings in `separator` have characters in common, the Split method proceeds from the beginning to the end of the value of the instance, and matches the first element in `separator` that is equal to a delimiter in the instance. The order in which substrings are encountered in the instance takes precedence over the order of elements in `separator`.

For example, consider an instance whose value is "abcdef". If the first element in `separator` was "ef" and the second element was "bcde", the result of the split operation would be "a" and "f". This is because the substring in the instance, "bcde", is encountered and matches an element in `separator` before the substring "f" is encountered.

However, if the first element of `separator` was "bcd" and the second element was "bc", the result of the split operation would be "a" and "ef". This is because "bcd" is the first delimiter in `separator` that matches a delimiter in the instance. If the order of the separators was reversed so the first element was "bc" and the second element was "bcd", the result would be "a" and "def".

Performance considerations

The Split methods allocate memory for the returned array object and a String object for each array element. If your application requires optimal performance or if managing memory allocation is critical in your application, consider using the IndexOf or IndexOfAny method, and optionally the Compare method, to locate a substring within a string.

If you are splitting a string at a separator character, use the IndexOf or IndexOfAny method to locate a separator character in the string. If you are splitting a string at a separator string, use the IndexOf or IndexOfAny method to locate the first character of the separator string. Then use the Compare method to determine whether the characters after that first character are equal to the remaining characters of the separator string.

In addition, if the same set of characters is used to split strings in multiple Split method calls, consider creating a single array and referencing it in each method call. This significantly reduces the additional overhead of each method call.

Notes to Callers

In .NET Framework 3.5 and earlier versions, if the Split(Char[]) method is passed a `separator` that is `null` or contains no characters, the method uses a slightly different set of white-space characters to split the string than the Trim(Char[]) method does to trim the string. Starting with .NET Framework 4, both methods use an identical set of Unicode white-space characters.

String.StartsWith Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

StartsWith(String, Boolean, CultureInfo)	Determines whether the beginning of this string instance matches the specified string when compared using the specified culture.
StartsWith(String, StringComparison)	Determines whether the beginning of this string instance matches the specified string when compared using the specified comparison option.
StartsWith(Char)	Determines whether this string instance starts with the specified character.
StartsWith(String)	Determines whether the beginning of this string instance matches the specified string.

StartsWith(String, Boolean, CultureInfo)

Determines whether the beginning of this string instance matches the specified string when compared using the specified culture.

C#

```
public bool StartsWith (string value, bool ignoreCase,
System.Globalization.CultureInfo? culture);
```

Parameters

`value` String

The string to compare.

`ignoreCase` Boolean

`true` to ignore case during the comparison; otherwise, `false`.

`culture` CultureInfo

Cultural information that determines how this string and `value` are compared. If `culture` is `null`, the current culture is used.

Returns

Boolean

`true` if the `value` parameter matches the beginning of this string; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example determines whether a string occurs at the beginning of another string. The StartsWith method is called several times using case sensitivity, case insensitivity, and different cultures that influence the results of the search.

C#

```
// This code example demonstrates the
// System.String.StartsWith(String, ..., CultureInfo) method.

using System;
using System.Threading;
using System.Globalization;

class Sample
{
    public static void Main()
    {
    string msg1 = "Search for the target string \"{0}\" in the string \"
{1}\".\n";
    string msg2 = "Using the {0} - \"{1}\" culture:";
    string msg3 = "  The string to search ends with the target string:
{0}";
    bool result = false;
    CultureInfo ci;

// Define a target string to search for.
// U+00c5 = LATIN CAPITAL LETTER A WITH RING ABOVE
```

```
    string capitalARing = "\u00c5";

// Define a string to search.
// The result of combining the characters LATIN SMALL LETTER A and
COMBINING
// RING ABOVE (U+0061, U+030a) is linguistically equivalent to the
character
// LATIN SMALL LETTER A WITH RING ABOVE (U+00e5).
    string aRingXYZ = "\u0061\u030a" + "xyz";

// Clear the screen and display an introduction.
    Console.Clear();

// Display the string to search for and the string to search.
    Console.WriteLine(msg1, capitalARing, aRingXYZ);

// Search using English-United States culture.
    ci = new CultureInfo("en-US");
    Console.WriteLine(msg2, ci.DisplayName, ci.Name);

    Console.WriteLine("Case sensitive:");
    result = aRingXYZ.StartsWith(capitalARing, false, ci);
    Console.WriteLine(msg3, result);

    Console.WriteLine("Case insensitive:");
    result = aRingXYZ.StartsWith(capitalARing, true, ci);
    Console.WriteLine(msg3, result);
    Console.WriteLine();

// Search using Swedish-Sweden culture.
    ci = new CultureInfo("sv-SE");
    Console.WriteLine(msg2, ci.DisplayName, ci.Name);

    Console.WriteLine("Case sensitive:");
    result = aRingXYZ.StartsWith(capitalARing, false, ci);
    Console.WriteLine(msg3, result);

    Console.WriteLine("Case insensitive:");
    result = aRingXYZ.StartsWith(capitalARing, true, ci);
    Console.WriteLine(msg3, result);
    }
}

/*
Note: This code example was executed on a console whose user interface
culture is "en-US" (English-United States).

Search for the target string "Å" in the string "a°xyz".

Using the English (United States) - "en-US" culture:
Case sensitive:
  The string to search ends with the target string: False
Case insensitive:
  The string to search ends with the target string: True
```

```
Using the Swedish (Sweden) - "sv-SE" culture:
Case sensitive:
  The string to search ends with the target string: False
Case insensitive:
  The string to search ends with the target string: False

*/
```

Remarks

This method compares the `value` parameter to the substring at the beginning of this string that is the same length as `value`, and returns a value that indicates whether they are equal. To be equal, `value` must be an empty string (String.Empty), must be a reference to this same instance, or must match the beginning of this instance.

This method performs a comparison using the specified casing and culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

StartsWith(String, StringComparison)

Determines whether the beginning of this string instance matches the specified string when compared using the specified comparison option.

C#

```
public bool StartsWith (string value, StringComparison comparisonType);
```

Parameters

`value` String

The string to compare.

`comparisonType` StringComparison

One of the enumeration values that determines how this string and `value` are compared.

Returns

Boolean

`true` if this instance begins with `value`; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`comparisonType` is not a StringComparison value.

Examples

The following example searches for the string "the" at the beginning of a longer string that begins with the word "The". As the output from the example shows, a call to the StartsWith(String, StringComparison) method that performs a culture-insensitive but case-sensitive comparison fails to match the string, while a call that performs a culture- and case-insensitive comparison matches the string.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      String title = "The House of the Seven Gables";
      String searchString = "the";
      StringComparison comparison = StringComparison.InvariantCulture;
      Console.WriteLine("'{0}':", title);
      Console.WriteLine("   Starts with '{0}' ({1:G} comparison): {2}",
                        searchString, comparison,
                        title.StartsWith(searchString, comparison));

      comparison = StringComparison.InvariantCultureIgnoreCase;
      Console.WriteLine("   Starts with '{0}' ({1:G} comparison): {2}",
                        searchString, comparison,
                        title.StartsWith(searchString, comparison));
```

```
   }
}
// The example displays the following output:
//       'The House of the Seven Gables':
//          Starts with 'the' (InvariantCulture comparison): False
//          Starts with 'the' (InvariantCultureIgnoreCase comparison):
True
```

The following example determines whether a string starts with a particular substring. It initializes a two-dimensional string array. The first element in the second dimension contains a string, and the second element contains the string to search for at the start of the first string. The results are affected by the choice of culture, whether case is ignored, and whether an ordinal comparison is performed. Note that when the string instance contains a ligature, culture-sensitive comparisons with its consecutive characters successfully match.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[,] strings = { {"ABCdef", "abc" },
                            {"ABCdef", "abc" },
                            {"œil","oe" },
                            { "læring}", "lae" } };
      for (int ctr1 = strings.GetLowerBound(0); ctr1 <=
strings.GetUpperBound(0); ctr1++)
      {
            foreach (string cmpName in
Enum.GetNames(typeof(StringComparison)))
            {
               StringComparison strCmp = (StringComparison)
Enum.Parse(typeof(StringComparison),
                                                      cmpName);
               string instance = strings[ctr1, 0];
               string value = strings[ctr1, 1];
               Console.WriteLine("{0} starts with {1}: {2} ({3}
comparison)",
                                 instance, value,
                                 instance.StartsWith(value, strCmp),
                                 strCmp);
            }
            Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       ABCdef starts with abc: False (CurrentCulture comparison)
```

```
//       ABCdef starts with abc: True (CurrentCultureIgnoreCase
comparison)
//       ABCdef starts with abc: False (InvariantCulture comparison)
//       ABCdef starts with abc: True (InvariantCultureIgnoreCase
comparison)
//       ABCdef starts with abc: False (Ordinal comparison)
//       ABCdef starts with abc: True (OrdinalIgnoreCase comparison)
//
//       ABCdef starts with abc: False (CurrentCulture comparison)
//       ABCdef starts with abc: True (CurrentCultureIgnoreCase
comparison)
//       ABCdef starts with abc: False (InvariantCulture comparison)
//       ABCdef starts with abc: True (InvariantCultureIgnoreCase
comparison)
//       ABCdef starts with abc: False (Ordinal comparison)
//       ABCdef starts with abc: True (OrdinalIgnoreCase comparison)
//
//       œil starts with oe: True (CurrentCulture comparison)
//       œil starts with oe: True (CurrentCultureIgnoreCase comparison)
//       œil starts with oe: True (InvariantCulture comparison)
//       œil starts with oe: True (InvariantCultureIgnoreCase comparison)
//       œil starts with oe: False (Ordinal comparison)
//       œil starts with oe: False (OrdinalIgnoreCase comparison)
//
//       læring} starts with lae: True (CurrentCulture comparison)
//       læring} starts with lae: True (CurrentCultureIgnoreCase
comparison)
//       læring} starts with lae: True (InvariantCulture comparison)
//       læring} starts with lae: True (InvariantCultureIgnoreCase
comparison)
//       læring} starts with lae: False (Ordinal comparison)
//       læring} starts with lae: False (OrdinalIgnoreCase comparison)
```

Remarks

The StartsWith method compares the `value` parameter to the substring at the beginning of this string and returns a value that indicates whether they are equal. To be equal, `value` must be a reference to this same string, must be the empty string ("""), or must match the beginning of this string. The type of comparison performed by the StartsWith method depends on the value of the `comparisonType` parameter. The comparison can use the conventions of the current culture (StringComparison.CurrentCulture and StringComparison.CurrentCultureIgnoreCase) or the invariant culture (StringComparison.InvariantCulture and StringComparison.InvariantCultureIgnoreCase), or it can consist of a character-by-character comparison of code points (StringComparison.Ordinal or StringComparison.OrdinalIgnoreCase). The comparison can also be case-sensitive (StringComparison.CurrentCulture, StringComparison.InvariantCulture, or StringComparison.Ordinal), or it can ignore case

(StringComparison.CurrentCultureIgnoreCase, StringComparison.InvariantCultureIgnoreCase, StringComparison.OrdinalIgnoreCase).

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

StartsWith(Char)

Determines whether this string instance starts with the specified character.

C#

```
public bool StartsWith (char value);
```

Parameters

`value` Char

The character to compare.

Returns

Boolean

`true` if `value` matches the beginning of this string; otherwise, `false`.

Remarks

This method performs an ordinal (case-sensitive and culture-insensitive) comparison.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

StartsWith(String)

Determines whether the beginning of this string instance matches the specified string.

C#

```
public bool StartsWith (string value);
```

Parameters

`value` String

The string to compare.

Returns

Boolean

`true` if `value` matches the beginning of this string; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

Examples

The following example defines a `StripStartTags` method that uses the StartsWith(String) method to remove HTML start tags from the beginning of a string. Note that the `StripStartTags` method is called recursively to ensure that multiple HTML start tags at the beginning of the line are removed. The example does not remove HTML tags embedded in a string.

C#

```
using System;

public class Example
{
   public static void Main() {
      string [] strSource = { "<b>This is bold text</b>", "<H1>This is
large Text</H1>",
                "<b><i><font color=green>This has multiple tags</font>
</i></b>",
                "<b>This has <i>embedded</i> tags.</b>",
                "<This line simply begins with a lesser than symbol, it
should not be modified" };

      // Display the initial string array.
      Console.WriteLine("The original strings:");
      Console.WriteLine("---------------------");
      foreach (var s in strSource)
         Console.WriteLine(s);
      Console.WriteLine();

      Console.WriteLine("Strings after starting tags have been
stripped:");
      Console.WriteLine("----------------------------------------------
");

      // Display the strings with starting tags removed.
     foreach (var s in strSource)
        Console.WriteLine(StripStartTags(s));
   }

   private static string StripStartTags(string item)
   {
      // Determine whether a tag begins the string.
      if (item.Trim().StartsWith("<")) {
         // Find the closing tag.
         int lastLocation = item.IndexOf( ">" );
         // Remove the tag.
         if (lastLocation >= 0) {
            item =  item.Substring( lastLocation + 1 );

            // Remove any additional starting tags.
            item = StripStartTags(item);
         }
      }
```

```
        return item;
    }
}
// The example displays the following output:
//    The original strings:
//    ---------------------
//    <b>This is bold text</b>
//    <H1>This is large Text</H1>
//    <b><i><font color = green>This has multiple tags</font></i></b>
//    <b>This has <i>embedded</i> tags.</b>
//    <This line simply begins with a lesser than symbol, it should not
be modified
//
//    Strings after starting tags have been stripped:
//    -----------------------------------------------
//    This is bold text</b>
//    This is large Text</H1>
//    This has multiple tags</font></i></b>
//    This has <i>embedded</i> tags.</b>
//    <This line simply begins with a lesser than symbol, it should not
be modified
```

Remarks

This method compares `value` to the substring at the beginning of this instance that is the same length as `value`, and returns an indication whether they are equal. To be equal, `value` must be an empty string (String.Empty), must be a reference to this same instance, or must match the beginning of this instance.

This method performs a word (case-sensitive and culture-sensitive) comparison using the current culture.

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string comparison methods that substitute default values and instead call methods that require parameters to be explicitly specified. To determine whether a string begins with a particular substring by using the string comparison rules of the current culture, signal your intention explicitly by calling the StartsWith(String, StringComparison) method overload with a value of CurrentCulture for its `comparisonType` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

String.Substring Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves a substring from this instance.

This member is overloaded. For complete information about this member, including syntax, usage, and examples, click a name in the overload list.

Overloads

Expand table

Substring(Int32)	Retrieves a substring from this instance. The substring starts at a specified character position and continues to the end of the string.
Substring(Int32, Int32)	Retrieves a substring from this instance. The substring starts at a specified character position and has a specified length.

Substring(Int32)

Retrieves a substring from this instance. The substring starts at a specified character position and continues to the end of the string.

C#

```
public string Substring (int startIndex);
```

Parameters

`startIndex` Int32

The zero-based starting character position of a substring in this instance.

Returns

String

A string that is equivalent to the substring that begins at `startIndex` in this instance, or Empty if `startIndex` is equal to the length of this instance.

Exceptions

ArgumentOutOfRangeException

`startIndex` is less than zero or greater than the length of this instance.

Examples

The following example demonstrates obtaining a substring from a string.

C#

```
string [] info = { "Name: Felica Walker", "Title: Mz.",
                   "Age: 47", "Location: Paris", "Gender: F"};
int found = 0;

Console.WriteLine("The initial values in the array are:");
foreach (string s in info)
    Console.WriteLine(s);

Console.WriteLine("\nWe want to retrieve only the key information. That
is:");
foreach (string s in info)
{
    found = s.IndexOf(": ");
    Console.WriteLine("   {0}", s.Substring(found + 2));
}

// The example displays the following output:
//       The initial values in the array are:
//       Name: Felica Walker
//       Title: Mz.
//       Age: 47
//       Location: Paris
//       Gender: F
//
//       We want to retrieve only the key information. That is:
//          Felica Walker
//          Mz.
//          47
//          Paris
//          F
```

The following example uses the Substring method to separate key/value pairs that are delimited by an equals (`=`) character.

```C#
String[] pairs = { "Color1=red", "Color2=green", "Color3=blue",
                   "Title=Code Repository" };
foreach (var pair in pairs)
{
    int position = pair.IndexOf("=");
    if (position < 0)
        continue;
    Console.WriteLine("Key: {0}, Value: '{1}'",
                      pair.Substring(0, position),
                      pair.Substring(position + 1));
}

// The example displays the following output:
//     Key: Color1, Value: 'red'
//     Key: Color2, Value: 'green'
//     Key: Color3, Value: 'blue'
//     Key: Title, Value: 'Code Repository'
```

The IndexOf method is used to get the position of the equals character in the string. The call to the Substring(Int32, Int32) method extracts the key name, which starts from the first character in the string and extends for the number of characters returned by the call to the IndexOf method. The call to the Substring(Int32) method then extracts the value assigned to the key. It starts at one character position beyond the equals character and extends to the end of the string.

Remarks

You call the Substring(Int32) method to extract a substring from a string that begins at a specified character position and ends at the end of the string. The starting character position is zero-based; in other words, the first character in the string is at index 0, not index 1. To extract a substring that begins at a specified character position and ends before the end of the string, call the Substring(Int32, Int32) method.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string that begins at the `startIndex` position in the current string.

To extract a substring that begins with a particular character or character sequence, call a method such as IndexOf or IndexOf to get the value of `startIndex`. The second

example illustrates this; it extracts a key value that begins one character position after the `=` character.

If `startIndex` is equal to zero, the method returns the original string unchanged.

Substring(Int32, Int32)

Retrieves a substring from this instance. The substring starts at a specified character position and has a specified length.

C#

```
public string Substring (int startIndex, int length);
```

Parameters

`startIndex` Int32

The zero-based starting character position of a substring in this instance.

`length` Int32

The number of characters in the substring.

Returns

String

A string that is equivalent to the substring of length `length` that begins at `startIndex` in this instance, or Empty if `startIndex` is equal to the length of this instance and `length` is zero.

Exceptions

ArgumentOutOfRangeException

`startIndex` plus `length` indicates a position not within this instance.

-or-

`startIndex` or `length` is less than zero.

Examples

The following example illustrates a simple call to the Substring(Int32, Int32) method that extracts two characters from a string starting at the sixth character position (that is, at index five).

C#

```
String value = "This is a string.";
int startIndex = 5;
int length = 2;
String substring = value.Substring(startIndex, length);
Console.WriteLine(substring);

// The example displays the following output:
//       is
```

The following example uses the Substring(Int32, Int32) method in the following three cases to isolate substrings within a string. In two cases the substrings are used in comparisons, and in the third case an exception is thrown because invalid parameters are specified.

- It extracts the single character at the third position in the string (at index 2) and compares it with a "c". This comparison returns `true`.
- It extracts zero characters starting at the fourth position in the string (at index 3) and passes it to the IsNullOrEmpty method. This returns true because the call to the Substring method returns String.Empty.
- It attempts to extract one character starting at the fourth position in the string. Because there is no character at that position, the method call throws an ArgumentOutOfRangeException exception.

C#

```
string myString = "abc";
bool test1 = myString.Substring(2, 1).Equals("c"); // This is true.
Console.WriteLine(test1);
bool test2 = string.IsNullOrEmpty(myString.Substring(3, 0)); // This is
true.
Console.WriteLine(test2);
try
{
   string str3 = myString.Substring(3, 1); // This throws
ArgumentOutOfRangeException.
   Console.WriteLine(str3);
}
catch (ArgumentOutOfRangeException e)
{
   Console.WriteLine(e.Message);
}

// The example displays the following output:
//       True
//       True
//       Index and length must refer to a location within the string.
//       Parameter name: length
```

The following example uses the Substring method to separate key/value pairs that are delimited by an equals (`=`) character.

C#

```
String[] pairs = { "Color1=red", "Color2=green", "Color3=blue",
                   "Title=Code Repository" };
foreach (var pair in pairs)
{
    int position = pair.IndexOf("=");
    if (position < 0)
        continue;
    Console.WriteLine("Key: {0}, Value: '{1}'",
                      pair.Substring(0, position),
```

```
                    pair.Substring(position + 1));
}

// The example displays the following output:
//     Key: Color1, Value: 'red'
//     Key: Color2, Value: 'green'
//     Key: Color3, Value: 'blue'
//     Key: Title, Value: 'Code Repository'
```

The IndexOf method is used to get the position of the equals character in the string. The call to the Substring(Int32, Int32) method extracts the key name, which starts from the first character in the string and extends for the number of characters returned by the call to the IndexOf method. The call to the Substring(Int32) method then extracts the value assigned to the key. It starts at one character position beyond the equals character and extends to the end of the string.

Remarks

You call the Substring(Int32, Int32) method to extract a substring from a string that begins at a specified character position and ends before the end of the string. The starting character position is zero-based; in other words, the first character in the string is at index 0, not index 1. To extract a substring that begins at a specified character position and continues to the end of the string, call the Substring(Int32) method.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string with `length` characters starting from the `startIndex` position in the current string.

The `length` parameter represents the total number of characters to extract from the current string instance. This includes the starting character found at index `startIndex`. In other words, the Substring method attempts to extract characters from index `startIndex` to index `startIndex` + `length` - 1.

To extract a substring that begins with a particular character or character sequence, call a method such as IndexOf or LastIndexOf to get the value of `startIndex`.

If the substring should extend from `startIndex` to a specified character sequence, you can call a method such as IndexOf or LastIndexOf to get the index of the ending

character or character sequence. You can then convert that value to an index position in the string as follows:

- If you've searched for a single character that is to mark the end of the substring, the `length` parameter equals `endIndex` - `startIndex` + 1, where `endIndex` is the return value of the IndexOf or LastIndexOf method. The following example extracts a continuous block of "b" characters from a string.

  C#

  ```
  String s = "aaaaabbbcccccccdd";
  Char charRange = 'b';
  int startIndex = s.IndexOf(charRange);
  int endIndex = s.LastIndexOf(charRange);
  int length = endIndex - startIndex + 1;
  Console.WriteLine("{0}.Substring({1}, {2}) = {3}",
                  s, startIndex, length,
                  s.Substring(startIndex, length));

  // The example displays the following output:
  //       aaaaabbbcccccccdd.Substring(5, 3) = bbb
  ```

- If you've searched for multiple characters that are to mark the end of the substring, the `length` parameter equals `endIndex` + `endMatchLength` - `startIndex`, where `endIndex` is the return value of the IndexOf or LastIndexOf method, and `endMatchLength` is the length of the character sequence that marks the end of the substring. The following example extracts a block of text that contains an XML `<definition>` element.

  C#

  ```
  String s = "<term>extant<definition>still in existence</definition>
  </term>";
  String searchString = "<definition>";
  int startIndex = s.IndexOf(searchString);
  searchString = "</" + searchString.Substring(1);
  int endIndex = s.IndexOf(searchString);
  String substring = s.Substring(startIndex, endIndex +
  searchString.Length - startIndex);
  Console.WriteLine("Original string: {0}", s);
  Console.WriteLine("Substring;       {0}", substring);

  // The example displays the following output:
  //     Original string: <term>extant<definition>still in
  existence</definition></term>
  //     Substring;       <definition>still in existence</definition>
  ```

- If the character or character sequence is not included in the end of the substring, the `length` parameter equals `endIndex` - `startIndex`, where `endIndex` is the return value of the IndexOf or LastIndexOf method.

If `startIndex` is equal to zero and `length` equals the length of the current string, the method returns the original string unchanged.

String.ToCharArray Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the characters in this instance to a Unicode character array.

Overloads

Expand table

ToCharArray(Int32, Int32)	Copies the characters in a specified substring in this instance to a Unicode character array.
ToCharArray()	Copies the characters in this instance to a Unicode character array.

ToCharArray(Int32, Int32)

Copies the characters in a specified substring in this instance to a Unicode character array.

C#

```
public char[] ToCharArray (int startIndex, int length);
```

Parameters

`startIndex` Int32

The starting position of a substring in this instance.

`length` Int32

The length of the substring in this instance.

Returns

Char[]

A Unicode character array whose elements are the `length` number of characters in this instance starting from character position `startIndex`.

Exceptions

ArgumentOutOfRangeException

`startIndex` or `length` is less than zero.

-or-

`startIndex` plus `length` is greater than the length of this instance.

Examples

The following example converts a substring within a string to an array of characters, then enumerates and displays the elements of the array.

C#

```
// Sample for String.ToCharArray(Int32, Int32)
using System;

class Sample {
    public static void Main() {
    string str = "012wxyz789";
    char[] arr;

    arr = str.ToCharArray(3, 4);
    Console.Write("The letters in '{0}' are: '", str);
    Console.Write(arr);
    Console.WriteLine("'");
    Console.WriteLine("Each letter in '{0}' is:", str);
    foreach (char c in arr)
        Console.WriteLine(c);
    }
}
/*
This example produces the following results:
The letters in '012wxyz789' are: 'wxyz'
Each letter in '012wxyz789' is:
w
x
y
z
*/
```

Remarks

This method copies the characters in a portion of a string to a character array. To create a string from a range of characters in a character array, call the String(Char[], Int32, Int32) constructor.

The `startIndex` parameter is zero-based. That is, the index of the first character in the string instance is zero.

If `length` is zero, the returned array is empty and has a zero length. If this instance is `null` or an empty string (""), the returned array is empty and has a zero length.

To create a byte array that contains the encoded characters in a portion of a string, instantiate the appropriate Encoding object and call its GetBytes(String, Int32, Int32, Byte[], Int32) method. Some of the standard encodings available in .NET include:

Expand table

Encoding	Object
ASCII	ASCIIEncoding
UTF-7	UTF7Encoding
UTF-8	UTF8Encoding
UTF-16	UnicodeEncoding
UTF-32	UTF32Encoding

For more information, see Character Encoding in .NET.

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToCharArray()

Copies the characters in this instance to a Unicode character array.

C#

```
public char[] ToCharArray ();
```

Returns

Char[]

A Unicode character array whose elements are the individual characters of this instance. If this instance is an empty string, the returned array is empty and has a zero length.

Examples

The following example calls the ToCharArray method to extract the characters in a string to a character array. It then displays the original string and the elements in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string s = "AaBbCcDd";
      char[] chars = s.ToCharArray();
      Console.WriteLine("Original string: {0}", s);
      Console.WriteLine("Character array:");
      for (int ctr = 0; ctr < chars.Length; ctr++)
      {
```

```
            Console.WriteLine("   {0}: {1}", ctr, chars[ctr]);
        }
    }
}

// The example displays the following output:
//     Original string: AaBbCcDd
//     Character array:
//        0: A
//        1: a
//        2: B
//        3: b
//        4: C
//        5: c
//        6: D
//        7: d
```

Remarks

This method copies each character (that is, each Char object) in a string to a character array. The first character copied is at index zero of the returned character array; the last character copied is at index Array.Length - 1.

To create a string from the characters in a character array, call the String(Char[]) constructor.

To create a byte array that contains the encoded characters in a string, instantiate the appropriate Encoding object and call its Encoding.GetBytes(String) method. Some of the standard encodings available in .NET include the following:

Expand table

Encoding	Object
ASCII	ASCIIEncoding
UTF-7	UTF7Encoding
UTF-8	UTF8Encoding
UTF-16	UnicodeEncoding
UTF-32	UTF32Encoding

For more information, see Character Encoding in .NET.

String.ToLower Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a copy of this string converted to lowercase.

Overloads

Expand table

ToLower()	Returns a copy of this string converted to lowercase.
ToLower(CultureInfo)	Returns a copy of this string converted to lowercase, using the casing rules of the specified culture.

ToLower()

Returns a copy of this string converted to lowercase.

C#

```
public string ToLower ();
```

Returns

String

A string in lowercase.

Examples

The following example converts several mixed case strings to lowercase.

C#

```
using System;

public class ToLowerTest {
    public static void Main() {

        string [] info = {"Name", "Title", "Age", "Location", "Gender"};

        Console.WriteLine("The initial values in the array are:");
        foreach (string s in info)
            Console.WriteLine(s);

        Console.WriteLine("{0}The lowercase of these values is:",
Environment.NewLine);

        foreach (string s in info)
            Console.WriteLine(s.ToLower());

        Console.WriteLine("{0}The uppercase of these values is:",
Environment.NewLine);

        foreach (string s in info)
            Console.WriteLine(s.ToUpper());
    }
}
// The example displays the following output:
//       The initial values in the array are:
//       Name
//       Title
//       Age
//       Location
//       Gender
//
//       The lowercase of these values is:
//       name
//       title
//       age
//       location
//       gender
//
//       The uppercase of these values is:
//       NAME
//       TITLE
//       AGE
//       LOCATION
//       GENDER
```

Remarks

This method takes into account the casing rules of the current culture.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters in the current instance are converted to lowercase.

The casing operation that results from calling the ToLower() method takes the casing conventions of the current culture into account. If you need the lowercase or uppercase version of an operating system identifier, such as a file name, named pipe, or registry key, use the ToLowerInvariant or ToUpperInvariant methods. This produces the same result in every culture (unlike the ToLower() method) and performs more efficiently.

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string casing methods that substitute default values and instead call methods that require parameters to be explicitly specified. To convert a character to lowercase by using the casing conventions of the current culture, signal your intention explicitly by calling the ToLower(CultureInfo) method overload with a value of CurrentCulture for its `culture` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToLower(CultureInfo)

Returns a copy of this string converted to lowercase, using the casing rules of the specified culture.

C#

```
public string ToLower (System.Globalization.CultureInfo? culture);
```

Parameters

`culture` CultureInfo

An object that supplies culture-specific casing rules. If `culture` is `null`, the current culture is used.

Returns

String

The lowercase equivalent of the current string.

Examples

The following example converts two strings of uppercase characters to lowercase characters using the English-United States and Turkish-Turkey cultures, then compares the lowercase strings. The uppercase strings are identical except that for each occurrence of the Unicode LATIN CAPITAL LETTER I in one string, the other string contains LATIN CAPITAL LETTER I WITH DOT ABOVE.

C#

```
// Sample for String.ToLower(CultureInfo)

using System;
using System.Globalization;

class Sample
```

```
{
    public static void Main()
    {
    String str1 = "INDIGO";
    // str2 = str1, except each 'I' is '\u0130' (Unicode LATIN CAPITAL I
WITH DOT ABOVE).
    String str2 = new String(new Char[] {'\u0130', 'N', 'D', '\u0130',
'G', 'O'});
    String str3, str4;

    Console.WriteLine();
    Console.WriteLine("str1 = '{0}'", str1);

    Console.WriteLine();
    Console.WriteLine("str1 is {0} to str2.",
         ((0 == String.CompareOrdinal(str1, str2)) ? "equal" : "not
equal"));
    CodePoints("str1", str1);
    CodePoints("str2", str2);

    Console.WriteLine();
    // str3 is a lower case copy of str2, using English-United States
culture.
    Console.WriteLine("str3 = Lower case copy of str2 using English-
United States culture.");
    str3 = str2.ToLower(new CultureInfo("en-US", false));

    // str4 is a lower case copy of str2, using Turkish-Turkey culture.
    Console.WriteLine("str4 = Lower case copy of str2 using Turkish-
Turkey culture.");
    str4 = str2.ToLower(new CultureInfo("tr-TR", false));

    // Compare the code points in str3 and str4.
    Console.WriteLine();
    Console.WriteLine("str3 is {0} to str4.",
         ((0 == String.CompareOrdinal(str3, str4)) ? "equal" : "not
equal"));
    CodePoints("str3", str3);
    CodePoints("str4", str4);
    }

    public static void CodePoints(String title, String s)
    {
    Console.Write("{0}The code points in {1} are: {0}",
Environment.NewLine, title);
    foreach (ushort u in s)
      Console.Write("{0:x4} ", u);
    Console.WriteLine();
    }
}
/*
This example produces the following results:

str1 = 'INDIGO'
```

```
str1 is not equal to str2.

The code points in str1 are:
0049 004e 0044 0049 0047 004f

The code points in str2 are:
0130 004e 0044 0130 0047 004f

str3 = Lower case copy of str2 using English-United States culture.
str4 = Lower case copy of str2 using Turkish-Turkey culture.

str3 is equal to str4.

The code points in str3 are:
0069 006e 0064 0069 0067 006f

The code points in str4 are:
0069 006e 0064 0069 0067 006f
*/
```

Remarks

The casing rules of the culture specified by the `culture` parameter determine the way the case of the string is changed.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters in the current instance are converted to lowercase.

If you pass the ToLower(CultureInfo) method a CultureInfo object other than CultureInfo.InvariantCulture, the casing operation will take culture-specific rules into account. If you need the lowercase or uppercase version of an operating system identifier, such as a file name, named pipe, or registry key, use the ToLowerInvariant or ToUpperInvariant method. This produces the same result in every culture and performs more efficiently.

String.ToLowerInvariant Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a copy of this String object converted to lowercase using the casing rules of the invariant culture.

C#

```
public string ToLowerInvariant ();
```

Returns

String

The lowercase equivalent of the current string.

Examples

The following example defines a string array that contains a single word in a number of languages. The ToLowerInvariant method is used to populate the elements of a parallel array with the case-insensitive version of each word. The Array.Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>) method is used to sort the case-sensitive array based on the order of elements in the lowercase array to ensure that elements appear in the same order regardless of language.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] words = { "Tuesday", "Salı", "Вторник", "Mardi",
                         "Τρίτη", "Martes", "יום שלישי",
                         "الثلاثاء", "วันอังคาร" };
      // Display array in unsorted order.
      foreach (string word in words)
```

```
         Console.WriteLine(word);
      Console.WriteLine();

      // Create parallel array of words by calling ToLowerInvariant.
      string[] lowerWords = new string[words.Length];
      for (int ctr = words.GetLowerBound(0); ctr <= words.GetUpperBound(0);
ctr++)
         lowerWords[ctr] = words[ctr].ToLowerInvariant();

      // Sort the words array based on the order of lowerWords.
      Array.Sort(lowerWords, words, StringComparer.InvariantCulture);

      // Display the sorted array.
      foreach (string word in words)
         Console.WriteLine(word);
   }
}
// The example displays the following output:
//       Tuesday
//       Salı
//       Вторник
//       Mardi
//       Τρίτη
//       Martes
//       יום שלישי
//       الثلاثاء
//       วันอังคาร
//
//       Mardi
//       Martes
//       Salı
//       Tuesday
//       Τρίτη
//       Вторник
//       יום שלישי
//       الثلاثاء
//       วันอังคาร
```

Remarks

The invariant culture represents a culture that is culture-insensitive. It is associated with the English language but not with a specific country or region. For more information, see the CultureInfo.InvariantCulture property.

If your application depends on the case of a string changing in a predictable way that is unaffected by the current culture, use the ToLowerInvariant method. The ToLowerInvariant method is equivalent to `ToLower(CultureInfo.InvariantCulture)`. The method is recommended when a collection of strings must appear in a predictable order in a user interface control.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters in the current instance are converted to lowercase.

If you need the lowercase or uppercase version of an operating system identifier, such as a file name, named pipe, or registry key, use the ToLowerInvariant or ToUpperInvariant methods.

Applies to

String.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to a String.

Overloads

Expand table

ToString()	Returns this instance of String; no actual conversion is performed.
ToString(IFormatProvider)	Returns this instance of String; no actual conversion is performed.

ToString()

Returns this instance of String; no actual conversion is performed.

C#

```
public override string ToString ();
```

Returns

String

The current string.

Examples

The following example demonstrates the ToString method.Note that the example does not explicitly call the ToString method. Instead, the method is called implicitly by the composite formatting feature.

C#

```
using System;

class stringToString {
    public static void Main() {
    String str1 = "123";
    String str2 = "abc";

    Console.WriteLine("Original str1: {0}", str1);
    Console.WriteLine("Original str2: {0}", str2);
    Console.WriteLine("str1 same as str2?: {0}",
Object.ReferenceEquals(str1, str2));

    str2 = str1.ToString();
    Console.WriteLine();
    Console.WriteLine("New str2:      {0}", str2);
    Console.WriteLine("str1 same as str2?: {0}",
Object.ReferenceEquals(str1, str2));
    }
}
/*
This code produces the following output:
Original str1: 123
Original str2: abc
str1 same as str2?: False

New str2:      123
str1 same as str2?: True
*/
```

Remarks

Because this method simply returns the current string unchanged, there is no need to call it directly. It is usually called implicitly in a composite formatting operation, as the example shows.

- Clone()

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Returns this instance of String; no actual conversion is performed.

```
C#
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

(Reserved) An object that supplies culture-specific formatting information.

Returns

String

The current string.

Implements

ToString(IFormatProvider)

Remarks

`provider` is reserved, and does not currently participate in this operation.

Because this method simply returns the current string unchanged, there is no need to call it directly.

Applies to

String.ToUpper Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a copy of this string converted to uppercase.

Overloads

Expand table

ToUpper()	Returns a copy of this string converted to uppercase.
ToUpper(CultureInfo)	Returns a copy of this string converted to uppercase, using the casing rules of the specified culture.

ToUpper()

Returns a copy of this string converted to uppercase.

C#

```
public string ToUpper ();
```

Returns

String

The uppercase equivalent of the current string.

Examples

The following example calls the ToUpper method to convert a series of one-character strings that contain each character in the Basic Latin, Latin-1 Supplement, and Latin Extended-A character sets. It then displays each string whose uppercase character is different from its lowercase character.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int n = 0;
      for (int ctr = 0x20; ctr <= 0x017F; ctr++) {
         string string1 = ((char)ctr).ToString();
         string upperString = string1.ToUpper();
         if (string1 != upperString) {
            Console.Write(@"{0} (\u+{1}) --> {2} (\u+{3})         ",
                          string1,
                          Convert.ToUInt16(string1[0]).ToString("X4"),
                          upperString,

Convert.ToUInt16(upperString[0]).ToString("X4"));
            n++;
            if (n % 2 == 0) Console.WriteLine();
         }
      }
   }
}
// The example displays the following output:
//    a (\u+0061) --> A (\u+0041)         b (\u+0062) --> B (\u+0042)
//    c (\u+0063) --> C (\u+0043)         d (\u+0064) --> D (\u+0044)
//    e (\u+0065) --> E (\u+0045)         f (\u+0066) --> F (\u+0046)
//    g (\u+0067) --> G (\u+0047)         h (\u+0068) --> H (\u+0048)
//    i (\u+0069) --> I (\u+0049)         j (\u+006A) --> J (\u+004A)
//    k (\u+006B) --> K (\u+004B)         l (\u+006C) --> L (\u+004C)
//    m (\u+006D) --> M (\u+004D)         n (\u+006E) --> N (\u+004E)
//    o (\u+006F) --> O (\u+004F)         p (\u+0070) --> P (\u+0050)
//    q (\u+0071) --> Q (\u+0051)         r (\u+0072) --> R (\u+0052)
//    s (\u+0073) --> S (\u+0053)         t (\u+0074) --> T (\u+0054)
//    u (\u+0075) --> U (\u+0055)         v (\u+0076) --> V (\u+0056)

//    ċ (\u010B) --> Ċ (\u010A)          č (\u010D) --> Č (\u010C)
//    ď (\u010F) --> Ď (\u010E)          đ (\u0111) --> Đ (\u0110)
//    ē (\u0113) --> Ē (\u0112)          ĕ (\u0115) --> Ĕ (\u0114)
//    ė (\u0117) --> Ė (\u0116)          ę (\u0119) --> Ę (\u0118)
//    ě (\u011B) --> Ě (\u011A)          ĝ (\u011D) --> Ĝ (\u011C)
//    ğ (\u011F) --> Ğ (\u011E)          ġ (\u0121) --> Ġ (\u0120)
//    ģ (\u0123) --> Ģ (\u0122)          ĥ (\u0125) --> Ĥ (\u0124)
//    ħ (\u0127) --> Ħ (\u0126)          ĩ (\u0129) --> Ĩ (\u0128)
//    ī (\u012B) --> Ī (\u012A)          ĭ (\u012D) --> Ĭ (\u012C)
//     į (\u012F) --> Ī (\u012E)          ı (\u0131) --> I (\u0049)
//    ij (\u0133) --> IJ (\u0132)        ĵ (\u0135) --> Ĵ (\u0134)
//    ķ (\u0137) --> Ķ (\u0136)          ĺ (\u013A) --> Ĺ (\u0139)
//    ļ (\u013C) --> Ļ (\u013B)          ľ (\u013E) --> Ľ (\u013D)
//    l· (\u0140) --> L· (\u013F)        ł (\u0142) --> Ł (\u0141)
//    ń (\u0144) --> Ń (\u0143)          ņ (\u0146) --> Ņ (\u0145)
//    ň (\u0148) --> Ň (\u0147)          ŋ (\u014B) --> Ŋ (\u014A)
//    ō (\u014D) --> Ō (\u014C)          ŏ (\u014F) --> Ŏ (\u014E)
//    ő (\u0151) --> Ő (\u0150)          œ (\u0153) --> Œ (\u0152)
//    ŕ (\u0155) --> Ŕ (\u0154)          ŗ (\u0157) --> Ŗ (\u0156)
//    ř (\u0159) --> Ř (\u0158)          ś (\u015B) --> Ś (\u015A)
//    ŝ (\u015D) --> Ŝ (\u015C)          ş (\u015F) --> Ş (\u015E)
//    š (\u0161) --> Š (\u0160)          ţ (\u0163) --> Ţ (\u0162)
//    ť (\u0165) --> Ť (\u0164)          ŧ (\u0167) --> Ŧ (\u0166)
//    ũ (\u0169) --> Ũ (\u0168)          ū (\u016B) --> Ū (\u016A)
//    ŭ (\u016D) --> Ŭ (\u016C)          ů (\u016F) --> Ů (\u016E)
//    ű (\u0171) --> Ű (\u0170)          ŭ (\u0173) --> Ŭ (\u0172)
//    ŵ (\u0175) --> Ŵ (\u0174)          ŷ (\u0177) --> Ŷ (\u0176)
//    ź (\u017A) --> Ź (\u0179)          ż (\u017C) --> Ż (\u017B)
//    ž (\u017E) --> Ž (\u017D)
```

Remarks

This method uses the casing rules of the current culture to convert each character in the current instance to its uppercase equivalent. If a character does not have an uppercase equivalent, it is included unchanged in the returned string.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters in the current instance are converted to uppercase.

The ToUpper method is often used to convert a string to uppercase so that it can be used in a case-insensitive comparison. A better method to perform case-insensitive comparison is to call a string comparison method that has a StringComparison

parameter whose value you set to StringComparison.CurrentCultureIgnoreCase for a culture-sensitive, case-insensitive comparison.

The casing operation that results from calling the ToUpper() method takes the casing conventions of the current culture into account. If you need the lowercase or uppercase version of an operating system identifier, such as a file name, named pipe, or registry key, use the ToLowerInvariant or ToUpperInvariant method. This produces the same result in every culture (unlike the ToUpper() method) and performs more efficiently.

Notes to Callers

As explained in Best Practices for Using Strings, we recommend that you avoid calling string casing methods that substitute default values and instead call methods that require parameters to be explicitly specified. To convert a string to uppercase by using the casing conventions of the current culture, signal your intention explicitly by calling the ToUpper(CultureInfo) method overload with a value of CurrentCulture for its `culture` parameter. If you don't need linguistic-aware comparison, consider using Ordinal.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToUpper(CultureInfo)

Returns a copy of this string converted to uppercase, using the casing rules of the specified culture.

```
C#

public string ToUpper (System.Globalization.CultureInfo? culture);
```

Parameters

`culture` CultureInfo

An object that supplies culture-specific casing rules. If `culture` is `null`, the current culture is used.

Returns

String

The uppercase equivalent of the current string.

Examples

The following example converts a string of lowercase characters to two strings of uppercase characters using the English-United States and Turkish-Turkey cultures, then compares the uppercase strings. The uppercase strings are identical except that for each occurrence of the Unicode LATIN CAPITAL LETTER I in one string, the other string contains LATIN CAPITAL LETTER I WITH DOT ABOVE.

```
C#

using System;
using System.Globalization;

class Example
{
    public static void Main()
    {
       string str1 = "indigo";
       string str2, str3;

       // str2 is an uppercase copy of str1, using English-United States
culture.
       str2 = str1.ToUpper(new CultureInfo("en-US", false));
```

```
        // str3 is an uppercase copy of str1, using Turkish-Turkey
culture.
        str3 = str1.ToUpper(new CultureInfo("tr-TR", false));

        // Compare the code points and compare the uppercase strings.
        ShowCodePoints("str1", str1);
        ShowCodePoints("str2", str2);
        ShowCodePoints("str3", str3);
        Console.WriteLine("str2 is {0} to str3.",
             String.CompareOrdinal(str2, str3) == 0 ? "equal" : "not
equal");
    }

    public static void ShowCodePoints(string varName, string s)
    {
        Console.Write("{0} = {1}: ", varName, s);
        foreach (ushort u in s)
          Console.Write("{0:x4} ", u);
        Console.WriteLine();
    }
}
// This example displays the following output:
//       str1 = indigo: 0069 006e 0064 0069 0067 006f
//       str2 = INDIGO: 0049 004e 0044 0049 0047 004f
//       str3 = İNDİGO: 0130 004e 0044 0130 0047 004f
//       str2 is not equal to str3.
```

Remarks

The casing rules of the culture specified by the `culture` parameter determine the way the case of a string is changed.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters in the current instance are converted to uppercase.

If you pass the ToUpper(CultureInfo) method a CultureInfo object other than CultureInfo.InvariantCulture, the casing operation will take culture-specific rules into account. If you need the lowercase or uppercase version of an operating system identifier, such as a file name, named pipe, or registry key, use the ToLowerInvariant or ToUpperInvariant method. This produces the same result in every culture and performs more efficiently.

String.ToUpperInvariant Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a copy of this String object converted to uppercase using the casing rules of the invariant culture.

C#

```
public string ToUpperInvariant ();
```

Returns

String

The uppercase equivalent of the current string.

Examples

The following example defines a string array that contains a single word in a number of languages. The ToUpperInvariant method is used to populate the elements of a parallel array with the case-insensitive version of each word. The Array.Sort<TKey,TValue>(TKey[], TValue[], IComparer<TKey>) method is used to sort the case-sensitive array based on the order of elements in the uppercase array to ensure that elements appear in the same order regardless of language.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      string[] words = { "Tuesday", "Salı", "Вторник", "Mardi",
                         "Τρίτη", "Martes", "יום שלישי",
                         "الثلاثاء", "วันอังคาร" };
      StreamWriter sw = new StreamWriter(@".\output.txt");
```

```
      // Display array in unsorted order.
      foreach (string word in words)
         sw.WriteLine(word);

      sw.WriteLine();

      // Create parallel array of words by calling ToUpperInvariant.
      string[] upperWords = new string[words.Length];
      for (int ctr = words.GetLowerBound(0); ctr <= words.GetUpperBound(0);
ctr++)
         upperWords[ctr] = words[ctr].ToUpperInvariant();

      // Sort the words array based on the order of upperWords.
      Array.Sort(upperWords, words, StringComparer.InvariantCulture);

      // Display the sorted array.
      foreach (string word in words)
         sw.WriteLine(word);

      sw.Close();
   }
}
// The example produces the following output:
//       Tuesday
//       Salı
//       Вторник
//       Mardi
//       Τρίτη
//       Martes
//       יום שלישי
//       الثلاثاء
//       วันอังคาร
//
//       Mardi
//       Martes
//       Salı
//       Tuesday
//       Τρίτη
//       Вторник
//       יום שלישי
//       الثلاثاء
//       วันอังคาร
```

Remarks

The invariant culture represents a culture that is culture-insensitive. It is associated with the English language but not with a specific country or region. For more information, see the CultureInfo.InvariantCulture property.

If your application depends on the case of a string changing in a predictable way that is unaffected by the current culture, use the ToUpperInvariant method. The ToUpperInvariant method is equivalent to `ToUpper(CultureInfo.InvariantCulture)`. The method is recommended when a collection of strings must appear in a predictable order in a user interface control.

> **Note**
>
> This method does not modify the value of the current instance. Instead, it returns a new string in which all characters in the current instance are converted to uppercase.

If you need the lowercase or uppercase version of an operating system identifier, such as a file name, named pipe, or registry key, use the ToLowerInvariant or ToUpperInvariant methods.

String.Trim Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new string in which all leading and trailing occurrences of a set of specified characters from the current string are removed.

Overloads

Expand table

Trim()	Removes all leading and trailing white-space characters from the current string.
Trim(Char[])	Removes all leading and trailing occurrences of a set of characters specified in an array from the current string.
Trim(Char)	Removes all leading and trailing instances of a character from the current string.

Trim()

Removes all leading and trailing white-space characters from the current string.

C#

```
public string Trim ();
```

Returns

String

The string that remains after all white-space characters are removed from the start and end of the current string. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Examples

The following example uses the String.Trim() method to remove any extra white space from strings entered by the user before concatenating them.

C#

```
using System;

public class Example
{
    public static void Main()
    {
        Console.Write("Enter your first name: ");
        string firstName = Console.ReadLine();

        Console.Write("Enter your middle name or initial: ");
        string middleName = Console.ReadLine();

        Console.Write("Enter your last name: ");
        string lastName = Console.ReadLine();

        Console.WriteLine();
        Console.WriteLine("You entered '{0}', '{1}', and '{2}'.",
                          firstName, middleName, lastName);

        string name = ((firstName.Trim() + " " +
middleName.Trim()).Trim() + " " +
                       lastName.Trim()).Trim();
        Console.WriteLine("The result is " + name + ".");

        // The following is a possible output from this example:
        //       Enter your first name:    John
        //       Enter your middle name or initial:
        //       Enter your last name:    Doe
        //
        //       You entered '   John  ', '', and '   Doe'.
        //       The result is John Doe.
    }
}
```

Remarks

The `Trim` method removes from the current string all leading and trailing white-space characters. Each leading and trailing trim operation stops when a non-white-space character is encountered. For example, if the current string is " abc xyz ", the `Trim` method returns "abc xyz". To remove white-space characters between words in a string, use .NET Regular Expressions.

ⓘ Note

If the `Trim` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all leading and trailing white space characters found in the current instance are removed.

If the current string equals Empty or all the characters in the current instance consist of white-space characters, the method returns Empty.

White-space characters are defined by the Unicode standard. The `Trim` method removes any leading and trailing characters that produce a return value of `true` when they are passed to the Char.IsWhiteSpace method.

Notes to Callers

The .NET Framework 3.5 SP1 and earlier versions maintain an internal list of white-space characters that this method trims. Starting with the .NET Framework 4, the method trims all Unicode white-space characters (that is, characters that produce a `true` return value when they are passed to the IsWhiteSpace(Char) method). Because of this change, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions removes two characters, ZERO WIDTH SPACE (U+200B) and ZERO WIDTH NO-BREAK SPACE (U+FEFF), that the Trim() method in the .NET Framework 4and later versions does not remove. In addition, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions does not trim three Unicode white-space characters: MONGOLIAN VOWEL SEPARATOR (U+180E), NARROW NO-BREAK SPACE (U+202F), and MEDIUM MATHEMATICAL SPACE (U+205F).

- TrimEnd(Char[])
- TrimStart(Char[])
- IsWhiteSpace(Char)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Trim(Char[])

Removes all leading and trailing occurrences of a set of characters specified in an array from the current string.

```
C#

public string Trim (params char[]? trimChars);
```

Parameters

`trimChars` Char[]

An array of Unicode characters to remove, or `null`.

Returns

String

The string that remains after all occurrences of the characters in the `trimChars` parameter are removed from the start and end of the current string. If `trimChars` is `null` or an empty array, white-space characters are removed instead. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Examples

The following example uses the `Trim(System.Char[])` method to remove space, asterisk (*), and apostrophe (') characters from a string.

```
C#

char[] charsToTrim = { '*', ' ', '\''};
string banner = "*** Much Ado About Nothing ***";
string result = banner.Trim(charsToTrim);
```

```
Console.WriteLine("Trimmed\n   {0}\nto\n   '{1}'", banner, result);

// The example displays the following output:
//       Trimmed
//          *** Much Ado About Nothing ***
//       to
//          'Much Ado About Nothing'
```

Remarks

The `Trim(System.Char[])` method removes from the current string all leading and trailing characters that are in the `trimChars` parameter. Each leading and trailing trim operation stops when a character that is not in `trimChars` is encountered. For example, if the current string is "123abc456xyz789" and `trimChars` contains the digits from "1" through "9", the `Trim(System.Char[])` method returns "abc456xyz".

> **Note**
>
> If the `Trim(System.Char[])` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all leading and trailing `trimChars` characters found in the current instance are removed.

If the current string equals Empty or all the characters in the current instance consist of characters in the `trimChars` array, the method returns Empty.

If `trimChars` is `null` or an empty array, this method removes any leading or trailing characters that result in the method returning `true` when they are passed to the Char.IsWhiteSpace method.

Notes to Callers

The .NET Framework 3.5 SP1 and earlier versions maintains an internal list of white-space characters that this method trims if `trimChars` is `null` or an empty array. Starting with the .NET Framework 4, if `trimChars` is `null` or an empty array, the method trims all Unicode white-space characters (that is, characters that produce a `true` return value when they are passed to the IsWhiteSpace(Char) method). Because of this change, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions removes two characters, ZERO WIDTH SPACE (U+200B) and ZERO WIDTH NO-BREAK SPACE (U+FEFF), that the Trim() method in the .NET Framework 4and later versions does not remove. In addition, the Trim() method in the .NET Framework 3.5 SP1 and

earlier versions does not trim three Unicode white-space characters: MONGOLIAN VOWEL SEPARATOR (U+180E), NARROW NO-BREAK SPACE (U+202F), and MEDIUM MATHEMATICAL SPACE (U+205F).

UWP	10.0

Trim(Char)

Removes all leading and trailing instances of a character from the current string.

C#

```
public string Trim (char trimChar);
```

Parameters

`trimChar` Char

A Unicode character to remove.

Returns

String

The string that remains after all instances of the `trimChar` character are removed from the start and end of the current string. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Remarks

The `Trim(System.Char)` method removes from the current string all leading and trailing instances of the `trimChar` character. Each leading and trailing trim operation stops when a character different from `trimChar` is encountered. For example, if `trimChar` is `-` and the current string is "---abc---xyz----", the `Trim(System.Char)` method returns "abc---xyz". To remove characters between words in a string, use .NET Regular Expressions.

> **Note**
>
> If the `Trim(System.Char)` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all leading and trailing `trimChar` characters found in the current instance are removed.

If the current string equals Empty or all the characters in the current instance consist of `trimChar` characters, the method returns Empty.

String.TrimEnd Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TrimEnd()	Removes all the trailing white-space characters from the current string.
TrimEnd(Char)	Removes all the trailing occurrences of a character from the current string.
TrimEnd(Char[])	Removes all the trailing occurrences of a set of characters specified in an array from the current string.

TrimEnd()

Removes all the trailing white-space characters from the current string.

C#

```
public string TrimEnd ();
```

Returns

String

The string that remains after all white-space characters are removed from the end of the current string. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Remarks

The `TrimEnd` method removes from the current string all trailing white-space characters. The trim operation stops when the first non white-space character is

encountered at the end of the string. For example, if the current string is " abc xyz ", the `TrimEnd` method returns " abc xyz".

> ⓘ **Note**
>
> If the `TrimEnd` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all trailing white-space characters are removed from the current string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimEnd(Char)

Removes all the trailing occurrences of a character from the current string.

C#

```
public string TrimEnd (char trimChar);
```

Parameters

`trimChar` Char

A Unicode character to remove.

Returns

String

The string that remains after all occurrences of the `trimChar` character are removed from the end of the current string. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Remarks

The `TrimEnd(System.Char)` method removes from the current string all trailing `trimChar` characters. The trim operation stops when the first character that is not `trimChar` is encountered at the end of the string. For example, if `trimChar` is `-` and the current string is "---abc---xyz----", the `TrimEnd(System.Char)` method returns "---abc---xyz".

> **Note**
>
> If the `TrimEnd(System.Char)` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all trailing `trimChar` characters are removed from the current string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimEnd(Char[])

Removes all the trailing occurrences of a set of characters specified in an array from the current string.

C#

```
public string TrimEnd (params char[]? trimChars);
```

Parameters

`trimChars` Char[]

An array of Unicode characters to remove, or `null`.

Returns

String

The string that remains after all occurrences of the characters in the `trimChars` parameter are removed from the end of the current string. If `trimChars` is `null` or an empty array, Unicode white-space characters are removed instead. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Examples

The following example demonstrates how you can use the `TrimEnd(System.Char[])` method to trim white space or punctuation marks from the end of a string.

C#

```
string sentence = "The dog had a bone, a ball, and other toys.";
char[] charsToTrim = {',', '.', ' '};
string[] words = sentence.Split();
foreach (string word in words)
   Console.WriteLine(word.TrimEnd(charsToTrim));

// The example displays the following output:
//       The
//       dog
//       had
//       a
//       bone
//       a
//       ball
//       and
//       other
//       toys
```

Remarks

The `TrimEnd(System.Char[])` method removes from the current string all trailing characters that are in the `trimChars` parameter. The trim operation stops when the first character that is not in `trimChars` is encountered at the end of the string. For example, if the current string is "123abc456xyz789" and `trimChars` contains the digits from "1" through "9", the `TrimEnd(System.Char[])` method returns "123abc456xyz".

ⓘ Note

If the `TrimEnd(System.Char[])` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all trailing characters found in `trimChars` are removed from the current string.

Notes to Callers

The .NET Framework 3.5 SP1 and earlier versions maintains an internal list of white-space characters that this method trims if `trimChars` is `null` or an empty array. Starting with the .NET Framework 4, if `trimChars` is `null` or an empty array, the method trims all Unicode white-space characters (that is, characters that produce a `true` return value when they are passed to the IsWhiteSpace(Char) method). Because of this change, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions removes two characters, ZERO WIDTH SPACE (U+200B) and ZERO WIDTH NO-BREAK SPACE (U+FEFF), that the Trim() method in the .NET Framework 4 and later versions does not remove. In addition, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions does not trim three Unicode white-space characters: MONGOLIAN VOWEL SEPARATOR (U+180E), NARROW NO-BREAK SPACE (U+202F), and MEDIUM MATHEMATICAL SPACE (U+205F).

String.TrimStart Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TrimStart()	Removes all the leading white-space characters from the current string.
TrimStart(Char)	Removes all the leading occurrences of a specified character from the current string.
TrimStart(Char[])	Removes all the leading occurrences of a set of characters specified in an array from the current string.

TrimStart()

Removes all the leading white-space characters from the current string.

C#

```
public string TrimStart ();
```

Returns

String

The string that remains after all white-space characters are removed from the start of the current string. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Remarks

The `TrimStart` method removes from the current string all leading white-space characters. The trim operation stops when a non white-space character is

encountered. For example, if the current string is " abc xyz ", the `TrimStart` method returns "abc xyz ".

> ⓘ **Note**
>
> If the `TrimStart` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all leading white space characters found in the current instance are removed.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimStart(Char)

Removes all the leading occurrences of a specified character from the current string.

C#

```
public string TrimStart (char trimChar);
```

Parameters

`trimChar` Char

The Unicode character to remove.

Returns

String

The string that remains after all occurrences of the `trimChar` character are removed from the start of the current string. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Remarks

The `TrimStart(System.Char)` method removes from the current string all leading `trimChar` characters. The trim operation stops when a character that is not `trimChar` is encountered. For example, if `trimChar` is `-` and the current string is "---abc---xyz-----", the `TrimStart(System.Char)` method returns "abc---xyz----".

> ⓘ **Note**
>
> If the `TrimStart(System.Char)` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all leading `trimChar` characters found in the current instance are removed.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TrimStart(Char[])

Removes all the leading occurrences of a set of characters specified in an array from the current string.

C#

```
public string TrimStart (params char[]? trimChars);
```

Parameters

`trimChars` Char[]

An array of Unicode characters to remove, or `null`.

Returns

String

The string that remains after all occurrences of characters in the `trimChars` parameter are removed from the start of the current string. If `trimChars` is `null` or an empty array, white-space characters are removed instead. If no characters can be trimmed from the current instance, the method returns the current instance unchanged.

Examples

The following example demonstrates the basic functionality of the TrimStart method:

C#

```
// TrimStart examples
string lineWithLeadingSpaces = "   Hello World!";
string lineWithLeadingSymbols = "$$$$Hello World!";
string lineWithLeadingUnderscores = "_____Hello World!";
string lineWithLeadingLetters = "xxxxHello World!";
string lineAfterTrimStart = string.Empty;

// Make it easy to print out and work with all of the examples
string[] lines = { lineWithLeadingSpaces, lineWithLeadingSymbols,
lineWithLeadingUnderscores, lineWithLeadingLetters };

foreach (var line in lines)
{
    Console.WriteLine($"This line has leading characters: {line}");
}
// Output:
// This line has leading characters:    Hello World!
// This line has leading characters: $$$$Hello World!
// This line has leading characters: _____Hello World!
// This line has leading characters: xxxxHello World!

// A basic demonstration of TrimStart in action
lineAfterTrimStart = lineWithLeadingSpaces.TrimStart(' ');
Console.WriteLine($"This is the result after calling TrimStart:
{lineAfterTrimStart}");
// This is the result after calling TrimStart: Hello World!

// Since TrimStart accepts a character array of leading items to be
removed as an argument,
// it's possible to do things like trim multiple pieces of data that each
have different
// leading characters,
foreach (var lineToEdit in lines)
{
    Console.WriteLine(lineToEdit.TrimStart(' ', '$', '_', 'x'));
}
// Result for each: Hello World!
```

```
// or handle pieces of data that have multiple kinds of leading
characters
var lineToBeTrimmed = "__###__ John Smith";
lineAfterTrimStart = lineToBeTrimmed.TrimStart('_', '#', ' ');
Console.WriteLine(lineAfterTrimStart);
// Result: John Smith
```

The following example uses the TrimStart method to trim white space and comment characters from lines of source code. The `StripComments` method wraps a call to TrimStart and passes it a character array that contains a space and the comment character, which is an apostrophe (') in Visual Basic and a slash (/) in C# or F#. The TrimStart method is also called to remove leading white space when evaluating whether a string is a comment.

C#

```
public static string[] StripComments(string[] lines)
{
    List<string> lineList = new List<string>();
    foreach (string line in lines)
    {
        if (line.TrimStart(' ').StartsWith("//"))
            lineList.Add(line.TrimStart(' ', '/'));
    }
    return lineList.ToArray();
}
```

The following example then illustrates a call to the `StripComments` method.

C#

```
public static void Main()
{
    string[] lines = {"using System;",
                      "",
                      "public class HelloWorld",
                      "{",
                      "   public static void Main()",
                      "   {",
                      "      // This code displays a simple greeting",
                      "      // to the console.",
                      "      Console.WriteLine(\"Hello, World.\");",
                      "   }",
                      "}"};
    Console.WriteLine("Before call to StripComments:");
    foreach (string line in lines)
        Console.WriteLine("   {0}", line);

    string[] strippedLines = StripComments(lines);
```

```
    Console.WriteLine("After call to StripComments:");
    foreach (string line in strippedLines)
        Console.WriteLine("   {0}", line);
}
// This code produces the following output to the console:
//    Before call to StripComments:
//       using System;
//
//       public class HelloWorld
//       {
//           public static void Main()
//           {
//               // This code displays a simple greeting
//               // to the console.
//               Console.WriteLine("Hello, World.");
//           }
//       }
//    After call to StripComments:
//       This code displays a simple greeting
//       to the console.
```

Remarks

The `TrimStart(System.Char[])` method removes from the current string all leading characters that are in the `trimChars` parameter. The trim operation stops when a character that is not in `trimChars` is encountered. For example, if the current string is "123abc456xyz789" and `trimChars` contains the digits from "1" through "9", the `TrimStart(System.Char[])` method returns "abc456xyz789".

> **Note**
>
> If the `TrimStart(System.Char[])` method removes any characters from the current instance, this method does not modify the value of the current instance. Instead, it returns a new string in which all leading characters that are in the `trimChars` parameter found in the current instance are removed.

Notes to Callers

The .NET Framework 3.5 SP1 and earlier versions maintains an internal list of white-space characters that this method trims if `trimChars` is `null` or an empty array. Starting with the .NET Framework 4, if `trimChars` is `null` or an empty array, the method trims all Unicode white-space characters (that is, characters that produce a `true` return value when they are passed to the IsWhiteSpace(Char) method). Because

of this change, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions removes two characters, ZERO WIDTH SPACE (U+200B) and ZERO WIDTH NO-BREAK SPACE (U+FEFF), that the Trim() method in the .NET Framework 4 and later versions does not remove. In addition, the Trim() method in the .NET Framework 3.5 SP1 and earlier versions does not trim three Unicode white-space characters: MONGOLIAN VOWEL SEPARATOR (U+180E), NARROW NO-BREAK SPACE (U+202F), and MEDIUM MATHEMATICAL SPACE (U+205F).

String.TryCopyTo(Span<Char>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the contents of this string into the destination span.

C#

```
public bool TryCopyTo (Span<char> destination);
```

Parameters

`destination` Span<Char>

The span into which to copy this string's contents.

Returns

Boolean

`true` if the data was copied; `false` if the destination was too short to fit the contents of the string.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

String.Equality(String, String) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified strings have the same value.

```C#
public static bool operator == (string? a, string? b);
```

Parameters

a String

The first string to compare, or `null`.

b String

The second string to compare, or `null`.

Returns

Boolean

`true` if the value of `a` is the same as the value of `b`; otherwise, `false`.

Examples

The following example demonstrates the equality operator.

```C#
// Example for the String Equality operator.
using System;

class EqualityOp
{
    public static void Main()
    {
        Console.WriteLine(
```

```
            "This example of the String Equality operator\n" +
            "generates the following output.\n" );

        CompareAndDisplay( "ijkl" );
        CompareAndDisplay( "ABCD" );
        CompareAndDisplay( "abcd" );
    }

    static void CompareAndDisplay( string Comparand )
    {
        String  Lower = "abcd";

        Console.WriteLine(
            "\"{0}\" == \"{1}\" ?  {2}",
            Lower, Comparand, Lower == Comparand );
    }
}

/*
This example of the String Equality operator
generates the following output.

"abcd" == "ijkl" ?  False
"abcd" == "ABCD" ?  False
"abcd" == "abcd" ?  True
*/
```

Remarks

The Equality method defines the operation of the equality operator for the String class. It enables code such as that shown in the Example section. The operator, in turn, calls the static Equals(String, String) method, which performs an ordinal (case-sensitive and culture-insensitive) comparison.

> ⓘ **Note**
>
> The Visual Basic compiler does not resolve the equality operator as a call to the **Equality** method. Instead, the equality operator wraps a call to the **Operators.CompareString** method.

Applies to

Product	Versions

String.Implicit(String to ReadOnlySpan<Char>) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines an implicit conversion of a given string to a read-only span of characters.

C#

```
public static implicit operator ReadOnlySpan<char> (string? value);
```

Parameters

`value` String

A string to implicitly convert.

Returns

ReadOnlySpan<Char>

A new read-only span of characters representing the string.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

String.Inequality(String, String) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified strings have different values.

C#

```
public static bool operator != (string? a, string? b);
```

Parameters

a String

The first string to compare, or `null`.

b String

The second string to compare, or `null`.

Returns

Boolean

`true` if the value of `a` is different from the value of `b`; otherwise, `false`.

Examples

The following example demonstrates the inequality operator.

C#

```
// Example for the String Inequality operator.
using System;

class InequalityOp
{
    public static void Main()
```

```
    {
        Console.WriteLine(
            "This example of the String Inequality operator\n" +
            "generates the following output.\n" );

        CompareAndDisplay( "ijkl" );
        CompareAndDisplay( "ABCD" );
        CompareAndDisplay( "abcd" );
    }

    static void CompareAndDisplay( String Comparand )
    {
        String  Lower = "abcd";

        Console.WriteLine(
            "\"{0}\" != \"{1}\" ?  {2}",
            Lower, Comparand, Lower != Comparand );
    }
}

/*
This example of the String Inequality operator
generates the following output.

"abcd" != "ijkl" ?  True
"abcd" != "ABCD" ?  True
"abcd" != "abcd" ?  False
*/
```

Remarks

The Inequality method defines the operation of the inequality operator for the String class. It enables code such as that shown in the Examples section.

The Inequality operator in turn calls the static Equals(String, String) method, which performs an ordinal (case-sensitive and culture-insensitive) comparison.

> ⓘ **Note**
>
> The Visual Basic compiler does not resolve the inequality operator as a call to the **Inequality** method. Instead, the inequality operator wraps a call to the **Operators.CompareString** method.

Applies to

String.IEnumerable<Char>.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumerator that iterates through the current String object.

C#

```
System.Collections.Generic.IEnumerator<char> IEnumerable<char>.GetEnumerator
();
```

Returns

IEnumerator<Char>

A strongly-typed enumerator that can be used to iterate through the current String object.

Implements

GetEnumerator()

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IEnumerable<T> interface object. For more information, see the GetEnumerator method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

String.IEnumerable.GetEnumerator Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an enumerator that iterates through the current String object.

```
C#
System.Collections.IEnumerator IEnumerable.GetEnumerator ();
```

Returns

IEnumerator

An enumerator that can be used to iterate through the current string.

Implements

GetEnumerator()

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IEnumerable interface. For more information, see the IEnumerable.GetEnumerator method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

String.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current string is TrueString; `false` if the value of the current string is FalseString.

Implements

ToBoolean(IFormatProvider)

Exceptions

FormatException

The value of the current string is not TrueString or FalseString.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(String) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

String.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

C#

```
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Byte

The converted value of the current String object.

Implements

ToByte(IFormatProvider)

Exceptions

FormatException

The value of the current String object cannot be parsed.

OverflowException

The value of the current String object is a number greater than Byte.MaxValue or less than Byte.MinValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

String.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

```
C#
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Char

The character at index 0 in the current String object.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDateTime(IFormatProvider).

C#

```
DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

DateTime

The converted value of the current String object.

Implements

ToDateTime(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDateTime(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Decimal

The converted value of the current String object.

Implements

ToDecimal(IFormatProvider)

Exceptions

FormatException

The value of the current String object cannot be parsed.

OverflowException

The value of the current String object is a number less than Decimal.MinValue or than Decimal.MaxValue greater.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

C#

```
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Double

The converted value of the current String object.

Implements

ToDouble(IFormatProvider)

Exceptions

FormatException

The value of the current String object cannot be parsed.

OverflowException

The value of the current String object is a number less than Double.MinValue or greater than Double.MaxValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Int16

The converted value of the current String object.

Implements

ToInt16(IFormatProvider)

Exceptions

FormatException

The value of the current String object cannot be parsed.

OverflowException

The value of the current String object is a number greater than Int16.MaxValue or less than Int16.MinValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Int32

The converted value of the current String object.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Int64

The converted value of the current String object.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

SByte

The converted value of the current String object.

Implements

ToSByte(IFormatProvider)

Exceptions

FormatException

The value of the current String object cannot be parsed.

OverflowException

The value of the current String object is a number greater than SByte.MaxValue or less than SByte.MinValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSByte(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Single

The converted value of the current String object.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type of the returned object.

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

Object

The converted value of the current String object.

Implements

ToType(Type, IFormatProvider)

Exceptions

ArgumentNullException

`type` is `null`.

InvalidCastException

The value of the current String object cannot be converted to the type specified by the `type` parameter.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

String.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

An object that provides culture-specific formatting information.

Returns

UInt16

The converted value of the current String object.

Implements

ToUInt16(IFormatProvider)

Exceptions

FormatException

The value of the current String object cannot be parsed.

OverflowException

The value of the current String object is a number greater than UInt16.MaxValue or less than UInt16.MinValue.

Remarks

This member is an explicit interface member implementation. It can be used only when the String instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToUInt16(String, IFormatProvider) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

String.IParsable<String>.Parse(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a string into a value.

```
C#
static string IParsable<string>.Parse (string s, IFormatProvider provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

String

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

String.IParsable<String>.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool IParsable<string>.TryParse (string s, IFormatProvider provider,
out string result);
```

Parameters

`s` String

`provider` IFormatProvider

`result` String

Returns

Boolean

Applies to

Product	Versions
.NET	8, 9

String.ISpanParsable<String>.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a span of characters into a value.

```
C#

static string ISpanParsable<string>.Parse (ReadOnlySpan<char> s,
IFormatProvider provider);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

String

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

StringComparer Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a string comparison operation that uses specific case and culture-based or ordinal comparison rules.

C#

```
public abstract class StringComparer :
System.Collections.Generic.IComparer<string>,
System.Collections.Generic.IEqualityComparer<string>,
System.Collections.IComparer, System.Collections.IEqualityComparer
```

Inheritance Object → StringComparer

Implements IComparer<String> , IEqualityComparer<String> , IComparer , IEqualityComparer

Examples

The following example demonstrates the properties and the Create method of the StringComparer class. The example illustrates how different StringComparer objects sort three versions of the Latin letter I.

C#

```
// This example demonstrates members of the
// System.StringComparer class.

using System;
using System.Collections;
using System.Collections.Generic;
using System.Globalization;
using System.Threading;

class Sample
{
    public static void Main()
```

```
    {
        // Create a list of string.
        List<string> list = new List<string>();

        // Get the tr-TR (Turkish-Turkey) culture.
        CultureInfo turkish = new CultureInfo("tr-TR");

        // Get the culture that is associated with the current thread.
        CultureInfo thisCulture = Thread.CurrentThread.CurrentCulture;

        // Get the standard StringComparers.
        StringComparer invCmp =   StringComparer.InvariantCulture;
        StringComparer invICCmp = StringComparer.InvariantCultureIgnoreCase;
        StringComparer currCmp = StringComparer.CurrentCulture;
        StringComparer currICCmp = StringComparer.CurrentCultureIgnoreCase;
        StringComparer ordCmp = StringComparer.Ordinal;
        StringComparer ordICCmp = StringComparer.OrdinalIgnoreCase;

        // Create a StringComparer that uses the Turkish culture and ignores
case.
        StringComparer turkICComp = StringComparer.Create(turkish, true);

        // Define three strings consisting of different versions of the
letter I.
        // LATIN CAPITAL LETTER I (U+0049)
        string capitalLetterI = "I";

        // LATIN SMALL LETTER I (U+0069)
        string smallLetterI   = "i";

        // LATIN SMALL LETTER DOTLESS I (U+0131)
        string smallLetterDotlessI = "\u0131";

        // Add the three strings to the list.
        list.Add(capitalLetterI);
        list.Add(smallLetterI);
        list.Add(smallLetterDotlessI);

        // Display the original list order.
        Display(list, "The original order of the list entries...");

        // Sort the list using the invariant culture.
        list.Sort(invCmp);
        Display(list, "Invariant culture...");
        list.Sort(invICCmp);
        Display(list, "Invariant culture, ignore case...");

        // Sort the list using the current culture.
        Console.WriteLine("The current culture is \"{0}\".",
thisCulture.Name);
        list.Sort(currCmp);
        Display(list, "Current culture...");
        list.Sort(currICCmp);
        Display(list, "Current culture, ignore case...");
```

```
        // Sort the list using the ordinal value of the character code
points.
        list.Sort(ordCmp);
        Display(list, "Ordinal...");
        list.Sort(ordICCmp);
        Display(list, "Ordinal, ignore case...");

        // Sort the list using the Turkish culture, which treats LATIN SMALL
LETTER
        // DOTLESS I differently than LATIN SMALL LETTER I.
        list.Sort(turkICComp);
        Display(list, "Turkish culture, ignore case...");
    }

    public static void Display(List<string> lst, string title)
    {
        Char c;
        int  codePoint;
        Console.WriteLine(title);
        foreach (string s in lst)
        {
            c = s[0];
            codePoint = Convert.ToInt32(c);
            Console.WriteLine("0x{0:x}", codePoint);
        }
        Console.WriteLine();
    }
}
/*
This code example produces the following results:

The original order of the list entries...
0x49
0x69
0x131

*/
```

Remarks

For more information about this API, see Supplemental API remarks for StringComparer.

Constructors

Expand table

StringComparer()	Initializes a new instance of the StringComparer class.

Properties

Expand table

CurrentCulture	Gets a StringComparer object that performs a case-sensitive string comparison using the word comparison rules of the current culture.
CurrentCulture IgnoreCase	Gets a StringComparer object that performs case-insensitive string comparisons using the word comparison rules of the current culture.
InvariantCulture	Gets a StringComparer object that performs a case-sensitive string comparison using the word comparison rules of the invariant culture.
InvariantCulture IgnoreCase	Gets a StringComparer object that performs a case-insensitive string comparison using the word comparison rules of the invariant culture.

Ordinal	Gets a StringComparer object that performs a case-sensitive ordinal string comparison.
OrdinalIgnoreCase	Gets a StringComparer object that performs a case-insensitive ordinal string comparison.

Methods

Expand table

Compare(Object, Object)	When overridden in a derived class, compares two objects and returns an indication of their relative sort order.
Compare(String, String)	When overridden in a derived class, compares two strings and returns an indication of their relative sort order.
Create(CultureInfo, Boolean)	Creates a StringComparer object that compares strings according to the rules of a specified culture.
Create(CultureInfo, CompareOptions)	Creates a StringComparer object that compares strings according to the rules of a specified culture and string options.
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
Equals(Object, Object)	When overridden in a derived class, indicates whether two objects are equal.
Equals(String, String)	When overridden in a derived class, indicates whether two strings are equal.
FromComparison(StringComparison)	Converts the specified StringComparison instance to a StringComparer instance.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetHashCode(Object)	When overridden in a derived class, gets the hash code for the specified object.
GetHashCode(String)	When overridden in a derived class, gets the hash code for the specified string.
GetType()	Gets the Type of the current instance.

	(Inherited from Object)
IsWellKnownCultureAwareComparer(IEqualityComparer<String>, CompareInfo, CompareOptions)	Determines whether the specified IEqualityComparer<T> is a well-known culture-aware string comparer.
IsWellKnownOrdinalComparer(IEqualityComparer<String>, Boolean)	Determines whether the specified IEqualityComparer<T> is a well-known ordinal string comparer.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

StringComparer.CurrentCulture Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StringComparer object that performs a case-sensitive string comparison using the word comparison rules of the current culture.

C#

```
public static StringComparer CurrentCulture { get; }
```

Property Value

StringComparer

A new StringComparer object.

Examples

The following code example demonstrates the properties and the Create method of the StringComparer class. The example illustrates how different StringComparer objects sort three versions of the Latin letter I.

C#

```
// This example demonstrates members of the
// System.StringComparer class.

using System;
using System.Collections;
using System.Collections.Generic;
using System.Globalization;
using System.Threading;

class Sample
{
    public static void Main()
    {
        // Create a list of string.
        List<string> list = new List<string>();
```

```
        // Get the tr-TR (Turkish-Turkey) culture.
        CultureInfo turkish = new CultureInfo("tr-TR");

        // Get the culture that is associated with the current thread.
        CultureInfo thisCulture = Thread.CurrentThread.CurrentCulture;

        // Get the standard StringComparers.
        StringComparer invCmp =   StringComparer.InvariantCulture;
        StringComparer invICCmp = StringComparer.InvariantCultureIgnoreCase;
        StringComparer currCmp = StringComparer.CurrentCulture;
        StringComparer currICCmp = StringComparer.CurrentCultureIgnoreCase;
        StringComparer ordCmp = StringComparer.Ordinal;
        StringComparer ordICCmp = StringComparer.OrdinalIgnoreCase;

        // Create a StringComparer that uses the Turkish culture and ignores
case.
        StringComparer turkICComp = StringComparer.Create(turkish, true);

        // Define three strings consisting of different versions of the
letter I.
        // LATIN CAPITAL LETTER I (U+0049)
        string capitalLetterI = "I";

        // LATIN SMALL LETTER I (U+0069)
        string smallLetterI   = "i";

        // LATIN SMALL LETTER DOTLESS I (U+0131)
        string smallLetterDotlessI = "\u0131";

        // Add the three strings to the list.
        list.Add(capitalLetterI);
        list.Add(smallLetterI);
        list.Add(smallLetterDotlessI);

        // Display the original list order.
        Display(list, "The original order of the list entries...");

        // Sort the list using the invariant culture.
        list.Sort(invCmp);
        Display(list, "Invariant culture...");
        list.Sort(invICCmp);
        Display(list, "Invariant culture, ignore case...");

        // Sort the list using the current culture.
        Console.WriteLine("The current culture is \"{0}\".",
thisCulture.Name);
        list.Sort(currCmp);
        Display(list, "Current culture...");
        list.Sort(currICCmp);
        Display(list, "Current culture, ignore case...");

        // Sort the list using the ordinal value of the character code
points.
        list.Sort(ordCmp);
```

```
        Display(list, "Ordinal...");
        list.Sort(ordICCmp);
        Display(list, "Ordinal, ignore case...");

        // Sort the list using the Turkish culture, which treats LATIN SMALL
LETTER
        // DOTLESS I differently than LATIN SMALL LETTER I.
        list.Sort(turkICComp);
        Display(list, "Turkish culture, ignore case...");
    }

    public static void Display(List<string> lst, string title)
    {
        Char c;
        int  codePoint;
        Console.WriteLine(title);
        foreach (string s in lst)
        {
            c = s[0];
            codePoint = Convert.ToInt32(c);
            Console.WriteLine("0x{0:x}", codePoint);
        }
        Console.WriteLine();
    }
}
/*
This code example produces the following results:

The original order of the list entries...
0x49
0x69
0x131

Invariant culture...
0x69
0x49
0x131

Invariant culture, ignore case...
0x49
0x69
0x131

The current culture is "en-US".
Current culture...
0x69
0x49
0x131

Current culture, ignore case...
0x49
0x69
0x131

Ordinal...
```

```
0x49
0x69
0x131

Ordinal, ignore case...
0x69
0x49
0x131

Turkish culture, ignore case...
0x131
0x49
0x69

*/
```

Remarks

The StringComparer returned by the CurrentCulture property can be used when strings are linguistically relevant. For example, if strings are displayed to the user, or if strings are the result of user interaction, culture-sensitive string comparison should be used to order the string data.

The current culture is the CultureInfo object associated with the current thread.

The CurrentCulture property actually returns an instance of an anonymous class derived from the StringComparer class.

Each call to the CurrentCulture property `get` accessor returns a new StringComparer object, as the following code shows.

C#

```
private void CompareCurrentCultureStringComparer()
{
   StringComparer stringComparer1 = StringComparer.CurrentCulture;
   StringComparer stringComparer2 = StringComparer.CurrentCulture;
   // Displays false
   Console.WriteLine(StringComparer.ReferenceEquals(stringComparer1,
                                                    stringComparer2));
}
```

To improve performance, you can store the StringComparer object in a local variable rather than retrieve the value of the CurrentCulture property multiple times.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

StringComparer.CurrentCultureIgnoreCase Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StringComparer object that performs case-insensitive string comparisons using the word comparison rules of the current culture.

C#

```
public static StringComparer CurrentCultureIgnoreCase { get; }
```

Property Value

StringComparer

A new object for string comparison.

Remarks

The current culture is the CultureInfo object associated with the current thread; it is returned by the CultureInfo.CurrentCulture property.

The StringComparer returned by the CurrentCultureIgnoreCase property can be used when strings are linguistically relevant but their case is not. For example, if strings are displayed to the user but case is unimportant, culture-sensitive, case-insensitive string comparison should be used to order the string data.

> ⓘ Note
>
> **.NET Core running on Linux and macOS systems only:** The collation behavior for the C and Posix cultures is always case-sensitive because these cultures do not use the expected Unicode collation order. We recommend that you use a culture other than C or Posix for performing culture-sensitive, case-insensitive sorting operations.

The CurrentCultureIgnoreCase property actually returns an instance of an anonymous class derived from the StringComparer class.

Each call to the CurrentCultureIgnoreCase property `get` accessor returns a new StringComparer object, as the following code shows.

C#

```
private void CompareCurrentCultureInsensitiveStringComparer()
{
   StringComparer stringComparer1, stringComparer2;
   stringComparer1 = StringComparer.CurrentCultureIgnoreCase;
   stringComparer2 = StringComparer.CurrentCultureIgnoreCase;
   // Displays false
   Console.WriteLine(StringComparer.ReferenceEquals(stringComparer1,
                                                    stringComparer2));
}
```

To improve performance, you can store the StringComparer object in a local variable rather than retrieve the value of the CurrentCultureIgnoreCase property multiple times.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

StringComparer.InvariantCulture Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StringComparer object that performs a case-sensitive string comparison using the word comparison rules of the invariant culture.

C#

```
public static StringComparer InvariantCulture { get; }
```

Property Value

StringComparer

A new StringComparer object.

Examples

The following code example demonstrates the properties and the Create method of the StringComparer class. The example illustrates how different StringComparer objects sort three versions of the Latin letter I.

C#

```
// This example demonstrates members of the
// System.StringComparer class.

using System;
using System.Collections;
using System.Collections.Generic;
using System.Globalization;
using System.Threading;

class Sample
{
    public static void Main()
```

```
    {
        // Create a list of string.
        List<string> list = new List<string>();

        // Get the tr-TR (Turkish-Turkey) culture.
        CultureInfo turkish = new CultureInfo("tr-TR");

        // Get the culture that is associated with the current thread.
        CultureInfo thisCulture = Thread.CurrentThread.CurrentCulture;

        // Get the standard StringComparers.
        StringComparer invCmp =   StringComparer.InvariantCulture;
        StringComparer invICCmp = StringComparer.InvariantCultureIgnoreCase;
        StringComparer currCmp = StringComparer.CurrentCulture;
        StringComparer currICCmp = StringComparer.CurrentCultureIgnoreCase;
        StringComparer ordCmp = StringComparer.Ordinal;
        StringComparer ordICCmp = StringComparer.OrdinalIgnoreCase;

        // Create a StringComparer that uses the Turkish culture and ignores
case.
        StringComparer turkICComp = StringComparer.Create(turkish, true);

        // Define three strings consisting of different versions of the
letter I.
        // LATIN CAPITAL LETTER I (U+0049)
        string capitalLetterI = "I";

        // LATIN SMALL LETTER I (U+0069)
        string smallLetterI   = "i";

        // LATIN SMALL LETTER DOTLESS I (U+0131)
        string smallLetterDotlessI = "\u0131";

        // Add the three strings to the list.
        list.Add(capitalLetterI);
        list.Add(smallLetterI);
        list.Add(smallLetterDotlessI);

        // Display the original list order.
        Display(list, "The original order of the list entries...");

        // Sort the list using the invariant culture.
        list.Sort(invCmp);
        Display(list, "Invariant culture...");
        list.Sort(invICCmp);
        Display(list, "Invariant culture, ignore case...");

        // Sort the list using the current culture.
        Console.WriteLine("The current culture is \"{0}\".",
thisCulture.Name);
        list.Sort(currCmp);
        Display(list, "Current culture...");
        list.Sort(currICCmp);
        Display(list, "Current culture, ignore case...");
```

```
        // Sort the list using the ordinal value of the character code
points.
        list.Sort(ordCmp);
        Display(list, "Ordinal...");
        list.Sort(ordICCmp);
        Display(list, "Ordinal, ignore case...");

        // Sort the list using the Turkish culture, which treats LATIN SMALL
LETTER
        // DOTLESS I differently than LATIN SMALL LETTER I.
        list.Sort(turkICComp);
        Display(list, "Turkish culture, ignore case...");
    }

    public static void Display(List<string> lst, string title)
    {
        Char c;
        int  codePoint;
        Console.WriteLine(title);
        foreach (string s in lst)
        {
            c = s[0];
            codePoint = Convert.ToInt32(c);
            Console.WriteLine("0x{0:x}", codePoint);
        }
        Console.WriteLine();
    }
}
/*
This code example produces the following results:

*/
```

Remarks

The StringComparer returned by the InvariantCulture property compares strings in a linguistically relevant manner, but it is not suitable for display in any particular culture. Its major application is to order strings in a way that will be identical across cultures.

The invariant culture is the CultureInfo object returned by the InvariantCulture property.

The InvariantCulture property actually returns an instance of an anonymous class derived from the StringComparer class.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

StringComparer.InvariantCultureIgnoreCase Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StringComparer object that performs a case-insensitive string comparison using the word comparison rules of the invariant culture.

C#

```
public static StringComparer InvariantCultureIgnoreCase { get; }
```

Property Value

StringComparer

A new StringComparer object.

Remarks

The StringComparer returned by the InvariantCultureIgnoreCase property compares strings in a linguistically relevant manner that ignores case, but it is not suitable for display in any particular culture. Its major application is to order strings in a way that will be identical across cultures.

The invariant culture is the CultureInfo object returned by the InvariantCulture property.

The InvariantCultureIgnoreCase property actually returns an instance of an anonymous class derived from the StringComparer class.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

StringComparer.Ordinal Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StringComparer object that performs a case-sensitive ordinal string comparison.

C#

```
public static StringComparer Ordinal { get; }
```

Property Value

StringComparer

A StringComparer object.

Examples

The following code example demonstrates the properties and the Create method of the StringComparer class. The example illustrates how different StringComparer objects sort three versions of the Latin letter I.

C#

```
// This example demonstrates members of the
// System.StringComparer class.

using System;
using System.Collections;
using System.Collections.Generic;
using System.Globalization;
using System.Threading;

class Sample
{
    public static void Main()
    {
        // Create a list of string.
        List<string> list = new List<string>();
```

```
        // Get the tr-TR (Turkish-Turkey) culture.
        CultureInfo turkish = new CultureInfo("tr-TR");

        // Get the culture that is associated with the current thread.
        CultureInfo thisCulture = Thread.CurrentThread.CurrentCulture;

        // Get the standard StringComparers.
        StringComparer invCmp =   StringComparer.InvariantCulture;
        StringComparer invICCmp = StringComparer.InvariantCultureIgnoreCase;
        StringComparer currCmp = StringComparer.CurrentCulture;
        StringComparer currICCmp = StringComparer.CurrentCultureIgnoreCase;
        StringComparer ordCmp = StringComparer.Ordinal;
        StringComparer ordICCmp = StringComparer.OrdinalIgnoreCase;

        // Create a StringComparer that uses the Turkish culture and ignores
case.
        StringComparer turkICComp = StringComparer.Create(turkish, true);

        // Define three strings consisting of different versions of the
letter I.
        // LATIN CAPITAL LETTER I (U+0049)
        string capitalLetterI = "I";

        // LATIN SMALL LETTER I (U+0069)
        string smallLetterI   = "i";

        // LATIN SMALL LETTER DOTLESS I (U+0131)
        string smallLetterDotlessI = "\u0131";

        // Add the three strings to the list.
        list.Add(capitalLetterI);
        list.Add(smallLetterI);
        list.Add(smallLetterDotlessI);

        // Display the original list order.
        Display(list, "The original order of the list entries...");

        // Sort the list using the invariant culture.
        list.Sort(invCmp);
        Display(list, "Invariant culture...");
        list.Sort(invICCmp);
        Display(list, "Invariant culture, ignore case...");

        // Sort the list using the current culture.
        Console.WriteLine("The current culture is \"{0}\".",
thisCulture.Name);
        list.Sort(currCmp);
        Display(list, "Current culture...");
        list.Sort(currICCmp);
        Display(list, "Current culture, ignore case...");

        // Sort the list using the ordinal value of the character code
points.
        list.Sort(ordCmp);
        Display(list, "Ordinal...");
```

```
        list.Sort(ordICCmp);
        Display(list, "Ordinal, ignore case...");

        // Sort the list using the Turkish culture, which treats LATIN SMALL
LETTER
        // DOTLESS I differently than LATIN SMALL LETTER I.
        list.Sort(turkICComp);
        Display(list, "Turkish culture, ignore case...");
    }

    public static void Display(List<string> lst, string title)
    {
        Char c;
        int  codePoint;
        Console.WriteLine(title);
        foreach (string s in lst)
        {
            c = s[0];
            codePoint = Convert.ToInt32(c);
            Console.WriteLine("0x{0:x}", codePoint);
        }
        Console.WriteLine();
    }
}
/*
This code example produces the following results:

The original order of the list entries...
0x49
0x69
0x131

Invariant culture...
0x69
0x49
0x131

Invariant culture, ignore case...
0x49
0x69
0x131

The current culture is "en-US".
Current culture...
0x69
0x49
0x131

Current culture, ignore case...
0x49
0x69
0x131

Ordinal...
0x49
```

```
0x69
0x131

Ordinal, ignore case...
0x69
0x49
0x131

Turkish culture, ignore case...
0x131
0x49
0x69

*/
```

Remarks

The StringComparer returned by the Ordinal property performs a simple byte comparison that is independent of language. This is most appropriate when comparing strings that are generated programmatically or when comparing case-sensitive resources such as passwords.

The Ordinal property actually returns an instance of an anonymous class derived from the StringComparer class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

StringComparer.OrdinalIgnoreCase Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StringComparer object that performs a case-insensitive ordinal string comparison.

C#

```
public static StringComparer OrdinalIgnoreCase { get; }
```

Property Value

StringComparer

A StringComparer object.

Examples

The following code example demonstrates the properties and the Create method of the StringComparer class. The example illustrates how different StringComparer objects sort three versions of the Latin letter I.

C#

```
// This example demonstrates members of the
// System.StringComparer class.

using System;
using System.Collections;
using System.Collections.Generic;
using System.Globalization;
using System.Threading;

class Sample
{
    public static void Main()
```

```
    {
        // Create a list of string.
        List<string> list = new List<string>();

        // Get the tr-TR (Turkish-Turkey) culture.
        CultureInfo turkish = new CultureInfo("tr-TR");

        // Get the culture that is associated with the current thread.
        CultureInfo thisCulture = Thread.CurrentThread.CurrentCulture;

        // Get the standard StringComparers.
        StringComparer invCmp =   StringComparer.InvariantCulture;
        StringComparer invICCmp = StringComparer.InvariantCultureIgnoreCase;
        StringComparer currCmp = StringComparer.CurrentCulture;
        StringComparer currICCmp = StringComparer.CurrentCultureIgnoreCase;
        StringComparer ordCmp = StringComparer.Ordinal;
        StringComparer ordICCmp = StringComparer.OrdinalIgnoreCase;

        // Create a StringComparer that uses the Turkish culture and ignores
case.
        StringComparer turkICComp = StringComparer.Create(turkish, true);

        // Define three strings consisting of different versions of the
letter I.
        // LATIN CAPITAL LETTER I (U+0049)
        string capitalLetterI = "I";

        // LATIN SMALL LETTER I (U+0069)
        string smallLetterI   = "i";

        // LATIN SMALL LETTER DOTLESS I (U+0131)
        string smallLetterDotlessI = "\u0131";

        // Add the three strings to the list.
        list.Add(capitalLetterI);
        list.Add(smallLetterI);
        list.Add(smallLetterDotlessI);

        // Display the original list order.
        Display(list, "The original order of the list entries...");

        // Sort the list using the invariant culture.
        list.Sort(invCmp);
        Display(list, "Invariant culture...");
        list.Sort(invICCmp);
        Display(list, "Invariant culture, ignore case...");

        // Sort the list using the current culture.
        Console.WriteLine("The current culture is \"{0}\".",
thisCulture.Name);
        list.Sort(currCmp);
        Display(list, "Current culture...");
        list.Sort(currICCmp);
        Display(list, "Current culture, ignore case...");
```

```
        // Sort the list using the ordinal value of the character code
points.
        list.Sort(ordCmp);
        Display(list, "Ordinal...");
        list.Sort(ordICCmp);
        Display(list, "Ordinal, ignore case...");

        // Sort the list using the Turkish culture, which treats LATIN SMALL
LETTER
        // DOTLESS I differently than LATIN SMALL LETTER I.
        list.Sort(turkICComp);
        Display(list, "Turkish culture, ignore case...");
    }

    public static void Display(List<string> lst, string title)
    {
        Char c;
        int  codePoint;
        Console.WriteLine(title);
        foreach (string s in lst)
        {
            c = s[0];
            codePoint = Convert.ToInt32(c);
            Console.WriteLine("0x{0:x}", codePoint);
        }
        Console.WriteLine();
    }
}
/*
This code example produces the following results:

The original order of the list entries...
0x49
0x69
0x131

Invariant culture...
0x69
0x49
0x131

Invariant culture, ignore case...
0x49
0x69
0x131

The current culture is "en-US".
Current culture...
0x69
0x49
0x131

Current culture, ignore case...
0x49
0x69
```

```
0x131

Ordinal...
0x49
0x69
0x131

Ordinal, ignore case...
0x69
0x49
0x131

Turkish culture, ignore case...
0x131
0x49
0x69

*/
```

Remarks

The StringComparer returned by the OrdinalIgnoreCase property treats the characters in the strings to compare as if they were converted to uppercase using the conventions of the invariant culture, and then performs a simple byte comparison that is independent of language. This is most appropriate when comparing strings that are generated programmatically or when comparing case-insensitive resources such as paths and filenames.

The OrdinalIgnoreCase property actually returns an instance of an anonymous class derived from the StringComparer class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

StringComparer.Compare Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two objects or strings and returns an indication of their relative sort order.

Overloads

Expand table

Compare(Object, Object)	When overridden in a derived class, compares two objects and returns an indication of their relative sort order.
Compare(String, String)	When overridden in a derived class, compares two strings and returns an indication of their relative sort order.

Compare(Object, Object)

When overridden in a derived class, compares two objects and returns an indication of their relative sort order.

C#

```
public int Compare (object? x, object? y);
```

Parameters

x Object

An object to compare to `y`.

y Object

An object to compare to `x`.

Returns

Int32

A signed integer that indicates the relative values of `x` and `y`, as shown in the following table.

Expand table

Value	Meaning
Less than zero	`x` precedes `y` in the sort order, or `x` is `null` and `y` is not `null`.
Zero	`x` is equal to `y`, or `x` and `y` are both `null`.
Greater than zero	`x` follows `y` in the sort order, or `y` is `null` and `x` is not `null`.

Implements

Compare(Object, Object)

Exceptions

ArgumentException

Neither `x` nor `y` is a String object, and neither `x` nor `y` implements the IComparable interface.

Remarks

The StringComparer.Compare(String, String) method is slightly more efficient than the StringComparer.Compare(Object, Object) method because no conversion of the `x` and `y` arguments is needed to perform the comparison.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Compare(String, String)

When overridden in a derived class, compares two strings and returns an indication of their relative sort order.

```
C#
public abstract int Compare (string? x, string? y);
```

Parameters

x String

A string to compare to `y`.

y String

A string to compare to `x`.

Returns

Int32

A signed integer that indicates the relative values of `x` and `y`, as shown in the following table.

Expand table

Value	Meaning
Less than zero	`x` precedes `y` in the sort order, or `x` is `null` and `y` is not `null`.
Zero	`x` is equal to `y`, or `x` and `y` are both `null`.
Greater than zero	`x` follows `y` in the sort order, or `y` is `null` and `x` is not `null`.

Implements

Compare(T, T)

Remarks

The StringComparer.Compare(String, String) method is slightly more efficient than the StringComparer.Compare(Object, Object) method because no conversion of the

`x` and `y` arguments is needed to perform the comparison.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

StringComparer.Create Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Create(CultureInfo, Boolean)	Creates a StringComparer object that compares strings according to the rules of a specified culture.
Create(CultureInfo, CompareOptions)	Creates a StringComparer object that compares strings according to the rules of a specified culture and string options.

Create(CultureInfo, Boolean)

Creates a StringComparer object that compares strings according to the rules of a specified culture.

C#

```
public static StringComparer Create (System.Globalization.CultureInfo
culture, bool ignoreCase);
```

Parameters

culture CultureInfo

A culture whose linguistic rules are used to perform a string comparison.

ignoreCase Boolean

`true` to specify that comparison operations be case-insensitive; `false` to specify that comparison operations be case-sensitive.

Returns

StringComparer

A new StringComparer object that performs string comparisons according to the comparison rules used by the `culture` parameter and the case rule specified by the `ignoreCase` parameter.

Exceptions

ArgumentNullException

`culture` is `null`.

Examples

The following code example demonstrates the properties and the Create method of the StringComparer class. The example illustrates how different StringComparer objects sort three versions of the Latin letter I.

C#

```
// This example demonstrates members of the
// System.StringComparer class.

using System;
using System.Collections;
using System.Collections.Generic;
using System.Globalization;
using System.Threading;

class Sample
{
    public static void Main()
    {
        // Create a list of string.
        List<string> list = new List<string>();

        // Get the tr-TR (Turkish-Turkey) culture.
        CultureInfo turkish = new CultureInfo("tr-TR");

        // Get the culture that is associated with the current thread.
        CultureInfo thisCulture = Thread.CurrentThread.CurrentCulture;

        // Get the standard StringComparers.
        StringComparer invCmp =   StringComparer.InvariantCulture;
        StringComparer invICCmp =
StringComparer.InvariantCultureIgnoreCase;
        StringComparer currCmp = StringComparer.CurrentCulture;
        StringComparer currICCmp =
StringComparer.CurrentCultureIgnoreCase;
        StringComparer ordCmp = StringComparer.Ordinal;
```

```
        StringComparer ordICCmp = StringComparer.OrdinalIgnoreCase;

        // Create a StringComparer that uses the Turkish culture and
ignores case.
        StringComparer turkICComp = StringComparer.Create(turkish, true);

        // Define three strings consisting of different versions of the
letter I.
        // LATIN CAPITAL LETTER I (U+0049)
        string capitalLetterI = "I";

        // LATIN SMALL LETTER I (U+0069)
        string smallLetterI   = "i";

        // LATIN SMALL LETTER DOTLESS I (U+0131)
        string smallLetterDotlessI = "\u0131";

        // Add the three strings to the list.
        list.Add(capitalLetterI);
        list.Add(smallLetterI);
        list.Add(smallLetterDotlessI);

        // Display the original list order.
        Display(list, "The original order of the list entries...");

        // Sort the list using the invariant culture.
        list.Sort(invCmp);
        Display(list, "Invariant culture...");
        list.Sort(invICCmp);
        Display(list, "Invariant culture, ignore case...");

        // Sort the list using the current culture.
        Console.WriteLine("The current culture is \"{0}\".",
thisCulture.Name);
        list.Sort(currCmp);
        Display(list, "Current culture...");
        list.Sort(currICCmp);
        Display(list, "Current culture, ignore case...");

        // Sort the list using the ordinal value of the character code
points.
        list.Sort(ordCmp);
        Display(list, "Ordinal...");
        list.Sort(ordICCmp);
        Display(list, "Ordinal, ignore case...");

        // Sort the list using the Turkish culture, which treats LATIN
SMALL LETTER
        // DOTLESS I differently than LATIN SMALL LETTER I.
        list.Sort(turkICComp);
        Display(list, "Turkish culture, ignore case...");
    }

    public static void Display(List<string> lst, string title)
    {
```

```
        Char c;
        int  codePoint;
        Console.WriteLine(title);
        foreach (string s in lst)
        {
            c = s[0];
            codePoint = Convert.ToInt32(c);
            Console.WriteLine("0x{0:x}", codePoint);
        }
        Console.WriteLine();
    }
}
/*

.NET Standard	2.0, 2.1

Create(CultureInfo, CompareOptions)

Creates a StringComparer object that compares strings according to the rules of a specified culture and string options.

C#

```
public static StringComparer Create (System.Globalization.CultureInfo
culture, System.Globalization.CompareOptions options);
```

Parameters

`culture` CultureInfo

A culture whose linguistic rules are used to perform a string comparison.

`options` CompareOptions

A bitwise combination of the CompareOptions values.

Returns

StringComparer

A new StringComparer object that performs string comparisons according to the comparison rules used by the `culture` parameter and the specified `options`.

Exceptions

ArgumentNullException

`culture` is `null`.

ArgumentException

`options` has invalid flags.

Applies to

StringComparer.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, indicates whether two objects or strings are equal.

Overloads

Expand table

Equals(Object, Object)	When overridden in a derived class, indicates whether two objects are equal.
Equals(String, String)	When overridden in a derived class, indicates whether two strings are equal.

Equals(Object, Object)

When overridden in a derived class, indicates whether two objects are equal.

C#

```
public bool Equals (object? x, object? y);
```

Parameters

x Object

An object to compare to `y`.

y Object

An object to compare to `x`.

Returns

Boolean

`true` if `x` and `y` refer to the same object, or `x` and `y` are both the same type of object and those objects are equal, or both `x` and `y` are `null`; otherwise, `false`.

Implements

Equals(Object, Object)

Remarks

Because the runtime does not have to unbox `x` or `y` if they are value types or attempt to downcast `x` or `y` to strings if they are reference types, the Equals(String, String) method may be slightly more efficient than the Equals(Object, Object) method.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

Equals(String, String)

When overridden in a derived class, indicates whether two strings are equal.

C#

```
public abstract bool Equals (string? x, string? y);
```

Parameters

x String

A string to compare to `y`.

y String

A string to compare to `x`.

Returns

Boolean

`true` if `x` and `y` refer to the same object, or `x` and `y` are equal, or `x` and `y` are `null`; otherwise, `false`.

Implements

Equals(T, T)

Remarks

Because the runtime does not have to unbox `x` or `y` if they are value types or attempt to downcast `x` or `y` to strings if they are reference types, the Equals(String, String) method may be slightly more efficient than the Equals(Object, Object) method.

Applies to

StringComparer.FromComparison(StringComparison) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified StringComparison instance to a StringComparer instance.

C#

```
public static StringComparer FromComparison (StringComparison
comparisonType);
```

Parameters

comparisonType StringComparison

A string comparer instance to convert.

Returns

StringComparer

A StringComparer instance representing the equivalent value of the specified StringComparison instance.

Exceptions

ArgumentException

The specified string comparison is not supported.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

StringComparer.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, gets the hash code for the current StringComparer object.

Overloads

Expand table

GetHashCode(String)	When overridden in a derived class, gets the hash code for the specified string.
GetHashCode(Object)	When overridden in a derived class, gets the hash code for the specified object.

GetHashCode(String)

When overridden in a derived class, gets the hash code for the specified string.

C#

```
public abstract int GetHashCode (string obj);
```

Parameters

obj String

A string.

Returns

Int32

A 32-bit signed hash code calculated from the value of the `obj` parameter.

Implements

GetHashCode(T)

Exceptions

ArgumentException

Not enough memory is available to allocate the buffer that is required to compute the hash code.

ArgumentNullException

`obj` is `null`.

Remarks

The GetHashCode(String) method is more efficient than the GetHashCode(Object) method because the `obj` parameter does not have to be unboxed to perform the operation.

The GetHashCode(String) method allocates an amount of memory that is proportional to the size of `obj` to calculate the hash code of `obj`. In the case of large strings, trying to retrieve the hash code can throw an ArgumentException. Instead, you can use an alternate algorithm that allocates a fixed amount of memory when calculating hash codes. To use this algorithm, add the <NetFx45_CultureAwareComparerGetHashCode_LongStrings> element to the <runtime> section of your application's configuration file.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetHashCode(Object)

When overridden in a derived class, gets the hash code for the specified object.

```
C#

public int GetHashCode (object obj);
```

Parameters

`obj` Object

An object.

Returns

Int32

A 32-bit signed hash code calculated from the value of the `obj` parameter.

Implements

GetHashCode(Object)

Exceptions

ArgumentException

Not enough memory is available to allocate the buffer that is required to compute the hash code.

ArgumentNullException

`obj` is `null`.

Remarks

The GetHashCode(String) method is more efficient than the GetHashCode method because the `obj` parameter does not have to be unboxed to perform the operation.

The GetHashCode(Object) method allocates an amount of memory that is proportional to the size of `obj` to calculate the hash code of `obj`. In the case of large strings, trying to retrieve the hash code can throw an ArgumentException. Instead, you can use an alternate algorithm that allocates a fixed amount of memory when

calculating hash codes. To use this algorithm, add the <NetFx45_CultureAwareComparerGetHashCode_LongStrings> element to the <runtime> section of your application's configuration file.

StringComparer.IsWellKnownCultureAwareComparer Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified IEqualityComparer<T> is a well-known culture-aware string comparer.

C#

```
public static bool IsWellKnownCultureAwareComparer
(System.Collections.Generic.IEqualityComparer<string?>? comparer, out
System.Globalization.CompareInfo? compareInfo, out
System.Globalization.CompareOptions compareOptions);
```

Parameters

comparer IEqualityComparer<String>

The comparer to query.

compareInfo CompareInfo

When this method returns, contains a value indicating which CompareInfo was used to create `comparer`. Set to `null` if this method returns `false`.

compareOptions CompareOptions

When this method returns, contains a value indicating which CompareOptions was used to create `comparer`. Set to None if this method returns `false`.

Returns

Boolean

`true` if `comparer` is a well-known culture-aware string comparer; otherwise, `false`.

Remarks

A "well-known culture-aware comparer" describes a comparer that's tied to a specific CompareInfo using some defined CompareOptions. To create a StringComparer instance wrapped around a CompareInfo and CompareOptions, use GetStringComparer(CompareInfo, CompareOptions). This method returns `false` when given Ordinal and other non-linguistic comparers as input.

Applies to

Product	Versions
.NET	6, 7, 8, 9

StringComparer.IsWellKnownOrdinalComparer Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified IEqualityComparer<T> is a well-known ordinal string comparer.

C#

```
public static bool IsWellKnownOrdinalComparer
(System.Collections.Generic.IEqualityComparer<string?>? comparer, out bool
ignoreCase);
```

Parameters

comparer IEqualityComparer<String>

The comparer to query.

ignoreCase Boolean

When this method returns, contains a value stating whether `comparer` is case-insensitive. Set to `false` if this method returns `false`.

Returns

Boolean

`true` if `comparer` is a well-known ordinal string comparer; otherwise, `false`.

Remarks

A "well-known ordinal comparer" describes a comparer that behaves identically to Ordinal when passed to Dictionary<TKey,TValue> or HashSet<T>. For example, Default is a well-known ordinal comparer because a Dictionary<TKey,TValue> given Default as a constructor argument will behave identically to a Dictionary<TKey,TValue> given

Ordinal as a constructor argument. If `ignoreCase` is `true` on method exit, then `comparer` behaves identically to OrdinalIgnoreCase when passed to the constructor of such a collection.

Applies to

Product	Versions
.NET	6, 7, 8, 9

StringComparison Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the culture, case, and sort rules to be used by certain overloads of the Compare(String, String) and Equals(Object) methods.

```
C#
public enum StringComparison
```

Inheritance Object → ValueType → Enum → StringComparison

Fields

Expand table

CurrentCulture	0	Compare strings using culture-sensitive sort rules and the current culture.
CurrentCultureIgnoreCase	1	Compare strings using culture-sensitive sort rules, the current culture, and ignoring the case of the strings being compared.
InvariantCulture	2	Compare strings using culture-sensitive sort rules and the invariant culture.
InvariantCultureIgnoreCase	3	Compare strings using culture-sensitive sort rules, the invariant culture, and ignoring the case of the strings being compared.
Ordinal	4	Compare strings using ordinal (binary) sort rules.
OrdinalIgnoreCase	5	Compare strings using ordinal (binary) sort rules and ignoring the case of the strings being compared.

Examples

The following example compares three sets of strings by using each member of the StringComparison enumeration. The comparisons use the conventions of the English

(United States), Thai (Thailand), and Turkish (Turkey) cultures. Note that the strings "a" and "a-" are considered equivalent in the "th-TH" culture but not in the others, while "i" and "İ" are considered equivalent in the "tr-TR" culture when case is ignored but not in the other cultures.

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example3
{
    public static void Main()
    {
        String[] cultureNames = { "en-US", "th-TH", "tr-TR" };
        String[] strings1 = { "a", "i", "case", };
        String[] strings2 = { "a-", "\u0130", "Case" };
        StringComparison[] comparisons =
(StringComparison[])Enum.GetValues(typeof(StringComparison));

        foreach (var cultureName in cultureNames)
        {
            Thread.CurrentThread.CurrentCulture =
CultureInfo.CreateSpecificCulture(cultureName);
            Console.WriteLine("Current Culture: {0}",
CultureInfo.CurrentCulture.Name);
            for (int ctr = 0; ctr <= strings1.GetUpperBound(0); ctr++)
            {
                foreach (var comparison in comparisons)
                    Console.WriteLine("   {0} = {1} ({2}): {3}",
strings1[ctr],
                                      strings2[ctr], comparison,
                                      String.Equals(strings1[ctr],
strings2[ctr], comparison));

                Console.WriteLine();
            }
            Console.WriteLine();
        }
    }
}
// The example displays the following output:
//    Current Culture: en-US
//       a = a- (CurrentCulture): False
//       a = a- (CurrentCultureIgnoreCase): False
//       a = a- (InvariantCulture): False
//       a = a- (InvariantCultureIgnoreCase): False
//       a = a- (Ordinal): False
//       a = a- (OrdinalIgnoreCase): False
//
//       i = İ (CurrentCulture): False
//       i = İ (CurrentCultureIgnoreCase): False
```

```
//       i = İ (InvariantCulture): False
//       i = İ (InvariantCultureIgnoreCase): False
//       i = İ (Ordinal): False
//       i = İ (OrdinalIgnoreCase): False
//
//       case = Case (CurrentCulture): False
//       case = Case (CurrentCultureIgnoreCase): True
//       case = Case (InvariantCulture): False
//       case = Case (InvariantCultureIgnoreCase): True
//       case = Case (Ordinal): False
//       case = Case (OrdinalIgnoreCase): True
//
//
//    Current Culture: th-TH
//       a = a- (CurrentCulture): True
//       a = a- (CurrentCultureIgnoreCase): True
//       a = a- (InvariantCulture): False
//       a = a- (InvariantCultureIgnoreCase): False
//       a = a- (Ordinal): False
//       a = a- (OrdinalIgnoreCase): False
//
//       i = İ (CurrentCulture): False
//       i = İ (CurrentCultureIgnoreCase): False
//       i = İ (InvariantCulture): False
//       i = İ (InvariantCultureIgnoreCase): False
//       i = İ (Ordinal): False
//       i = İ (OrdinalIgnoreCase): False
//
//       case = Case (CurrentCulture): False
//       case = Case (CurrentCultureIgnoreCase): True
//       case = Case (InvariantCulture): False
//       case = Case (InvariantCultureIgnoreCase): True
//       case = Case (Ordinal): False
//       case = Case (OrdinalIgnoreCase): True
//
//
//    Current Culture: tr-TR
//       a = a- (CurrentCulture): False
//       a = a- (CurrentCultureIgnoreCase): False
//       a = a- (InvariantCulture): False
//       a = a- (InvariantCultureIgnoreCase): False
//       a = a- (Ordinal): False
//       a = a- (OrdinalIgnoreCase): False
//
//       i = İ (CurrentCulture): False
//       i = İ (CurrentCultureIgnoreCase): True
//       i = İ (InvariantCulture): False
//       i = İ (InvariantCultureIgnoreCase): False
//       i = İ (Ordinal): False
//       i = İ (OrdinalIgnoreCase): False
//
//       case = Case (CurrentCulture): False
//       case = Case (CurrentCultureIgnoreCase): True
//       case = Case (InvariantCulture): False
//       case = Case (InvariantCultureIgnoreCase): True
```

```
//       case = Case (Ordinal): False
//       case = Case (OrdinalIgnoreCase): True
```

Remarks

The StringComparison enumeration is used to specify whether a string comparison should use the current culture or the invariant culture, word or ordinal sort rules, and be case-sensitive or case-insensitive.

> ⓘ **Important**
>
> When you call a string comparison method such as **String.Compare**, **String.Equals**, or **String.IndexOf**, you should always call an overload that includes a parameter of type **StringComparison** so that you can specify the type of comparison that the method performs. For more information, see **Best Practices for Using Strings**.

An operation that uses word sort rules performs a culture-sensitive comparison wherein certain nonalphanumeric Unicode characters might have special weights assigned to them. Using word sort rules and the conventions of a specific culture, the hyphen ("-") might have a very small weight assigned to it so that "coop" and "co-op" appear next to each other in a sorted list.

> ⓘ **Note**
>
> **.NET Core running on Linux and macOS systems only:** The collation behavior for the C and Posix cultures is always case-sensitive because these cultures do not use the expected Unicode collation order. We recommend that you use a culture other than C or Posix for performing culture-sensitive, case-insensitive sorting operations.

An operation that uses ordinal sort rules performs a comparison based on the numeric value (Unicode code point) of each Char in the string. An ordinal comparison is fast but culture-insensitive. When you use ordinal sort rules to sort strings that start with Unicode characters (U+), the string U+xxxx comes before the string U+yyyy if the value of xxxx is numerically less than yyyy.

For more information about comparisons, see the System.String class remarks. For more information about culture, see the System.Globalization.CultureInfo class remarks. For guidelines on when to use ordinal or culture-sensitive comparison rules or the rules of the invariant culture, see Best Practices for Using Strings. For a set of text files that contain information on the character weights used in sorting and comparison

operations for Windows operating systems, see Sorting Weight Tables. For the sort weight table for Linux and macOS, see the Default Unicode Collation Element Table.

StringNormalizationExtensions Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides extension methods to work with string normalization.

C#

```
public static class StringNormalizationExtensions
```

Inheritance Object → StringNormalizationExtensions

Remarks

The extension methods of the StringNormalizationExtensions class are designed to work with .NET implementations that do not support the String.IsNormalized and String.Normalize methods. However, these methods are included in the String class in .NET Standard 2.0 and are therefore available on all .NET implementations that support the .NET Standard 2.0. For more information, see .NET Standard.

Methods

Expand table

IsNormalized(String)	Indicates whether the specified string is in Unicode normalization form C.
IsNormalized(String, NormalizationForm)	Indicates whether a string is in a specified Unicode normalization form.
Normalize(String)	Normalizes a string to a Unicode normalization form C.
Normalize(String, NormalizationForm)	Normalizes a string to the specified Unicode normalization form.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1
UWP	10.0

StringNormalizationExtensions.IsNormalized Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a string is normalized.

Overloads

Expand table

IsNormalized(String)	Indicates whether the specified string is in Unicode normalization form C.
IsNormalized(String, NormalizationForm)	Indicates whether a string is in a specified Unicode normalization form.

IsNormalized(String)

Indicates whether the specified string is in Unicode normalization form C.

Parameters

String

A string.

Returns

`true` if `value` is in normalization form C; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`value` contains invalid Unicode characters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1
UWP	10.0

IsNormalized(String, NormalizationForm)

Indicates whether a string is in a specified Unicode normalization form.

Parameters

String

A string.

`normalizationForm` NormalizationForm

A Unicode normalization form.

Returns

`true` if `value` is in normalization form `normalizationForm`; otherwise, `false`.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`value` contains invalid Unicode characters.

Applies to

StringNormalizationExtensions.Normalize Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Normalizes a string.

Overloads

Expand table

Normalize(String)	Normalizes a string to a Unicode normalization form C.
Normalize(String, NormalizationForm)	Normalizes a string to the specified Unicode normalization form.

Normalize(String)

Normalizes a string to a Unicode normalization form C.

Parameters

String

The string to normalize.

Returns

A new string whose textual value is the same as `value` but whose binary representation is in Unicode normalization form C.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`value` contains invalid Unicode characters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1
UWP	10.0

Normalize(String, NormalizationForm)

Normalizes a string to the specified Unicode normalization form.

Parameters

String

The string to normalize.

`normalizationForm` NormalizationForm

The Unicode normalization form.

Returns

A new string whose textual value is the same as `value` but whose binary representation is in the `normalizationForm` normalization form.

Exceptions

ArgumentNullException

`value` is `null`.

ArgumentException

`value` contains invalid Unicode characters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

StringSplitOptions Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies options for applicable Split method overloads, such as whether to omit empty substrings from the returned array or trim whitespace from substrings.

This enumeration supports a bitwise combination of its member values.

C#

```
[System.Flags]
public enum StringSplitOptions
```

Inheritance Object → ValueType → Enum → StringSplitOptions

Attributes FlagsAttribute

Fields

Expand table

None	0	Use the default options when splitting strings.
RemoveEmptyEntries	1	Omit array elements that contain an empty string from the result. If RemoveEmptyEntries and TrimEntries are specified together, then substrings that consist only of white-space characters are also removed from the result.
TrimEntries	2	Trim white-space characters from each substring in the result. This field is available in .NET 5 and later versions only. If RemoveEmptyEntries and TrimEntries are specified together, then substrings that consist only of white-space characters are also removed from the result.

Examples

The following example shows how the `StringSplitOptions` enumeration is used to include or exclude substrings generated by the String.Split method:

C#

```
// This example demonstrates the String.Split() methods that use
// the StringSplitOptions enumeration.
string s1 = ",ONE,,TWO,,,THREE,,";
string s2 = "[stop]" +
            "ONE[stop][stop]" +
            "TWO[stop][stop][stop]" +
            "THREE[stop][stop]";
char[] charSeparators = new char[] { ',' };
string[] stringSeparators = new string[] { "[stop]" };
string[] result;
// ----------------------------------------------------------------------
-----
// Split a string delimited by characters.
// ----------------------------------------------------------------------
-----
Console.WriteLine("1) Split a string delimited by characters:\n");

// Display the original string and delimiter characters.
Console.WriteLine($"1a) The original string is \"{s1}\".");
Console.WriteLine($"The delimiter character is '{charSeparators[0]}'.\n");

// Split a string delimited by characters and return all elements.
Console.WriteLine("1b) Split a string delimited by characters and " +
                  "return all elements:");
result = s1.Split(charSeparators, StringSplitOptions.None);
Show(result);

// Split a string delimited by characters and return all non-empty elements.
Console.WriteLine("1c) Split a string delimited by characters and " +
                  "return all non-empty elements:");
result = s1.Split(charSeparators, StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the string and empty string before the
// delimiter and the remainder of the original string after the delimiter.
Console.WriteLine("1d) Split a string delimited by characters and " +
                  "return 2 elements:");
result = s1.Split(charSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
// remainder of the original string after the delimiter.
Console.WriteLine("1e) Split a string delimited by characters and " +
                  "return 2 non-empty elements:");
result = s1.Split(charSeparators, 2, StringSplitOptions.RemoveEmptyEntries);
Show(result);
```

```
// ---------------------------------------------------------------------------
// Split a string delimited by another string.
// ---------------------------------------------------------------------------
Console.WriteLine("2) Split a string delimited by another string:\n");

// Display the original string and delimiter string.
Console.WriteLine($"2a) The original string is \"{s2}\".");
Console.WriteLine($"The delimiter string is \"{stringSeparators[0]}\".\n");

// Split a string delimited by another string and return all elements.
Console.WriteLine("2b) Split a string delimited by another string and " +
                  "return all elements:");
result = s2.Split(stringSeparators, StringSplitOptions.None);
Show(result);

// Split the original string at the delimiter and return all non-empty
elements.
Console.WriteLine("2c) Split a string delimited by another string and " +
                  "return all non-empty elements:");
result = s2.Split(stringSeparators, StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Split the original string into the empty string before the
// delimiter and the remainder of the original string after the delimiter.
Console.WriteLine("2d) Split a string delimited by another string and " +
                  "return 2 elements:");
result = s2.Split(stringSeparators, 2, StringSplitOptions.None);
Show(result);

// Split the original string into the string after the delimiter and the
// remainder of the original string after the delimiter.
Console.WriteLine("2e) Split a string delimited by another string and " +
                  "return 2 non-empty elements:");
result = s2.Split(stringSeparators, 2,
StringSplitOptions.RemoveEmptyEntries);
Show(result);

// Display the array of separated strings using a local function
void Show(string[] entries)
{
    Console.WriteLine($"The return value contains these {entries.Length}
elements:");
    foreach (string entry in entries)
    {
        Console.Write($"<{entry}>");
    }
    Console.Write("\n\n");
}

/*
This example produces the following results:
```

```
1) Split a string delimited by characters:

1a) The original string is ",ONE,,TWO,,,THREE,,".
The delimiter character is ',',

1b) Split a string delimited by characters and return all elements:
The return value contains these 9 elements:
<><ONE><><TWO><><><THREE><><>

1c) Split a string delimited by characters and return all non-empty
elements:
The return value contains these 3 elements:
<ONE><TWO><THREE>

1d) Split a string delimited by characters and return 2 elements:
The return value contains these 2 elements:
<><ONE,,TWO,,,THREE,,>

1e) Split a string delimited by characters and return 2 non-empty elements:
The return value contains these 2 elements:
<ONE><TWO,,,THREE,,>

2) Split a string delimited by another string:

2a) The original string is "[stop]ONE[stop][stop]TWO[stop][stop]
[stop]THREE[stop][stop]".
The delimiter string is "[stop]".

2b) Split a string delimited by another string and return all elements:
The return value contains these 9 elements:
<><ONE><><TWO><><><THREE><><>

2c) Split a string delimited by another string and return all non-empty
elements:
The return value contains these 3 elements:
<ONE><TWO><THREE>

2d) Split a string delimited by another string and return 2 elements:
The return value contains these 2 elements:
<><ONE[stop][stop]TWO[stop][stop][stop]THREE[stop][stop]>

2e) Split a string delimited by another string and return 2 non-empty
elements:
The return value contains these 2 elements:
<ONE><TWO[stop][stop][stop]THREE[stop][stop]>

*/
```

Remarks

The String.Split method returns an array of the substrings in a given string that are delimited by specified characters or strings. Adjacent delimiters yield an array element

that contains an empty string (`""`). One of the fields of the `StringSplitOptions` enumeration specifies whether an element that contains an empty string should be included in the returned array.

Specify the `None` field to invoke the default behavior of the String.Split method, which is not to trim white-space characters and to include empty substrings.

The `TrimEntries` field is only available in .NET 5 and later versions.

Applies to

SystemException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as the base class for system exceptions namespace.

C#

```
public class SystemException : Exception
```

Inheritance Object → Exception → SystemException

Derived System.AccessViolationException
System.Activities.ValidationException
System.AppDomainUnloadedException
System.ArgumentException
System.ArithmeticException
More...

Remarks

This class is provided as a means to differentiate between system exceptions and application exceptions. It is the base class of such exceptions as ArgumentException, FormatException, and InvalidOperationException.

> ⓘ **Important**
>
> Because **SystemException** serves as the base class of a variety of exception types, your code should not throw a **SystemException** exception, nor should it attempt to handle a **SystemException** exception unless you intend to re-throw the original exception.

SystemException uses the HRESULT COR_E_SYSTEM, that has the value 0x80131501.

Constructors

Expand table

SystemException()	Initializes a new instance of the SystemException class.
SystemException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the SystemException class with serialized data.
SystemException(String)	Initializes a new instance of the SystemException class with a specified error message.
SystemException(String, Exception)	Initializes a new instance of the SystemException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

SystemException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the SystemException class.

Overloads

Expand table

SystemException()	Initializes a new instance of the SystemException class.
SystemException(String)	Initializes a new instance of the SystemException class with a specified error message.
SystemException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the SystemException class with serialized data.
SystemException(String, Exception)	Initializes a new instance of the SystemException class with a specified error message and a reference to the inner exception that is the cause of this exception.

SystemException()

Initializes a new instance of the SystemException class.

C#

```
public SystemException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "A system error has occurred."

This message takes into account the current system culture.

The following table shows the initial property values for an instance of SystemException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

SystemException(String)

Initializes a new instance of the SystemException class with a specified error message.

C#

```
public SystemException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of SystemException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

SystemException(SerializationInfo, StreamingContext)

Caution

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the SystemException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
```

```
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected SystemException (System.Runtime.Serialization.SerializationInfo
info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

SystemException(String, Exception)

Initializes a new instance of the SystemException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#
public SystemException (string? message, Exception? innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of SystemException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

ThreadStaticAttribute Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates that the value of a static field is unique for each thread.

C#

```
[System.AttributeUsage(System.AttributeTargets.Field, Inherited=false)]
public class ThreadStaticAttribute : Attribute
```

Inheritance Object → Attribute → ThreadStaticAttribute

Attributes AttributeUsageAttribute

Examples

The following example instantiates a random number generator, creates ten threads in addition to the main thread, and then generates two million random numbers in each thread. It uses the ThreadStaticAttribute attribute to calculate the sum and the count of random numbers per thread. It also defines two additional per-thread fields, `previous` and `abnormal`, that allows it to detect corruption of the random number generator.

C#

```
using System;
using System.Threading;

public class Example
{
   [ThreadStatic] static double previous = 0.0;
   [ThreadStatic] static double sum = 0.0;
   [ThreadStatic] static int calls = 0;
   [ThreadStatic] static bool abnormal;
   static int totalNumbers = 0;
   static CountdownEvent countdown;
   private static Object lockObj;
   Random rand;
```

```
   public Example()
   {
      rand = new Random();
      lockObj = new Object();
      countdown = new CountdownEvent(1);
   }

   public static void Main()
   {
      Example ex = new Example();
      Thread.CurrentThread.Name = "Main";
      ex.Execute();
      countdown.Wait();
      Console.WriteLine("{0:N0} random numbers were generated.",
totalNumbers);
   }

   private void Execute()
   {
      for (int threads = 1; threads <= 10; threads++)
      {
         Thread newThread = new Thread(new
ThreadStart(this.GetRandomNumbers));
         countdown.AddCount();
         newThread.Name = threads.ToString();
         newThread.Start();
      }
      this.GetRandomNumbers();
   }

   private void GetRandomNumbers()
   {
      double result = 0.0;

      for (int ctr = 0; ctr < 2000000; ctr++)
      {
         lock (lockObj) {
            result = rand.NextDouble();
            calls++;
            Interlocked.Increment(ref totalNumbers);
            // We should never get the same random number twice.
            if (result == previous) {
               abnormal = true;
               break;
            }
            else {
               previous = result;
               sum += result;
            }
         }
      }
      // get last result
      if (abnormal)
         Console.WriteLine("Result is {0} in {1}", previous,
Thread.CurrentThread.Name);
```

```
      Console.WriteLine("Thread {0} finished random number generation.",
Thread.CurrentThread.Name);
      Console.WriteLine("Sum = {0:N4}, Mean = {1:N4}, n = {2:N0}\n", sum,
sum/calls, calls);
      countdown.Signal();
   }
}
// The example displays output similar to the following:
//    Thread 1 finished random number generation.
//    Sum = 1,000,556.7483, Mean = 0.5003, n = 2,000,000
//
//    Thread 6 finished random number generation.
//    Sum = 999,704.3865, Mean = 0.4999, n = 2,000,000
//
//    Thread 2 finished random number generation.
//    Sum = 999,680.8904, Mean = 0.4998, n = 2,000,000
//
//    Thread 10 finished random number generation.
//    Sum = 999,437.5132, Mean = 0.4997, n = 2,000,000
//
//    Thread 8 finished random number generation.
//    Sum = 1,000,663.7789, Mean = 0.5003, n = 2,000,000
//
//    Thread 4 finished random number generation.
//    Sum = 999,379.5978, Mean = 0.4997, n = 2,000,000
//
//    Thread 5 finished random number generation.
//    Sum = 1,000,011.0605, Mean = 0.5000, n = 2,000,000
//
//    Thread 9 finished random number generation.
//    Sum = 1,000,637.4556, Mean = 0.5003, n = 2,000,000
//
//    Thread Main finished random number generation.
//    Sum = 1,000,676.2381, Mean = 0.5003, n = 2,000,000
//
//    Thread 3 finished random number generation.
//    Sum = 999,951.1025, Mean = 0.5000, n = 2,000,000
//
//    Thread 7 finished random number generation.
//    Sum = 1,000,844.5217, Mean = 0.5004, n = 2,000,000
//
//    22,000,000 random numbers were generated.
```

The example uses the `lock` statement in C#, the `lock` function in F#, and the `SyncLock` construct in Visual Basic to synchronize access to the random number generator. This prevents corruption of the random number generator, which typically results in its returning a value of zero for all subsequent calls.

The example also uses the CountdownEvent class to ensure that each thread has finished generating random numbers before it displays the total number of calls.

Otherwise, if the main thread completes execution before the additional threads that it spawns, it displays an inaccurate value for the total number of method calls.

Remarks

A `static` field marked with ThreadStaticAttribute is not shared between threads. Each executing thread has a separate instance of the field, and independently sets and gets values for that field. If the field is accessed on a different thread, it will contain a different value.

Note that in addition to applying the ThreadStaticAttribute attribute to a field, you must also define it as a `static` field (in C# or F#) or a `Shared` field (in Visual Basic).

> **Note**
>
> Do not specify initial values for fields marked with `ThreadStaticAttribute`, because such initialization occurs only once, when the class constructor executes, and therefore affects only one thread. If you do not specify an initial value, you can rely on the field being initialized to its default value if it is a value type, or to `null` if it is a reference type.

Use this attribute as it is, and do not derive from it.

For more information about using attributes, see Attributes.

Constructors

Expand table

ThreadStaticAttribute()	Initializes a new instance of the ThreadStaticAttribute class.

Properties

Expand table

TypeId	When implemented in a derived class, gets a unique identifier for this Attribute. (Inherited from Attribute)

Methods

Expand table

Equals(Object)	Returns a value that indicates whether this instance is equal to a specified object. (Inherited from Attribute)
GetHashCode()	Returns the hash code for this instance. (Inherited from Attribute)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsDefaultAttribute()	When overridden in a derived class, indicates whether the value of this instance is the default value for the derived class. (Inherited from Attribute)
Match(Object)	When overridden in a derived class, returns a value that indicates whether this instance equals a specified object. (Inherited from Attribute)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ThreadStaticAttribute Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the ThreadStaticAttribute class.

C#

```
public ThreadStaticAttribute ();
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

TimeOnly Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a time of day, as would be read from a clock, within the range 00:00:00 to 23:59:59.9999999.

C#

```
public readonly struct TimeOnly : IComparable, IComparable<TimeOnly>,
IEquatable<TimeOnly>, IParsable<TimeOnly>, ISpanFormattable,
ISpanParsable<TimeOnly>, IUtf8SpanFormattable
```

Inheritance Object → ValueType → TimeOnly

Implements IComparable , IComparable<TimeOnly> , IEquatable<TimeOnly> , IFormattable , ISpanFormattable , IParsable<TimeOnly> , IParsable<TSelf> , ISpanParsable<TimeOnly> , IUtf8SpanFormattable

Constructors

Expand table

TimeOnly(Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour and the minute.
TimeOnly(Int32, Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour, minute, and second.
TimeOnly(Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour, minute, second, and millisecond.
TimeOnly(Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour, minute, second, millisecond, and microsecond.
TimeOnly(Int64)	Initializes a new instance of the TimeOnly structure using a specified number of ticks.

Properties

Expand table

Hour	Gets the hour component of the time represented by this instance.
MaxValue	Gets the largest possible value of TimeOnly.
Microsecond	Gets the microsecond component of the time represented by this instance.
Millisecond	Gets the millisecond component of the time represented by this instance.
Minute	Gets the minute component of the time represented by this instance.
MinValue	Gets the smallest possible value of TimeOnly.
Nanosecond	Gets the nanosecond component of the time represented by this instance.
Second	Gets the seconds component of the time represented by this instance.
Ticks	Gets the number of ticks that represent the time of this instance.

Methods

Expand table

Add(TimeSpan)	Returns a new TimeOnly that adds the value of the specified time span to the value of this instance.
Add(TimeSpan, Int32)	Returns a new TimeOnly that adds the value of the specified time span to the value of this instance. If the result wraps past the end of the day, this method returns the number of excess days as an out parameter.
AddHours(Double)	Returns a new TimeOnly that adds the specified number of hours to the value of this instance.
AddHours(Double, Int32)	Returns a new TimeOnly that adds the specified number of hours to the value of this instance. If the result wraps past the end of the day, this method returns the number of excess days as an out parameter.
AddMinutes(Double)	Returns a new TimeOnly that adds the specified number of minutes to the value of this instance.
AddMinutes(Double, Int32)	Returns a new TimeOnly that adds the specified number of minutes to the value of this instance. If the result wraps

	past the end of the day, this method returns the number of excess days as an out parameter.
CompareTo(Object)	Compares the value of this instance to a specified object that contains a specified TimeOnly value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified TimeOnly value.
CompareTo(TimeOnly)	Compares the value of this instance to a specified TimeOnly value and indicates whether this instance is earlier than, the same as, or later than the specified TimeOnly value.
Deconstruct(Int32, Int32)	Deconstructs this TimeOnly instance into Hour and Minute.
Deconstruct(Int32, Int32, Int32)	Deconstructs this TimeOnly instance into Hour, Minute, and Second.
Deconstruct(Int32, Int32, Int32, Int32)	Deconstructs this TimeOnly instance into Hour, Minute, Second, and Millisecond.
Deconstruct(Int32, Int32, Int32, Int32, Int32)	Deconstructs this TimeOnly instance into Hour, Minute, Second, Millisecond, and Microsecond.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(TimeOnly)	Returns a value indicating whether the value of this instance is equal to the value of the specified TimeOnly instance.
FromDateTime(DateTime)	Constructs a TimeOnly object from a DateTime representing the time of the day in this DateTime object.
FromTimeSpan(TimeSpan)	Constructs a TimeOnly object from a time span representing the time elapsed since midnight.
GetHashCode()	Returns the hash code for this instance.
IsBetween(TimeOnly, TimeOnly)	Determines if a time falls within the range provided. Supports both "normal" ranges such as 10:00-12:00, and ranges that span midnight such as 23:00-01:00.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a memory span that contains string representation of a time to its TimeOnly equivalent by using culture-specific format information and a formatting style.

Parse(String)	Converts the string representation of a time to its TimeOnly equivalent by using the conventions of the current culture.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(String, IFormatProvider, DateTimeStyles)	Converts the string representation of a time to its TimeOnly equivalent by using culture-specific format information and a formatting style.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[])	Converts the specified span to its TimeOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified format. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(String, String[])	Converts the specified span to a TimeOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ToLongTimeString()	Converts the value of the current TimeOnly instance to its equivalent long date string representation.

ToShortTimeString()	Converts the current TimeOnly instance to its equivalent short time string representation.
ToString()	Converts the current TimeOnly instance to its equivalent short time string representation using the formatting conventions of the current culture.
ToString(IFormatProvider)	Converts the value of the current TimeOnly instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the current TimeOnly instance to its equivalent string representation using the specified format and the formatting conventions of the current culture.
ToString(String, IFormatProvider)	Converts the value of the current TimeOnly instance to its equivalent string representation using the specified culture-specific format information.
ToTimeSpan()	Convert the current TimeOnly instance to a TimeSpan object.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current TimeOnly instance into the provided span of characters.
TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information and style, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, TimeOnly)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information and style, and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, TimeOnly)	Tries to parse a string into a value.
TryParse(String, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified character span of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, String[], TimeOnly)	Converts the specified character span of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

Operators

Expand table

Equality(TimeOnly, TimeOnly)	Determines whether two specified instances of TimeOnlyare equal.

GreaterThan(TimeOnly, TimeOnly)	Determines whether one specified TimeOnly is later than another specified TimeOnly.
GreaterThanOrEqual(TimeOnly, TimeOnly)	Determines whether one specified TimeOnly represents a time that is the same as or later than another specified TimeOnly.
Inequality(TimeOnly, TimeOnly)	Determines whether two specified instances of TimeOnly are not equal.
LessThan(TimeOnly, TimeOnly)	Determines whether one specified TimeOnly is earlier than another specified TimeOnly.
LessThanOrEqual(TimeOnly, TimeOnly)	Determines whether one specified TimeOnly represents a time that is the same as or earlier than another specified TimeOnly.
Subtraction(TimeOnly, TimeOnly)	Gives the elapsed time between two points on a circular clock, which will always be a positive value.

Applies to

Product	Versions
.NET	6, 7, 8, 9

TimeOnly Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TimeOnly(Int64)	Initializes a new instance of the TimeOnly structure using a specified number of ticks.
TimeOnly(Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour and the minute.
TimeOnly(Int32, Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour, minute, and second.
TimeOnly(Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour, minute, second, and millisecond.
TimeOnly(Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeOnly structure to the specified hour, minute, second, millisecond, and microsecond.

TimeOnly(Int64)

Initializes a new instance of the TimeOnly structure using a specified number of ticks.

C#

```
public TimeOnly (long ticks);
```

Parameters

`ticks` Int64

A time of day expressed in the number of 100-nanosecond units since 00:00:00.0000000.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly(Int32, Int32)

Initializes a new instance of the TimeOnly structure to the specified hour and the minute.

C#

```
public TimeOnly (int hour, int minute);
```

Parameters

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly(Int32, Int32, Int32)

Initializes a new instance of the TimeOnly structure to the specified hour, minute, and second.

C#

```
public TimeOnly (int hour, int minute, int second);
```

Parameters

hour Int32

The hours (0 through 23).

minute Int32

The minutes (0 through 59).

second Int32

The seconds (0 through 59).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly(Int32, Int32, Int32, Int32)

Initializes a new instance of the TimeOnly structure to the specified hour, minute, second, and millisecond.

C#

```
public TimeOnly (int hour, int minute, int second, int millisecond);
```

Parameters

hour Int32

The hours (0 through 23).

minute Int32

The minutes (0 through 59).

second Int32

The seconds (0 through 59).

`millisecond` Int32

The millisecond (0 through 999).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly(Int32, Int32, Int32, Int32, Int32)

Initializes a new instance of the TimeOnly structure to the specified hour, minute, second, millisecond, and microsecond.

```
C#

public TimeOnly (int hour, int minute, int second, int millisecond, int
microsecond);
```

Parameters

`hour` Int32

The hours (0 through 23).

`minute` Int32

The minutes (0 through 59).

`second` Int32

The seconds (0 through 59).

`millisecond` Int32

The millisecond (0 through 999).

`microsecond` Int32

The microsecond (0 through 999).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TimeOnly.Millisecond Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the millisecond component of the time represented by this instance.

C#

```
public int Millisecond { get; }
```

Property Value

Int32

A number representing the millisecond component of this TimeOnly.

Applies to

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the smallest possible value of TimeOnly.

C#

```
public static TimeOnly MinValue { get; }
```

Property Value

TimeOnly

The smallest possible value of TimeOnly, which is 00:00:00 (midnight).

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.Add Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Add(TimeSpan)	Returns a new TimeOnly that adds the value of the specified time span to the value of this instance.
Add(TimeSpan, Int32)	Returns a new TimeOnly that adds the value of the specified time span to the value of this instance. If the result wraps past the end of the day, this method returns the number of excess days as an out parameter.

Add(TimeSpan)

Returns a new TimeOnly that adds the value of the specified time span to the value of this instance.

C#

```
public TimeOnly Add (TimeSpan value);
```

Parameters

`value` TimeSpan

A positive or negative time interval.

Returns

TimeOnly

An object whose value is the sum of the time represented by this instance and the time interval represented by value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Add(TimeSpan, Int32)

Returns a new TimeOnly that adds the value of the specified time span to the value of this instance. If the result wraps past the end of the day, this method returns the number of excess days as an out parameter.

C#

```
public TimeOnly Add (TimeSpan value, out int wrappedDays);
```

Parameters

`value` TimeSpan

A positive or negative time interval.

`wrappedDays` Int32

When this method returns, contains the number of excess days, if any, that resulted from wrapping during this addition operation.

Returns

TimeOnly

An object whose value is the sum of the time represented by this instance and the time interval represented by value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.AddHours Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

AddHours(Double, Int32)	Returns a new TimeOnly that adds the specified number of hours to the value of this instance. If the result wraps past the end of the day, this method returns the number of excess days as an out parameter.
AddHours(Double)	Returns a new TimeOnly that adds the specified number of hours to the value of this instance.

AddHours(Double, Int32)

Returns a new TimeOnly that adds the specified number of hours to the value of this instance. If the result wraps past the end of the day, this method returns the number of excess days as an out parameter.

C#

```
public TimeOnly AddHours (double value, out int wrappedDays);
```

Parameters

`value` Double

A number of whole and fractional hours. The value parameter can be negative or positive.

`wrappedDays` Int32

When this method returns, contains the number of excess days, if any, that resulted from wrapping during this addition operation.

Returns

TimeOnly

An object whose value is the sum of the time represented by this instance and the number of hours represented by value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

AddHours(Double)

Returns a new TimeOnly that adds the specified number of hours to the value of this instance.

```
C#

public TimeOnly AddHours (double value);
```

Parameters

`value` Double

A number of whole and fractional hours. The value parameter can be negative or positive.

Returns

TimeOnly

An object whose value is the sum of the time represented by this instance and the number of hours represented by value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parameters

`value` Double

A number of whole and fractional minutes. The value parameter can be negative or positive.

`wrappedDays` Int32

When this method returns, contains the number of excess days, if any, that resulted from wrapping during this addition operation.

Returns

TimeOnly

An object whose value is the sum of the time represented by this instance and the number of minutes represented by value.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(Object)	Compares the value of this instance to a specified object that contains a specified TimeOnly value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified TimeOnly value.
CompareTo(TimeOnly)	Compares the value of this instance to a specified TimeOnly value and indicates whether this instance is earlier than, the same as, or later than the specified TimeOnly value.

CompareTo(Object)

Compares the value of this instance to a specified object that contains a specified TimeOnly value, and returns an integer that indicates whether this instance is earlier than, the same as, or later than the specified TimeOnly value.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

A boxed object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and the value parameter. Less than zero if this instance is earlier than value. Zero if this instance is the same as value. Greater than zero if this instance is later than value.

Implements

CompareTo(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

CompareTo(TimeOnly)

Compares the value of this instance to a specified TimeOnly value and indicates whether this instance is earlier than, the same as, or later than the specified TimeOnly value.

```
C#

public int CompareTo (TimeOnly value);
```

Parameters

`value` TimeOnly

The object to compare to the current instance.

Returns

Int32

A signed number indicating the relative values of this instance and the value parameter.

- Less than zero if this instance is earlier than value.
- Zero if this instance is the same as value.

- Greater than zero if this instance is later than value.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

TimeOnly.Deconstruct Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Deconstruct(Int32, Int32, Int32, Int32, Int32)	Deconstructs this TimeOnly instance into Hour, Minute, Second, Millisecond, and Microsecond.
Deconstruct(Int32, Int32)	Deconstructs this TimeOnly instance into Hour and Minute.
Deconstruct(Int32, Int32, Int32)	Deconstructs this TimeOnly instance into Hour, Minute, and Second.
Deconstruct(Int32, Int32, Int32, Int32)	Deconstructs this TimeOnly instance into Hour, Minute, Second, and Millisecond.

Deconstruct(Int32, Int32, Int32, Int32, Int32)

Deconstructs this TimeOnly instance into Hour, Minute, Second, Millisecond, and Microsecond.

C#

```
public void Deconstruct (out int hour, out int minute, out int second,
out int millisecond, out int microsecond);
```

Parameters

hour Int32

When this method returns, contains the Hour value for this TimeOnly instance.

minute Int32

When this method returns, contains the Minute value for this TimeOnly instance.

`second` Int32

When this method returns, contains the Second value for this TimeOnly instance.

`millisecond` Int32

When this method returns, contains the Millisecond value for this TimeOnly instance.

`microsecond` Int32

When this method returns, contains the Microsecond value for this TimeOnly instance.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Deconstruct(Int32, Int32)

Deconstructs this TimeOnly instance into Hour and Minute.

C#

```
public void Deconstruct (out int hour, out int minute);
```

Parameters

`hour` Int32

When this method returns, contains the Hour value for this TimeOnly instance.

`minute` Int32

When this method returns, contains the Minute value for this TimeOnly instance.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Deconstruct(Int32, Int32, Int32)

Deconstructs this TimeOnly instance into Hour, Minute, and Second.

```
C#

public void Deconstruct (out int hour, out int minute, out int second);
```

Parameters

hour Int32

When this method returns, contains the Hour value for this TimeOnly instance.

minute Int32

When this method returns, contains the Minute value for this TimeOnly instance.

second Int32

When this method returns, contains the Second value for this TimeOnly instance.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Deconstruct(Int32, Int32, Int32, Int32)

Deconstructs this TimeOnly instance into Hour, Minute, Second, and Millisecond.

```
C#

public void Deconstruct (out int hour, out int minute, out int second,
out int millisecond);
```

Parameters

`hour` Int32

When this method returns, contains the Hour value for this TimeOnly instance.

`minute` Int32

When this method returns, contains the Minute value for this TimeOnly instance.

`second` Int32

When this method returns, contains the Second value for this TimeOnly instance.

`millisecond` Int32

When this method returns, contains the Millisecond value for this TimeOnly instance.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TimeOnly.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(TimeOnly)	Returns a value indicating whether the value of this instance is equal to the value of the specified TimeOnly instance.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.

Equals(TimeOnly)

Returns a value indicating whether the value of this instance is equal to the value of the specified TimeOnly instance.

```
C#

public bool Equals (TimeOnly value);
```

Parameters

`value` TimeOnly

The object to compare to this instance.

Returns

Boolean

`true` if the value parameter equals the value of this instance; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

```
C#
public override bool Equals (object? value);
```

Parameters

`value` Object

The object to compare to this instance.

Returns

Boolean

`true` if value is an instance of TimeOnly and equals the value of this instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.FromDateTime(DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Constructs a TimeOnly object from a DateTime representing the time of the day in this DateTime object.

```
C#
public static TimeOnly FromDateTime (DateTime dateTime);
```

Parameters

`dateTime` DateTime

The DateTime object to extract the time of the day from.

Returns

TimeOnly

A TimeOnly object representing time of the day specified in the DateTime object.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.FromTimeSpan(TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Constructs a TimeOnly object from a time span representing the time elapsed since midnight.

C#

```
public static TimeOnly FromTimeSpan (TimeSpan timeSpan);
```

Parameters

`timeSpan` TimeSpan

The time interval measured since midnight. This value has to be positive and not exceeding the time of the day.

Returns

TimeOnly

A TimeOnly object representing the time elapsed since midnight using the specified time span value.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.IsBetween(TimeOnly, TimeOnly) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a time falls within the range provided. Supports both "normal" ranges such as 10:00-12:00, and ranges that span midnight such as 23:00-01:00.

```
C#
public bool IsBetween (TimeOnly start, TimeOnly end);
```

Parameters

`start` TimeOnly

The starting time of day, inclusive.

`end` TimeOnly

The ending time of day, exclusive.

Returns

Boolean

`true`, if the time falls within the range, `false` otherwise.

Remarks

If `start` and `end` are equal, this method returns `false`, meaning there is zero elapsed time between the two values. If you wish to treat such cases as representing one or more whole days, then first check for equality before calling this method.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

TimeOnly.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String)	Converts the string representation of a time to its TimeOnly equivalent by using the conventions of the current culture.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts a memory span that contains string representation of a time to its TimeOnly equivalent by using culture-specific format information and a formatting style.
Parse(String, IFormatProvider, DateTimeStyles)	Converts the string representation of a time to its TimeOnly equivalent by using culture-specific format information and a formatting style.

Parse(String)

Converts the string representation of a time to its TimeOnly equivalent by using the conventions of the current culture.

C#

```
public static TimeOnly Parse (string s);
```

Parameters

`s` String

The string to parse.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static TimeOnly Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

A span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

TimeOnly

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, IFormatProvider)

Parses a string into a value.

```
C#

public static TimeOnly Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

TimeOnly

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts a memory span that contains string representation of a time to its TimeOnly equivalent by using culture-specific format information and a formatting style.

C#

```
public static TimeOnly Parse (ReadOnlySpan<char> s, IFormatProvider?
provider = default, System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

The memory span that contains the time to parse.

`provider` IFormatProvider

The culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(String, IFormatProvider, DateTimeStyles)

Converts the string representation of a time to its TimeOnly equivalent by using culture-specific format information and a formatting style.

C#

```
public static TimeOnly Parse (string s, IFormatProvider? provider,
System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

`s` String

The string containing the time to parse.

`provider` IFormatProvider

The culture-specific format information about `s`.

`style` DateTimeStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in s for the parse operation to succeed, and that defines how to interpret the parsed date. A typical value to specify is None.

Returns

TimeOnly

ATimeOnly instance.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

TimeOnly.ParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ParseExact(String, String[], IFormatProvider, DateTimeStyles)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(String, String, IFormatProvider, DateTimeStyles)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(String, String[])	Converts the specified span to a TimeOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

ParseExact(String, String)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified format. The format of the string representation must match the specified format exactly or an exception is thrown.
ParseExact(ReadOnlySpan<Char>, String[])	Converts the specified span to its TimeOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

ParseExact(String, String[], IFormatProvider, DateTimeStyles)

Converts the specified string representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (string s, string[] formats,
IFormatProvider? provider, System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

s String

A string containing the time to convert.

formats String[]

An array of allowable formats of `s`.

provider IFormatProvider

The culture-specific formatting information about `s`.

style DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(String, String, IFormatProvider, DateTimeStyles)

Converts the specified string representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (string s, string format,
IFormatProvider? provider, System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

s String

A string containing the time to convert.

format String

The format specifier that defines the required format of `s`.

`provider` IFormatProvider

The culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of the enumeration values that provides additional information about `s`, about style elements that may be present in `s`, or about the conversion from `s` to a TimeOnly value. A typical value to specify is None.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles)

Converts the specified span representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information, and style. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (ReadOnlySpan<char> s, string[]
formats, IFormatProvider? provider, System.Globalization.DateTimeStyles
style = System.Globalization.DateTimeStyles.None);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the time to convert.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

The culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles)

Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, IFormatProvider? provider = default,
System.Globalization.DateTimeStyles style =
System.Globalization.DateTimeStyles.None);
```

Parameters

s ReadOnlySpan<Char>

A span containing the time to convert.

format ReadOnlySpan<Char>

The format specifier that defines the required format of `s`.

provider IFormatProvider

The culture-specific formatting information about `s`.

style DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(String, String[])

Converts the specified span to a TimeOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (string s, string[] formats);
```

Parameters

`s` String

A span containing the time to convert.

`formats` String[]

An array of allowable formats of `s`.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(String, String)

Converts the specified string representation of a time to its TimeOnly equivalent using the specified format. The format of the string representation must match the specified format exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (string s, string format);
```

Parameters

`s` String

A string containing a time to convert.

`format` String

A format specifier that defines the required format of `s`.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` does not contain a valid string representation of a time.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ParseExact(ReadOnlySpan<Char>, String[])

Converts the specified span to its TimeOnly equivalent using the specified array of formats. The format of the string representation must match at least one of the specified formats exactly or an exception is thrown.

C#

```
public static TimeOnly ParseExact (ReadOnlySpan<char> s, string[]
formats);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the time to convert.

`formats` String[]

An array of allowable formats of `s`.

Returns

TimeOnly

A TimeOnly instance.

Exceptions

FormatException

`s` does not contain a valid string representation of a time.

Applies to

TimeOnly.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToString(String, IFormatProvider)	Converts the value of the current TimeOnly instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the current TimeOnly instance to its equivalent string representation using the specified format and the formatting conventions of the current culture.
ToString()	Converts the current TimeOnly instance to its equivalent short time string representation using the formatting conventions of the current culture.
ToString(IFormatProvider)	Converts the value of the current TimeOnly instance to its equivalent string representation using the specified culture-specific format information.

ToString(String, IFormatProvider)

Converts the value of the current TimeOnly instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

format String

A standard or custom time format string.

`provider` IFormatProvider

The culture-specific formatting information.

Returns

String

A string representation of value of the current instance.

Implements

ToString(String, IFormatProvider)

Remarks

The accepted standard formats are 'r', 'R', 'o', 'O', 't' and 'T'.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToString(String)

Converts the current TimeOnly instance to its equivalent string representation using the specified format and the formatting conventions of the current culture.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

A standard or custom time format string.

Returns

String

A string representation of the current instance with the specified format and the formatting conventions of the current culture.

Remarks

The accepted standard formats are 'r', 'R', 'o', 'O', 't' and 'T'.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToString()

Converts the current TimeOnly instance to its equivalent short time string representation using the formatting conventions of the current culture.

C#

```
public override string ToString ();
```

Returns

String

The short time string representation of the current instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

ToString(IFormatProvider)

Converts the value of the current TimeOnly instance to its equivalent string representation using the specified culture-specific format information.

```
C#

public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

The culture-specific formatting information.

Returns

String

A string representation of the current instance as specified by the provider.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.ToTimeSpan Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Convert the current TimeOnly instance to a TimeSpan object.

C#

```
public TimeSpan ToTimeSpan ();
```

Returns

TimeSpan

A TimeSpan object spanning to the time specified in the current TimeOnly instance.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current TimeOnly instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current TimeOnly instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Remarks

The accepted standard formats are 'r', 'R', 'o', 'O', 't', and 'T'.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information and style, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, TimeOnly)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, TimeOnly)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information and style, and returns a value that indicates whether the conversion succeeded.

TryParse(ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, TimeOnly)

Converts the specified span representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information and style, and returns a value that indicates whether the conversion succeeded.

```C#
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, System.Globalization.DateTimeStyles style, out TimeOnly
result);
```

Parameters

`s` ReadOnlySpan<Char>

A string containing the characters that represent a time to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a valid string representation of a date. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(ReadOnlySpan<Char>, TimeOnly)

Converts the specified span representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out TimeOnly result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the time to convert.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or MinValue if the conversion failed. The conversion fails if `s` is the empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if the conversion was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(String, TimeOnly)

Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParse (string? s, out TimeOnly result);
```

Parameters

s String

A string containing the time to convert.

result TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, TimeOnly)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out TimeOnly result);
```

Parameters

s ReadOnlySpan<Char>

A span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or MinValue if the conversion failed. The conversion fails if `s` is the empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, TimeOnly)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider, out
TimeOnly result);
```

Parameters

`s` String

A string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or MinValue if the conversion failed. The conversion fails if `s` is the empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was parsed successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, DateTimeStyles, TimeOnly)

Converts the specified string representation of a time to its TimeOnly equivalent using the specified array of formats, culture-specific format information and style, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider,
System.Globalization.DateTimeStyles style, out TimeOnly result);
```

Parameters

`s` String

A string containing the time to convert.

`provider` IFormatProvider

The culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is None.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.TryParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified character span of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, String[], TimeOnly)	Converts the specified character span of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, TimeOnly)	Converts the specified span representation of a time to its TimeOnly equivalent using the specified format and style. The format of the string representation must match the specified

	format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.
TryParseExact(String, String[], IFormatProvider, DateTimeStyles, TimeOnly)	Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, DateTimeStyles, TimeOnly)

Converts the specified character span of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s, string?[]?
formats, IFormatProvider? provider, System.Globalization.DateTimeStyles
style, out TimeOnly result);
```

Parameters

s ReadOnlySpan<Char>

The span containing the time to parse.

formats String[]

An array of allowable formats of `s`.

provider IFormatProvider

An object that supplies culture-specific formatting information about `s`.

style DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed time. A typical value to specify is None.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, DateTimeStyles, TimeOnly)

Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, IFormatProvider? provider,
System.Globalization.DateTimeStyles style, out TimeOnly result);
```

Parameters

s ReadOnlySpan<Char>

A span containing the time to convert.

`format` ReadOnlySpan<Char>

The required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of one or more enumeration values that indicate the permitted format of `s`.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a time that corresponds to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String[], TimeOnly)

Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (string? s, string?[]? formats, out
TimeOnly result);
```

Parameters

`s` String

The string containing the time to parse.

`formats` String[]

An array of allowable formats of `s`.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String, IFormatProvider, DateTimeStyles, TimeOnly)

Converts the specified span representation of a time to its TimeOnly equivalent using the specified format, culture-specific format information, and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParseExact (string? s, string? format,
IFormatProvider? provider, System.Globalization.DateTimeStyles style, out
TimeOnly result);
```

Parameters

`s` String

A span containing the characters representing a time to convert.

`format` String

The required format of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of one or more enumeration values that indicate the permitted format of `s`.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a time that corresponds to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, String[], TimeOnly)

Converts the specified character span of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParseExact (ReadOnlySpan<char> s, string?[]?
formats, out TimeOnly result);
```

Parameters

s ReadOnlySpan<Char>

The span containing the time to convert.

formats String[]

An array of allowable formats of `s`.

result TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if the `s` parameter is an empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, TimeOnly)

Converts the specified span representation of a time to its TimeOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParseExact (ReadOnlySpan<char> s,
ReadOnlySpan<char> format, out TimeOnly result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the time to convert.

`format` ReadOnlySpan<Char>

The required format of `s`.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a time that corresponds to the pattern specified in `format`. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String, TimeOnly)

Converts the specified string representation of a time to its TimeOnly equivalent using the specified format and style. The format of the string representation must match the specified format exactly. The method returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParseExact (string? s, string? format, out TimeOnly
result);
```

Parameters

s String

A string containing the time to convert.

format String

The required format of `s`.

result TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a time that corresponds to the pattern specified in format. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParseExact(String, String[], IFormatProvider, DateTimeStyles, TimeOnly)

Converts the specified string representation of a time to its TimeOnly equivalent and returns a value that indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParseExact (string? s, string?[]? formats,
IFormatProvider? provider, System.Globalization.DateTimeStyles style, out
TimeOnly result);
```

Parameters

`s` String

The string containing the time to parse.

`formats` String[]

An array of allowable formats of `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`style` DateTimeStyles

A bitwise combination of enumeration values that defines how to interpret the parsed date. A typical value to specify is None.

`result` TimeOnly

When this method returns, contains the TimeOnly value equivalent to the time contained in `s`, if the conversion succeeded, or TimeOnly.MinValue if the conversion failed. The conversion fails if `s` is an empty string or does not contain a valid string representation of a time. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.Equality(TimeOnly, TimeOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of TimeOnlyare equal.

C#

```
public static bool operator == (TimeOnly left, TimeOnly right);
```

Parameters

`left` TimeOnly

The first object to compare.

`right` TimeOnly

The second object to compare.

Returns

Boolean

`true` if left and right represent the same time; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.GreaterThan(TimeOnly, TimeOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified TimeOnly is later than another specified TimeOnly.

```
C#
public static bool operator > (TimeOnly left, TimeOnly right);
```

Parameters

`left` TimeOnly

The first object to compare.

`right` TimeOnly

The second object to compare.

Returns

Boolean

`true` if left is later than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.GreaterThanOrEqual(TimeOnly, TimeOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified TimeOnly represents a time that is the same as or later than another specified TimeOnly.

C#

```
public static bool operator >= (TimeOnly left, TimeOnly right);
```

Parameters

`left` TimeOnly

The first object to compare.

`right` TimeOnly

The second object to compare.

Returns

Boolean

`true` if left is the same as or later than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeOnly.Inequality(TimeOnly, TimeOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of TimeOnly are not equal.

C#

```
public static bool operator != (TimeOnly left, TimeOnly right);
```

Parameters

`left` TimeOnly

The first object to compare.

`right` TimeOnly

The second object to compare.

Returns

Boolean

`true` if left and right do not represent the same time; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.LessThan(TimeOnly, TimeOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether one specified TimeOnly is earlier than another specified TimeOnly.

C#

```
public static bool operator < (TimeOnly left, TimeOnly right);
```

Parameters

`left` TimeOnly

The first object to compare.

`right` TimeOnly

The second object to compare.

Returns

Boolean

`true` if left is earlier than right; otherwise, `false`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

TimeOnly.Subtraction(TimeOnly, TimeOnly) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gives the elapsed time between two points on a circular clock, which will always be a positive value.

C#

```
public static TimeSpan operator - (TimeOnly t1, TimeOnly t2);
```

Parameters

`t1` TimeOnly

The first TimeOnly instance.

`t2` TimeOnly

The second TimeOnly instance..

Returns

TimeSpan

The elapsed time between `t1` and `t2`.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

TimeoutException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when the time allotted for a process or operation has expired.

C#

```
public class TimeoutException : SystemException
```

Inheritance Object → Exception → SystemException → TimeoutException

Derived System.Text.RegularExpressions.RegexMatchTimeoutException

Examples

The following code example demonstrates the use of TimeoutException in conjunction with members of the System.IO.Ports.SerialPort class.

C#

```
// This example demonstrates the use of the TimeoutException
// exception in conjunction with the SerialPort class.

using System;
using System.IO.Ports;

class Sample
{
    public static void Main()
    {
    string input;
    try
        {
// Set the COM1 serial port to speed = 4800 baud, parity = odd,
// data bits = 8, stop bits = 1.
        SerialPort sp = new SerialPort("COM1",
                        4800, Parity.Odd, 8, StopBits.One);
// Timeout after 2 seconds.
```

```
        sp.ReadTimeout = 2000;
        sp.Open();

// Read until either the default newline termination string
// is detected or the read operation times out.
        input = sp.ReadLine();

        sp.Close();

// Echo the input.
        Console.WriteLine(input);
        }

// Only catch timeout exceptions.
    catch (TimeoutException e)
        {
        Console.WriteLine(e);
        }
    }
}
/*
This example produces the following results:

(Data received at the serial port is echoed to the console if the
read operation completes successfully before the specified timeout period
expires. Otherwise, a timeout exception like the following is thrown.)

System.TimeoutException: The operation has timed-out.
   at System.IO.Ports.SerialStream.ReadByte(Int32 timeout)
   at System.IO.Ports.SerialPort.ReadOneChar(Int32 timeout)
   at System.IO.Ports.SerialPort.ReadTo(String value)
   at System.IO.Ports.SerialPort.ReadLine()
   at Sample.Main()
*/
```

Remarks

For information about setting the time-out interval before a TimeoutException exception is thrown, consult the documentation for the type whose method timed out. For information about handling the time-out, see the documentation for the method that threw the exception.

TimeoutException uses the HRESULT, COR_E_TIMEOUT, which has the value 0x80131505.

For a list of initial property values for an instance of TimeoutException, see the TimeoutException constructors.

Constructors

Expand table

TimeoutException()	Initializes a new instance of the TimeoutException class.
TimeoutException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TimeoutException class with serialized data.
TimeoutException(String)	Initializes a new instance of the TimeoutException class with the specified error message.
TimeoutException(String, Exception)	Initializes a new instance of the TimeoutException class with the specified error message and inner exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

TimeoutException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the TimeoutException class.

Overloads

Expand table

TimeoutException()	Initializes a new instance of the TimeoutException class.
TimeoutException(String)	Initializes a new instance of the TimeoutException class with the specified error message.
TimeoutException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TimeoutException class with serialized data.
TimeoutException(String, Exception)	Initializes a new instance of the TimeoutException class with the specified error message and inner exception.

TimeoutException()

Initializes a new instance of the TimeoutException class.

C#

```
public TimeoutException ();
```

Remarks

This constructor initializes the inherited Exception.Message property of the new instance with a system-supplied error message. This message takes into account the

current system culture.

The following table shows the initial property values for an instance of TimeoutException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TimeoutException(String)

Initializes a new instance of the TimeoutException class with the specified error message.

C#

```
public TimeoutException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

This constructor initializes the inherited Exception.Message property of the new instance using the value of the `message` parameter.

The following table shows the initial property values for an instance of TimeoutException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TimeoutException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the TimeoutException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected TimeoutException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo object that contains serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext object that contains contextual information about the source or destination. The `context` parameter is reserved for future use, and can be specified as `null`.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` parameter is `null`.

SerializationException

The class name is `null`, or HResult is zero (0).

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see Binary Serialization.

See also

- SerializationInfo
- StreamingContext
- Binary Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeoutException(String, Exception)

Initializes a new instance of the TimeoutException class with the specified error message and inner exception.

C#

```
public TimeoutException (string? message, Exception? innerException);
```

Parameters

`message` String

The message that describes the error.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

This constructor initializes the inherited Exception.Message property of the new instance using the value of the `message` parameter.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed to the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of TimeoutException.

Expand table

Property	Value
Message	The error message string.
InnerException	The inner exception reference.

Applies to

TimeProvider Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides an abstraction for time.

C#

```
public abstract class TimeProvider
```

Inheritance Object → TimeProvider

Derived Microsoft.Extensions.Time.Testing.FakeTimeProvider

Constructors

Expand table

TimeProvider()	Initializes a new instance of TimeProvider.

Properties

Expand table

LocalTimeZone	Gets the local time zone according to this TimeProvider's notion of time.
System	Gets a TimeProvider that provides a clock based on UtcNow, a time zone based on Local, a high-performance time stamp based on Stopwatch, and a timer based on Timer.
TimestampFrequency	Gets the frequency of GetTimestamp() as the number of ticks per second.

Methods

Expand table

CreateTimer(TimerCallback, Object, TimeSpan, TimeSpan)	Creates a new ITimer instance, using TimeSpan values to measure time intervals.
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetElapsedTime(Int64)	Gets the elapsed time since the `startingTimestamp` value was retrieved using GetTimestamp().
GetElapsedTime(Int64, Int64)	Gets the elapsed time between two timestamps retrieved using GetTimestamp().
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetLocalNow()	Gets the current date and time according to this TimeProvider's notion of time based on GetUtcNow(), with the offset set to the LocalTimeZone's offset from Coordinated Universal Time (UTC).
GetTimestamp()	Gets the current high-frequency value designed to measure small time intervals with high accuracy in the timer mechanism.
GetType()	Gets the Type of the current instance. (Inherited from Object)
GetUtcNow()	Gets the current Coordinated Universal Time (UTC) date and time with an offset of zero, according to this TimeProvider's notion of time.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

TimeProvider.System Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a TimeProvider that provides a clock based on UtcNow, a time zone based on Local, a high-performance time stamp based on Stopwatch, and a timer based on Timer.

C#

```
public static TimeProvider System { get; }
```

Property Value

TimeProvider

Remarks

If the Local changes after the object is returned, the change will be reflected in any subsequent operations that retrieve GetLocalNow().

Applies to

TimeProvider.TimestampFrequency Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the frequency of GetTimestamp() as the number of ticks per second.

C#

```
public virtual long TimestampFrequency { get; }
```

Property Value

Int64

Remarks

The default implementation returns Frequency. For a given TimeProvider instance, the value must be idempotent and remain unchanged.

TimeProvider.CreateTimer(TimerCallback, Object, TimeSpan, TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new ITimer instance, using TimeSpan values to measure time intervals.

C#

```
public virtual System.Threading.ITimer CreateTimer
(System.Threading.TimerCallback callback, object? state, TimeSpan dueTime,
TimeSpan period);
```

Parameters

`callback` TimerCallback

A delegate representing a method to be executed when the timer fires. The method should be reentrant, as it may be invoked simultaneously on two threads if the timer fires again while a previous callback is still being handled.

`state` Object

An object to be passed to the `callback`. This may be `null`.

`dueTime` TimeSpan

The amount of time to delay before `callback` is invoked. Specify InfiniteTimeSpan to prevent the timer from starting. Specify Zero to start the timer immediately.

`period` TimeSpan

The time interval between invocations of `callback`. Specify InfiniteTimeSpan to disable periodic signaling.

Returns

ITimer

The newly created ITimer instance.

Exceptions

ArgumentNullException

`callback` is `null`.

ArgumentOutOfRangeException

The number of milliseconds in the value of `dueTime` or `period` is negative and not equal to Infinite, or is greater than Int32.MaxValue.

Remarks

The delegate specified by the callback parameter is invoked once after `dueTime` elapses, and thereafter each time the `period` time interval elapses.

If `dueTime` is zero, the callback is invoked immediately. If `dueTime` is -1 milliseconds, `callback` is not invoked; the timer is disabled, but can be re-enabled by calling the Change(TimeSpan, TimeSpan) method.

If `period` is 0 or -1 milliseconds and `dueTime` is positive, `callback` is invoked once; the periodic behavior of the timer is disabled, but can be re-enabled using the Change(TimeSpan, TimeSpan) method.

The returned ITimer instance is implicitly rooted while the timer is still scheduled.

CreateTimer(TimerCallback, Object, TimeSpan, TimeSpan) captures the ExecutionContext and stores that with the ITimer for use in invoking `callback` each time it's called. That capture can be suppressed with SuppressFlow().

TimeProvider.GetElapsedTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetElapsedTime(Int64)	Gets the elapsed time since the `startingTimestamp` value was retrieved using GetTimestamp().
GetElapsedTime(Int64, Int64)	Gets the elapsed time between two timestamps retrieved using GetTimestamp().

GetElapsedTime(Int64)

Gets the elapsed time since the `startingTimestamp` value was retrieved using GetTimestamp().

C#

```
public TimeSpan GetElapsedTime (long startingTimestamp);
```

Parameters

`startingTimestamp` Int64

The timestamp marking the beginning of the time period.

Returns

TimeSpan

The elapsed time between the starting timestamp and the time of this call.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

GetElapsedTime(Int64, Int64)

Gets the elapsed time between two timestamps retrieved using GetTimestamp().

C#

```
public TimeSpan GetElapsedTime (long startingTimestamp, long
endingTimestamp);
```

Parameters

`startingTimestamp` Int64

The timestamp marking the beginning of the time period.

`endingTimestamp` Int64

The timestamp marking the end of the time period.

Returns

TimeSpan

The elapsed time between the starting and ending timestamps.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TimeProvider.GetTimestamp Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current high-frequency value designed to measure small time intervals with high accuracy in the timer mechanism.

C#

```
public virtual long GetTimestamp ();
```

Returns

Int64

A long integer representing the high-frequency counter value of the underlying timer mechanism.

Remarks

The default implementation returns GetTimestamp().

TimeSpan Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a time interval.

C#

```
public readonly struct TimeSpan : IComparable, IComparable<TimeSpan>,
IEquatable<TimeSpan>, IParsable<TimeSpan>, ISpanFormattable,
ISpanParsable<TimeSpan>, IUtf8SpanFormattable
```

Inheritance Object → ValueType → TimeSpan

Implements IComparable , IComparable<TimeSpan> , IEquatable<TimeSpan> , IFormattable , ISpanFormattable , IParsable<TimeSpan> , IParsable<TSelf> , ISpanParsable<TimeSpan> , IUtf8SpanFormattable

Examples

The following example instantiates a TimeSpan object that represents the difference between two dates. It then displays the TimeSpan object's properties.

C#

```
// Define two dates.
DateTime date1 = new DateTime(2010, 1, 1, 8, 0, 15);
DateTime date2 = new DateTime(2010, 8, 18, 13, 30, 30);

// Calculate the interval between the two dates.
TimeSpan interval = date2 - date1;
Console.WriteLine("{0} - {1} = {2}", date2, date1, interval.ToString());

// Display individual properties of the resulting TimeSpan object.
Console.WriteLine("   {0,-35} {1,20}", "Value of Days Component:",
interval.Days);
Console.WriteLine("   {0,-35} {1,20}", "Total Number of Days:",
interval.TotalDays);
Console.WriteLine("   {0,-35} {1,20}", "Value of Hours Component:",
```

```
interval.Hours);
Console.WriteLine("   {0,-35} {1,20}", "Total Number of Hours:",
interval.TotalHours);
Console.WriteLine("   {0,-35} {1,20}", "Value of Minutes Component:",
interval.Minutes);
Console.WriteLine("   {0,-35} {1,20}", "Total Number of Minutes:",
interval.TotalMinutes);
Console.WriteLine("   {0,-35} {1,20:N0}", "Value of Seconds Component:",
interval.Seconds);
Console.WriteLine("   {0,-35} {1,20:N0}", "Total Number of Seconds:",
interval.TotalSeconds);
Console.WriteLine("   {0,-35} {1,20:N0}", "Value of Milliseconds
Component:", interval.Milliseconds);
Console.WriteLine("   {0,-35} {1,20:N0}", "Total Number of Milliseconds:",
interval.TotalMilliseconds);
Console.WriteLine("   {0,-35} {1,20:N0}", "Ticks:", interval.Ticks);

// This example displays the following output:
//       8/18/2010 1:30:30 PM - 1/1/2010 8:00:15 AM = 229.05:30:15
//          Value of Days Component:                              229
//          Total Number of Days:                   229.229340277778
//          Value of Hours Component:                               5
//          Total Number of Hours:                  5501.50416666667
//          Value of Minutes Component:                            30
//          Total Number of Minutes:                       330090.25
//          Value of Seconds Component:                            15
//          Total Number of Seconds:                       19,805,415
//          Value of Milliseconds Component:                        0
//          Total Number of Milliseconds:             19,805,415,000
//          Ticks:                                198,054,150,000,000
```

PowerShell

```
# Define two dates.
$Date2 = Get-Date -Date '2010/8/18' -Hour 13 -Minute 30 -Second 30
$Date1 = Get-Date -Date '2010/1/1'  -Hour 8  -Minute 0  -Second 15

# Calculate the interval between the two dates.
$Interval = $Date2 - $Date1
"{0} - {1} = {2}" -f $Date2, $Date1, ($Interval.ToString())

#  Display individual properties of the resulting TimeSpan object.
"   {0,-35} {1,20}"    -f "Value of Days Component:", $Interval.Days
"   {0,-35} {1,20}"    -f "Total Number of Days:", $Interval.TotalDays
"   {0,-35} {1,20}"    -f "Value of Hours Component:", $Interval.Hours
"   {0,-35} {1,20}"    -f "Total Number of Hours:", $Interval.TotalHours
"   {0,-35} {1,20}"    -f "Value of Minutes Component:", $Interval.Minutes
"   {0,-35} {1,20}"    -f "Total Number of Minutes:", $Interval.TotalMinutes
"   {0,-35} {1,20:N0}" -f "Value of Seconds Component:", $Interval.Seconds
"   {0,-35} {1,20:N0}" -f "Total Number of Seconds:", $Interval.TotalSeconds
"   {0,-35} {1,20:N0}" -f "Value of Milliseconds Component:",
$Interval.Milliseconds
"   {0,-35} {1,20:N0}" -f "Total Number of Milliseconds:",
```

```
$Interval.TotalMilliseconds
"   {0,-35} {1,20:N0}" -f "Ticks:", $Interval.Ticks

<# This sample produces the following output:

18/08/2010 13:30:30 - 01/01/2010 08:00:15 = 229.05:30:15
   Value of Days Component:                              229
   Total Number of Days:                   229.229340277778
   Value of Hours Component:                               5
   Total Number of Hours:                  5501.50416666667
   Value of Minutes Component:                            30
   Total Number of Minutes:                       330090.25
   Value of Seconds Component:                            15

Remarks

For more information about this API, see Supplemental API remarks for TimeSpan.

Constructors

Expand table

TimeSpan(Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of hours, minutes, and seconds.
TimeSpan(Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, and seconds.
TimeSpan(Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, seconds, and milliseconds.
TimeSpan(Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, seconds, milliseconds, and microseconds.
TimeSpan(Int64)	Initializes a new instance of the TimeSpan structure to the specified number of ticks.

Fields

Expand table

MaxValue	Represents the maximum TimeSpan value. This field is read-only.
MinValue	Represents the minimum TimeSpan value. This field is read-only.
NanosecondsPerTick	Represents the number of nanoseconds per tick. This field is constant.
TicksPerDay	Represents the number of ticks in 1 day. This field is constant.
TicksPerHour	Represents the number of ticks in 1 hour. This field is constant.
TicksPerMicrosecond	Represents the number of ticks in 1 microsecond. This field is constant.
TicksPerMillisecond	Represents the number of ticks in 1 millisecond. This field is constant.
TicksPerMinute	Represents the number of ticks in 1 minute. This field is constant.
TicksPerSecond	Represents the number of ticks in 1 second.
Zero	Represents the zero TimeSpan value. This field is read-only.

Properties

Expand table

Days	Gets the days component of the time interval represented by the current TimeSpan structure.
Hours	Gets the hours component of the time interval represented by the current TimeSpan structure.
Microseconds	Gets the microseconds component of the time interval represented by the current TimeSpan structure.
Milliseconds	Gets the milliseconds component of the time interval represented by the current TimeSpan structure.
Minutes	Gets the minutes component of the time interval represented by the current TimeSpan structure.
Nanoseconds	Gets the nanoseconds component of the time interval represented by the current TimeSpan structure.
Seconds	Gets the seconds component of the time interval represented by the current TimeSpan structure.
Ticks	Gets the number of ticks that represent the value of the current TimeSpan structure.

TotalDays	Gets the value of the current TimeSpan structure expressed in whole and fractional days.
TotalHours	Gets the value of the current TimeSpan structure expressed in whole and fractional hours.
Total Microseconds	Gets the value of the current TimeSpan structure expressed in whole and fractional microseconds.
TotalMilliseconds	Gets the value of the current TimeSpan structure expressed in whole and fractional milliseconds.
TotalMinutes	Gets the value of the current TimeSpan structure expressed in whole and fractional minutes.
Total Nanoseconds	Gets the value of the current TimeSpan structure expressed in whole and fractional nanoseconds.
TotalSeconds	Gets the value of the current TimeSpan structure expressed in whole and fractional seconds.

Methods

Expand table

Add(TimeSpan)	Returns a new TimeSpan object whose value is the sum of the specified TimeSpan object and this instance.
Compare(TimeSpan, TimeSpan)	Compares two TimeSpan values and returns an integer that indicates whether the first value is shorter than, equal to, or longer than the second value.
CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the specified object.
CompareTo(TimeSpan)	Compares this instance to a specified TimeSpan object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the TimeSpan object.
Divide(Double)	Returns a new TimeSpan object whose value is the result of dividing this instance by the specified `divisor`.
Divide(TimeSpan)	Returns a new Double value that's the result of dividing this instance by `ts`.
Duration()	Returns a new TimeSpan object whose value is the absolute value of the current TimeSpan object.

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(TimeSpan)	Returns a value indicating whether this instance is equal to a specified TimeSpan object.
Equals(TimeSpan, TimeSpan)	Returns a value that indicates whether two specified instances of TimeSpan are equal.
FromDays(Double)	Returns a TimeSpan that represents a specified number of days, where the specification is accurate to the nearest millisecond.
FromHours(Double)	Returns a TimeSpan that represents a specified number of hours, where the specification is accurate to the nearest millisecond.
FromMicroseconds(Double)	Returns a TimeSpan that represents a specified number of microseconds.
FromMilliseconds(Double)	Returns a TimeSpan that represents a specified number of milliseconds.
FromMinutes(Double)	Returns a TimeSpan that represents a specified number of minutes, where the specification is accurate to the nearest millisecond.
FromSeconds(Double)	Returns a TimeSpan that represents a specified number of seconds, where the specification is accurate to the nearest millisecond.
FromTicks(Int64)	Returns a TimeSpan that represents a specified time, where the specification is in units of ticks.
GetHashCode()	Returns a hash code for this instance.
Multiply(Double)	Returns a new TimeSpan object which value is the result of multiplication of this instance and the specified `factor`.
Negate()	Returns a new TimeSpan object whose value is the negated value of this instance.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Converts the span representation of a time interval to its TimeSpan equivalent by using the specified culture-specific format information.
Parse(String)	Converts the string representation of a time interval to its TimeSpan equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified culture-

	specific format information.
ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpanStyles)	Converts the char span of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpanStyles)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information, and styles. The format of the string representation must match one of the specified formats exactly.
ParseExact(String, String, IFormatProvider)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
ParseExact(String, String, IFormatProvider, TimeSpanStyles)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information, and styles. The format of the string representation must match the specified format exactly.
ParseExact(String, String[], IFormatProvider)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified array of format strings and culture-specific format information. The format of the string representation must match one of the specified formats exactly.
ParseExact(String, String[], IFormatProvider, TimeSpanStyles)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information, and styles. The format of the string representation must match one of the specified formats exactly.
Subtract(TimeSpan)	Returns a new TimeSpan object whose value is the difference between the specified TimeSpan object and this instance.
ToString()	Converts the value of the current TimeSpan object to its equivalent string representation.
ToString(String)	Converts the value of the current TimeSpan object to its equivalent string representation by using the specified format.
ToString(String, IFormatProvider)	Converts the value of the current TimeSpan object to its equivalent string representation by using the specified format and culture-specific formatting information.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current timespan number instance into the provided span of characters.
TryParse(ReadOnlySpan<Char>, IFormatProvider, TimeSpan)	Converts the span representation of a time interval to its TimeSpan equivalent by using the specified culture-specific formatting information, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, TimeSpan)	Converts the span representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified culture-specific formatting information, and returns a value that indicates whether the conversion succeeded.
TryParse(String, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information, and styles, and returns a value that indicates whether the conversion succeeded. The format of the string representation must match the specified format exactly.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified formats and culture-specific format information. The format of the string representation must match one of the specified formats exactly.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information and styles. The format of the string representation must match one of the specified formats exactly.
TryParseExact(String, String, IFormatProvider, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format and

	culture-specific format information. The format of the string representation must match the specified format exactly.
TryParseExact(String, String, IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information and styles. The format of the string representation must match the specified format exactly.
TryParseExact(String, String[], IFormatProvider, TimeSpan)	Converts the specified string representation of a time interval to its TimeSpan equivalent by using the specified formats and culture-specific format information. The format of the string representation must match one of the specified formats exactly.
TryParseExact(String, String[], IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the specified string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information and styles. The format of the string representation must match one of the specified formats exactly.

Operators

Expand table

Addition(TimeSpan, TimeSpan)	Adds two specified TimeSpan instances.
Division(TimeSpan, Double)	Returns a new TimeSpan object whose value is the result of dividing the specified `timeSpan` by the specified `divisor`.
Division(TimeSpan, TimeSpan)	Returns a new Double value that's the result of dividing `t1` by `t2`.
Equality(TimeSpan, TimeSpan)	Indicates whether two TimeSpan instances are equal.
GreaterThan(TimeSpan, TimeSpan)	Indicates whether a specified TimeSpan is greater than another specified TimeSpan.
GreaterThanOrEqual(TimeSpan, TimeSpan)	Indicates whether a specified TimeSpan is greater than or equal to another specified TimeSpan.
Inequality(TimeSpan, TimeSpan)	Indicates whether two TimeSpan instances are not equal.
LessThan(TimeSpan, TimeSpan)	Indicates whether a specified TimeSpan is less than another specified TimeSpan.

LessThanOrEqual(TimeSpan, TimeSpan)	Indicates whether a specified TimeSpan is less than or equal to another specified TimeSpan.
Multiply(Double, TimeSpan)	Returns a new TimeSpan object whose value is the result of multiplying the specified `factor` and the specified `timeSpan` instance.
Multiply(TimeSpan, Double)	Returns a new TimeSpan object whose value is the result of multiplying the specified `timeSpan` instance and the specified `factor`.
Subtraction(TimeSpan, Time Span)	Subtracts a specified TimeSpan from another specified TimeSpan.
UnaryNegation(TimeSpan)	Returns a TimeSpan whose value is the negated value of the specified instance.
UnaryPlus(TimeSpan)	Returns the specified instance of TimeSpan.

TimeSpan Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the TimeSpan structure.

Overloads

Expand table

TimeSpan(Int64)	Initializes a new instance of the TimeSpan structure to the specified number of ticks.
TimeSpan(Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of hours, minutes, and seconds.
TimeSpan(Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, and seconds.
TimeSpan(Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, seconds, and milliseconds.
TimeSpan(Int32, Int32, Int32, Int32, Int32, Int32)	Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, seconds, milliseconds, and microseconds.

TimeSpan(Int64)

Initializes a new instance of the TimeSpan structure to the specified number of ticks.

C#

```
public TimeSpan (long ticks);
```

Parameters

`ticks` Int64

A time period expressed in 100-nanosecond units.

Examples

The following example creates several TimeSpan objects using the constructor overload that initializes a TimeSpan to a specified number of ticks.

C#

```
// Example of the TimeSpan( long ) constructor.
using System;

class TimeSpanCtorLDemo
{
    // Create a TimeSpan object and display its value.
    static void CreateTimeSpan( long ticks )
    {
        TimeSpan elapsedTime = new TimeSpan( ticks );

        // Format the constructor for display.
        string ctor = String.Format( "TimeSpan( {0} )", ticks );

        // Pad the end of a TimeSpan string with spaces if
        // it does not contain milliseconds.
        string  elapsedStr = elapsedTime.ToString( );
        int     pointIndex = elapsedStr.IndexOf( ':' );

        pointIndex = elapsedStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) elapsedStr += "        ";

        // Display the constructor and its value.
        Console.WriteLine( "{0,-33}{1,24}", ctor, elapsedStr );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of the TimeSpan( long ) constructor " +
            "\ngenerates the following output.\n" );
        Console.WriteLine( "{0,-33}{1,16}", "Constructor", "Value" );
        Console.WriteLine( "{0,-33}{1,16}", "-----------", "-----" );

        CreateTimeSpan( 1 );
        CreateTimeSpan( 999999 );
        CreateTimeSpan( -1000000000000 );
        CreateTimeSpan( 18012202000000 );
        CreateTimeSpan( 999999999999999999 );
        CreateTimeSpan( 1000000000000000000 );
    }
}

/*
```

```
This example of the TimeSpan( long ) constructor
generates the following output.

Constructor                                  Value
-----------                                  -----
TimeSpan( 1 )                              00:00:00.0000001
TimeSpan( 999999 )                         00:00:00.0999999
TimeSpan( -1000000000000 )             -1.03:46:40
TimeSpan( 18012202000000 )             20.20:20:20.2000000
TimeSpan( 999999999999999999 )    1157407.09:46:39.9999999
TimeSpan( 1000000000000000000 )   1157407.09:46:40
*/
```

Remarks

A single tick represents one hundred nanoseconds or one ten-millionth of a second. There are 10,000 ticks in a millisecond.

TimeSpan(Int32, Int32, Int32)

Initializes a new instance of the TimeSpan structure to a specified number of hours, minutes, and seconds.

```
C#
```

```
public TimeSpan (int hours, int minutes, int seconds);
```

Parameters

hours Int32

Number of hours.

minutes Int32

Number of minutes.

seconds Int32

Number of seconds.

Exceptions

ArgumentOutOfRangeException

The parameters specify a TimeSpan value less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Examples

The following example creates several TimeSpan objects using the constructor overload that initializes a TimeSpan to a specified number of hours, minutes, and seconds.

C#

```
// Example of the TimeSpan( int, int, int ) constructor.
using System;

class TimeSpanCtorIIIDemo
{
    // Create a TimeSpan object and display its value.
    static void CreateTimeSpan( int hours, int minutes,
        int seconds )
    {
        TimeSpan elapsedTime =
            new TimeSpan( hours, minutes, seconds );

        // Format the constructor for display.
        string ctor = String.Format( "TimeSpan( {0}, {1}, {2} )",
            hours, minutes, seconds);

        // Display the constructor and its value.
        Console.WriteLine( "{0,-37}{1,16}",
```

```
            ctor, elapsedTime.ToString( ) );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of the TimeSpan( int, int, int ) " +
            "\nconstructor generates the following output.\n" );
        Console.WriteLine( "{0,-37}{1,16}", "Constructor", "Value" );
        Console.WriteLine( "{0,-37}{1,16}", "-----------", "-----" );

        CreateTimeSpan( 10, 20, 30 );
        CreateTimeSpan( -10, 20, 30 );
        CreateTimeSpan( 0, 0, 37230 );
        CreateTimeSpan( 1000, 2000, 3000 );
        CreateTimeSpan( 1000, -2000, -3000 );
        CreateTimeSpan( 999999, 999999, 999999 );
    }
}

/*
This example of the TimeSpan( int, int, int )
constructor generates the following output.

Constructor                                     Value
-----------                                     -----
TimeSpan( 10, 20, 30 )                       10:20:30
TimeSpan( -10, 20, 30 )                     -09:39:30
TimeSpan( 0, 0, 37230 )                      10:20:30
TimeSpan( 1000, 2000, 3000 )              43.02:10:00
TimeSpan( 1000, -2000, -3000 )            40.05:50:00
TimeSpan( 999999, 999999, 999999 )     42372.15:25:39
*/
```

Remarks

The specified `hours`, `minutes`, and `seconds` are converted to ticks, and that value initializes this instance.

TimeSpan(Int32, Int32, Int32, Int32)

Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, and seconds.

C#

```
public TimeSpan (int days, int hours, int minutes, int seconds);
```

Parameters

`days` Int32

Number of days.

`hours` Int32

Number of hours.

`minutes` Int32

Number of minutes.

`seconds` Int32

Number of seconds.

Exceptions

ArgumentOutOfRangeException

The parameters specify a TimeSpan value less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Examples

The following example creates several TimeSpan objects using the constructor overload that initializes a TimeSpan to a specified number of days, hours, minutes, and seconds.

C#

```
using System;

class Example
{
    // Create a TimeSpan object and display its value.
    static void CreateTimeSpan( int days, int hours,
        int minutes, int seconds )
    {
        TimeSpan elapsedTime =
            new TimeSpan( days, hours, minutes, seconds );

        // Format the constructor for display.
        string ctor =
            String.Format( "TimeSpan( {0}, {1}, {2}, {3} )",
                days, hours, minutes, seconds);

        // Display the constructor and its value.
        Console.WriteLine( "{0,-44}{1,16}",
            ctor, elapsedTime.ToString( ) );
    }

    static void Main( )
    {
        Console.WriteLine( "{0,-44}{1,16}", "Constructor", "Value" );
        Console.WriteLine( "{0,-44}{1,16}", "-----------", "-----" );

        CreateTimeSpan( 10, 20, 30, 40 );
        CreateTimeSpan( -10, 20, 30, 40 );
        CreateTimeSpan( 0, 0, 0, 937840 );
        CreateTimeSpan( 1000, 2000, 3000, 4000 );
        CreateTimeSpan( 1000, -2000, -3000, -4000 );
        CreateTimeSpan( 999999, 999999, 999999, 999999 );
    }
}
// The example displays the following output:
//       Constructor                                          Value
//       -----------                                          -----
//       TimeSpan( 10, 20, 30, 40 )                      10.20:30:40
//       TimeSpan( -10, 20, 30, 40 )                     -9.03:29:20
//       TimeSpan( 0, 0, 0, 937840 )                     10.20:30:40
//       TimeSpan( 1000, 2000, 3000, 4000 )            1085.11:06:40
//       TimeSpan( 1000, -2000, -3000, -4000 )          914.12:53:20
//       TimeSpan( 999999, 999999, 999999, 999999 )  1042371.15:25:39
```

Remarks

The specified `days`, `hours`, `minutes`, and `seconds` are converted to ticks, and that value initializes this instance.

TimeSpan(Int32, Int32, Int32, Int32, Int32)

Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, seconds, and milliseconds.

C#

```
public TimeSpan (int days, int hours, int minutes, int seconds, int
milliseconds);
```

Parameters

days Int32

Number of days.

hours Int32

Number of hours.

`minutes` Int32

Number of minutes.

`seconds` Int32

Number of seconds.

`milliseconds` Int32

Number of milliseconds.

Exceptions

ArgumentOutOfRangeException

The parameters specify a TimeSpan value less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Examples

The following example creates several TimeSpan objects using the constructor overload that initializes a TimeSpan to a specified number of days, hours, minutes, seconds, and milliseconds.

C#

```
// Example of the TimeSpan( int, int, int, int, int ) constructor.
using System;

class TimeSpanCtorIIIIIDemo
{
    // Create a TimeSpan object and display its value.
    static void CreateTimeSpan( int days, int hours,
        int minutes, int seconds, int millisec )
    {
        TimeSpan elapsedTime = new TimeSpan(
            days, hours, minutes, seconds, millisec );

        // Format the constructor for display.
        string ctor =
            String.Format( "TimeSpan( {0}, {1}, {2}, {3}, {4} )",
                days, hours, minutes, seconds, millisec);

        // Display the constructor and its value.
        Console.WriteLine( "{0,-48}{1,24}",
            ctor, elapsedTime.ToString( ) );
    }

    static void Main( )
    {
```

```
        Console.WriteLine(
            "This example of the " +
            "TimeSpan( int, int, int, int, int ) " +
            "\nconstructor generates the following output.\n" );
        Console.WriteLine( "{0,-48}{1,16}", "Constructor", "Value" );
        Console.WriteLine( "{0,-48}{1,16}", "-----------", "-----" );

        CreateTimeSpan( 10, 20, 30, 40, 50 );
        CreateTimeSpan( -10, 20, 30, 40, 50 );
        CreateTimeSpan( 0, 0, 0, 0, 937840050 );
        CreateTimeSpan( 1111, 2222, 3333, 4444, 5555 );
        CreateTimeSpan( 1111, -2222, -3333, -4444, -5555 );
        CreateTimeSpan( 99999, 99999, 99999, 99999, 99999 );
    }
}

/*
This example of the TimeSpan( int, int, int, int, int )
constructor generates the following output.

Constructor                                                Value
-----------                                                -----
TimeSpan( 10, 20, 30, 40, 50 )                       10.20:30:40.0500000
TimeSpan( -10, 20, 30, 40, 50 )                      -9.03:29:19.9500000
TimeSpan( 0, 0, 0, 0, 937840050 )                    10.20:30:40.0500000
TimeSpan( 1111, 2222, 3333, 4444, 5555 )           1205.22:47:09.5550000
TimeSpan( 1111, -2222, -3333, -4444, -5555 )       1016.01:12:50.4450000
TimeSpan( 99999, 99999, 99999, 99999, 99999 )    104236.05:27:18.9990000
*/
```

Remarks

The specified `days`, `hours`, `minutes`, `seconds`, and `milliseconds` are converted to ticks, and that value initializes this instance.

UWP	10.0

TimeSpan(Int32, Int32, Int32, Int32, Int32, Int32)

Initializes a new instance of the TimeSpan structure to a specified number of days, hours, minutes, seconds, milliseconds, and microseconds.

C#

```
public TimeSpan (int days, int hours, int minutes, int seconds, int
milliseconds, int microseconds);
```

Parameters

days Int32

Number of days.

hours Int32

Number of hours.

minutes Int32

Number of minutes.

seconds Int32

Number of seconds.

milliseconds Int32

Number of milliseconds.

microseconds Int32

Number of microseconds.

Exceptions

ArgumentOutOfRangeException

The parameters specify a TimeSpan value less than MinValue or greater than MaxValue

Remarks

The specified `days`, `hours`, `minutes`, `seconds`, `milliseconds`, and `microseconds` are converted to ticks, and that value initializes this instance.

TimeSpan.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the maximum TimeSpan value. This field is read-only.

C#

```
public static readonly TimeSpan MaxValue;
```

Field Value

TimeSpan

Examples

The following example references and displays the value of the MaxValue field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
        const string timeFmt = "{0,-22}{1,26}" ;
```

```
        Console.WriteLine(
            "This example of the fields of the TimeSpan class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field", "Value" );
        Console.WriteLine( numberFmt, "-----", "-----" );

        // Display the maximum, minimum, and zero TimeSpan values.
        Console.WriteLine( timeFmt, "Maximum TimeSpan",
            Align( TimeSpan.MaxValue ) );
        Console.WriteLine( timeFmt, "Minimum TimeSpan",
            Align( TimeSpan.MinValue ) );
        Console.WriteLine( timeFmt, "Zero TimeSpan",
            Align( TimeSpan.Zero ) );
        Console.WriteLine( );

        // Display the ticks-per-time-unit fields.
        Console.WriteLine( numberFmt, "Ticks per day",
            TimeSpan.TicksPerDay );
        Console.WriteLine( numberFmt, "Ticks per hour",
            TimeSpan.TicksPerHour );
        Console.WriteLine( numberFmt, "Ticks per minute",
            TimeSpan.TicksPerMinute );
        Console.WriteLine( numberFmt, "Ticks per second",
            TimeSpan.TicksPerSecond );
        Console.WriteLine( numberFmt, "Ticks per millisecond",
            TimeSpan.TicksPerMillisecond );
    }
}

/*
This example of the fields of the TimeSpan class
generates the following output.

Field                              Value
-----                              -----
Maximum TimeSpan       10675199.02:48:05.4775807
Minimum TimeSpan      -10675199.02:48:05.4775808
Zero TimeSpan                   00:00:00

Ticks per day            864,000,000,000
Ticks per hour            36,000,000,000
Ticks per minute             600,000,000
Ticks per second              10,000,000
Ticks per millisecond             10,000
*/
```

Remarks

The value of this field is equivalent to Int64.MaxValue ticks. The string representation of this value is positive 10675199.02:48:05.4775807, or slightly more than 10,675,199 days.

TimeSpan.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the minimum TimeSpan value. This field is read-only.

C#

```
public static readonly TimeSpan MinValue;
```

Field Value

TimeSpan

Examples

The following example references and displays the value of the MinValue field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
        const string timeFmt = "{0,-22}{1,26}" ;
```

```
        Console.WriteLine(

TimeSpan.TicksPerHour Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of ticks in 1 hour. This field is constant.

C#

```
public const long TicksPerHour = 36000000000;
```

Field Value

***Value* = 36000000000**

Int64

Examples

The following example references and displays the value of the TicksPerHour field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
```

```
        const string timeFmt = "{0,-22}{1,26}" ;

        Console.WriteLine(
            "This example of the fields of the TimeSpan class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field", "Value" );
        Console.WriteLine( numberFmt, "-----", "-----" );

        // Display the maximum, minimum, and zero TimeSpan values.
        Console.WriteLine( timeFmt, "Maximum TimeSpan",
            Align( TimeSpan.MaxValue ) );
        Console.WriteLine( timeFmt, "Minimum TimeSpan",
            Align( TimeSpan.MinValue ) );
        Console.WriteLine( timeFmt, "Zero TimeSpan",
            Align( TimeSpan.Zero ) );
        Console.WriteLine( );

        // Display the ticks-per-time-unit fields.
        Console.WriteLine( numberFmt, "Ticks per day",
            TimeSpan.TicksPerDay );
        Console.WriteLine( numberFmt, "Ticks per hour",
            TimeSpan.TicksPerHour );
        Console.WriteLine( numberFmt, "Ticks per minute",
            TimeSpan.TicksPerMinute );

TimeSpan.TicksPerMicrosecond Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of ticks in 1 microsecond. This field is constant.

C#

```
public const long TicksPerMicrosecond = 10;
```

Field Value

Value* = *10

Int64

Remarks

The value of this constant is 10.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

TimeSpan.TicksPerMillisecond Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of ticks in 1 millisecond. This field is constant.

C#

```
public const long TicksPerMillisecond = 10000;
```

Field Value

Value* = *10000

Int64

Examples

The following example references and displays the value of the TicksPerMillisecond field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
```

```
        const string timeFmt = "{0,-22}{1,26}" ;

        Console.WriteLine(
            "This example of the fields of the TimeSpan class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field", "Value" );
        Console.WriteLine( numberFmt, "-----", "-----" );

        // Display the maximum, minimum, and zero TimeSpan values.
        Console.WriteLine( timeFmt, "Maximum TimeSpan",
            Align( TimeSpan.MaxValue ) );
        Console.WriteLine( timeFmt, "Minimum TimeSpan",
            Align( TimeSpan.MinValue ) );
        Console.WriteLine( timeFmt, "Zero TimeSpan",
            Align( TimeSpan.Zero ) );
        Console.WriteLine( );

        // Display the ticks-per-time-unit fields.
        Console.WriteLine( numberFmt, "Ticks per day",
            TimeSpan.TicksPerDay );
        Console.WriteLine( numberFmt, "Ticks per hour",
            TimeSpan.TicksPerHour );
        Console.WriteLine( numberFmt, "Ticks per minute",
            TimeSpan.TicksPerMinute );
        Console.WriteLine( numberFmt, "Ticks per second",
            TimeSpan.TicksPerSecond );
        Console.WriteLine( numberFmt, "Ticks per millisecond",
            TimeSpan.TicksPerMillisecond );
    }
}

/*
This example of the fields of the TimeSpan class
generates the following output.

Field                                Value
-----                                -----
Maximum TimeSpan       10675199.02:48:05.4775807
Minimum TimeSpan      -10675199.02:48:05.4775808
Zero TimeSpan                   00:00:00

Ticks per day            864,000,000,000
Ticks per hour            36,000,000,000
Ticks per minute             600,000,000
Ticks per second              10,000,000
Ticks per millisecond             10,000
*/
```

Remarks

The value of this constant is 10 thousand; that is, 10,000.

Applies to

TimeSpan.TicksPerMinute Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of ticks in 1 minute. This field is constant.

C#

```
public const long TicksPerMinute = 600000000;
```

Field Value

***Value* = 600000000**

Int64

Examples

The following example references and displays the value of the TicksPerMinute field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
```

```
        const string timeFmt = "{0,-22}{1,26}" ;

        Console.WriteLine(
            "This example of the fields of the TimeSpan class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field", "Value" );
        Console.WriteLine( numberFmt, "-----", "-----" );

        // Display the maximum, minimum, and zero TimeSpan values.
        Console.WriteLine( timeFmt, "Maximum TimeSpan",
            Align( TimeSpan.MaxValue ) );
        Console.WriteLine( timeFmt, "Minimum TimeSpan",
            Align( TimeSpan.MinValue ) );
        Console.WriteLine( timeFmt, "Zero TimeSpan",
            Align( TimeSpan.Zero ) );
        Console.WriteLine( );

        // Display the ticks-per-time-unit fields.
        Console.WriteLine( numberFmt, "Ticks per day",
            TimeSpan.TicksPerDay );
        Console.WriteLine( numberFmt, "Ticks per hour",
            TimeSpan.TicksPerHour );
        Console.WriteLine( numberFmt, "Ticks per minute",
            TimeSpan.TicksPerMinute );
        Console.WriteLine( numberFmt, "Ticks per second",
            TimeSpan.TicksPerSecond );
        Console.WriteLine( numberFmt, "Ticks per millisecond",
            TimeSpan.TicksPerMillisecond );
    }
}

/*
This example of the fields of the TimeSpan class
generates the following output.

Field                                Value
-----                                -----
Maximum TimeSpan       10675199.02:48:05.4775807
Minimum TimeSpan      -10675199.02:48:05.4775808
Zero TimeSpan                   00:00:00

Ticks per day            864,000,000,000

TimeSpan.TicksPerSecond Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the number of ticks in 1 second.

C#

```
public const long TicksPerSecond = 10000000;
```

Field Value

Value* = *10000000

Int64

Examples

The following example references and displays the value of the TicksPerSecond field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
```

```
        const string timeFmt = "{0,-22}{1,26}" ;

        Console.WriteLine(
            "This example of the fields of the TimeSpan class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field", "Value" );
        Console.WriteLine( numberFmt, "-----", "-----" );

        // Display the maximum, minimum, and zero TimeSpan values.
        Console.WriteLine( timeFmt, "Maximum TimeSpan",
            Align( TimeSpan.MaxValue ) );
        Console.WriteLine( timeFmt, "Minimum TimeSpan",
            Align( TimeSpan.MinValue ) );
        Console.WriteLine( timeFmt, "Zero TimeSpan",
            Align( TimeSpan.Zero ) );
        Console.WriteLine( );

        // Display the ticks-per-time-unit fields.
        Console.WriteLine( numberFmt, "Ticks per day",
            TimeSpan.TicksPerDay );
        Console.WriteLine( numberFmt, "Ticks per hour",
            TimeSpan.TicksPerHour );
        Console.WriteLine( numberFmt, "Ticks per minute",
            TimeSpan.TicksPerMinute );

TimeSpan.Zero Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the zero TimeSpan value. This field is read-only.

C#

```
public static readonly TimeSpan Zero;
```

Field Value

TimeSpan

Examples

The following example references and displays the value of the Zero field.

C#

```
// Example of the TimeSpan fields.
using System;

class TimeSpanFieldsDemo
{
    // Pad the end of a TimeSpan string with spaces if it does not
    // contain milliseconds.
    static string Align( TimeSpan interval )
    {
        string  intervalStr = interval.ToString( );
        int     pointIndex = intervalStr.IndexOf( ':' );

        pointIndex = intervalStr.IndexOf( '.', pointIndex );
        if( pointIndex < 0 ) intervalStr += "        ";
        return intervalStr;
    }

    static void Main( )
    {
        const string numberFmt = "{0,-22}{1,18:N0}" ;
        const string timeFmt = "{0,-22}{1,26}" ;
```

```
        Console.WriteLine(
            "This example of the fields of the TimeSpan class" +
            "\ngenerates the following output.\n" );
        Console.WriteLine( numberFmt, "Field", "Value" );
        Console.WriteLine( numberFmt, "-----", "-----" );

        // Display the maximum, minimum, and zero TimeSpan values.
        Console.WriteLine( timeFmt, "Maximum TimeSpan",
            Align( TimeSpan.MaxValue ) );
        Console.WriteLine( timeFmt, "Minimum TimeSpan",
            Align( TimeSpan.MinValue ) );
        Console.WriteLine( timeFmt, "Zero TimeSpan",
            Align( TimeSpan.Zero ) );
        Console.WriteLine( );

        // Display the ticks-per-time-unit fields.
        Console.WriteLine( numberFmt, "Ticks per day",
            TimeSpan.TicksPerDay );
        Console.WriteLine( numberFmt, "Ticks per hour",
            TimeSpan.TicksPerHour );
        Console.WriteLine( numberFmt, "Ticks per minute",
            TimeSpan.TicksPerMinute );
        Console.WriteLine( numberFmt, "Ticks per second",
            TimeSpan.TicksPerSecond );
        Console.WriteLine( numberFmt, "Ticks per millisecond",
            TimeSpan.TicksPerMillisecond );
    }
}

/*
This example of the fields of the TimeSpan class
generates the following output.

Field                              Value
-----                              -----
Maximum TimeSpan       10675199.02:48:05.4775807
Minimum TimeSpan      -10675199.02:48:05.4775808
Zero TimeSpan                   00:00:00

Ticks per day            864,000,000,000
Ticks per hour            36,000,000,000
Ticks per minute             600,000,000
Ticks per second              10,000,000
Ticks per millisecond             10,000
*/
```

Remarks

Because the value of the Zero field is a TimeSpan object that represents a zero time value, you can compare it with other TimeSpan objects to determine whether the latter

represent positive, non-zero, or negative time intervals. You can also use this field to initialize a TimeSpan object to a zero time value.

TimeSpan.Days Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the days component of the time interval represented by the current TimeSpan structure.

C#

```
public int Days { get; }
```

Property Value

Int32

The day component of this instance. The return value can be positive or negative.

Examples

The following example creates several TimeSpan objects and displays the Days property of each.

C#

```
using System;

class Example
{
    static void Main()
    {
        // Create and display a TimeSpan value of 1 tick.
        Console.Write("\n{0,-45}", "TimeSpan( 1 )");
        ShowTimeSpanProperties(new TimeSpan(1));

        // Create a TimeSpan value with a large number of ticks.
        Console.Write("\n{0,-45}", "TimeSpan( 111222333444555 )");
        ShowTimeSpanProperties(new TimeSpan(111222333444555));

        // This TimeSpan has all fields specified.
        Console.Write("\n{0,-45}", "TimeSpan( 10, 20, 30, 40, 50 )");
```

```
        ShowTimeSpanProperties(new TimeSpan(10, 20, 30, 40, 50));

        // This TimeSpan has all fields overflowing.
        Console.Write("\n{0,-45}",
                      "TimeSpan( 1111, 2222, 3333, 4444, 5555 )");
        ShowTimeSpanProperties(
           new TimeSpan(1111, 2222, 3333, 4444, 5555));

        // This TimeSpan is based on a number of days.
        Console.Write("\n{0,-45}", "FromDays( 20.84745602 )");
        ShowTimeSpanProperties(TimeSpan.FromDays( 20.84745602));
    }

    static void ShowTimeSpanProperties( TimeSpan interval )
    {
        Console.WriteLine("{0,21}", interval);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Days",
                          interval.Days, "TotalDays", interval.TotalDays);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Hours",
                          interval.Hours, "TotalHours",
interval.TotalHours);

```

Remarks

A TimeSpan value can be represented as [-]*d.hh*:*mm*:*ss.ff*, where the optional minus sign indicates a negative time interval, the *d* component is days, *hh* is hours as measured on a 24-hour clock, *mm* is minutes, *ss* is seconds, and *ff* is fractions of a second. The value of the Days property is the day component, *d*.

The Days property represents whole days, whereas the TotalDays property represents whole and fractional days.

TimeSpan.Hours Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the hours component of the time interval represented by the current TimeSpan structure.

C#

```
public int Hours { get; }
```

Property Value

Int32

The hour component of the current TimeSpan structure. The return value ranges from -23 through 23.

Examples

The following example creates several TimeSpan objects and displays the Hours property of each.

C#

```
using System;

class Example
{
    static void Main()
    {
        // Create and display a TimeSpan value of 1 tick.
        Console.Write("\n{0,-45}", "TimeSpan( 1 )");
        ShowTimeSpanProperties(new TimeSpan(1));

        // Create a TimeSpan value with a large number of ticks.
        Console.Write("\n{0,-45}", "TimeSpan( 111222333444555 )");
        ShowTimeSpanProperties(new TimeSpan(111222333444555));

        // This TimeSpan has all fields specified.
```

```
        Console.Write("\n{0,-45}", "TimeSpan( 10, 20, 30, 40, 50 )");
        ShowTimeSpanProperties(new TimeSpan(10, 20, 30, 40, 50));

        // This TimeSpan has all fields overflowing.
        Console.Write("\n{0,-45}",
                      "TimeSpan( 1111, 2222, 3333, 4444, 5555 )");
        ShowTimeSpanProperties(
           new TimeSpan(1111, 2222, 3333, 4444, 5555));

        // This TimeSpan is based on a number of days.
        Console.Write("\n{0,-45}", "FromDays( 20.84745602 )");
        ShowTimeSpanProperties(TimeSpan.FromDays( 20.84745602));
    }

    static void ShowTimeSpanProperties( TimeSpan interval )
    {
        Console.WriteLine("{0,21}", interval);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Days",
                          interval.Days, "TotalDays", interval.TotalDays);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Hours",
                          interval.Hours, "TotalHours",
interval.TotalHours);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Minutes",
                          interval.Minutes, "TotalMinutes",
interval.TotalMinutes);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Seconds",
                          interval.Seconds, "TotalSeconds",
interval.TotalSeconds);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}",
"Milliseconds",
                          interval.Milliseconds, "TotalMilliseconds",
                          interval.TotalMilliseconds);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N0}", null, null,
            "Ticks", interval.Ticks);
    }
}
// The example displays the following output if the current culture is en-
US:
//    TimeSpan( 1 )                                        00:00:00.0000001
//    Days               0       TotalDays                          0.000

TimeSpan.Microseconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the microseconds component of the time interval represented by the current TimeSpan structure.

C#

```
public int Microseconds { get; }
```

Property Value

Int32

Remarks

The Microseconds property represents whole microseconds, whereas the TotalMicroseconds property represents whole and fractional microseconds.

TimeSpan.Milliseconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the milliseconds component of the time interval represented by the current TimeSpan structure.

C#

```
public int Milliseconds { get; }
```

Property Value

Int32

The millisecond component of the current TimeSpan structure. The return value ranges from -999 through 999.

Examples

The following example creates several TimeSpan objects and displays the Milliseconds property of each.

C#

```
using System;

class Example
{
    static void Main()
    {
        // Create and display a TimeSpan value of 1 tick.
        Console.Write("\n{0,-45}", "TimeSpan( 1 )");
        ShowTimeSpanProperties(new TimeSpan(1));

        // Create a TimeSpan value with a large number of ticks.
        Console.Write("\n{0,-45}", "TimeSpan( 111222333444555 )");
        ShowTimeSpanProperties(new TimeSpan(111222333444555));

        // This TimeSpan has all fields specified.
```

```
        Console.Write("\n{0,-45}", "TimeSpan( 10, 20, 30, 40, 50 )");
        ShowTimeSpanProperties(new TimeSpan(10, 20, 30, 40, 50));

        // This TimeSpan has all fields overflowing.
        Console.Write("\n{0,-45}",
                      "TimeSpan( 1111, 2222, 3333, 4444, 5555 )");
        ShowTimeSpanProperties(
           new TimeSpan(1111, 2222, 3333, 4444, 5555));

        // This TimeSpan is based on a number of days.
        Console.Write("\n{0,-45}", "FromDays( 20.84745602 )");
        ShowTimeSpanProperties(TimeSpan.FromDays( 20.84745602));
    }

    static void ShowTimeSpanProperties( TimeSpan interval )
    {
        Console.WriteLine("{0,21}", interval);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Days",
                          interval.Days, "TotalDays", interval.TotalDays);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Hours",

```

Remarks

A TimeSpan value can be represented as [-]*d.hh*:*mm*:*ss.ff*, where the optional minus sign indicates a negative time interval, the *d* component is days, *hh* is hours as measured on a 24-hour clock, *mm* is minutes, *ss* is seconds, and *ff* is fractions of a second. The value of the Milliseconds property is the fractional second component, *ff*.

The Milliseconds property represents whole milliseconds, whereas the TotalMilliseconds property represents whole and fractional milliseconds.

TimeSpan.Minutes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minutes component of the time interval represented by the current TimeSpan structure.

C#

```
public int Minutes { get; }
```

Property Value

Int32

The minute component of the current TimeSpan structure. The return value ranges from -59 through 59.

Examples

The following example creates several TimeSpan objects and displays the Minutes property of each.

C#

```
using System;

class Example
{
    static void Main()
    {
        // Create and display a TimeSpan value of 1 tick.
        Console.Write("\n{0,-45}", "TimeSpan( 1 )");
        ShowTimeSpanProperties(new TimeSpan(1));

        // Create a TimeSpan value with a large number of ticks.
        Console.Write("\n{0,-45}", "TimeSpan( 111222333444555 )");
        ShowTimeSpanProperties(new TimeSpan(111222333444555));

        // This TimeSpan has all fields specified.
```

```
        Console.Write("\n{0,-45}", "TimeSpan( 10, 20, 30, 40, 50 )");
        ShowTimeSpanProperties(new TimeSpan(10, 20, 30, 40, 50));

        // This TimeSpan has all fields overflowing.
        Console.Write("\n{0,-45}",
                      "TimeSpan( 1111, 2222, 3333, 4444, 5555 )");
        ShowTimeSpanProperties(
           new TimeSpan(1111, 2222, 3333, 4444, 5555));

        // This TimeSpan is based on a number of days.
        Console.Write("\n{0,-45}", "FromDays( 20.84745602 )");
        ShowTimeSpanProperties(TimeSpan.FromDays( 20.84745602));
    }

    static void ShowTimeSpanProperties( TimeSpan interval )
    {
        Console.WriteLine("{0,21}", interval);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Days",
                          interval.Days, "TotalDays", interval.TotalDays);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Hours",
                          interval.Hours, "TotalHours",
interval.TotalHours);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Minutes",
                          interval.Minutes, "TotalMinutes",
interval.TotalMinutes);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Seconds",
                          interval.Seconds, "TotalSeconds",
interval.TotalSeconds);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}",
"Milliseconds",
                          interval.Milliseconds, "TotalMilliseconds",
                          interval.TotalMilliseconds);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N0}", null, null,
            "Ticks", interval.Ticks);
    }
}
// The example displays the following output if the current culture is en-
US:
//    TimeSpan( 1 )                                        00:00:00.0000001

TimeSpan.Seconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the seconds component of the time interval represented by the current TimeSpan structure.

C#

```
public int Seconds { get; }
```

Property Value

Int32

The second component of the current TimeSpan structure. The return value ranges from -59 through 59.

Examples

The following example creates several TimeSpan objects and displays the Seconds property of each.

C#

```
using System;

class Example
{
    static void Main()
    {
        // Create and display a TimeSpan value of 1 tick.
        Console.Write("\n{0,-45}", "TimeSpan( 1 )");
        ShowTimeSpanProperties(new TimeSpan(1));

        // Create a TimeSpan value with a large number of ticks.
        Console.Write("\n{0,-45}", "TimeSpan( 111222333444555 )");
        ShowTimeSpanProperties(new TimeSpan(111222333444555));

        // This TimeSpan has all fields specified.
```

```
        Console.Write("\n{0,-45}", "TimeSpan( 10, 20, 30, 40, 50 )");
        ShowTimeSpanProperties(new TimeSpan(10, 20, 30, 40, 50));

        // This TimeSpan has all fields overflowing.
        Console.Write("\n{0,-45}",
                      "TimeSpan( 1111, 2222, 3333, 4444, 5555 )");
        ShowTimeSpanProperties(
           new TimeSpan(1111, 2222, 3333, 4444, 5555));

        // This TimeSpan is based on a number of days.
        Console.Write("\n{0,-45}", "FromDays( 20.84745602 )");
        ShowTimeSpanProperties(TimeSpan.FromDays( 20.84745602));
    }

    static void ShowTimeSpanProperties( TimeSpan interval )
    {
        Console.WriteLine("{0,21}", interval);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Days",
                          interval.Days, "TotalDays", interval.TotalDays);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Hours",

//                               Ticks             1,041,940,295,550,000
//
//    FromDays( 20.84745602 )                          20.20:20:20.2000000
//    Days              20       TotalDays                       20.847
//    Hours             20       TotalHours                     500.339
//    Minutes           20       TotalMinutes                30,020.337
//    Seconds           20       TotalSeconds             1,801,220.200
//    Milliseconds     200       TotalMilliseconds     1,801,220,200.000
//                               Ticks                18,012,202,000,000
```

Remarks

A TimeSpan value can be represented as [-]*d.hh*:*mm*:*ss.ff*, where the optional minus sign indicates a negative time interval, the *d* component is days, *hh* is hours as measured on a 24-hour clock, *mm* is minutes, *ss* is seconds, and *ff* is fractions of a second. The value of the Seconds property is the seconds component, *ss*.

The Seconds property represents whole seconds, whereas the TotalSeconds property represents whole and fractional seconds.

TimeSpan.Ticks Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of ticks that represent the value of the current TimeSpan structure.

C#

```
public long Ticks { get; }
```

Property Value

Int64

The number of ticks contained in this instance.

Examples

The following example creates several TimeSpan objects and displays the Ticks property of each.

C#

```
using System;

class Example
{
    static void Main()
    {
        // Create and display a TimeSpan value of 1 tick.
        Console.Write("\n{0,-45}", "TimeSpan( 1 )");
        ShowTimeSpanProperties(new TimeSpan(1));

        // Create a TimeSpan value with a large number of ticks.
        Console.Write("\n{0,-45}", "TimeSpan( 111222333444555 )");
        ShowTimeSpanProperties(new TimeSpan(111222333444555));

        // This TimeSpan has all fields specified.
        Console.Write("\n{0,-45}", "TimeSpan( 10, 20, 30, 40, 50 )");
        ShowTimeSpanProperties(new TimeSpan(10, 20, 30, 40, 50));
```

```
        // This TimeSpan has all fields overflowing.
        Console.Write("\n{0,-45}",
                      "TimeSpan( 1111, 2222, 3333, 4444, 5555 )");
        ShowTimeSpanProperties(
           new TimeSpan(1111, 2222, 3333, 4444, 5555));

        // This TimeSpan is based on a number of days.
        Console.Write("\n{0,-45}", "FromDays( 20.84745602 )");
        ShowTimeSpanProperties(TimeSpan.FromDays( 20.84745602));
    }

    static void ShowTimeSpanProperties( TimeSpan interval )
    {
        Console.WriteLine("{0,21}", interval);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Days",
                          interval.Days, "TotalDays", interval.TotalDays);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Hours",
                          interval.Hours, "TotalHours",
interval.TotalHours);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Minutes",
                          interval.Minutes, "TotalMinutes",
interval.TotalMinutes);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}", "Seconds",
                          interval.Seconds, "TotalSeconds",
interval.TotalSeconds);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N3}",
"Milliseconds",
                          interval.Milliseconds, "TotalMilliseconds",
                          interval.TotalMilliseconds);
        Console.WriteLine("{0,-12}{1,8}       {2,-18}{3,21:N0}", null, null,
            "Ticks", interval.Ticks);
    }
}
// The example displays the following output if the current culture is en-
US:
//    TimeSpan( 1 )                                       00:00:00.0000001
//    Days               0       TotalDays                          0.000
//    Hours              0       TotalHours                         0.000
//    Minutes            0       TotalMinutes                       0.000
//    Seconds            0       TotalSeconds                       0.000
//    Milliseconds       0       TotalMilliseconds                  0.000
//                               Ticks                                  1

//    Milliseconds     555       TotalMilliseconds   104,194,029,555.000
//                               Ticks             1,041,940,295,550,000
//
//    FromDays( 20.84745602 )                          20.20:20:20.2000000
//    Days              20       TotalDays                       20.847
//    Hours             20       TotalHours                     500.339
//    Minutes           20       TotalMinutes                30,020.337
//    Seconds           20       TotalSeconds             1,801,220.200
//    Milliseconds     200       TotalMilliseconds     1,801,220,200.000
//                               Ticks                18,012,202,000,000
```

Remarks

The smallest unit of time is the tick, which is equal to 100 nanoseconds or one ten-millionth of a second. There are 10,000 ticks in a millisecond. The value of the Ticks property can be negative or positive to represent a negative or positive time interval.

TimeSpan.TotalDays Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional days.

C#

```
public double TotalDays { get; }
```

Property Value

Double

The total number of days represented by this instance.

Examples

The following example instantiates a TimeSpan object and displays the value of its TotalDays property. It also displays the value of each component (hours, minutes, seconds, milliseconds) that forms the fractional part of the value of its TotalDays property.

C#

```
// Define an interval of 3 days, 16+ hours.
TimeSpan interval = new TimeSpan(3, 16, 42, 45, 750);
Console.WriteLine("Value of TimeSpan: {0}", interval);

Console.WriteLine("{0:N5} days, as follows:", interval.TotalDays);
Console.WriteLine("   Days:         {0,3}", interval.Days);
Console.WriteLine("   Hours:        {0,3}", interval.Hours);
Console.WriteLine("   Minutes:      {0,3}", interval.Minutes);
Console.WriteLine("   Seconds:      {0,3}", interval.Seconds);
Console.WriteLine("   Milliseconds: {0,3}", interval.Milliseconds);

// The example displays the following output:
//       Value of TimeSpan: 3.16:42:45.7500000
//       3.69636 days, as follows:
//          Days:           3
```

```
//          Hours:         16
//          Minutes:       42
//          Seconds:       45
//          Milliseconds: 750
```

Remarks

This property converts the value of this instance from ticks to days. This number might include whole and fractional days.

The TotalDays property represents whole and fractional days, whereas the Days property represents whole days.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeSpan.TotalHours Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional hours.

C#

```
public double TotalHours { get; }
```

Property Value

Double

The total number of hours represented by this instance.

Examples

The following example instantiates a TimeSpan object and displays the value its TotalHours property. It also displays the value of each component (hours, minutes, seconds, and milliseconds) that forms the fractional part of the value of its TotalHours property.

C#

```
// Define an interval of 1 day, 15+ hours.
TimeSpan interval = new TimeSpan(1, 15, 42, 45, 750);
Console.WriteLine("Value of TimeSpan: {0}", interval);

Console.WriteLine("{0:N5} hours, as follows:", interval.TotalHours);
Console.WriteLine("   Hours:        {0,3}",
                  interval.Days * 24 + interval.Hours);
Console.WriteLine("   Minutes:      {0,3}", interval.Minutes);
Console.WriteLine("   Seconds:      {0,3}", interval.Seconds);
Console.WriteLine("   Milliseconds: {0,3}", interval.Milliseconds);

// The example displays the following output:
//       Value of TimeSpan: 1.15:42:45.7500000
```

```
//        39.71271 hours, as follows:
//           Hours:         39
//           Minutes:       42
//           Seconds:       45
//           Milliseconds: 750
```

Remarks

This property converts the value of this instance from ticks to hours. This number might include whole and fractional hours.

The TotalHours property represents whole and fractional hours, whereas the Hours property represents whole hours.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeSpan.TotalMicroseconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional microseconds.

C#

```
public double TotalMicroseconds { get; }
```

Property Value

Double

Remarks

This property converts the value of this instance from ticks to microseconds. This number might include whole and fractional microseconds.

The TotalMicroseconds property represents whole and fractional microseconds, whereas the Microseconds property represents whole microseconds.

TimeSpan.TotalMilliseconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional milliseconds.

C#

```
public double TotalMilliseconds { get; }
```

Property Value

Double

The total number of milliseconds represented by this instance.

Examples

The following example instantiates a TimeSpan object and displays the value of its TotalMilliseconds property.

C#

```
// Define an interval of 1 day, 15+ hours.
TimeSpan interval = new TimeSpan(1, 15, 42, 45, 750);
Console.WriteLine("Value of TimeSpan: {0}", interval);

Console.WriteLine("There are {0:N5} milliseconds, as follows:",
interval.TotalMilliseconds);
long nMilliseconds = interval.Days * 24 * 60 * 60 * 1000 +
                     interval.Hours *60 * 60 * 1000 +
                     interval.Minutes * 60 * 1000 +
                     interval.Seconds * 1000 +
                     interval.Milliseconds;
Console.WriteLine("   Milliseconds:     {0,18:N0}", nMilliseconds);
Console.WriteLine("   Ticks:            {0,18:N0}",
                  nMilliseconds * 10000 - interval.Ticks);

// The example displays the following output:
```

```
//       Value of TimeSpan: 1.15:42:45.7500000
//       There are 142,965,750.00000 milliseconds, as follows:
//          Milliseconds:            142,965,750
//          Ticks:                             0
```

Remarks

This property converts the value of this instance from ticks to milliseconds. This number might include whole and fractional milliseconds.

The TotalMilliseconds property represents whole and fractional milliseconds, whereas the Milliseconds property represents whole milliseconds.

Applies to

Product	Versions

TimeSpan.TotalMinutes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional minutes.

C#

```
public double TotalMinutes { get; }
```

Property Value

Double

The total number of minutes represented by this instance.

Examples

The following example instantiates a TimeSpan object and displays the value of its TotalMinutes property. It also displays the value of each component (seconds, milliseconds) that forms the fractional part of the value of its TotalMinutes property.

C#

```
// Define an interval of 1 day, 15+ hours.
TimeSpan interval = new TimeSpan(1, 15, 42, 45, 750);
Console.WriteLine("Value of TimeSpan: {0}", interval);

Console.WriteLine("{0:N5} minutes, as follows:", interval.TotalMinutes);
Console.WriteLine("   Minutes:      {0,5}", interval.Days * 24 * 60 +
                                             interval.Hours * 60 +
                                             interval.Minutes);
Console.WriteLine("   Seconds:      {0,5}", interval.Seconds);
Console.WriteLine("   Milliseconds: {0,5}", interval.Milliseconds);

// The example displays the following output:
//       Value of TimeSpan: 1.15:42:45.7500000
//       2,382.76250 minutes, as follows:
//          Minutes:       2382
```

```
//          Seconds:         45
//          Milliseconds:   750
```

Remarks

This property converts the value of this instance from ticks to minutes. This number might include whole and fractional minutes.

The TotalMinutes property represents whole and fractional minutes, whereas the Minutes property represents whole minutes.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TimeSpan.TotalNanoseconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional nanoseconds.

C#

```
public double TotalNanoseconds { get; }
```

Property Value

Double

Remarks

This property converts the value of this instance from ticks to nanoseconds. This number might include whole and fractional nanoseconds.

The TotalNanoseconds property represents whole and fractional nanoseconds, whereas the Nanoseconds property represents whole nanoseconds.

Applies to

Product	Versions
.NET	7, 8, 9

TimeSpan.TotalSeconds Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current TimeSpan structure expressed in whole and fractional seconds.

C#

```
public double TotalSeconds { get; }
```

Property Value

Double

The total number of seconds represented by this instance.

Examples

The following example instantiates a TimeSpan object and displays the value of its TotalSeconds property. It also displays the value of its milliseconds component, which forms the fractional part of the value of its TotalSeconds property.

C#

```
// Define an interval of 1 day, 15+ hours.
TimeSpan interval = new TimeSpan(1, 15, 42, 45, 750);
Console.WriteLine("Value of TimeSpan: {0}", interval);

Console.WriteLine("{0:N5} seconds, as follows:", interval.TotalSeconds);
Console.WriteLine("   Seconds:      {0,8:N0}", interval.Days * 24 * 60 * 60
+
                                                interval.Hours *60 * 60 +
                                                interval.Minutes * 60 +
                                                interval.Seconds);
Console.WriteLine("   Milliseconds: {0,8}", interval.Milliseconds);

// The example displays the following output:
//       Value of TimeSpan: 1.15:42:45.7500000
//       142,965.75000 seconds, as follows:
```

```
//          Seconds:       142,965
//          Milliseconds:      750
```

Remarks

This property converts the value of this instance from ticks to seconds. This number might include whole and fractional seconds.

The TotalSeconds property represents whole and fractional seconds, whereas the Seconds property represents whole seconds.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeSpan.Add(TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new TimeSpan object whose value is the sum of the specified TimeSpan object and this instance.

C#

```
public TimeSpan Add (TimeSpan ts);
```

Parameters

`ts` TimeSpan

The time interval to add.

Returns

TimeSpan

A new object that represents the value of this instance plus the value of `ts`.

Exceptions

OverflowException

The resulting TimeSpan is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Examples

The following example calls the Add method to add each element in an array of time intervals to a base TimeSpan value.

C#

```
TimeSpan baseTimeSpan = new TimeSpan(1, 12, 15, 16);
```

```
// Create an array of timespan intervals.
TimeSpan[] intervals = {
   TimeSpan.FromDays(1.5),
   TimeSpan.FromHours(1.5),
   TimeSpan.FromMinutes(45),
   TimeSpan.FromMilliseconds(505),
   new TimeSpan(1, 17, 32, 20),
   new TimeSpan(-8, 30, 0)
};

// Calculate a new time interval by adding each element to the base
interval.
foreach (var interval in intervals)
   Console.WriteLine(@"{0,-10:g} {3} {1,15:%d\:hh\:mm\:ss\.ffff} =
{2:%d\:hh\:mm\:ss\.ffff}",
                     baseTimeSpan, interval, baseTimeSpan.Add(interval),
                     interval < TimeSpan.Zero ? "-" : "+");

// The example displays the following output:
//       1:12:15:16 + 1:12:00:00.0000 = 3:00:15:16.0000
//       1:12:15:16 + 0:01:30:00.0000 = 1:13:45:16.0000
//       1:12:15:16 + 0:00:45:00.0000 = 1:13:00:16.0000
//       1:12:15:16 + 0:00:00:00.5050 = 1:12:15:16.5050
//       1:12:15:16 + 1:17:32:20.0000 = 3:05:47:36.0000
//       1:12:15:16 - 0:07:30:00.0000 = 1:04:45:16.0000
```

Remarks

The return value must be between TimeSpan.MinValue and TimeSpan.MaxValue; otherwise, an exception is thrown.

The return value is a new TimeSpan; the original TimeSpan is not modified.

Applies to

TimeSpan.Compare(TimeSpan, TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two TimeSpan values and returns an integer that indicates whether the first value is shorter than, equal to, or longer than the second value.

C#

```
public static int Compare (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Int32

One of the following values.

Expand table

Value	Description
-1	`t1` is shorter than `t2`.
0	`t1` is equal to `t2`.
1	`t1` is longer than `t2`.

Examples

The following example uses the Compare method to compare several TimeSpan objects with a TimeSpan object whose value is a 2-hour time interval.

C#

```
// Define a time interval equal to two hours.
TimeSpan baseInterval = new TimeSpan( 2, 0, 0);

// Define an array of time intervals to compare with
// the base interval.
TimeSpan[] spans = {
    TimeSpan.FromSeconds(-2.5),
    TimeSpan.FromMinutes(20),
    TimeSpan.FromHours(1),
    TimeSpan.FromMinutes(90),
    baseInterval,
    TimeSpan.FromDays(.5),
    TimeSpan.FromDays(1)
};

// Compare the time intervals.
foreach (var span in spans) {
   int result = TimeSpan.Compare(baseInterval, span);
   Console.WriteLine("{0} {1} {2} (Compare returns {3})",
                     baseInterval,
                     result == 1 ? ">" : result == 0 ? "=" : "<",
                     span, result);
}

// The example displays the following output:
//       02:00:00 > -00:00:02.5000000 (Compare returns 1)
//       02:00:00 > 00:20:00 (Compare returns 1)
//       02:00:00 > 01:00:00 (Compare returns 1)
//       02:00:00 > 01:30:00 (Compare returns 1)
//       02:00:00 = 02:00:00 (Compare returns 0)
//       02:00:00 < 12:00:00 (Compare returns -1)
//       02:00:00 < 1.00:00:00 (Compare returns -1)
```

TimeSpan.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or TimeSpan object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the specified object or TimeSpan object.

Overloads

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the specified object.
CompareTo(TimeSpan)	Compares this instance to a specified TimeSpan object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the TimeSpan object.

Remarks

The two overloads of the CompareTo method return a signed number that indicates the relative value of this instance and the `value` argument, as shown in the following table.

Expand table

Value	Description
Less than zero	This instance is shorter than `value`.
Zero	This instance is the same as `value`.
Greater than zero	This instance is longer than `value`.

CompareTo(Object)

Compares this instance to a specified object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the specified object.

```
C#

public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

One of the following values.

Expand table

Value	Description
-1	This instance is shorter than `value`.
0	This instance is equal to `value`.
1	This instance is longer than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a TimeSpan.

Examples

The following example compares several TimeSpan structures and other objects to a reference TimeSpan structure using the CompareTo method.

```
C#
```

```
// Example of the TimeSpan.CompareTo( Object ) and
// TimeSpan.Equals( Object ) methods.
using System;

class TSCompToEqualsObjDemo
{
    // Compare the TimeSpan to the Object parameters,
    // and display the Object parameters with the results.
    static void CompTimeSpanToObject( TimeSpan Left, object Right,
        string RightText )
    {
        Console.WriteLine( "{0,-33}{1}", "Object: " + RightText,
            Right );
        Console.WriteLine( "{0,-33}{1}", "Left.Equals( Object )",
            Left.Equals( Right ) );
        Console.Write( "{0,-33}", "Left.CompareTo( Object )" );

        // Catch the exception if CompareTo( ) throws one.
        try
        {
            Console.WriteLine( "{0}\n", Left.CompareTo( Right ) );
        }
        catch( Exception ex )
        {
            Console.WriteLine( "Error: {0}\n", ex.Message );
        }
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 0, 5, 0 );

        Console.WriteLine(
            "This example of the TimeSpan.Equals( Object ) " +
            "and \nTimeSpan.CompareTo( Object ) methods generates " +
            "the \nfollowing output by creating several different " +
            "TimeSpan \nobjects and comparing them with a " +
            "5-minute TimeSpan.\n" );
        Console.WriteLine( "{0,-33}{1}\n",
            "Left: TimeSpan( 0, 5, 0 )", Left );

        // Create objects to compare with a 5-minute TimeSpan.
        CompTimeSpanToObject( Left, new TimeSpan( 0, 0, 300 ),
            "TimeSpan( 0, 0, 300 )" );
        CompTimeSpanToObject( Left, new TimeSpan( 0, 5, 1 ),
            "TimeSpan( 0, 5, 1 )" );
        CompTimeSpanToObject( Left, new TimeSpan( 0, 5, -1 ),
            "TimeSpan( 0, 5, -1 )" );
        CompTimeSpanToObject( Left, new TimeSpan( 3000000000 ),
            "TimeSpan( 3000000000 )" );
        CompTimeSpanToObject( Left, 3000000000L,
            "long 3000000000L" );
        CompTimeSpanToObject( Left, "00:05:00",
            "string \"00:05:00\"" );
```

```
    }
}

/*
This example of the TimeSpan.Equals( Object ) and
TimeSpan.CompareTo( Object ) methods generates the
following output by creating several different TimeSpan
objects and comparing them with a 5-minute TimeSpan.

Left: TimeSpan( 0, 5, 0 )        00:05:00

Object: TimeSpan( 0, 0, 300 )    00:05:00
Left.Equals( Object )            True
Left.CompareTo( Object )         0

Object: TimeSpan( 0, 5, 1 )      00:05:01
Left.Equals( Object )            False
Left.CompareTo( Object )         -1

Object: TimeSpan( 0, 5, -1 )     00:04:59
Left.Equals( Object )            False
Left.CompareTo( Object )         1

Object: TimeSpan( 3000000000 )   00:05:00
Left.Equals( Object )            True
Left.CompareTo( Object )         0

Object: long 3000000000L         3000000000
Left.Equals( Object )            False
Left.CompareTo( Object )         Error: Object must be of type TimeSpan.

Object: string "00:05:00"        00:05:00
Left.Equals( Object )            False
Left.CompareTo( Object )         Error: Object must be of type TimeSpan.
*/
```

Remarks

Any instance of TimeSpan, regardless of its value, is considered greater than `null`.

The `value` parameter must be an instance of TimeSpan or `null`; otherwise, an exception is thrown.

.NET Standard	2.0, 2.1

CompareTo(TimeSpan)

Compares this instance to a specified TimeSpan object and returns an integer that indicates whether this instance is shorter than, equal to, or longer than the TimeSpan object.

C#

```
public int CompareTo (TimeSpan value);
```

Parameters

`value` TimeSpan

An object to compare to this instance.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Value	Description
A negative integer	This instance is shorter than `value`.
Zero	This instance is equal to `value`.
A positive integer	This instance is longer than `value`.

Implements

CompareTo(T)

Examples

The following example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

        }
```

```
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223
```

```
The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the TimeSpan.CompareTo method because it does not have to convert the `value` parameter to an object.

TimeSpan.Divide Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Divide(TimeSpan)	Returns a new Double value that's the result of dividing this instance by `ts`.
Divide(Double)	Returns a new TimeSpan object whose value is the result of dividing this instance by the specified `divisor`.

Divide(TimeSpan)

Returns a new Double value that's the result of dividing this instance by `ts`.

C#

```
public double Divide (TimeSpan ts);
```

Parameters

`ts` TimeSpan

The value to be divided by.

Returns

Double

A new value that represents result of dividing this instance by the value of `ts`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Divide(Double)

Returns a new TimeSpan object whose value is the result of dividing this instance by the specified `divisor`.

```
C#
public TimeSpan Divide (double divisor);
```

Parameters

`divisor` Double

The value to be divided by.

Returns

TimeSpan

A new object that represents the value of this instance divided by the value of `divisor`.

Applies to

▼ .NET 9 and other versions

Product	Versions

TimeSpan.Duration Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new TimeSpan object whose value is the absolute value of the current TimeSpan object.

C#

```
public TimeSpan Duration ();
```

Returns

TimeSpan

A new object whose value is the absolute value of the current TimeSpan object.

Exceptions

OverflowException

The value of this instance is TimeSpan.MinValue.

Examples

The following example applies the Duration method to several TimeSpan objects.

C#

```
// Example of the TimeSpan.Duration( ) and TimeSpan.Negate( ) methods,
// and the TimeSpan Unary Negation and Unary Plus operators.
using System;

class DuraNegaUnaryDemo
{
    const string dataFmt = "{0,22}{1,22}{2,22}" ;

    static void ShowDurationNegate( TimeSpan interval )
    {
        // Display the TimeSpan value and the results of the
```

```
        // Duration and Negate methods.
        Console.WriteLine( dataFmt,
            interval, interval.Duration( ), interval.Negate( ) );
    }

    static void Main()
    {
        Console.WriteLine(
            "This example of TimeSpan.Duration( ), " +
            "TimeSpan.Negate( ), \nand the TimeSpan Unary " +
            "Negation and Unary Plus operators \n" +
            "generates the following output.\n" );
        Console.WriteLine( dataFmt,
            "TimeSpan", "Duration( )", "Negate( )" );
        Console.WriteLine( dataFmt,
            "--------", "-----------", "---------" );

        // Create TimeSpan objects and apply the Unary Negation
        // and Unary Plus operators to them.
        ShowDurationNegate( new TimeSpan( 1 ) );
        ShowDurationNegate( new TimeSpan( -1234567 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, 0, 10, -20, -30 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, -10, 20, -30, 40 ) );
        ShowDurationNegate(
            - new TimeSpan( 1, 10, 20, 40, 160 ) );
        ShowDurationNegate(
            - new TimeSpan( -10, -20, -30, -40, -50 ) );
    }
}

/*
This example of TimeSpan.Duration( ), TimeSpan.Negate( ),
and the TimeSpan Unary Negation and Unary Plus operators
generates the following output.

              TimeSpan           Duration( )             Negate( )
              --------           -----------             ---------
      00:00:00.0000001      00:00:00.0000001     -00:00:00.0000001

TimeSpan.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two instances of TimeSpan are equal.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(TimeSpan)	Returns a value indicating whether this instance is equal to a specified TimeSpan object.
Equals(TimeSpan, TimeSpan)	Returns a value that indicates whether two specified instances of TimeSpan are equal.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? value);
```

Parameters

`value` Object

An object to compare with this instance.

Returns

Boolean

`true` if `value` is a TimeSpan object that represents the same time interval as the current TimeSpan structure; otherwise, `false`.

Examples

The following example compares several TimeSpan and other objects to a reference TimeSpan using the Equals method.

C#

```
// Example of the TimeSpan.CompareTo( Object ) and
// TimeSpan.Equals( Object ) methods.
using System;

class TSCompToEqualsObjDemo
{
    // Compare the TimeSpan to the Object parameters,
    // and display the Object parameters with the results.
    static void CompTimeSpanToObject( TimeSpan Left, object Right,
        string RightText )
    {
        Console.WriteLine( "{0,-33}{1}", "Object: " + RightText,
            Right );
        Console.WriteLine( "{0,-33}{1}", "Left.Equals( Object )",
            Left.Equals( Right ) );
        Console.Write( "{0,-33}", "Left.CompareTo( Object )" );

        // Catch the exception if CompareTo( ) throws one.
        try
        {
            Console.WriteLine( "{0}\n", Left.CompareTo( Right ) );
        }
        catch( Exception ex )
        {
            Console.WriteLine( "Error: {0}\n", ex.Message );
        }
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 0, 5, 0 );

        Console.WriteLine(
            "This example of the TimeSpan.Equals( Object ) " +
            "and \nTimeSpan.CompareTo( Object ) methods generates " +
            "the \nfollowing output by creating several different " +
            "TimeSpan \nobjects and comparing them with a " +
            "5-minute TimeSpan.\n" );
        Console.WriteLine( "{0,-33}{1}\n",
            "Left: TimeSpan( 0, 5, 0 )", Left );

        // Create objects to compare with a 5-minute TimeSpan.
```

```
        CompTimeSpanToObject( Left, new TimeSpan( 0, 0, 300 ),
            "TimeSpan( 0, 0, 300 )" );
        CompTimeSpanToObject( Left, new TimeSpan( 0, 5, 1 ),
            "TimeSpan( 0, 5, 1 )" );
        CompTimeSpanToObject( Left, new TimeSpan( 0, 5, -1 ),
            "TimeSpan( 0, 5, -1 )" );
        CompTimeSpanToObject( Left, new TimeSpan( 3000000000 ),
            "TimeSpan( 3000000000 )" );
        CompTimeSpanToObject( Left, 3000000000L,
            "long 3000000000L" );
        CompTimeSpanToObject( Left, "00:05:00",
            "string \"00:05:00\"" );
    }
}

/*
This example of the TimeSpan.Equals( Object ) and
TimeSpan.CompareTo( Object ) methods generates the
following output by creating several different TimeSpan
objects and comparing them with a 5-minute TimeSpan.

Left: TimeSpan( 0, 5, 0 )        00:05:00

Object: TimeSpan( 0, 0, 300 )    00:05:00
Left.Equals( Object )            True
Left.CompareTo( Object )         0

Object: TimeSpan( 0, 5, 1 )      00:05:01
Left.Equals( Object )            False
Left.CompareTo( Object )         -1

Object: TimeSpan( 0, 5, -1 )     00:04:59
Left.Equals( Object )            False
Left.CompareTo( Object )         1

Object: TimeSpan( 3000000000 )   00:05:00
Left.Equals( Object )            True
Left.CompareTo( Object )         0

Object: long 3000000000L         3000000000
Left.Equals( Object )            False
Left.CompareTo( Object )         Error: Object must be of type TimeSpan.

Object: string "00:05:00"        00:05:00
Left.Equals( Object )            False
Left.CompareTo( Object )         Error: Object must be of type TimeSpan.
*/

Equals(TimeSpan)

Returns a value indicating whether this instance is equal to a specified TimeSpan object.

```
C#

public bool Equals (TimeSpan obj);
```

Parameters

`obj` TimeSpan

An object to compare with this instance.

Returns

Boolean

`true` if `obj` represents the same time interval as this instance; otherwise, `false`.

Implements

Equals(T)

Examples

The following example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

w1.CompareTo((Object)w2));
        Show("UInt16:   ", x1, x2, x1.CompareTo(x2),
x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
```

```
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

Equals(TimeSpan, TimeSpan)

Returns a value that indicates whether two specified instances of TimeSpan are equal.

C#

```
public static bool Equals (TimeSpan t1, TimeSpan t2);
```

Parameters

`t1` TimeSpan

The first time interval to compare.

`t2` TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the values of `t1` and `t2` are equal; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan object using the static Equals method.

C#

```
// Example of the TimeSpan.Compare( TimeSpan, TimeSpan ) and
// TimeSpan.Equals( TimeSpan, TimeSpan ) methods.
using System;

class TSCompareEqualsDemo
{
    const string dataFmt = "{0,-38}{1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "TimeSpan.Equals( Left, Right )",
            TimeSpan.Equals( Left, Right ) );
        Console.WriteLine( dataFmt,
            "TimeSpan.Compare( Left, Right )",
            TimeSpan.Compare( Left, Right ) );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan.Equals( TimeSpan, Time" +
            "Span ) and \nTimeSpan.Compare( TimeSpan, TimeSpan ) " +
            "methods generates the \nfollowing output by creating " +
            "several different TimeSpan \nobjects and comparing " +
            "them with a 2-hour TimeSpan.\n" );

TimeSpan.FromDays(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan that represents a specified number of days, where the specification is accurate to the nearest millisecond.

```
C#
public static TimeSpan FromDays (double value);
```

Parameters

`value` Double

A number of days, accurate to the nearest millisecond.

Returns

TimeSpan

An object that represents `value`.

Exceptions

OverflowException

`value` is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

`value` is PositiveInfinity.

-or-

`value` is NegativeInfinity.

ArgumentException

`value` is equal to NaN.

Examples

The following example creates several TimeSpan objects using the FromDays method.

C#

```
// Example of the TimeSpan.FromDays( double ) method.
using System;

class FromDaysDemo
{
    static void GenTimeSpanFromDays( double days )
    {
        // Create a TimeSpan object and TimeSpan string from
        // a number of days.
        TimeSpan interval = TimeSpan.FromDays( days );
        string   timeInterval = interval.ToString( );

        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";

        Console.WriteLine( "{0,21}{1,26}", days, timeInterval );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.FromDays( double )\n" +
            "generates the following output.\n" );
        Console.WriteLine( "{0,21}{1,18}",
            "FromDays", "TimeSpan" );
        Console.WriteLine( "{0,21}{1,18}",
            "--------", "--------" );

        GenTimeSpanFromDays( 0.000000006 );
        GenTimeSpanFromDays( 0.000000017 );
        GenTimeSpanFromDays( 0.000123456 );
        GenTimeSpanFromDays( 1.234567898 );
        GenTimeSpanFromDays( 12345.678987654 );
        GenTimeSpanFromDays( 0.000011574 );
        GenTimeSpanFromDays( 0.000694444 );
        GenTimeSpanFromDays( 0.041666666 );
        GenTimeSpanFromDays( 1 );
        GenTimeSpanFromDays( 20.84745602 );
    }
}

/*
This example of TimeSpan.FromDays( double )
generates the following output.
```

```
              FromDays          TimeSpan
              --------          --------
                 6E-09          00:00:00.0010000
               1.7E-08          00:00:00.0010000
           0.000123456          00:00:10.6670000
           1.234567898        1.05:37:46.6660000
       12345.678987654    12345.16:17:44.5330000
            1.1574E-05          00:00:01
           0.000694444          00:01:00
           0.041666666          01:00:00
                     1        1.00:00:00
           20.84745602       20.20:20:20.2000000
*/
```

Remarks

The `value` parameter is converted to milliseconds, which is converted to ticks, and that number of ticks is used to initialize the new TimeSpan. Therefore, `value` will only be considered accurate to the nearest millisecond. Note that, because of the loss of precision of the Double data type, this conversion can cause an OverflowException for values that are near to but still in the range of either MinValue or MaxValue. For example, this causes an OverflowException in the following attempt to instantiate a TimeSpan object.

C#

```
// The following throws an OverflowException at runtime
TimeSpan maxSpan = TimeSpan.FromDays(TimeSpan.MaxValue.TotalDays);
```

TimeSpan.FromHours(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan that represents a specified number of hours, where the specification is accurate to the nearest millisecond.

```
C#
public static TimeSpan FromHours (double value);
```

Parameters

`value` Double

A number of hours accurate to the nearest millisecond.

Returns

TimeSpan

An object that represents `value`.

Exceptions

OverflowException

`value` is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

`value` is PositiveInfinity.

-or-

`value` is NegativeInfinity.

ArgumentException

`value` is equal to NaN.

Examples

The following example creates several TimeSpan objects using the FromHours method.

C#

```
// Example of the TimeSpan.FromHours( double ) method.
using System;

class FromHoursDemo
{
    static void GenTimeSpanFromHours( double hours )
    {
        // Create a TimeSpan object and TimeSpan string from
        // a number of hours.
        TimeSpan    interval = TimeSpan.FromHours( hours );
        string      timeInterval = interval.ToString( );

        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";

        Console.WriteLine( "{0,21}{1,26}", hours, timeInterval );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.FromHours( double )\n" +
            "generates the following output.\n" );
        Console.WriteLine( "{0,21}{1,18}",
            "FromHours", "TimeSpan" );
        Console.WriteLine( "{0,21}{1,18}",
            "---------", "--------" );

        GenTimeSpanFromHours( 0.0000002 );
        GenTimeSpanFromHours( 0.0000003 );
        GenTimeSpanFromHours( 0.0012345 );

TimeSpan.FromMilliseconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan that represents a specified number of milliseconds.

```
C#
public static TimeSpan FromMilliseconds (double value);
```

Parameters

`value` Double

A number of milliseconds.

Returns

TimeSpan

An object that represents `value`.

Exceptions

OverflowException

`value` is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

`value` is PositiveInfinity.

-or-

`value` is NegativeInfinity.

ArgumentException

`value` is equal to NaN.

Examples

The following example creates several TimeSpan objects by using the FromMilliseconds method.

C#

```
// Example of the TimeSpan.FromMilliseconds( double ) method.
using System;

class FromMillisecDemo
{
    static void GenTimeSpanFromMillisec( Double millisec )
    {
        // Create a TimeSpan object and TimeSpan string from
        // a number of milliseconds.
        TimeSpan    interval = TimeSpan.FromMilliseconds( millisec );
        string      timeInterval = interval.ToString( );

        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";

        Console.WriteLine( "{0,21}{1,26}", millisec, timeInterval );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.FromMilliseconds( " +
            "double )\ngenerates the following output.\n" );
        Console.WriteLine( "{0,21}{1,18}",
            "FromMilliseconds", "TimeSpan" );
        Console.WriteLine( "{0,21}{1,18}",
            "----------------", "--------" );

        GenTimeSpanFromMillisec( 1 );
        GenTimeSpanFromMillisec( 1.5 );
        GenTimeSpanFromMillisec( 12345.6 );
        GenTimeSpanFromMillisec( 123456789.8 );
        GenTimeSpanFromMillisec( 1234567898765.4 );
        GenTimeSpanFromMillisec( 1000 );
        GenTimeSpanFromMillisec( 60000 );
        GenTimeSpanFromMillisec( 3600000 );
        GenTimeSpanFromMillisec( 86400000 );
        GenTimeSpanFromMillisec( 1801220200 );
    }
}

/*
This example of TimeSpan.FromMilliseconds( double )
```

```
generates the following output.

     FromMilliseconds          TimeSpan
     ----------------          --------
                    1          00:00:00.0010000
                  1.5          00:00:00.0020000
              12345.6          00:00:12.3460000
          123456789.8        1.10:17:36.7900000
       1234567898765.4    14288.23:31:38.7650000
                 1000          00:00:01
                60000          00:01:00
              3600000          01:00:00
             86400000        1.00:00:00
           1801220200       20.20:20:20.2000000
*/
```

Remarks

The `value` parameter is converted to ticks, and that number of ticks is used to initialize the new TimeSpan. Therefore, `value` will only be considered accurate to the nearest millisecond. Note that, because of the loss of precision of the Double data type, this conversion can generate an OverflowException for values that are near to but still in the range of either MinValue or MaxValue. For example, this causes an OverflowException in the following attempt to instantiate a TimeSpan object.

C#

```
// The following throws an OverflowException at runtime
TimeSpan maxSpan =
TimeSpan.FromMilliseconds(TimeSpan.MaxValue.TotalMilliseconds);
```

TimeSpan.FromMinutes(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan that represents a specified number of minutes, where the specification is accurate to the nearest millisecond.

```
C#

public static TimeSpan FromMinutes (double value);
```

Parameters

`value` Double

A number of minutes, accurate to the nearest millisecond.

Returns

TimeSpan

An object that represents `value`.

Exceptions

OverflowException

`value` is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

`value` is PositiveInfinity.

-or-

`value` is NegativeInfinity.

ArgumentException

`value` is equal to NaN.

Examples

The following example creates several TimeSpan objects using the FromMinutes method.

C#

```
// Example of the TimeSpan.FromMinutes( double ) method.
using System;

class FromMinutesDemo
{
    static void GenTimeSpanFromMinutes( double minutes )
    {
        // Create a TimeSpan object and TimeSpan string from
        // a number of minutes.
        TimeSpan    interval = TimeSpan.FromMinutes( minutes );
        string      timeInterval = interval.ToString( );

        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";

        Console.WriteLine( "{0,21}{1,26}", minutes, timeInterval );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.FromMinutes( double )\n" +
            "generates the following output.\n" );
        Console.WriteLine( "{0,21}{1,18}",
            "FromMinutes", "TimeSpan" );
        Console.WriteLine( "{0,21}{1,18}",
            "-----------", "--------" );

        GenTimeSpanFromMinutes( 0.00001 );
        GenTimeSpanFromMinutes( 0.00002 );
        GenTimeSpanFromMinutes( 0.12345 );
        GenTimeSpanFromMinutes( 1234.56789 );
        GenTimeSpanFromMinutes( 12345678.98765 );
        GenTimeSpanFromMinutes( 0.01666 );
        GenTimeSpanFromMinutes( 1 );
        GenTimeSpanFromMinutes( 60 );
        GenTimeSpanFromMinutes( 1440 );
        GenTimeSpanFromMinutes( 30020.33667 );
    }
}
```

```
/*
This example of TimeSpan.FromMinutes( double )
generates the following output.

          FromMinutes          TimeSpan
          -----------          --------

TimeSpan.FromSeconds(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan that represents a specified number of seconds, where the specification is accurate to the nearest millisecond.

```
C#

public static TimeSpan FromSeconds (double value);
```

Parameters

`value` Double

A number of seconds, accurate to the nearest millisecond.

Returns

TimeSpan

An object that represents `value`.

Exceptions

OverflowException

`value` is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

`value` is PositiveInfinity.

-or-

`value` is NegativeInfinity.

ArgumentException

`value` is equal to NaN.

Examples

The following example creates several TimeSpan objects using the FromSeconds method.

C#

```
// Example of the TimeSpan.FromSeconds( double ) method.
using System;

class FromSecondsDemo
{
    static void GenTimeSpanFromSeconds( double seconds )
    {
        // Create a TimeSpan object and TimeSpan string from
        // a number of seconds.
        TimeSpan    interval = TimeSpan.FromSeconds( seconds );
        string      timeInterval = interval.ToString( );

        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";

        Console.WriteLine( "{0,21}{1,26}", seconds, timeInterval );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.FromSeconds( double )\n" +
            "generates the following output.\n" );
        Console.WriteLine( "{0,21}{1,18}",
            "FromSeconds", "TimeSpan" );
        Console.WriteLine( "{0,21}{1,18}",
            "-----------", "--------" );

        GenTimeSpanFromSeconds( 0.001 );
        GenTimeSpanFromSeconds( 0.0015 );
        GenTimeSpanFromSeconds( 12.3456 );
        GenTimeSpanFromSeconds( 123456.7898 );
        GenTimeSpanFromSeconds( 1234567898.7654 );
        GenTimeSpanFromSeconds( 1 );
        GenTimeSpanFromSeconds( 60 );
        GenTimeSpanFromSeconds( 3600 );
        GenTimeSpanFromSeconds( 86400 );
        GenTimeSpanFromSeconds( 1801220.2 );
    }
}
```

```
/*
This example of TimeSpan.FromSeconds( double )
generates the following output.

          FromSeconds          TimeSpan
          -----------          --------

TimeSpan.FromTicks(Int64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan that represents a specified time, where the specification is in units of ticks.

C#

```
public static TimeSpan FromTicks (long value);
```

Parameters

`value` Int64

A number of ticks that represent a time.

Returns

TimeSpan

An object that represents `value`.

Examples

The following example creates several TimeSpan objects using the FromTicks method.

C#

```
// Example of the TimeSpan.FromTicks( long ) method.
using System;

class FromTicksDemo
{
    static void GenTimeSpanFromTicks( long ticks )
    {
        // Create a TimeSpan object and TimeSpan string from
        // a number of ticks.
        TimeSpan    interval = TimeSpan.FromTicks( ticks );
        string      timeInterval = interval.ToString( );
```

```
        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";

        Console.WriteLine( "{0,21}{1,26}", ticks, timeInterval );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.FromTicks( long )\n" +
            "generates the following output.\n" );
        Console.WriteLine( "{0,21}{1,18}",
            "FromTicks", "TimeSpan" );
        Console.WriteLine( "{0,21}{1,18}",
            "---------", "--------" );

        GenTimeSpanFromTicks( 1 );
        GenTimeSpanFromTicks( 12345 );
        GenTimeSpanFromTicks( 123456789 );
        GenTimeSpanFromTicks( 1234567898765 );
        GenTimeSpanFromTicks( 12345678987654321 );
        GenTimeSpanFromTicks( 10000000 );
        GenTimeSpanFromTicks( 600000000 );
        GenTimeSpanFromTicks( 36000000000 );
        GenTimeSpanFromTicks( 864000000000 );
        GenTimeSpanFromTicks( 18012202000000 );
    }
}

/*
This example of TimeSpan.FromTicks( long )
generates the following output.

            FromTicks          TimeSpan
            ---------          --------
                    1          00:00:00.0000001
                12345          00:00:00.0012345
            123456789          00:00:12.3456789
        1234567898765        1.10:17:36.7898765
    12345678987654321    14288.23:31:38.7654321
             10000000          00:00:01
            600000000          00:01:00
          36000000000          01:00:00
         864000000000        1.00:00:00
       18012202000000       20.20:20:20.2000000
*/
```

Remarks

This is a convenience method with the same behavior as the TimeSpan.TimeSpan(Int64) constructor. A single tick represents one hundred nanoseconds or one ten-millionth of a second. There are 10,000 ticks in a millisecond.

TimeSpan.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Examples

The following example generates the hash codes of several TimeSpan objects using the GetHashCode method.

C#

```
// Example for the TimeSpan.GetHashCode( ) method.
using System;

class GetHashCode
{
    static void DisplayHashCode( TimeSpan interval )
    {
        // Create a hash code and a string representation of
        // the TimeSpan parameter.
        string  timeInterval = interval.ToString( );
        int     hashCode = interval.GetHashCode( );

        // Pad the end of the TimeSpan string with spaces if it
        // does not contain milliseconds.
        int pIndex = timeInterval.IndexOf( ':' );
        pIndex = timeInterval.IndexOf( '.', pIndex );
        if( pIndex < 0 )   timeInterval += "        ";
```

```
        Console.WriteLine( "{0,22}   0x{1:X8}, {1}",
            timeInterval, hashCode );
    }

    static void Main( )
    {
        Console.WriteLine(
            "This example of TimeSpan.GetHashCode( ) generates " +
            "the following \noutput, which displays " +
            "the hash codes of representative TimeSpan \n" +
            "objects in hexadecimal and decimal formats.\n" );
        Console.WriteLine( "{0,22}   {1,10}",
            "TimeSpan        ", "Hash Code" );
        Console.WriteLine( "{0,22}   {1,10}",
            "--------        ", "---------" );

        DisplayHashCode( new TimeSpan( 0 ) );
        DisplayHashCode( new TimeSpan( 1 ) );
        DisplayHashCode( new TimeSpan( 0, 0, 0, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 0, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 0, 1, 0 ) );
        DisplayHashCode( new TimeSpan( 1, 0, 0 ) );
        DisplayHashCode( new TimeSpan( 36000000001 ) );
        DisplayHashCode( new TimeSpan( 0, 1, 0, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 1, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 1, 0, 0, 0 ) );
        DisplayHashCode( new TimeSpan( 864000000001 ) );
        DisplayHashCode( new TimeSpan( 1, 0, 0, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 1, 0, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 100, 0, 0, 0 ) );
        DisplayHashCode( new TimeSpan( 100, 0, 0, 0, 1 ) );
        DisplayHashCode( new TimeSpan( 100, 0, 0, 1 ) );
    }
}

/*
This example of TimeSpan.GetHashCode( ) generates the following
output, which displays the hash codes of representative TimeSpan
objects in hexadecimal and decimal formats.

      TimeSpan            Hash Code

  100.00:00:01           0x91E7D814, -1847076844
*/
```

Remarks

Two TimeSpan objects might have the same hash code even though they represent different time values.

Applies to

Product	Versions

TimeSpan.Multiply(Double) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new TimeSpan object which value is the result of multiplication of this instance and the specified `factor`.

```
C#
public TimeSpan Multiply (double factor);
```

Parameters

`factor` Double

The value to be multiplied by.

Returns

TimeSpan

A new object that represents the value of this instance multiplied by the value of `factor`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TimeSpan.Negate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new TimeSpan object whose value is the negated value of this instance.

C#

```
public TimeSpan Negate ();
```

Returns

TimeSpan

A new object with the same numeric value as this instance, but with the opposite sign.

Exceptions

OverflowException

The negated value of this instance cannot be represented by a TimeSpan; that is, the value of this instance is TimeSpan.MinValue.

Examples

The following example applies the Negate method to several TimeSpan objects.

C#

```
// Example of the TimeSpan.Duration( ) and TimeSpan.Negate( ) methods,
// and the TimeSpan Unary Negation and Unary Plus operators.
using System;

class DuraNegaUnaryDemo
{
    const string dataFmt = "{0,22}{1,22}{2,22}" ;

    static void ShowDurationNegate( TimeSpan interval )
    {
        // Display the TimeSpan value and the results of the
```

```
        // Duration and Negate methods.
        Console.WriteLine( dataFmt,
            interval, interval.Duration( ), interval.Negate( ) );
    }

    static void Main()
    {
        Console.WriteLine(
            "This example of TimeSpan.Duration( ), " +
            "TimeSpan.Negate( ), \nand the TimeSpan Unary " +
            "Negation and Unary Plus operators \n" +
            "generates the following output.\n" );
        Console.WriteLine( dataFmt,
            "TimeSpan", "Duration( )", "Negate( )" );
        Console.WriteLine( dataFmt,
            "--------", "-----------", "---------" );

        // Create TimeSpan objects and apply the Unary Negation
        // and Unary Plus operators to them.
        ShowDurationNegate( new TimeSpan( 1 ) );
        ShowDurationNegate( new TimeSpan( -1234567 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, 0, 10, -20, -30 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, -10, 20, -30, 40 ) );
        ShowDurationNegate(
            - new TimeSpan( 1, 10, 20, 40, 160 ) );
        ShowDurationNegate(
            - new TimeSpan( -10, -20, -30, -40, -50 ) );
    }
}

/*
This example of TimeSpan.Duration( ), TimeSpan.Negate( ),
and the TimeSpan Unary Negation and Unary Plus operators
generates the following output.

              TimeSpan           Duration( )             Negate( )
              --------           -----------             ---------
      00:00:00.0000001      00:00:00.0000001     -00:00:00.0000001
     -00:00:00.1234567      00:00:00.1234567      00:00:00.1234567

TimeSpan.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a time interval to its TimeSpan equivalent.

Overloads

Expand table

Parse(String)	Converts the string representation of a time interval to its TimeSpan equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Converts the span representation of a time interval to its TimeSpan equivalent by using the specified culture-specific format information.
Parse(String, IFormatProvider)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified culture-specific format information.

Parse(String)

Converts the string representation of a time interval to its TimeSpan equivalent.

C#

```
public static TimeSpan Parse (string s);
```

Parameters

s String

A string that specifies the time interval to convert.

Returns

TimeSpan

A time interval that corresponds to `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` has an invalid format.

OverflowException

`s` represents a number that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

At least one of the days, hours, minutes, or seconds components is outside its valid range.

Examples

The following example uses the Parse method to convert each element in a string array to a TimeSpan value. It changes the current system culture to Croatian - Croatia ("hr-HR") and English - United States ("en-US") to illustrate how the current system culture affects the parsing operation.

C#

```
using System;
using System.Globalization;
using System.Threading;

public class Example
{
   public static void Main()
   {
      string[] values = { "6", "6:12", "6:12:14", "6:12:14:45",
                          "6.12:14:45", "6:12:14:45.3448",
                          "6:12:14:45,3448", "6:34:14:45" };
      string[] cultureNames = { "hr-HR", "en-US"};

      // Change the current culture.
      foreach (string cultureName in cultureNames)
      {
```

```
            Thread.CurrentThread.CurrentCulture = new
CultureInfo(cultureName);
            Console.WriteLine("Current Culture: {0}",
                              Thread.CurrentThread.CurrentCulture.Name);
            foreach (string value in values)
            {
               try {
                  TimeSpan ts = TimeSpan.Parse(value);
                  Console.WriteLine("{0} --> {1}", value, ts.ToString("c"));
               }
               catch (FormatException) {
                  Console.WriteLine("{0}: Bad Format", value);
               }
               catch (OverflowException) {
                  Console.WriteLine("{0}: Overflow", value);
               }
            }
            Console.WriteLine();
         }
      }
   }
// The example displays the following output:
//    Current Culture: hr-HR
//    6 --> 6.00:00:00
//    6:12 --> 06:12:00
//    6:12:14 --> 06:12:14
//    6:12:14:45 --> 6.12:14:45
//    6.12:14:45 --> 6.12:14:45
//    6:12:14:45.3448: Bad Format
//    6:12:14:45,3448 --> 6.12:14:45.3448000
//    6:34:14:45: Overflow
//
//    Current Culture: en-US
//    6 --> 6.00:00:00
//    6:12 --> 06:12:00
//    6:12:14 --> 06:12:14
//    6:12:14:45 --> 6.12:14:45
//    6.12:14:45 --> 6.12:14:45
//    6:12:14:45.3448 --> 6.12:14:45.3448000
//    6:12:14:45,3448: Bad Format
//    6:34:14:45: Overflow
```

Remarks

For more information about this API, see Supplemental API remarks for TimeSpan.Parse.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Parse(ReadOnlySpan<Char>, IFormatProvider)

Converts the span representation of a time interval to its TimeSpan equivalent by using the specified culture-specific format information.

C#

```
public static TimeSpan Parse (ReadOnlySpan<char> input, IFormatProvider?
formatProvider = default);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent the time interval to convert.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `formatProvider`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(String, IFormatProvider)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified culture-specific format information.

C#

```
public static TimeSpan Parse (string input, IFormatProvider?
formatProvider);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `formatProvider`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`input` is `null`.

FormatException

`input` has an invalid format.

OverflowException

`input` represents a number that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

At least one of the days, hours, minutes, or seconds components in `input` is outside its valid range.

Examples

The following example defines an array of CultureInfo objects, and uses each object in calls to the Parse(String, IFormatProvider) method to parse the elements in a string array. The example illustrates how the conventions of a specific culture influence the formatting operation.

C#

```
using System;
using System.Globalization;
using System.Text.RegularExpressions;

public class Example
{
   public static void Main()
   {
      string[] values = { "6", "6:12", "6:12:14", "6:12:14:45",
                          "6.12:14:45", "6:12:14:45.3448",
                          "6:12:14:45,3448", "6:34:14:45" };
      CultureInfo[] cultures = { new CultureInfo("en-US"),
                                 new CultureInfo("ru-RU"),
                                 CultureInfo.InvariantCulture };

      string header = String.Format("{0,-17}", "String");
      foreach (CultureInfo culture in cultures)
         header += culture.Equals(CultureInfo.InvariantCulture) ?
                      String.Format("{0,20}", "Invariant") :
                      String.Format("{0,20}", culture.Name);
      Console.WriteLine(header);
      Console.WriteLine();

      foreach (string value in values)
      {
         Console.Write("{0,-17}", value);
         foreach (CultureInfo culture in cultures)
         {
            try {
               TimeSpan ts = TimeSpan.Parse(value, culture);
               Console.Write("{0,20}", ts.ToString("c"));
            }
```

```
            catch (FormatException) {
               Console.Write("{0,20}", "Bad Format");
            }
            catch (OverflowException) {
               Console.Write("{0,20}", "Overflow");
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    String                          en-US               ru-RU
Invariant
//
//    6                         6.00:00:00          6.00:00:00
6.00:00:00
//    6:12                        06:12:00            06:12:00
06:12:00
//    6:12:14                     06:12:14            06:12:14
06:12:14
//    6:12:14:45                6.12:14:45          6.12:14:45
6.12:14:45
//    6.12:14:45                6.12:14:45          6.12:14:45
6.12:14:45
//    6:12:14:45.3448    6.12:14:45.3448000          Bad Format
6.12:14:45.3448000
//    6:12:14:45,3448           Bad Format  6.12:14:45.3448000
Bad Format
//    6:34:14:45                  Overflow            Overflow
Overflow
```

Remarks

This method tries to parse `input` by using each of the culture-specific formats for the culture specified by `formatProvider`.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that

provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

For more information about this API, see Supplemental API remarks for System.TimeSpan.Parse.

TimeSpan.ParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a time interval to its TimeSpan equivalent. The format of the string representation must match a specified format exactly.

Overloads

Expand table

ParseExact(String, String, IFormatProvider, TimeSpanStyles)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information, and styles. The format of the string representation must match the specified format exactly.
ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpanStyles)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information, and styles. The format of the string representation must match one of the specified formats exactly.
ParseExact(String, String[], IFormatProvider, TimeSpanStyles)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information, and styles. The format of the string representation must match one of the specified formats exactly.
ParseExact(String, String[], IFormatProvider)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified array of format strings and culture-specific format information. The format of the string representation must match one of the specified formats exactly.
ParseExact(String, String, IFormatProvider)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpanStyles)	Converts the char span of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

ParseExact(String, String, IFormatProvider, TimeSpanStyles)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information, and styles. The format of the string representation must match the specified format exactly.

C#

```
public static TimeSpan ParseExact (string input, string format,
IFormatProvider? formatProvider, System.Globalization.TimeSpanStyles
styles);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`format` String

A standard or custom format string that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

`styles` TimeSpanStyles

A bitwise combination of enumeration values that defines the style elements that may be present in `input`.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `format`, `formatProvider`, and `styles`.

Exceptions

ArgumentException

`styles` is an invalid TimeSpanStyles value.

ArgumentNullException

`input` is `null`.

FormatException

`input` has an invalid format.

OverflowException

`input` represents a number that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

At least one of the days, hours, minutes, or seconds components in `input` is outside its valid range.

Examples

The following example uses the ParseExact(String, String, IFormatProvider) method to parse several string representations of time intervals using various format strings and cultures. It also uses the TimeSpanStyles.AssumeNegative value to interpret each string as a negative time interval. The output from the example illustrates that the TimeSpanStyles.AssumeNegative style affects the return value only when it is used with custom format strings.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string intervalString, format;
      TimeSpan interval;
      CultureInfo culture = null;

      // Parse hour:minute value with custom format specifier.
      intervalString = "17:14";
      format = "h\\:mm";
      culture = CultureInfo.CurrentCulture;
```

```
      try {
         interval = TimeSpan.ParseExact(intervalString, format,
                                        culture,
TimeSpanStyles.AssumeNegative);
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse hour:minute:second value with "g" specifier.
      intervalString = "17:14:48";
      format = "g";
      culture = CultureInfo.InvariantCulture;
      try {
         interval = TimeSpan.ParseExact(intervalString, format,

         Console.WriteLine("'{0}': Overflow", intervalString);
      }
   }
```

```
}
// The example displays the following output:
//    '17:14' (h\:mm) --> -17:14:00
//    '17:14:48' (g) --> 17:14:48
//    '17:14:48.153' (h\:mm\:ss\.fff) --> -17:14:48.1530000
//    '3:17:14:48.153' (G) --> 3.17:14:48.1530000
//    '3:17:14:48.153' (d\:hh\:mm\:ss\.fff) --> -3.17:14:48.1530000
//    '3:17:14:48,153' (G) --> 3.17:14:48.1530000
//    '12' (c) --> 12.00:00:00
//    '12' (%h) --> -12:00:00
//    '12' (%s) --> -00:00:12
```

Remarks

The ParseExact method parses the string representation of a time interval, which must be in the format defined by the `format` parameter, except that leading and trailing white-space characters are ignored. Because `input` must conform to the format of `format` exactly, you should always use exception handling when converting a string input by the user to a time interval. If you prefer not to use exception handling, you can call the TryParseExact(String, String, IFormatProvider, TimeSpanStyles, TimeSpan) method instead.

The `format` parameter is a string that contains either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings.

> **Important**
>
> The **ParseExact** method uses the conventions of the culture specified by the `formatProvider` parameter only if `format` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if `format` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object

returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.

- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

The `styles` parameter affects the interpretation of strings that are parsed using custom format strings. It determines whether `input` is interpreted as a negative time interval only if a negative sign is present (TimeSpanStyles.None), or whether it is always interpreted as a negative time interval (TimeSpanStyles.AssumeNegative). If TimeSpanStyles.AssumeNegative is not used, `format` must include a literal negative sign symbol (such as "\-") to successfully parse a negative time interval.

ParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpanStyles)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information, and styles. The format of the string representation must match one of the specified formats exactly.

```
C#

public static TimeSpan ParseExact (ReadOnlySpan<char> input, string[]
formats, IFormatProvider? formatProvider,
System.Globalization.TimeSpanStyles styles =
System.Globalization.TimeSpanStyles.None);
```

Parameters

`input` ReadOnlySpan<Char>

A span that specifies the time interval to convert.

`formats` String[]

An array of standard or custom format strings that define the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

`styles` TimeSpanStyles

A bitwise combination of enumeration values that defines the style elements that may be present in input.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `formats`, `formatProvider`, and `styles`.

ParseExact(String, String[], IFormatProvider, TimeSpanStyles)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information, and styles. The format of the string representation must match one of the specified formats exactly.

```
C#

public static TimeSpan ParseExact (string input, string[] formats,
IFormatProvider? formatProvider, System.Globalization.TimeSpanStyles
styles);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`formats` String[]

An array of standard or custom format strings that define the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

`styles` TimeSpanStyles

A bitwise combination of enumeration values that defines the style elements that may be present in input.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `formats`, `formatProvider`, and `styles`.

Exceptions

ArgumentException

`styles` is an invalid TimeSpanStyles value.

ArgumentNullException

`input` is `null`.

FormatException

`input` has an invalid format.

OverflowException

`input` represents a number that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

At least one of the days, hours, minutes, or seconds components in `input` is outside its valid range.

Examples

The following example calls the ParseExact(String, String[], IFormatProvider, TimeSpanStyles) method to convert each element of a string array to a TimeSpan value. The strings can represent a time interval in either the general short format or the general long format.

In addition, the example changes the way in which the time interval parsing methods interpret a single digit. Ordinarily, a single digit is interpreted as the number of days in a time interval. Instead, the `%h` custom format string is used to interpret a single digit as the number of hours. For this change to be effective, note that the `%h` custom format string must precede the other format strings in the `formats` array. Also note from the output that the TimeSpanStyles.AssumeNegative flag specified in the method call is used only when parsing a string with this format specifier.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
```

```
        string[] inputs = { "3", "16:42", "1:6:52:35.0625",
                            "1:6:52:35,0625" };
        string[] formats = { "%h", "g", "G" };
        TimeSpan interval;
        CultureInfo culture = new CultureInfo("de-DE");

        // Parse each string in inputs using formats and the de-DE culture.
        foreach (string input in inputs) {
           try {
              interval = TimeSpan.ParseExact(input, formats, culture,

 TimeSpanStyles.AssumeNegative);
              Console.WriteLine("{0} --> {1:c}", input, interval);
           }
           catch (FormatException) {
              Console.WriteLine("{0} --> Bad Format", input);
           }
           catch (OverflowException) {
              Console.WriteLine("{0} --> Overflow", input);
           }
        }
    }
 }
 // The example displays the following output:
 //       3 --> -03:00:00
 //       16:42 --> 16:42:00
 //       1:6:52:35.0625 --> Bad Format
 //       1:6:52:35,0625 --> 1.06:52:35.0625000
```

Remarks

The ParseExact(String, String[], IFormatProvider, TimeSpanStyles) method parses the string representation of a time interval, which must be in one of the formats defined by the `formats` parameter, except that leading and trailing white-space characters are ignored. Because `input` must exactly conform to one of the formats specified in `formats`, you should always use exception handling when converting a string input by the user to a time interval. If you prefer not to use exception handling, you can call the TryParseExact(String, String[], IFormatProvider, TimeSpanStyles, TimeSpan) method instead.

The `formats` parameter is a string array whose elements consist of either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings. `input` must correspond exactly to a member of `formats` for the parse operation to succeed. The parse operation attempts to match `input` to each element in `formats` starting with the first element in the array.

> **Important**
>
> The **ParseExact** method uses the conventions of the culture specified by the `formatProvider` parameter only if the format string used to parse `input` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if the format string used to parse `input` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

The `styles` parameter affects the interpretation of strings that are parsed using custom format strings. It determines whether `input` is interpreted as a negative time interval only if a negative sign is present (TimeSpanStyles.None), or whether it is always interpreted as a negative time interval (TimeSpanStyles.AssumeNegative). If TimeSpanStyles.AssumeNegative is not used, `format` must include a literal negative sign symbol (such as "\-") to successfully parse a negative time interval.

ParseExact(String, String[], IFormatProvider)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified array of format strings and culture-specific format information. The format of the string representation must match one of the specified formats exactly.

C#

```
public static TimeSpan ParseExact (string input, string[] formats,
IFormatProvider? formatProvider);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`formats` String[]

An array of standard or custom format strings that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `formats` and `formatProvider`.

Exceptions

ArgumentNullException

`input` is `null`.

FormatException

`input` has an invalid format.

OverflowException

`input` represents a number that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

At least one of the days, hours, minutes, or seconds components in `input` is outside its valid range.

Examples

The following example calls the ParseExact(String, String[], IFormatProvider) method to convert each element of a string array to a TimeSpan value. The example interprets the strings using the formatting conventions of the French - France ("fr-FR") culture. The strings can represent a time interval in either the general short format or the general long format.

In addition, the example changes the way in which the time interval parsing methods interpret a single digit. Ordinarily, a single digit is interpreted as the number of days in a time interval. Instead, the `%h` custom format string is used to interpret a single digit as the number of hours. For this change to be effective, note that the `%h` custom format string must precede the other format strings in the `formats` array.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] inputs = { "3", "16:42", "1:6:52:35.0625",
```

```
                                "1:6:52:35,0625" };
        string[] formats = { "g", "G", "%h"};
        TimeSpan interval;
        CultureInfo culture = new CultureInfo("fr-FR");

        // Parse each string in inputs using formats and the fr-FR culture.
        foreach (string input in inputs) {
           try {
              interval = TimeSpan.ParseExact(input, formats, culture);
              Console.WriteLine("{0} --> {1:c}", input, interval);
           }
           catch (FormatException) {
              Console.WriteLine("{0} --> Bad Format", input);
           }
           catch (OverflowException) {
              Console.WriteLine("{0} --> Overflow", input);
           }
        }
     }
  }
  // The example displays the following output:
  //       3 --> 03:00:00
  //       16:42 --> 16:42:00
  //       1:6:52:35.0625 --> Bad Format
  //       1:6:52:35,0625 --> 1.06:52:35.0625000
```

Remarks

The ParseExact(String, String, IFormatProvider) method parses the string representation of a time interval, which must be in one of the formats defined by the `formats` parameter, except that leading and trailing white-space characters are ignored. Because `input` must exactly conform to one of the formats specified in `formats`, you should always use exception handling when converting a string input by the user to a time interval. If you prefer not to use exception handling, you can call the TryParseExact(String, String[], IFormatProvider, TimeSpan) method instead.

The `formats` parameter is a string array whose elements consist of either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings. `input` must correspond exactly to a member of `formats` for the parse operation to succeed. The parse operation attempts to match `input` to each element in `formats` starting with the first element in the array.

> **Important**

The **ParseExact** method uses the conventions of the culture specified by the `formatProvider` parameter only if the format string used to parse `input` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if the format string used to parse `input` is a standard format string. The `formatProvider` parameter can be any of the following:

ParseExact(String, String, IFormatProvider)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

C#

```
public static TimeSpan ParseExact (string input, string format,
IFormatProvider? formatProvider);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`format` String

A standard or custom format string that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `format` and `formatProvider`.

Exceptions

ArgumentNullException

`input` is `null`.

FormatException

`input` has an invalid format.

OverflowException

`input` represents a number that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

-or-

At least one of the days, hours, minutes, or seconds components in `input` is outside its valid range.

Examples

The following example uses the ParseExact(String, String, IFormatProvider) method to parse several string representations of time intervals using various format strings and cultures.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string intervalString, format;
      TimeSpan interval;
      CultureInfo culture;

      // Parse hour:minute value with "g" specifier current culture.
      intervalString = "17:14";
      format = "g";
      culture = CultureInfo.CurrentCulture;
      try {
         interval = TimeSpan.ParseExact(intervalString, format, culture);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'",
                           intervalString, format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse hour:minute:second value with "G" specifier.
      intervalString = "17:14:48";
```

```
      format = "G";
      culture = CultureInfo.InvariantCulture;
      try {
         interval = TimeSpan.ParseExact(intervalString, format, culture);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse hours:minute.second value with "G" specifier
      // and current (en-US) culture.
      intervalString = "17:14:48.153";
      format = "G";
      culture = CultureInfo.CurrentCulture;
      try {
         interval = TimeSpan.ParseExact(intervalString, format, culture);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse days:hours:minute.second value with "G" specifier
      // and fr-FR culture.
      intervalString = "3:17:14:48.153";
      format = "G";
      culture = new CultureInfo("fr-FR");
      try {
         interval = TimeSpan.ParseExact(intervalString, format, culture);
```

```
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse days:hours:minute.second value with "G" specifier
      // and fr-FR culture.
      intervalString = "3:17:14:48,153";
      format = "G";
      try {
         interval = TimeSpan.ParseExact(intervalString, format, culture);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse a single number using the "c" standard format string.
      intervalString = "12";
      format = "c";
      try {
         interval = TimeSpan.ParseExact(intervalString, format, null);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }

      // Parse a single number using the "%h" custom format string.
      format = "%h";
      try {
         interval = TimeSpan.ParseExact(intervalString, format, null);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }
```

```
      // Parse a single number using the "%s" custom format string.
      format = "%s";
      try {
         interval = TimeSpan.ParseExact(intervalString, format, null);
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      }
      catch (FormatException) {
         Console.WriteLine("'{0}': Bad Format for '{1}'", intervalString,
format);
      }
      catch (OverflowException) {
         Console.WriteLine("'{0}': Overflow", intervalString);
      }
   }
}
// The example displays the following output:
//       '17:14' --> 17:14:00
//       '17:14:48': Bad Format for 'G'
//       '17:14:48.153': Bad Format for 'G'
//       '3:17:14:48.153' --> 3.17:14:48.1530000
//       '3:17:14:48.153': Bad Format for 'G'
//       '3:17:14:48,153' --> 3.17:14:48.1530000
//       '12' --> 12.00:00:00
//       '12' --> 12:00:00
//       '12' --> 00:00:12
```

Remarks

The ParseExact(String, String, IFormatProvider) method parses the string representation of a time interval, which must be in the format defined by the `format` parameter, except that leading and trailing white-space characters are ignored. Because `input` must conform to the format of `format` exactly, you should always use exception handling when converting a string input by the user to a time interval. If you prefer not to use exception handling, you can call the TryParseExact(String, String, IFormatProvider, TimeSpan) method instead.

The `format` parameter is a string that contains either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings.

> **ⓘ Important**
>
> The **ParseExact** method uses the conventions of the culture specified by the `formatProvider` parameter only if `format` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use

the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if `format` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

UWP	10.0

ParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpanStyles)

Converts the char span of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

C#

```
public static TimeSpan ParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format, IFormatProvider? formatProvider,
System.Globalization.TimeSpanStyles styles =
System.Globalization.TimeSpanStyles.None);
```

Parameters

`input` ReadOnlySpan<Char>

A span that specifies the time interval to convert.

`format` ReadOnlySpan<Char>

A standard or custom format string that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

`styles` TimeSpanStyles

A bitwise combination of enumeration values that defines the style elements that may be present in `input`.

Returns

TimeSpan

A time interval that corresponds to `input`, as specified by `format` and `formatProvider`.

TimeSpan.Subtract(TimeSpan) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new TimeSpan object whose value is the difference between the specified TimeSpan object and this instance.

```
C#
public TimeSpan Subtract (TimeSpan ts);
```

Parameters

`ts` TimeSpan

The time interval to be subtracted.

Returns

TimeSpan

A new time interval whose value is the result of the value of this instance minus the value of `ts`.

Exceptions

OverflowException

The return value is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Examples

The following example uses the Subtract method to calculate the difference between a single TimeSpan value and each of the time intervals in an array. Note that, because TimeSpan format strings do not include negative signs in the result string, the example uses conditional logic to include a negative sign with negative time intervals.

```
C#
```

```
TimeSpan baseTimeSpan = new TimeSpan(1, 12, 15, 16);

// Create an array of timespan intervals.
TimeSpan[] intervals = {
   TimeSpan.FromDays(1.5),
   TimeSpan.FromHours(1.5),
   TimeSpan.FromMinutes(45),
   TimeSpan.FromMilliseconds(505),
   new TimeSpan(1, 17, 32, 20),
   new TimeSpan(-8, 30, 0)
};

// Calculate a new time interval by adding each element to the base
interval.
foreach (var interval in intervals)
   Console.WriteLine(@"{0,-10:g} - {3}{1,15:%d\:hh\:mm\:ss\.ffff} = {4}
{2:%d\:hh\:mm\:ss\.ffff}",
                     baseTimeSpan, interval,
baseTimeSpan.Subtract(interval),
                     interval < TimeSpan.Zero ? "-" : "",
                     baseTimeSpan < interval.Duration() ? "-" : "");

// The example displays the following output:
//       1:12:15:16 - 1:12:00:00.0000 = 0:00:15:16.0000
//       1:12:15:16 - 0:01:30:00.0000 = 1:10:45:16.0000
//       1:12:15:16 - 0:00:45:00.0000 = 1:11:30:16.0000
//       1:12:15:16 - 0:00:00:00.5050 = 1:12:15:15.4950
//       1:12:15:16 - 1:17:32:20.0000 = -0:05:17:04.0000
//       1:12:15:16 - -0:07:30:00.0000 = 1:19:45:16.0000
```

Remarks

The return value must be between TimeSpan.MinValue and TimeSpan.MaxValue; otherwise, an exception is thrown.

The return value is a new TimeSpan; the original TimeSpan is not modified.

TimeSpan.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current TimeSpan object to its equivalent string representation.

Overloads

Expand table

ToString(String, IFormatProvider)	Converts the value of the current TimeSpan object to its equivalent string representation by using the specified format and culture-specific formatting information.
ToString(String)	Converts the value of the current TimeSpan object to its equivalent string representation by using the specified format.
ToString()	Converts the value of the current TimeSpan object to its equivalent string representation.

ToString(String, IFormatProvider)

Converts the value of the current TimeSpan object to its equivalent string representation by using the specified format and culture-specific formatting information.

C#

```
public string ToString (string? format, IFormatProvider? formatProvider);
```

Parameters

format String

A standard or custom TimeSpan format string.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the current TimeSpan value, as specified by `format` and `formatProvider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

The `format` parameter is not recognized or is not supported.

Examples

The following example calls the ToString(String, IFormatProvider) method to format two time intervals. The example calls the method twice for each format string, first to display it using the conventions of the en-US culture and then to display it using the conventions of the fr-FR culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      TimeSpan[] intervals = { new TimeSpan(38, 30, 15),
                               new TimeSpan(16, 14, 30) };
      CultureInfo[] cultures = { new CultureInfo("en-US"),
                                 new CultureInfo("fr-FR") };
      string[] formats = {"c", "g", "G", @"hh\:mm\:ss" };
      Console.WriteLine("{0,12}      Format  {1,22}  {2,22}\n",
                        "Interval", cultures[0].Name, cultures[1].Name);

      foreach (var interval in intervals) {
         foreach (var fmt in formats)
            Console.WriteLine("{0,12}  {1,10}  {2,22}  {3,22}",
```

```
                                interval, fmt,
                                interval.ToString(fmt, cultures[0]),
                                interval.ToString(fmt, cultures[1]));
            Console.WriteLine();
        }
    }
}
// The example displays the following output:
//        Interval      Format                    en-US
fr-FR
//
//      1.14:30:15           c              1.14:30:15
1.14:30:15
//      1.14:30:15           g              1:14:30:15
1:14:30:15
//      1.14:30:15           G      1:14:30:15.0000000
1:14:30:15,0000000
//      1.14:30:15  hh\:mm\:ss                14:30:15
14:30:15
//
//        16:14:30           c                16:14:30
16:14:30
//        16:14:30           g                16:14:30
16:14:30
//        16:14:30           G      0:16:14:30.0000000
0:16:14:30,0000000
//        16:14:30  hh\:mm\:ss                16:14:30
16:14:30
```

Remarks

The `format` parameter can be any valid standard or custom format specifier for TimeSpan values. If `format` is equal to String.Empty or is `null`, the return value of the current TimeSpan object is formatted with the common format specifier ("c"). If format is any other value, the method throws a FormatException.

> **Important**
>
> The custom format strings for **TimeSpan** values do not include a date or time separator. If you want to include these elements in your format string, you must treat them as character literals. See the example for an illustration, and see the **Custom TimeSpan Format Strings** topic for more information.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about format strings for TimeSpan values, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used. If `format` is a custom format string, the `formatProvider` parameter is ignored.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(String)

Converts the value of the current TimeSpan object to its equivalent string representation by using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

format String

A standard or custom TimeSpan format string.

Returns

String

The string representation of the current TimeSpan value in the format specified by the `format` parameter.

Exceptions

FormatException

The `format` parameter is not recognized or is not supported.

Examples

The following example uses standard and custom TimeSpan format strings to display the string representation of each element in an array of TimeSpan values

```
C#

TimeSpan[] spans = {
   TimeSpan.Zero,
   new TimeSpan(-14, 0, 0, 0, 0),
   new TimeSpan(1, 2, 3),
   new TimeSpan(0, 0, 0, 0, 250),
   new TimeSpan(99, 23, 59, 59, 999),
   new TimeSpan(3, 0, 0),
   new TimeSpan(0, 0, 0, 0, 25)
};

string[] fmts = { "c", "g", "G", @"hh\:mm\:ss", "%m' min.'" };
foreach (TimeSpan span in spans)
```

```
{
   foreach (string fmt in fmts)
      Console.WriteLine("{0}: {1}", fmt, span.ToString(fmt));

   Console.WriteLine();
}
// The example displays the following output:
//       c: 00:00:00
//       g: 0:00:00
//       G: 0:00:00:00.0000000
//       hh\:mm\:ss: 00:00:00
//       %m' min.': 0 min.
//
//       c: -14.00:00:00
//       g: -14:0:00:00
//       G: -14:00:00:00.0000000
//       hh\:mm\:ss: 00:00:00
//       %m' min.': 0 min.
//
//       c: 01:02:03
//       g: 1:02:03
//       G: 0:01:02:03.0000000
//       hh\:mm\:ss: 01:02:03
//       %m' min.': 2 min.
//
//       c: 00:00:00.2500000
//       g: 0:00:00.25
//       G: 0:00:00:00.2500000
//       hh\:mm\:ss: 00:00:00
//       %m' min.': 0 min.
//
//       c: 99.23:59:59.9990000
//       g: 99:23:59:59.999
//       G: 99:23:59:59.9990000
//       hh\:mm\:ss: 23:59:59
//       %m' min.': 59 min.
//
//       c: 03:00:00
//       g: 3:00:00
//       G: 0:03:00:00.0000000
//       hh\:mm\:ss: 03:00:00
//       %m' min.': 0 min.
//
//       c: 00:00:00.0250000
//       g: 0:00:00.025
//       G: 0:00:00:00.0250000
//       hh\:mm\:ss: 00:00:00
//       %m' min.': 0 min.
```

Remarks

The `format` parameter can be any valid standard or custom format specifier for TimeSpan values. If `format` is equal to String.Empty or is `null`, the return value of the current TimeSpan object is formatted with the common format specifier ("c"). If `format` is any other value, the method throws a FormatException.

If `format` is a standard format string, the format of the returned string is defined by the formatting conventions of the current culture.

> **Important**
>
> The custom format strings for **TimeSpan** values do not include a date or time separator. If you want to include these elements in your format string, you must treat them as character literals. See the example for an illustration, and see the **Custom TimeSpan Format Strings** topic for more information.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about format strings for TimeSpan values, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

ToString()

Converts the value of the current TimeSpan object to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the current TimeSpan value.

Examples

The following example displays the strings returned by calling the ToString method with a number of TimeSpan values. Note that although the example does not call the ToString method directly, it is called by the Console.WriteLine method when it attempts to convert a TimeSpan value to its string representation.

C#

```
TimeSpan span;

// Initialize a time span to zero.
span = TimeSpan.Zero;
Console.WriteLine(span);

// Initialize a time span to 14 days.
span = new TimeSpan(-14, 0, 0, 0, 0);
Console.WriteLine(span);

// Initialize a time span to 1:02:03.
span = new TimeSpan(1, 2, 3);
Console.WriteLine(span);

// Initialize a time span to 250 milliseconds.
span = new TimeSpan(0, 0, 0, 0, 250);
Console.WriteLine(span);
```

```
 // Initialize a time span to 99 days, 23 hours, 59 minutes, and 59.999
seconds.
 span = new TimeSpan(99, 23, 59, 59, 999);
 Console.WriteLine(span);

 // Initialize a time span to 3 hours.
 span = new TimeSpan(3, 0, 0);
 Console.WriteLine(span);

 // Initialize a timespan to 25 milliseconds.
 span = new TimeSpan(0, 0, 0, 0, 25);
 Console.WriteLine(span);

 // The example displays the following output:
 //       00:00:00
 //       -14.00:00:00
 //       01:02:03
 //       00:00:00.2500000
 //       99.23:59:59.9990000
 //       03:00:00
 //       00:00:00.0250000
```

Remarks

The returned string is formatted with the "c" format specifier and has the following format:

[-][*d*.]*hh*:*mm*:*ss*[.*fffffff*]

Elements in square brackets ([and]) may not be included in the returned string. Colons and periods (: and.) are literal characters. The non-literal elements are listed in the following table. Note that the string returned by the ToString() method is not culture-sensitive.

Expand table

Item	Description
"-"	A minus sign, which indicates a negative time interval. No sign is included for a positive time span.
"*d*"	The number of days in the time interval. This element is omitted if the time interval is less than one day.
"*hh*"	The number of hours in the time interval, ranging from 0 to 23.
"*mm*"	The number of minutes in the time interval, ranging from 0 to 59.
"*ss*"	The number of seconds in the time interval, ranging from 0 to 59.

Item	Description
"*fffffff*"	Fractional seconds in the time interval. This element is omitted if the time interval does not include fractional seconds. If present, fractional seconds are always expressed using seven decimal digits.

Notes to Callers

Support for formatting TimeSpan values was added in the .NET Framework 4. However, the ToString() method overload remains culture-insensitive. Its behavior remains unchanged from previous versions of the .NET Framework. To control the formatting of a TimeSpan value, call the ToString(String) or ToString(String, IFormatProvider) overload.

TimeSpan.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current timespan number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? formatProvider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`formatProvider` IFormatProvider

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current timespan number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? formatProvider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the charactes that represent a standard or custom format string that defines the acceptable format for `destination`.

`formatProvider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

TimeSpan.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified string representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.

Overloads

Expand table

TryParse(String, IFormatProvider, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified culture-specific formatting information, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, IFormatProvider, TimeSpan)	Converts the span representation of a time interval to its TimeSpan equivalent by using the specified culture-specific formatting information, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, TimeSpan)	Converts the span representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.
TryParse(String, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.

TryParse(String, IFormatProvider, TimeSpan)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified culture-specific formatting information, and returns a value that indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParse (string? input, IFormatProvider?
formatProvider, out TimeSpan result);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`. This operation returns `false` if the `input` parameter is `null` or Empty, has an invalid format, represents a time interval that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue, or has at least one days, hours, minutes, or seconds component outside its valid range.

Examples

The following example defines an array of CultureInfo objects, and uses each object in calls to the TryParse(String, IFormatProvider, TimeSpan) method to parse the elements in a string array. The example illustrates how the conventions of a specific culture influence the formatting operation.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
```

```
      string[] values = { "6", "6:12", "6:12:14", "6:12:14:45",
                          "6.12:14:45", "6:12:14:45.3448",
                          "6:12:14:45,3448", "6:34:14:45" };
      CultureInfo[] cultures = { new CultureInfo("en-US"),
                                 new CultureInfo("ru-RU"),
                                 CultureInfo.InvariantCulture };

      string header = String.Format("{0,-17}", "String");
      foreach (CultureInfo culture in cultures)
         header += culture.Equals(CultureInfo.InvariantCulture) ?
                      String.Format("{0,20}", "Invariant") :
                      String.Format("{0,20}", culture.Name);

      Console.WriteLine(header);
      Console.WriteLine();

      foreach (string value in values)
      {
         Console.Write("{0,-17}", value);
         foreach (CultureInfo culture in cultures)
         {
            TimeSpan interval = new TimeSpan();
            if (TimeSpan.TryParse(value, culture, out interval))
               Console.Write("{0,20}", interval.ToString("c"));
            else
               Console.Write("{0,20}", "Unable to Parse");
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    String                          en-US               ru-RU
Invariant
//
//    6                         6.00:00:00          6.00:00:00
6.00:00:00
//    6:12                        06:12:00            06:12:00
06:12:00
//    6:12:14                     06:12:14            06:12:14
06:12:14
//    6:12:14:45                6.12:14:45          6.12:14:45
6.12:14:45
//    6.12:14:45                6.12:14:45          6.12:14:45
6.12:14:45
//    6:12:14:45.3448    6.12:14:45.3448000     Unable to Parse
6.12:14:45.3448000
//    6:12:14:45,3448       Unable to Parse  6.12:14:45.3448000
Unable to Parse
//    6:34:14:45            Unable to Parse     Unable to Parse
Unable to Parse
```

Remarks

For more information about this API, see Supplemental API remarks for TimeSpan.TryParse.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, TimeSpan)

Converts the span representation of a time interval to its TimeSpan equivalent by using the specified culture-specific formatting information, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> input, IFormatProvider?
formatProvider, out TimeSpan result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters representing the time interval to convert.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed

uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`. This operation returns `false` if the `input` parameter is `null` or Empty, has an invalid format, represents a time interval that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue, or has at least one days, hours, minutes, or seconds component outside its valid range.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(ReadOnlySpan<Char>, TimeSpan)

Converts the span representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, out TimeSpan result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the time interval to convert.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `s`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`. This operation returns `false` if the `s` parameter is `null` or Empty, has an invalid format, represents a time interval that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue, or has at least one days, hours, minutes, or seconds component outside its valid range.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, TimeSpan)

Converts the string representation of a time interval to its TimeSpan equivalent and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, out TimeSpan result);
```

Parameters

`s` String

A string that specifies the time interval to convert.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `s`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`. This operation returns `false` if the `s` parameter is `null` or Empty, has an invalid format, represents a time interval

that is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue, or has at least one days, hours, minutes, or seconds component outside its valid range.

Examples

The following example uses the TryParse method to create TimeSpan objects from valid TimeSpan strings and to indicate when the parse operation has failed because the time span string is invalid.

C#

```
using System;

public class TryParse
{
   private static void ParseTimeSpan(string intervalStr)
   {
      // Write the first part of the output line.
      Console.Write( "{0,20}   ", intervalStr );

      // Parse the parameter, and then convert it back to a string.
      TimeSpan intervalVal;
      if (TimeSpan.TryParse(intervalStr, out intervalVal))
      {
         string intervalToStr = intervalVal.ToString();

         // Pad the end of the TimeSpan string with spaces if it
         // does not contain milliseconds.
         int pIndex = intervalToStr.IndexOf(':');
         pIndex = intervalToStr.IndexOf('.', pIndex);
         if (pIndex < 0)
            intervalToStr += "        ";

         Console.WriteLine("{0,21}", intervalToStr);
         // Handle failure of TryParse method.
      }
      else
      {
         Console.WriteLine("Parse operation failed.");
      }
   }

   public static void Main()
   {
        Console.WriteLine( "{0,20}   {1,21}",
            "String to Parse", "TimeSpan" );
        Console.WriteLine( "{0,20}   {1,21}",
            "---------------", "---------------------" );

        ParseTimeSpan("0");
        ParseTimeSpan("14");
```

```
        ParseTimeSpan("1:2:3");
        ParseTimeSpan("0:0:0.250");
        ParseTimeSpan("10.20:30:40.50");
        ParseTimeSpan("99.23:59:59.9999999");
        ParseTimeSpan("0023:0059:0059.0099");
        ParseTimeSpan("23:0:0");
        ParseTimeSpan("24:0:0");
        ParseTimeSpan("0:59:0");
        ParseTimeSpan("0:60:0");
        ParseTimeSpan("0:0:59");
        ParseTimeSpan("0:0:60");
        ParseTimeSpan("10:");
        ParseTimeSpan("10:0");
        ParseTimeSpan(":10");
        ParseTimeSpan("0:10");
        ParseTimeSpan("10:20:");
        ParseTimeSpan("10:20:0");
        ParseTimeSpan(".123");
        ParseTimeSpan("0.12:00");
        ParseTimeSpan("10.");
        ParseTimeSpan("10.12");
        ParseTimeSpan("10.12:00");
    }
}
//            String to Parse                TimeSpan
//            ---------------   ---------------------
//                          0        00:00:00

TimeSpan.TryParseExact Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a time interval to its TimeSpan equivalent, and returns a value that indicates whether the conversion succeeded. The format of the string representation must match a specified format exactly.

Overloads

Expand table

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information, and styles, and returns a value that indicates whether the conversion succeeded. The format of the string representation must match the specified format exactly.
TryParseExact(String, String, IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information and styles. The format of the string representation must match the specified format exactly.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information and styles. The format of the string representation must match one of the specified formats exactly.
TryParseExact(String, String[], IFormatProvider, TimeSpan)	Converts the specified string representation of a time interval to its TimeSpan equivalent by using the specified formats and culture-specific format information. The format of the string representation must match one of the specified formats exactly.

TryParseExact(String, String[], IFormatProvider, TimeSpanStyles, TimeSpan)	Converts the specified string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information and styles. The format of the string representation must match one of the specified formats exactly.
TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified formats and culture-specific format information. The format of the string representation must match one of the specified formats exactly.
TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpan)	Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.
TryParseExact(String, String, IFormatProvider, TimeSpan)	Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpanStyles, TimeSpan)

Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information, and styles, and returns a value that indicates whether the conversion succeeded. The format of the string representation must match the specified format exactly.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format, IFormatProvider? formatProvider,
System.Globalization.TimeSpanStyles styles, out TimeSpan result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a time interval to convert.

`format` ReadOnlySpan<Char>

A span containing the charactes that represent a standard or custom format string that defines the acceptable format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`styles` TimeSpanStyles

One or more enumeration values that indicate the style of `input`.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TryParseExact(String, String, IFormatProvider, TimeSpanStyles, TimeSpan)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format, culture-specific format information and styles. The format of the string representation must match the specified format exactly.

```
C#

public static bool TryParseExact (string? input, string? format,
IFormatProvider? formatProvider, System.Globalization.TimeSpanStyles
styles, out TimeSpan result);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`format` String

A standard or custom format string that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

`styles` TimeSpanStyles

One or more enumeration values that indicate the style of `input`.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Examples

The following example uses the ParseExact(String, String, IFormatProvider) method to parse several string representations of time intervals using various format strings and cultures. It also uses the TimeSpanStyles.AssumeNegative value to interpret each string as a negative time interval. The output from the example illustrates that the TimeSpanStyles.AssumeNegative style affects the return value only when it is used with custom format strings.

```
C#
```

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string intervalString, format;
      TimeSpan interval;
      CultureInfo culture = null;

      // Parse hour:minute value with custom format specifier.
      intervalString = "17:14";
      format = "h\\:mm";
      culture = CultureInfo.CurrentCulture;
      if (TimeSpan.TryParseExact(intervalString, format,
                                 culture, TimeSpanStyles.AssumeNegative,
out interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse hour:minute:second value with "g" specifier.
      intervalString = "17:14:48";
      format = "g";
      culture = CultureInfo.InvariantCulture;
      if (TimeSpan.TryParseExact(intervalString, format,
                                 culture, TimeSpanStyles.AssumeNegative,
out interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse hours:minute.second value with custom format specifier.
      intervalString = "17:14:48.153";
      format = @"h\:mm\:ss\.fff";
      culture = null;
      if (TimeSpan.TryParseExact(intervalString, format,
                                 culture, TimeSpanStyles.AssumeNegative,
out interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse days:hours:minute.second value with "G" specifier
      // and current (en-US) culture.
      intervalString = "3:17:14:48.153";
      format = "G";
```

```
      culture = CultureInfo.CurrentCulture;
      if (TimeSpan.TryParseExact(intervalString, format,
                                 culture, TimeSpanStyles.AssumeNegative,
out interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse days:hours:minute.second value with a custom format
specifier.
      intervalString = "3:17:14:48.153";
      format = @"d\:hh\:mm\:ss\.fff";
      culture = null;
      if (TimeSpan.TryParseExact(intervalString, format,
                                 culture, TimeSpanStyles.AssumeNegative,
out interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse days:hours:minute.second value with "G" specifier
      // and fr-FR culture.
      intervalString = "3:17:14:48,153";
      format = "G";
      culture = new CultureInfo("fr-FR");
      if (TimeSpan.TryParseExact(intervalString, format,
                                 culture, TimeSpanStyles.AssumeNegative,
out interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse a single number using the "c" standard format string.
      intervalString = "12";
      format = "c";
      if (TimeSpan.TryParseExact(intervalString, format,
                                 null, TimeSpanStyles.AssumeNegative, out
interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse a single number using the "%h" custom format string.
      format = "%h";
      if (TimeSpan.TryParseExact(intervalString, format,
                                 null, TimeSpanStyles.AssumeNegative, out
interval))
```

```
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);

      // Parse a single number using the "%s" custom format string.
      format = "%s";
      if (TimeSpan.TryParseExact(intervalString, format,
                                 null, TimeSpanStyles.AssumeNegative, out
interval))
         Console.WriteLine("'{0}' ({1}) --> {2}", intervalString, format,
interval);
      else
         Console.WriteLine("Unable to parse '{0}' using format {1}",
                           intervalString, format);
   }
}
// The example displays the following output:
//    '17:14' (h\:mm) --> -17:14:00
//    '17:14:48' (g) --> 17:14:48
//    '17:14:48.153' (h\:mm\:ss\.fff) --> -17:14:48.1530000
//    '3:17:14:48.153' (G) --> 3.17:14:48.1530000
//    '3:17:14:48.153' (d\:hh\:mm\:ss\.fff) --> -3.17:14:48.1530000
//    '3:17:14:48,153' (G) --> 3.17:14:48.1530000
//    '12' (c) --> 12.00:00:00
//    '12' (%h) --> -12:00:00
//    '12' (%s) --> -00:00:12
```

Remarks

The TryParseExact(String, String, IFormatProvider, TimeSpanStyles, TimeSpan) method parses the string representation of a time interval, which must be in the format defined by the `format` parameter, except that leading and trailing white-space characters are ignored. This method is similar to the ParseExact(String, String, IFormatProvider, TimeSpanStyles) method, except that it does not throw an exception if the conversion fails.

The `format` parameter is a string that contains either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if `format` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

The `styles` parameter affects the interpretation of strings parsed using custom format strings. It determines whether `input` is interpreted as a negative time interval only if a negative sign is present (TimeSpanStyles.None), or whether it is always interpreted as a negative time interval (TimeSpanStyles.AssumeNegative). If TimeSpanStyles.AssumeNegative is not used, `format` must include a literal negative sign symbol (such as "\-") to successfully parse a negative time interval.

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpanStyles, TimeSpan)

Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information and styles. The format of the string representation must match one of the specified formats exactly.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> input, string?[]?
formats, IFormatProvider? formatProvider,
System.Globalization.TimeSpanStyles styles, out TimeSpan result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a time interval to convert.

`formats` String[]

An array of standard or custom format strings that define the acceptable formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`styles` TimeSpanStyles

One or more enumeration values that indicate the style of `input`.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

TryParseExact(String, String[], IFormatProvider, TimeSpan)

Converts the specified string representation of a time interval to its TimeSpan equivalent by using the specified formats and culture-specific format information. The format of the string representation must match one of the specified formats exactly.

C#

```
public static bool TryParseExact (string? input, string?[]? formats,
IFormatProvider? formatProvider, out TimeSpan result);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`formats` String[]

An array of standard or custom format strings that define the acceptable formats of `input`.

`formatProvider` IFormatProvider

An object that provides culture-specific formatting information.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParseExact(String, String[], IFormatProvider, TimeSpan) method to convert each element of a string array to a TimeSpan value. The example interprets the strings by using the formatting conventions of the French - France ("fr-FR") culture. The strings can represent a time interval in either the general short format or the general long format.

In addition, the example changes the way in which the time interval parsing methods interpret a single digit. Ordinarily, a single digit is interpreted as the number of days in a time interval. Instead, the `%h` custom format string is used to interpret a single digit as the number of hours. For this change to be effective, note that the `%h` custom format string must precede the other format strings in the `formats` array.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] inputs = { "3", "16:42", "1:6:52:35.0625",
                          "1:6:52:35,0625" };
      string[] formats = { "g", "G", "%h"};
      TimeSpan interval;
      CultureInfo culture = new CultureInfo("fr-FR");

      // Parse each string in inputs using formats and the fr-FR culture.
      foreach (string input in inputs) {
         if(TimeSpan.TryParseExact(input, formats, culture, out
interval))
            Console.WriteLine("{0} --> {1:c}", input, interval);
         else
            Console.WriteLine("Unable to parse {0}", input);
      }
   }
}
// The example displays the following output:
//       3 --> 03:00:00
//       16:42 --> 16:42:00
```

```
//       Unable to parse 1:6:52:35.0625
//       1:6:52:35,0625 --> 1.06:52:35.0625000
```

Remarks

The TryParseExact(String, String[], IFormatProvider, TimeSpan) method parses the string representation of a time interval, which must be in the format defined by one of the format strings specified by the `formats` parameter, except that leading and trailing white-space characters are ignored. This method is similar to the ParseExact(String, String[], IFormatProvider) method, except that it does not throw an exception if the conversion fails.

The `formats` parameter is a string array whose elements consist of either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings. `input` must correspond exactly to a member of `formats` for the parse operation to succeed. The parse operation attempts to match `input` to each element in `formats` starting with the first element in the array.

> **Important**
>
> The **TryParseExact** method uses the conventions of the culture specified by the `formatProvider` parameter only if the format string used to parse `input` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if the format string used to parse `input` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.

- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

TryParseExact(String, String[], IFormatProvider, TimeSpanStyles, TimeSpan)

Converts the specified string representation of a time interval to its TimeSpan equivalent by using the specified formats, culture-specific format information and styles. The format of the string representation must match one of the specified formats exactly.

C#

```
public static bool TryParseExact (string? input, string?[]? formats,
IFormatProvider? formatProvider, System.Globalization.TimeSpanStyles
styles, out TimeSpan result);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`formats` String[]

An array of standard or custom format strings that define the acceptable formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`styles` TimeSpanStyles

One or more enumeration values that indicate the style of `input`.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParseExact(String, String[], IFormatProvider, TimeSpanStyles, TimeSpan) method to convert each element of a string array to a TimeSpan value. The strings can represent a time interval in either the general short format or the general long format.

In addition, the example changes the way in which the time interval parsing methods interpret a single digit. Ordinarily, a single digit is interpreted as the number of days in a time interval. Instead, the `%h` custom format string is used to interpret a single digit as the number of hours. For this change to be effective, note that the `%h` custom format string must precede the other format strings in the `formats` array. Also note from the output that the TimeSpanStyles.AssumeNegative flag specified in the method call is used only when parsing a string with this format specifier.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] inputs = { "3", "16:42", "1:6:52:35.0625",
                          "1:6:52:35,0625" };
      string[] formats = { "%h", "g", "G" };
      TimeSpan interval;
      CultureInfo culture = new CultureInfo("fr-FR");

      // Parse each string in inputs using formats and the fr-FR culture.
      foreach (string input in inputs) {
         if(TimeSpan.TryParseExact(input, formats, culture,
                                   TimeSpanStyles.AssumeNegative, out
interval))
            Console.WriteLine("{0} --> {1:c}", input, interval);
         else
            Console.WriteLine("Unable to parse {0}", input);
      }
   }
}
// The example displays the following output:
//       3 --> -03:00:00
//       16:42 --> 16:42:00
//       Unable to parse 1:6:52:35.0625
//       1:6:52:35,0625 --> 1.06:52:35.0625000
```

Remarks

The TryParseExact(String, String[], IFormatProvider, TimeSpanStyles, TimeSpan) method parses the string representation of a time interval, which must be in the format defined by one of the format strings specified by the `formats` parameter, except that leading and trailing white-space characters are ignored. This method is similar to the ParseExact(String, String[], IFormatProvider, TimeSpanStyles) method, except that it does not throw an exception if the conversion fails.

The `formats` parameter is a string array whose elements consist of either a single standard format specifier, or one or more custom format specifiers that define the required format of `input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings. `input` must correspond exactly to a member of `formats` for the parse operation to succeed.

The parse operation attempts to match `input` to each element in `formats` starting with the first element in the array.

> **Important**
>
> The **ParseExact** method uses the conventions of the culture specified by the `formatProvider` parameter only if the format string used to parse `input` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if the format string used to parse `input` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

The `styles` parameter affects the interpretation of strings that are parsed using custom format strings. It determines whether `input` is interpreted as a negative time interval only if a negative sign is present (TimeSpanStyles.None), or whether it is always interpreted as a negative time interval (TimeSpanStyles.AssumeNegative). If TimeSpanStyles.AssumeNegative is not used, `format` must include a literal negative sign symbol (such as "\-") to successfully parse a negative time interval.

TryParseExact(ReadOnlySpan<Char>, String[], IFormatProvider, TimeSpan)

Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified formats and culture-specific format information. The format of the string representation must match one of the specified formats exactly.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> input, string?[]? formats, IFormatProvider? formatProvider, out TimeSpan result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a time interval to convert.

`formats` String[]

An array of standard or custom format strings that define the acceptable formats of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParseExact(ReadOnlySpan<Char>, ReadOnlySpan<Char>, IFormatProvider, TimeSpan)

Converts the specified span representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

C#

```
public static bool TryParseExact (ReadOnlySpan<char> input,
ReadOnlySpan<char> format, IFormatProvider? formatProvider, out TimeSpan
result);
```

Parameters

`input` ReadOnlySpan<Char>

A span containing the characters that represent a time interval to convert.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParseExact(String, String, IFormatProvider, TimeSpan)

Converts the string representation of a time interval to its TimeSpan equivalent by using the specified format and culture-specific format information. The format of the string representation must match the specified format exactly.

C#

```
public static bool TryParseExact (string? input, string? format,
IFormatProvider? formatProvider, out TimeSpan result);
```

Parameters

`input` String

A string that specifies the time interval to convert.

`format` String

A standard or custom format string that defines the required format of `input`.

`formatProvider` IFormatProvider

An object that supplies culture-specific formatting information.

`result` TimeSpan

When this method returns, contains an object that represents the time interval specified by `input`, or Zero if the conversion failed. This parameter is passed uninitialized.

Returns

Boolean

`true` if `input` was converted successfully; otherwise, `false`.

Examples

The following example uses the TryParseExact(String, String, IFormatProvider, TimeSpanStyles, TimeSpan) method to parse several string representations of time intervals using various format strings and cultures.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string intervalString, format;
      TimeSpan interval;
      CultureInfo culture;

      // Parse hour:minute value with "g" specifier current culture.
      intervalString = "17:14";
      format = "g";
      culture = CultureInfo.CurrentCulture;
      if (TimeSpan.TryParseExact(intervalString, format, culture, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
```

```
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse hour:minute:second value with "G" specifier.
      intervalString = "17:14:48";
      format = "G";
      culture = CultureInfo.InvariantCulture;
      if (TimeSpan.TryParseExact(intervalString, format, culture, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse hours:minute.second value with "G" specifier
      // and current (en-US) culture.
      intervalString = "17:14:48.153";
      format = "G";
      culture = CultureInfo.CurrentCulture;
      if (TimeSpan.TryParseExact(intervalString, format, culture, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse days:hours:minute.second value with "G" specifier
      // and current (en-US) culture.
      intervalString = "3:17:14:48.153";
      format = "G";
      culture = CultureInfo.CurrentCulture;
      if (TimeSpan.TryParseExact(intervalString, format, culture, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse days:hours:minute.second value with "G" specifier
      // and fr-FR culture.
      intervalString = "3:17:14:48.153";
      format = "G";
      culture = new CultureInfo("fr-FR");
      if (TimeSpan.TryParseExact(intervalString, format, culture, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse days:hours:minute.second value with "G" specifier
      // and fr-FR culture.
      intervalString = "3:17:14:48,153";
      format = "G";
      if (TimeSpan.TryParseExact(intervalString, format, culture, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);
```

```
      // Parse a single number using the "c" standard format string.
      intervalString = "12";
      format = "c";
      if (TimeSpan.TryParseExact(intervalString, format, null, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse a single number using the "%h" custom format string.
      format = "%h";
      if (TimeSpan.TryParseExact(intervalString, format, null, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);

      // Parse a single number using the "%s" custom format string.
      format = "%s";
      if (TimeSpan.TryParseExact(intervalString, format, null, out
interval))
         Console.WriteLine("'{0}' --> {1}", intervalString, interval);
      else
         Console.WriteLine("Unable to parse {0}", intervalString);
   }
}
// The example displays the following output:
//       '17:14' --> 17:14:00
//       Unable to parse 17:14:48
//       Unable to parse 17:14:48.153
//       '3:17:14:48.153' --> 3.17:14:48.1530000
//       Unable to parse 3:17:14:48.153
//       '3:17:14:48,153' --> 3.17:14:48.1530000
//       '12' --> 12.00:00:00
//       '12' --> 12:00:00
//       '12' --> 00:00:12
```

Remarks

The TryParseExact(String, String, IFormatProvider, TimeSpan) method parses the string representation of a time interval, which must be in the format defined by the `format` parameter, except that leading and trailing white-space characters are ignored. This method is similar to the ParseExact(String, String, IFormatProvider) method, except that it does not throw an exception if the conversion fails.

The `format` parameter is a string that contains either a single standard format specifier, or one or more custom format specifiers that define the required format of

`input`. For more information about valid format strings, see Standard TimeSpan Format Strings and Custom TimeSpan Format Strings.

> ⓘ **Important**
>
> The **TryParseExact(String, String, IFormatProvider, TimeSpan)** method uses the conventions of the culture specified by the `formatProvider` parameter only if `format` is a standard **TimeSpan** format string whose value is either "g" or "G". The "c", "t", and "T" standard format strings use the formatting conventions of the invariant culture. Custom format strings define the precise format of the input string and use literal characters to separate the components of a time interval.

The `formatProvider` parameter is an IFormatProvider implementation that provides culture-specific information about the format of the returned string if `format` is a standard format string. The `formatProvider` parameter can be any of the following:

- A CultureInfo object that represents the culture whose formatting conventions are to be reflected in the returned string. The DateTimeFormatInfo object returned by the CultureInfo.DateTimeFormat property defines the formatting of the returned string.
- A DateTimeFormatInfo object that defines the formatting of the returned string.
- A custom object that implements the IFormatProvider interface. Its IFormatProvider.GetFormat method returns a DateTimeFormatInfo object that provides formatting information.

If `formatProvider` is `null`, the DateTimeFormatInfo object that is associated with the current culture is used.

TimeSpan.Addition(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two specified TimeSpan instances.

C#

```
public static TimeSpan operator + (TimeSpan t1, TimeSpan t2);
```

Parameters

`t1` TimeSpan

The first time interval to add.

`t2` TimeSpan

The second time interval to add.

Returns

TimeSpan

An object whose value is the sum of the values of `t1` and `t2`.

Exceptions

OverflowException

The resulting TimeSpan is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Remarks

The Addition method defines the addition operator for TimeSpan values. It enables code such as the following:

C#

```
TimeSpan time1 = new TimeSpan(1, 0, 0, 0);   // TimeSpan equivalent to 1
day.
TimeSpan time2 = new TimeSpan(12, 0, 0);     // TimeSpan equivalent to 1/2
day.
TimeSpan time3 = time1 + time2;              // Add the two time spans.

Console.WriteLine("  {0,12}\n +  {1,10}\n   {3}\n    {2,10}",
                  time1, time2, time3, new String('_', 10));

// The example displays the following output:
//           1.00:00:00
//        +    12:00:00
//          __________
//           1.12:00:00
```

Languages that do not support custom operators can call the Add method instead.

The equivalent method for this operator is TimeSpan.Add(TimeSpan)

TimeSpan.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Division(TimeSpan, Double)	Returns a new TimeSpan object whose value is the result of dividing the specified `timeSpan` by the specified `divisor`.
Division(TimeSpan, TimeSpan)	Returns a new Double value that's the result of dividing `t1` by `t2`.

Division(TimeSpan, Double)

Returns a new TimeSpan object whose value is the result of dividing the specified `timeSpan` by the specified `divisor`.

C#

```
public static TimeSpan operator / (TimeSpan timeSpan, double divisor);
```

Parameters

`timeSpan` TimeSpan

Dividend or the value to be divided.

`divisor` Double

The value to be divided by.

Returns

TimeSpan

A new object that represents the value of `timeSpan` divided by the value of `divisor`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Division(TimeSpan, TimeSpan)

Returns a new Double value that's the result of dividing `t1` by `t2`.

C#

```
public static double operator / (TimeSpan t1, TimeSpan t2);
```

Parameters

`t1` TimeSpan

The divident or the value to be divided.

`t2` TimeSpan

The value to be divided by.

Returns

Double

A new value that represents result of dividing `t1` by the value of `t2`.

Applies to

TimeSpan.Equality(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two TimeSpan instances are equal.

```
C#
public static bool operator == (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the values of `t1` and `t2` are equal; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan using the Equality operator.

```
C#
// Example of the TimeSpan relational operators.
using System;

class TSRelationalOpsDemo
```

```
{
    const string dataFmt = "{0,34}    {1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "Left == Right", Left == Right );
        Console.WriteLine( dataFmt, "Left >  Right", Left > Right );
        Console.WriteLine( dataFmt, "Left >= Right", Left >= Right );
        Console.WriteLine( dataFmt, "Left != Right", Left != Right );
        Console.WriteLine( dataFmt, "Left <  Right", Left < Right );
        Console.WriteLine( dataFmt, "Left <= Right", Left <= Right );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan relational operators " +
            "generates \nthe following output. It creates several " +
            "different TimeSpan \nobjects and compares them with " +
            "a 2-hour TimeSpan.\n" );
        Console.WriteLine( dataFmt,
            "Left: TimeSpan( 2, 0, 0 )", Left );

        // Create objects to compare with a 2-hour TimeSpan.
        CompareTimeSpans( Left, new TimeSpan( 0, 120, 0 ),
            "TimeSpan( 0, 120, 0 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, 1 ),
            "TimeSpan( 2, 0, 1 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, -1 ),
            "TimeSpan( 2, 0, -1 )" );
        CompareTimeSpans( Left, TimeSpan.FromDays( 1.0 / 12D ),
            "TimeSpan.FromDays( 1 / 12 )" );
    }
}

/*
This example of the TimeSpan relational operators generates
the following output. It creates several different TimeSpan
objects and compares them with a 2-hour TimeSpan.

         Left: TimeSpan( 2, 0, 0 )    02:00:00

      Right: TimeSpan( 0, 120, 0 )    02:00:00
                      Left == Right    True
                      Left >  Right    False
                      Left >= Right    True
                      Left != Right    False
                      Left <  Right    False
                      Left <= Right    True
```

```
         Right: TimeSpan( 2, 0, 1 )    02:00:01
                      Left == Right    False
                      Left >  Right    False
                      Left >= Right    False
                      Left != Right    True
                      Left <  Right    True
                      Left <= Right    True

        Right: TimeSpan( 2, 0, -1 )    01:59:59
                      Left == Right    False
                      Left >  Right    True
                      Left >= Right    True
                      Left != Right    True
                      Left <  Right    False
                      Left <= Right    False

 Right: TimeSpan.FromDays( 1 / 12 )    02:00:00
                      Left == Right    True
                      Left >  Right    False
                      Left >= Right    True
                      Left != Right    False
                      Left <  Right    False
                      Left <= Right    True
 */
```

Remarks

The equivalent method for this operator is TimeSpan.Equals(Object)

TimeSpan.GreaterThan(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified TimeSpan is greater than another specified TimeSpan.

C#

```
public static bool operator > (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the value of `t1` is greater than the value of `t2`; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan using the GreaterThan operator.

C#

```
// Example of the TimeSpan relational operators.
using System;

class TSRelationalOpsDemo
```

```
{
    const string dataFmt = "{0,34}    {1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "Left == Right", Left == Right );
        Console.WriteLine( dataFmt, "Left >  Right", Left > Right );
        Console.WriteLine( dataFmt, "Left >= Right", Left >= Right );
        Console.WriteLine( dataFmt, "Left != Right", Left != Right );
        Console.WriteLine( dataFmt, "Left <  Right", Left < Right );
        Console.WriteLine( dataFmt, "Left <= Right", Left <= Right );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan relational operators " +
            "generates \nthe following output. It creates several " +
            "different TimeSpan \nobjects and compares them with " +
            "a 2-hour TimeSpan.\n" );
        Console.WriteLine( dataFmt,
            "Left: TimeSpan( 2, 0, 0 )", Left );

        // Create objects to compare with a 2-hour TimeSpan.
        CompareTimeSpans( Left, new TimeSpan( 0, 120, 0 ),
            "TimeSpan( 0, 120, 0 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, 1 ),
            "TimeSpan( 2, 0, 1 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, -1 ),
            "TimeSpan( 2, 0, -1 )" );
        CompareTimeSpans( Left, TimeSpan.FromDays( 1.0 / 12D ),
            "TimeSpan.FromDays( 1 / 12 )" );
    }
}

/*
This example of the TimeSpan relational operators generates
the following output. It creates several different TimeSpan
objects and compares them with a 2-hour TimeSpan.

         Left: TimeSpan( 2, 0, 0 )    02:00:00

      Right: TimeSpan( 0, 120, 0 )    02:00:00
                      Left == Right    True
                      Left >  Right    False
                      Left >= Right    True
                      Left != Right    False
                      Left <  Right    False
                      Left <= Right    True
```

```
        Right: TimeSpan( 2, 0, 1 )    02:00:01
                     Left == Right    False
                     Left >  Right    False
                     Left >= Right    False
                     Left != Right    True
                     Left <  Right    True
                     Left <= Right    True

       Right: TimeSpan( 2, 0, -1 )    01:59:59
                     Left == Right    False
                     Left >  Right    True
                     Left >= Right    True
                     Left != Right    True
                     Left <  Right    False
                     Left <= Right    False

Right: TimeSpan.FromDays( 1 / 12 )    02:00:00
                     Left == Right    True

TimeSpan.GreaterThanOrEqual(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified TimeSpan is greater than or equal to another specified TimeSpan.

```
C#

public static bool operator >= (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the value of `t1` is greater than or equal to the value of `t2`; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan using the GreaterThanOrEqual operator.

```
C#

// Example of the TimeSpan relational operators.
using System;
```

```
class TSRelationalOpsDemo
{
    const string dataFmt = "{0,34}    {1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "Left == Right", Left == Right );
        Console.WriteLine( dataFmt, "Left >  Right", Left > Right );
        Console.WriteLine( dataFmt, "Left >= Right", Left >= Right );
        Console.WriteLine( dataFmt, "Left != Right", Left != Right );
        Console.WriteLine( dataFmt, "Left <  Right", Left < Right );
        Console.WriteLine( dataFmt, "Left <= Right", Left <= Right );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan relational operators " +
            "generates \nthe following output. It creates several " +
            "different TimeSpan \nobjects and compares them with " +
            "a 2-hour TimeSpan.\n" );
        Console.WriteLine( dataFmt,
            "Left: TimeSpan( 2, 0, 0 )", Left );

        // Create objects to compare with a 2-hour TimeSpan.
        CompareTimeSpans( Left, new TimeSpan( 0, 120, 0 ),
            "TimeSpan( 0, 120, 0 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, 1 ),
            "TimeSpan( 2, 0, 1 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, -1 ),
            "TimeSpan( 2, 0, -1 )" );
        CompareTimeSpans( Left, TimeSpan.FromDays( 1.0 / 12D ),
            "TimeSpan.FromDays( 1 / 12 )" );
    }
}

/*
This example of the TimeSpan relational operators generates
the following output. It creates several different TimeSpan
objects and compares them with a 2-hour TimeSpan.

         Left: TimeSpan( 2, 0, 0 )    02:00:00

      Right: TimeSpan( 0, 120, 0 )    02:00:00
                     Left == Right    True
                     Left >  Right    False
                     Left >= Right    True
                     Left != Right    False
                     Left <  Right    False
```

```
                      Left <= Right    True

         Right: TimeSpan( 2, 0, 1 )    02:00:01
                      Left == Right    False
                      Left >  Right    False
                      Left >= Right    False
                      Left != Right    True
                      Left <  Right    True
                      Left <= Right    True

        Right: TimeSpan( 2, 0, -1 )    01:59:59
                      Left == Right    False
                      Left >  Right    True
                      Left >= Right    True
                      Left != Right    True
                      Left <  Right    False
                      Left <= Right    False

 Right: TimeSpan.FromDays( 1 / 12 )    02:00:00
                      Left == Right    True
                      Left >  Right    False
                      Left >= Right    True
                      Left != Right    False
                      Left <  Right    False
                      Left <= Right    True
 */
```

TimeSpan.Inequality(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two TimeSpan instances are not equal.

```
C#
public static bool operator != (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the values of `t1` and `t2` are not equal; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan using the Inequality operator.

```
C#
// Example of the TimeSpan relational operators.
using System;

class TSRelationalOpsDemo
```

```
{
    const string dataFmt = "{0,34}    {1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "Left == Right", Left == Right );
        Console.WriteLine( dataFmt, "Left >  Right", Left > Right );
        Console.WriteLine( dataFmt, "Left >= Right", Left >= Right );
        Console.WriteLine( dataFmt, "Left != Right", Left != Right );
        Console.WriteLine( dataFmt, "Left <  Right", Left < Right );
        Console.WriteLine( dataFmt, "Left <= Right", Left <= Right );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan relational operators " +
            "generates \nthe following output. It creates several " +
            "different TimeSpan \nobjects and compares them with " +
            "a 2-hour TimeSpan.\n" );
        Console.WriteLine( dataFmt,
            "Left: TimeSpan( 2, 0, 0 )", Left );

        // Create objects to compare with a 2-hour TimeSpan.
        CompareTimeSpans( Left, new TimeSpan( 0, 120, 0 ),
            "TimeSpan( 0, 120, 0 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, 1 ),
            "TimeSpan( 2, 0, 1 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, -1 ),
            "TimeSpan( 2, 0, -1 )" );
        CompareTimeSpans( Left, TimeSpan.FromDays( 1.0 / 12D ),
            "TimeSpan.FromDays( 1 / 12 )" );
    }
}

/*
This example of the TimeSpan relational operators generates
the following output. It creates several different TimeSpan
objects and compares them with a 2-hour TimeSpan.

         Left: TimeSpan( 2, 0, 0 )    02:00:00

      Right: TimeSpan( 0, 120, 0 )    02:00:00
                      Left == Right    True
                      Left >  Right    False
                      Left >= Right    True
                      Left != Right    False
                      Left <  Right    False
                      Left <= Right    True
```

```
        Right: TimeSpan( 2, 0, 1 )    02:00:01
                     Left == Right    False
                     Left >  Right    False
                     Left >= Right    False
                     Left != Right    True
                     Left <  Right    True
                     Left <= Right    True

       Right: TimeSpan( 2, 0, -1 )    01:59:59
                     Left == Right    False
                     Left >  Right    True
                     Left >= Right    True
                     Left != Right    True
                     Left <  Right    False
                     Left <= Right    False

Right: TimeSpan.FromDays( 1 / 12 )    02:00:00
                     Left == Right    True
                     Left >  Right    False
                     Left >= Right    True
                     Left != Right    False
                     Left <  Right    False
                     Left <= Right    True
*/
```

TimeSpan.LessThan(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified TimeSpan is less than another specified TimeSpan.

C#

```
public static bool operator < (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the value of `t1` is less than the value of `t2`; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan using the LessThan operator.

C#

```
// Example of the TimeSpan relational operators.
using System;

class TSRelationalOpsDemo
```

```
{
    const string dataFmt = "{0,34}    {1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "Left == Right", Left == Right );
        Console.WriteLine( dataFmt, "Left >  Right", Left > Right );
        Console.WriteLine( dataFmt, "Left >= Right", Left >= Right );
        Console.WriteLine( dataFmt, "Left != Right", Left != Right );
        Console.WriteLine( dataFmt, "Left <  Right", Left < Right );
        Console.WriteLine( dataFmt, "Left <= Right", Left <= Right );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan relational operators " +
            "generates \nthe following output. It creates several " +
            "different TimeSpan \nobjects and compares them with " +
            "a 2-hour TimeSpan.\n" );
        Console.WriteLine( dataFmt,
            "Left: TimeSpan( 2, 0, 0 )", Left );

        // Create objects to compare with a 2-hour TimeSpan.
        CompareTimeSpans( Left, new TimeSpan( 0, 120, 0 ),
            "TimeSpan( 0, 120, 0 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, 1 ),
            "TimeSpan( 2, 0, 1 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, -1 ),
            "TimeSpan( 2, 0, -1 )" );
        CompareTimeSpans( Left, TimeSpan.FromDays( 1.0 / 12D ),
            "TimeSpan.FromDays( 1 / 12 )" );
    }
}

/*
This example of the TimeSpan relational operators generates
the following output. It creates several different TimeSpan
objects and compares them with a 2-hour TimeSpan.

         Left: TimeSpan( 2, 0, 0 )    02:00:00

      Right: TimeSpan( 0, 120, 0 )    02:00:00
                      Left == Right    True

TimeSpan.LessThanOrEqual(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified TimeSpan is less than or equal to another specified TimeSpan.

C#

```
public static bool operator <= (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The first time interval to compare.

t2 TimeSpan

The second time interval to compare.

Returns

Boolean

`true` if the value of `t1` is less than or equal to the value of `t2`; otherwise, `false`.

Examples

The following example compares several TimeSpan objects to a reference TimeSpan using the LessThanOrEqual operator.

C#

```
// Example of the TimeSpan relational operators.
using System;
```

```
class TSRelationalOpsDemo
{
    const string dataFmt = "{0,34}    {1}" ;

    // Compare TimeSpan parameters, and display them with the results.
    static void CompareTimeSpans( TimeSpan Left, TimeSpan Right,
        string RightText )
    {
        Console.WriteLine( );
        Console.WriteLine( dataFmt, "Right: " + RightText, Right );
        Console.WriteLine( dataFmt, "Left == Right", Left == Right );
        Console.WriteLine( dataFmt, "Left >  Right", Left > Right );
        Console.WriteLine( dataFmt, "Left >= Right", Left >= Right );
        Console.WriteLine( dataFmt, "Left != Right", Left != Right );
        Console.WriteLine( dataFmt, "Left <  Right", Left < Right );
        Console.WriteLine( dataFmt, "Left <= Right", Left <= Right );
    }

    static void Main( )
    {
        TimeSpan Left = new TimeSpan( 2, 0, 0 );

        Console.WriteLine(
            "This example of the TimeSpan relational operators " +
            "generates \nthe following output. It creates several " +
            "different TimeSpan \nobjects and compares them with " +
            "a 2-hour TimeSpan.\n" );
        Console.WriteLine( dataFmt,
            "Left: TimeSpan( 2, 0, 0 )", Left );

        // Create objects to compare with a 2-hour TimeSpan.
        CompareTimeSpans( Left, new TimeSpan( 0, 120, 0 ),
            "TimeSpan( 0, 120, 0 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, 1 ),
            "TimeSpan( 2, 0, 1 )" );
        CompareTimeSpans( Left, new TimeSpan( 2, 0, -1 ),
            "TimeSpan( 2, 0, -1 )" );
        CompareTimeSpans( Left, TimeSpan.FromDays( 1.0 / 12D ),
            "TimeSpan.FromDays( 1 / 12 )" );
    }
}

/*
This example of the TimeSpan relational operators generates
the following output. It creates several different TimeSpan
objects and compares them with a 2-hour TimeSpan.

         Left: TimeSpan( 2, 0, 0 )    02:00:00

      Right: TimeSpan( 0, 120, 0 )    02:00:00
                     Left == Right    True
                     Left >  Right    False
                     Left >= Right    True
                     Left != Right    False
                     Left <  Right    False
```

```
                      Left <= Right    True

         Right: TimeSpan( 2, 0, 1 )    02:00:01
                      Left == Right    False
                      Left >  Right    False
                      Left >= Right    False
                      Left != Right    True
                      Left <  Right    True
                      Left <= Right    True

        Right: TimeSpan( 2, 0, -1 )    01:59:59
                      Left == Right    False
                      Left >  Right    True
                      Left >= Right    True
                      Left != Right    True
                      Left <  Right    False
                      Left <= Right    False

 Right: TimeSpan.FromDays( 1 / 12 )    02:00:00
                      Left == Right    True
                      Left >  Right    False
                      Left >= Right    True
                      Left != Right    False
                      Left <  Right    False
                      Left <= Right    True
 */
```

Remarks

The equivalent method for this operator is TimeSpan.Compare(TimeSpan, TimeSpan)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TimeSpan.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Multiply(Double, TimeSpan)	Returns a new TimeSpan object whose value is the result of multiplying the specified `factor` and the specified `timeSpan` instance.
Multiply(TimeSpan, Double)	Returns a new TimeSpan object whose value is the result of multiplying the specified `timeSpan` instance and the specified `factor`.

Multiply(Double, TimeSpan)

Returns a new TimeSpan object whose value is the result of multiplying the specified `factor` and the specified `timeSpan` instance.

C#

```
public static TimeSpan operator * (double factor, TimeSpan timeSpan);
```

Parameters

`factor` Double

The value to be multiplied by.

`timeSpan` TimeSpan

The value to be multiplied.

Returns

TimeSpan

A new object that represents the value of the specified `factor` multiplied by the value of the specified `timeSpan` instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Multiply(TimeSpan, Double)

Returns a new TimeSpan object whose value is the result of multiplying the specified `timeSpan` instance and the specified `factor`.

C#

```
public static TimeSpan operator * (TimeSpan timeSpan, double factor);
```

Parameters

`timeSpan` TimeSpan

The value to be multiplied.

`factor` Double

The value to be multiplied by.

Returns

TimeSpan

A new object that represents the value of the specified `timeSpan` instance multiplied by the value of the specified `factor`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeSpan.Subtraction(TimeSpan, TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts a specified TimeSpan from another specified TimeSpan.

C#

```
public static TimeSpan operator - (TimeSpan t1, TimeSpan t2);
```

Parameters

t1 TimeSpan

The minuend.

t2 TimeSpan

The subtrahend.

Returns

TimeSpan

An object whose value is the result of the value of `t1` minus the value of `t2`.

Exceptions

OverflowException

The return value is less than TimeSpan.MinValue or greater than TimeSpan.MaxValue.

Examples

The following example uses the TimeSpan subtraction operator to calculate the total length of the weekly work day. It also uses the TimeSpan addition operator to compute

the total time of the daily breaks before using it in a subtraction operation to compute the total actual daily working time.

C#

```
var startWork = new TimeSpan(08,00,00);
var endWork = new TimeSpan(18,30,00);
var lunchBreak = new TimeSpan(1, 0, 0);
var breaks = new TimeSpan(0, 30, 0);

Console.WriteLine("Length of work day: {0}",
                  endWork - startWork);
Console.WriteLine("Actual time worked: {0}",
                  endWork - startWork - (lunchBreak + breaks));

// The example displays the following output:
//     Length of work day: 10:30:00
//     Actual time worked: 09:00:00
```

Remarks

The equivalent method for this operator is TimeSpan.Subtract(TimeSpan)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeSpan.UnaryNegation(TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a TimeSpan whose value is the negated value of the specified instance.

C#

```
public static TimeSpan operator - (TimeSpan t);
```

Parameters

`t` TimeSpan

The time interval to be negated.

Returns

TimeSpan

An object that has the same numeric value as this instance, but the opposite sign.

Exceptions

OverflowException

The negated value of this instance cannot be represented by a TimeSpan; that is, the value of this instance is TimeSpan.MinValue.

Examples

The following example applies the UnaryNegation operator to several TimeSpan objects.

C#

```
// Example of the TimeSpan.Duration( ) and TimeSpan.Negate( ) methods,
// and the TimeSpan Unary Negation and Unary Plus operators.
```

```
using System;

class DuraNegaUnaryDemo
{
    const string dataFmt = "{0,22}{1,22}{2,22}" ;

    static void ShowDurationNegate( TimeSpan interval )
    {
        // Display the TimeSpan value and the results of the
        // Duration and Negate methods.
        Console.WriteLine( dataFmt,
            interval, interval.Duration( ), interval.Negate( ) );
    }

    static void Main()
    {
        Console.WriteLine(
            "This example of TimeSpan.Duration( ), " +
            "TimeSpan.Negate( ), \nand the TimeSpan Unary " +
            "Negation and Unary Plus operators \n" +
            "generates the following output.\n" );
        Console.WriteLine( dataFmt,
            "TimeSpan", "Duration( )", "Negate( )" );
        Console.WriteLine( dataFmt,
            "--------", "-----------", "---------" );

        // Create TimeSpan objects and apply the Unary Negation
        // and Unary Plus operators to them.
        ShowDurationNegate( new TimeSpan( 1 ) );
        ShowDurationNegate( new TimeSpan( -1234567 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, 0, 10, -20, -30 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, -10, 20, -30, 40 ) );
        ShowDurationNegate(
            - new TimeSpan( 1, 10, 20, 40, 160 ) );
        ShowDurationNegate(
            - new TimeSpan( -10, -20, -30, -40, -50 ) );
    }
}

/*
This example of TimeSpan.Duration( ), TimeSpan.Negate( ),
and the TimeSpan Unary Negation and Unary Plus operators
generates the following output.

              TimeSpan           Duration( )             Negate( )
              --------           -----------             ---------
      00:00:00.0000001      00:00:00.0000001     -00:00:00.0000001
     -00:00:00.1234567      00:00:00.1234567      00:00:00.1234567
      00:09:39.9700000      00:09:39.9700000     -00:09:39.9700000
     -09:40:29.9600000      09:40:29.9600000      09:40:29.9600000
   -1.10:20:40.1600000    1.10:20:40.1600000    1.10:20:40.1600000
   10.20:30:40.0500000   10.20:30:40.0500000  -10.20:30:40.0500000
*/
```

Remarks

The equivalent method for this operator is TimeSpan.Negate()

Applies to

TimeSpan.UnaryPlus(TimeSpan) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the specified instance of TimeSpan.

C#

```
public static TimeSpan operator + (TimeSpan t);
```

Parameters

`t` TimeSpan

The time interval to return.

Returns

TimeSpan

The time interval specified by `t`.

Examples

The following example applies the UnaryPlus operator to several TimeSpan objects.

C#

```
// Example of the TimeSpan.Duration( ) and TimeSpan.Negate( ) methods,
// and the TimeSpan Unary Negation and Unary Plus operators.
using System;

class DuraNegaUnaryDemo
{
    const string dataFmt = "{0,22}{1,22}{2,22}" ;

    static void ShowDurationNegate( TimeSpan interval )
    {
```

```
        // Display the TimeSpan value and the results of the
        // Duration and Negate methods.
        Console.WriteLine( dataFmt,
            interval, interval.Duration( ), interval.Negate( ) );
    }

    static void Main()
    {
        Console.WriteLine(
            "This example of TimeSpan.Duration( ), " +
            "TimeSpan.Negate( ), \nand the TimeSpan Unary " +
            "Negation and Unary Plus operators \n" +
            "generates the following output.\n" );
        Console.WriteLine( dataFmt,
            "TimeSpan", "Duration( )", "Negate( )" );
        Console.WriteLine( dataFmt,
            "--------", "-----------", "---------" );

        // Create TimeSpan objects and apply the Unary Negation
        // and Unary Plus operators to them.
        ShowDurationNegate( new TimeSpan( 1 ) );
        ShowDurationNegate( new TimeSpan( -1234567 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, 0, 10, -20, -30 ) );
        ShowDurationNegate(
            + new TimeSpan( 0, -10, 20, -30, 40 ) );
        ShowDurationNegate(
            - new TimeSpan( 1, 10, 20, 40, 160 ) );
        ShowDurationNegate(
            - new TimeSpan( -10, -20, -30, -40, -50 ) );
    }
}

/*
This example of TimeSpan.Duration( ), TimeSpan.Negate( ),
and the TimeSpan Unary Negation and Unary Plus operators
generates the following output.

              TimeSpan           Duration( )             Negate( )
              --------           -----------             ---------
      00:00:00.0000001      00:00:00.0000001     -00:00:00.0000001

TimeZone Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> System.TimeZone has been deprecated. Investigate the use of System.TimeZoneInfo instead.

Represents a time zone.

C#

```
[System.Obsolete("System.TimeZone has been deprecated. Investigate the use of System.TimeZoneInfo instead.")]
public abstract class TimeZone
```

Inheritance Object → TimeZone

Attributes ObsoleteAttribute

Examples

The following example references and displays selected `TimeZone` class elements.

C#

```
// Example of selected TimeZone class elements.
using System;
using System.Globalization;

class TimeZoneDemo
{
    static void Main( )
    {
        const string dataFmt = "{0,-30}{1}";
        const string timeFmt = "{0,-30}{1:yyyy-MM-dd HH:mm}";
```

```
        Console.WriteLine(
            "This example of selected TimeZone class " +
            "elements generates the following \n" +
            "output, which varies depending on the " +
            "time zone in which it is run.\n" );

        // Get the local time zone and the current local time and year.
        TimeZone localZone = TimeZone.CurrentTimeZone;
        DateTime currentDate = DateTime.Now;
        int      currentYear = currentDate.Year;

        // Display the names for standard time and daylight saving
        // time for the local time zone.
        Console.WriteLine( dataFmt, "Standard time name:",
            localZone.StandardName );
        Console.WriteLine( dataFmt, "Daylight saving time name:",
            localZone.DaylightName );

        // Display the current date and time and show if they occur
        // in daylight saving time.
        Console.WriteLine( "\n" + timeFmt, "Current date and time:",
            currentDate );
        Console.WriteLine( dataFmt, "Daylight saving time?",
            localZone.IsDaylightSavingTime( currentDate ) );

        // Get the current Coordinated Universal Time (UTC) and UTC
        // offset.
        DateTime currentUTC =
            localZone.ToUniversalTime( currentDate );
        TimeSpan currentOffset =
            localZone.GetUtcOffset( currentDate );

        Console.WriteLine( timeFmt, "Coordinated Universal Time:",
            currentUTC );
        Console.WriteLine( dataFmt, "UTC offset:", currentOffset );

        // Get the DaylightTime object for the current year.
        DaylightTime daylight =
            localZone.GetDaylightChanges( currentYear );

        // Display the daylight saving time range for the current year.
        Console.WriteLine(
            "\nDaylight saving time for year {0}:", currentYear );
        Console.WriteLine( "{0:yyyy-MM-dd HH:mm} to " +
            "{1:yyyy-MM-dd HH:mm}, delta: {2}",
            daylight.Start, daylight.End, daylight.Delta );
    }
}

/*
This example of selected TimeZone class elements generates the following
output, which varies depending on the time zone in which it is run.

Standard time name:           Pacific Standard Time
```

```
Daylight saving time name:    Pacific Daylight Time

Current date and time:        2006-01-06 16:47
Daylight saving time?         False
Coordinated Universal Time:   2006-01-07 00:47
UTC offset:                   -08:00:00

Daylight saving time for year 2006:
2006-04-02 02:00 to 2006-10-29 02:00, delta: 01:00:00
*/
```

Remarks

A time zone is a geographical region in which the same standard time is used.

> ⓘ **Important**
>
> Whenever possible, use the **TimeZoneInfo** class instead of the **TimeZone** class.

You can use the TimeZone class to retrieve information about the current time zone, and to convert times from local time to Coordinated Universal Time (UTC) or vice versa. However, you cannot use the TimeZone class to represent time zones other than the local zone or to handle date and time conversions from one time zone to another. For this purpose, use the TimeZoneInfo class. You can use this class to retrieve information on any time zone defined on the local system, to create custom time zones, and to convert times from one time zone to another.

The TimeZone class supports only a single daylight saving time adjustment rule for the local time zone. As a result, the TimeZone class can accurately report daylight saving time information or convert between UTC and local time only for the period in which the latest adjustment rule is in effect. In contrast, the TimeZoneInfo class supports multiple adjustment rules, which makes it possible to work with historic time zone data.

Notes to Implementers

In addition to providing implementations for its `abstract` members (those marked `MustOverride` in Visual Basic), it is important that classes derived from TimeZone override the default behavior of the ToLocalTime(DateTime) method. This is because the default behavior of ToLocalTime(DateTime) in the .NET Framework version 2.0 does not depend on a call to GetUtcOffset(DateTime), as it did in the .NET Framework versions 1.0 and 1.1. For details, see the ToLocalTime(DateTime) method.

Constructors

Expand table

TimeZone()	Initializes a new instance of the TimeZone class.

Properties

Expand table

CurrentTimeZone	Gets the time zone of the current computer.
DaylightName	Gets the daylight saving time zone name.
StandardName	Gets the standard time zone name.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetDaylightChanges(Int32)	Returns the daylight saving time period for a particular year.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
GetUtcOffset(DateTime)	Returns the Coordinated Universal Time (UTC) offset for the specified local time.
IsDaylightSavingTime(DateTime)	Returns a value indicating whether the specified date and time is within a daylight saving time period.
IsDaylightSavingTime(DateTime, DaylightTime)	Returns a value indicating whether the specified date and time is within the specified daylight saving time period.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToLocalTime(DateTime)	Returns the local time that corresponds to a specified date and

	time value.
ToString()	Returns a string that represents the current object. (Inherited from Object)
ToUniversalTime(DateTime)	Returns the Coordinated Universal Time (UTC) that corresponds to a specified time.

TimeZone.CurrentTimeZone Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time zone of the current computer.

C#

```
public static TimeZone CurrentTimeZone { get; }
```

Property Value

TimeZone

A TimeZone object that represents the current local time zone.

Examples

The following example references the `CurrentTimeZone` property and displays the names for standard time and daylight saving time for the local time zone.

C#

```
// Example of selected TimeZone class elements.
using System;
using System.Globalization;

class TimeZoneDemo
{
    static void Main( )
    {
        const string dataFmt = "{0,-30}{1}";
        const string timeFmt = "{0,-30}{1:yyyy-MM-dd HH:mm}";

        Console.WriteLine(
            "This example of selected TimeZone class " +
            "elements generates the following \n" +
            "output, which varies depending on the " +
            "time zone in which it is run.\n" );
```

```
        // Get the local time zone and the current local time and year.
        TimeZone localZone = TimeZone.CurrentTimeZone;
        DateTime currentDate = DateTime.Now;
        int      currentYear = currentDate.Year;

        // Display the names for standard time and daylight saving
        // time for the local time zone.
        Console.WriteLine( dataFmt, "Standard time name:",
            localZone.StandardName );
        Console.WriteLine( dataFmt, "Daylight saving time name:",
            localZone.DaylightName );

        // Display the current date and time and show if they occur
        // in daylight saving time.
        Console.WriteLine( "\n" + timeFmt, "Current date and time:",
            currentDate );
        Console.WriteLine( dataFmt, "Daylight saving time?",
            localZone.IsDaylightSavingTime( currentDate ) );

        // Get the current Coordinated Universal Time (UTC) and UTC
        // offset.
        DateTime currentUTC =
            localZone.ToUniversalTime( currentDate );
        TimeSpan currentOffset =
            localZone.GetUtcOffset( currentDate );

        Console.WriteLine( timeFmt, "Coordinated Universal Time:",
            currentUTC );
        Console.WriteLine( dataFmt, "UTC offset:", currentOffset );

        // Get the DaylightTime object for the current year.
        DaylightTime daylight =
            localZone.GetDaylightChanges( currentYear );

        // Display the daylight saving time range for the current year.
        Console.WriteLine(
            "\nDaylight saving time for year {0}:", currentYear );
        Console.WriteLine( "{0:yyyy-MM-dd HH:mm} to " +
            "{1:yyyy-MM-dd HH:mm}, delta: {2}",
            daylight.Start, daylight.End, daylight.Delta );
    }
}

/*
This example of selected TimeZone class elements generates the following
output, which varies depending on the time zone in which it is run.

Standard time name:           Pacific Standard Time
Daylight saving time name:    Pacific Daylight Time

Current date and time:        2006-01-06 16:47
Daylight saving time?         False
Coordinated Universal Time:   2006-01-07 00:47
UTC offset:                   -08:00:00
```

```
Daylight saving time for year 2006:
2006-04-02 02:00 to 2006-10-29 02:00, delta: 01:00:00
*/
```

Remarks

The CurrentTimeZone property corresponds to the TimeZoneInfo.Local property. Whenever possible, use the TimeZoneInfo.Local property.

Notes to Callers

Local time zone data is cached after CurrentTimeZone is first used to retrieve time zone information. If the system's local time zone subsequently changes, the CurrentTimeZone property does not reflect this change. If you need to handle time zone changes while your application is running, use the TimeZoneInfo class and call its ClearCachedData() method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZone.DaylightName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the daylight saving time zone name.

C#

```
public abstract string DaylightName { get; }
```

Property Value

String

The daylight saving time zone name.

Examples

The following example references and displays the `DaylightName` property of the current time zone.

C#

```
// Example of selected TimeZone class elements.
using System;
using System.Globalization;

class TimeZoneDemo
{
    static void Main( )
    {
        const string dataFmt = "{0,-30}{1}";
        const string timeFmt = "{0,-30}{1:yyyy-MM-dd HH:mm}";

        Console.WriteLine(
            "This example of selected TimeZone class " +
            "elements generates the following \n" +
            "output, which varies depending on the " +
            "time zone in which it is run.\n" );
```

```
        // Get the local time zone and the current local time and year.
        TimeZone localZone = TimeZone.CurrentTimeZone;
        DateTime currentDate = DateTime.Now;
        int      currentYear = currentDate.Year;

        // Display the names for standard time and daylight saving
        // time for the local time zone.
        Console.WriteLine( dataFmt, "Standard time name:",
            localZone.StandardName );
        Console.WriteLine( dataFmt, "Daylight saving time name:",
            localZone.DaylightName );

        // Display the current date and time and show if they occur
        // in daylight saving time.
        Console.WriteLine( "\n" + timeFmt, "Current date and time:",
            currentDate );
        Console.WriteLine( dataFmt, "Daylight saving time?",
            localZone.IsDaylightSavingTime( currentDate ) );

        // Get the current Coordinated Universal Time (UTC) and UTC
        // offset.
        DateTime currentUTC =
            localZone.ToUniversalTime( currentDate );
        TimeSpan currentOffset =
            localZone.GetUtcOffset( currentDate );

        Console.WriteLine( timeFmt, "Coordinated Universal Time:",
            currentUTC );
        Console.WriteLine( dataFmt, "UTC offset:", currentOffset );

        // Get the DaylightTime object for the current year.
        DaylightTime daylight =
            localZone.GetDaylightChanges( currentYear );

        // Display the daylight saving time range for the current year.
        Console.WriteLine(
            "\nDaylight saving time for year {0}:", currentYear );
        Console.WriteLine( "{0:yyyy-MM-dd HH:mm} to " +
            "{1:yyyy-MM-dd HH:mm}, delta: {2}",
            daylight.Start, daylight.End, daylight.Delta );
    }
}

/*
This example of selected TimeZone class elements generates the following
output, which varies depending on the time zone in which it is run.

Standard time name:           Pacific Standard Time
Daylight saving time name:    Pacific Daylight Time

Current date and time:        2006-01-06 16:47
Daylight saving time?         False
Coordinated Universal Time:   2006-01-07 00:47
UTC offset:                   -08:00:00
```

```
Daylight saving time for year 2006:
2006-04-02 02:00 to 2006-10-29 02:00, delta: 01:00:00
*/
```

Remarks

If daylight saving time is not used in the time zone, an empty string ("") is returned.

The DaylightName property corresponds to the TimeZoneInfo.DaylightName property. Whenever possible, use the TimeZoneInfo.DaylightName property.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZone.StandardName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the standard time zone name.

C#

```
public abstract string StandardName { get; }
```

Property Value

String

The standard time zone name.

Exceptions

ArgumentNullException

An attempt was made to set this property to `null`.

Examples

The following example references and displays the `StandardName` property of the current time zone.

C#

```
// Example of selected TimeZone class elements.
using System;
using System.Globalization;

class TimeZoneDemo
{
    static void Main( )
    {
        const string dataFmt = "{0,-30}{1}";
        const string timeFmt = "{0,-30}{1:yyyy-MM-dd HH:mm}";
```

```
        Console.WriteLine(
            "This example of selected TimeZone class " +
            "elements generates the following \n" +
            "output, which varies depending on the " +
            "time zone in which it is run.\n" );

        // Get the local time zone and the current local time and year.
        TimeZone localZone = TimeZone.CurrentTimeZone;
        DateTime currentDate = DateTime.Now;
        int      currentYear = currentDate.Year;

        // Display the names for standard time and daylight saving
        // time for the local time zone.
        Console.WriteLine( dataFmt, "Standard time name:",
            localZone.StandardName );
        Console.WriteLine( dataFmt, "Daylight saving time name:",
            localZone.DaylightName );

        // Display the current date and time and show if they occur
        // in daylight saving time.
        Console.WriteLine( "\n" + timeFmt, "Current date and time:",
            currentDate );
        Console.WriteLine( dataFmt, "Daylight saving time?",
            localZone.IsDaylightSavingTime( currentDate ) );

        // Get the current Coordinated Universal Time (UTC) and UTC
        // offset.
        DateTime currentUTC =
            localZone.ToUniversalTime( currentDate );
        TimeSpan currentOffset =
            localZone.GetUtcOffset( currentDate );

        Console.WriteLine( timeFmt, "Coordinated Universal Time:",
            currentUTC );
        Console.WriteLine( dataFmt, "UTC offset:", currentOffset );

        // Get the DaylightTime object for the current year.
        DaylightTime daylight =
            localZone.GetDaylightChanges( currentYear );

        // Display the daylight saving time range for the current year.
        Console.WriteLine(
            "\nDaylight saving time for year {0}:", currentYear );
        Console.WriteLine( "{0:yyyy-MM-dd HH:mm} to " +
            "{1:yyyy-MM-dd HH:mm}, delta: {2}",
            daylight.Start, daylight.End, daylight.Delta );
    }
}

/*
This example of selected TimeZone class elements generates the following
output, which varies depending on the time zone in which it is run.

Standard time name:           Pacific Standard Time
Daylight saving time name:    Pacific Daylight Time
```

```
Current date and time:        2006-01-06 16:47
Daylight saving time?         False
Coordinated Universal Time:   2006-01-07 00:47
UTC offset:                   -08:00:00

Daylight saving time for year 2006:
2006-04-02 02:00 to 2006-10-29 02:00, delta: 01:00:00
*/
```

Remarks

The StandardName property corresponds to the TimeZoneInfo.StandardName property. Whenever possible, use the TimeZoneInfo.StandardName property.

Applies to

TimeZone.GetDaylightChanges(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the daylight saving time period for a particular year.

```
C#

public abstract System.Globalization.DaylightTime GetDaylightChanges (int
year);
```

Parameters

year Int32

The year that the daylight saving time period applies to.

Returns

DaylightTime

A DaylightTime object that contains the start and end date for daylight saving time in `year`.

Exceptions

ArgumentOutOfRangeException

`year` is less than 1 or greater than 9999.

Remarks

Only one daylight saving time period per year is supported.

If daylight saving time is not used in the current time zone, the return value is a DaylightTime object, where the value of Start and End is DateTime.MinValue, and the value of DaylightTime.Delta is a TimeSpan initialized to 0 ticks.

Notes to Callers

Because the TimeZone class supports only one daylight saving time adjustment rule, the GetDaylightChanges(Int32) method applies the current adjustment rule to any year, regardless of whether the adjustment rule actually applies to that year. Assuming that the operating system itself has accurate data for a particular year, a more accurate result is available by working with the array of TimeZoneInfo.AdjustmentRule objects returned by the GetAdjustmentRules() method. The Start, End, and Delta properties correspond to the DateStart, DateEnd, and DaylightDelta properties.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZone.GetUtcOffset(DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the Coordinated Universal Time (UTC) offset for the specified local time.

```
C#
public abstract TimeSpan GetUtcOffset (DateTime time);
```

Parameters

`time` DateTime

A date and time value.

Returns

TimeSpan

The Coordinated Universal Time (UTC) offset from `time`.

Remarks

This method returns the offset, or difference, between the `time` parameter and Coordinated Universal Time (UTC). That is:

`time` = UTC + offset

The method interprets the time zone of `time` based on its Kind property. If the value of the Kind property is DateTimeKind.Local or DateTimeKind.Unspecified, the method returns the offset of the local time zone. If the value of the Kind property is DateTimeKind.Utc, the method returns an offset equal to TimeSpan.Zero.

If the local time zone observes daylight saving time, GetUtcOffset applies the current adjustment rule to `time` when determining the offset of the local time zone. That is, the

offset returned by GetUtcOffset reflects whether `time` falls in the time zone's standard time or its daylight saving time.

> **Note**
>
> The **GetUtcOffset** method recognizes only the current daylight saving time adjustment rule for the local time zone. As a result, it is guaranteed to accurately return the UTC offset of a local time only during the period in which the latest adjustment rule is in effect. It may return inaccurate results if `time` is a historic date and time value that was subject to a previous adjustment rule.

The GetUtcOffset method corresponds to the TimeZoneInfo.GetUtcOffset method. Whenever possible, use the TimeZoneInfo.GetUtcOffset method.

Because the date and time value represented by `time` and this value's offset from UTC are not tightly coupled, a local or unspecified date and time value can return a different offset value when run on different computers or when run on the same computer under different time zones. If this behavior is undesirable, use a DateTimeOffset value instead. The DateTimeOffset data type tightly couples a date and time value with its offset from UTC.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZone.IsDaylightSavingTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether a specified date and time is within a daylight saving time period.

Overloads

Expand table

IsDaylightSavingTime(DateTime)	Returns a value indicating whether the specified date and time is within a daylight saving time period.
IsDaylightSavingTime(DateTime, DaylightTime)	Returns a value indicating whether the specified date and time is within the specified daylight saving time period.

IsDaylightSavingTime(DateTime)

Returns a value indicating whether the specified date and time is within a daylight saving time period.

C#

```
public virtual bool IsDaylightSavingTime (DateTime time);
```

Parameters

`time` DateTime

A date and time.

Returns

Boolean

`true` if `time` is in a daylight saving time period; otherwise, `false`.

Remarks

The year to which the daylight saving time period applies is derived from the `time` parameter.

Because the TimeZone class supports a single daylight saving time adjustment rule, the IsDaylightSavingTime(DateTime) method applies the current adjustment rule to any date, regardless of whether the adjustment rule was in effect on that date. Assuming that the operating system itself has accurate historic daylight saving time data, a more accurate result is available by using the TimeZoneInfo.IsDaylightSavingTime method. Whenever possible, use the TimeZoneInfo.IsDaylightSavingTime method.

See also

- IsDaylightSavingTime(DateTime)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

IsDaylightSavingTime(DateTime, DaylightTime)

Returns a value indicating whether the specified date and time is within the specified daylight saving time period.

C#

```
public static bool IsDaylightSavingTime (DateTime time,
```

```
System.Globalization.DaylightTime daylightTimes);
```

Parameters

`time` DateTime

A date and time.

`daylightTimes` DaylightTime

A daylight saving time period.

Returns

Boolean

`true` if `time` is in `daylightTimes`; otherwise, `false`.

Exceptions

ArgumentNullException

`daylightTimes` is `null`.

Remarks

The TimeZoneInfo.IsDaylightSavingTime method provides the same functionality as this overload of the IsDaylightSavingTime method. Whenever possible, use the TimeZoneInfo.IsDaylightSavingTime method.

TimeZone.ToLocalTime(DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the local time that corresponds to a specified date and time value.

C#

```
public virtual DateTime ToLocalTime (DateTime time);
```

Parameters

`time` DateTime

A Coordinated Universal Time (UTC) time.

Returns

DateTime

A DateTime object whose value is the local time that corresponds to `time`.

Remarks

The following table shows the relationship between the `time` parameter and the DateTime value returned by this method.

Expand table

`time` parameter	Behavior	Return value
A Coordinated Universal Time (UTC) time (DateTimeKind.Utc).	Converts the time from UTC to the local time.	A DateTime object whose value is the local time that corresponds to `time`.

`time` parameter	Behavior	Return value
A local time (DateTimeKind.Local).	No conversion necessary.	The same DateTime value represented by the `time` parameter.
An unspecified time (DateTimeKind.Unspecified).	Assumes that the time is UTC and converts it from UTC to the local time.	A DateTime object whose value is the local time that corresponds to `time`.

If the local time zone observes daylight saving time, ToLocalTime applies the current adjustment rule to `time` when performing the conversion.

> **Note**
>
> The **ToLocalTime** method recognizes only the current daylight saving time adjustment rule for the local time zone. As a result, it is guaranteed to accurately return the local time corresponding to a particular UTC time only during the period in which the latest adjustment rule is in effect. It may return inaccurate results if `time` is a historic date and time value that was subject to a previous adjustment rule.

The ToLocalTime method corresponds to the TimeZoneInfo.ConvertTimeFromUtc method with its `destinationTimeZone` parameter set to TimeZoneInfo.Local. Whenever possible, use the TimeZoneInfo.ConvertTimeFromUtc method.

Notes to Inheritors

Although it is not required, in most cases derived classes running under the .NET Framework version 2.0 should override the default implementation of this method. In the .NET Framework versions 1.0 and 1.1, the `ToLocalTime` method called the GetUtcOffset(DateTime) method and adjusted for daylight saving time when returning the local time. However, starting with the .NET Framework 2.0, the behavior of the default implementation depends on the Kind property of the `time` parameter. If its value is Local, this method returns `time` unchanged. If its value is either Utc or Unspecified, this method assumes `time` is UTC and converts it to the local system time without calling the GetUtcOffset(DateTime) method.

The following code provides a simple override of the default implementation of the `ToLocalTime` method. In this code, the `internalTimeZone` variable represents a private instance of the `TimeZone` class:

C#

```
public override DateTime ToLocalTime(DateTime time)
{
   if (time.Kind == DateTimeKind.Local)
   {
      return time;
   }
   else if (time.Kind == DateTimeKind.Utc)
   {
      DateTime returnTime = new DateTime(time.Ticks, DateTimeKind.Local);
      returnTime += this.GetUtcOffset(returnTime);
      if (internalTimeZone.IsDaylightSavingTime(returnTime))
         returnTime -= new TimeSpan(1, 0, 0);
      return returnTime;
   }
   else
   {
      throw new ArgumentException("The source time zone cannot be
determined.");
   }
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZone.ToUniversalTime(DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the Coordinated Universal Time (UTC) that corresponds to a specified time.

C#

```
public virtual DateTime ToUniversalTime (DateTime time);
```

Parameters

`time` DateTime

A date and time.

Returns

DateTime

A DateTime object whose value is the Coordinated Universal Time (UTC) that corresponds to `time`.

Remarks

If the local time zone observes daylight saving time, ToUniversalTime applies the current adjustment rule to the `time` parameter when performing the conversion.

> **Note**
>
> The **ToUniversalTime** method recognizes only the current daylight saving time adjustment rule for the local time zone. As a result, it is guaranteed to accurately return the Coordinated Universal Time (UTC) corresponding to a particular local time only during the period in which the latest adjustment rule is in effect. It may

return inaccurate results if `time` is a historic date and time value that was subject to a previous adjustment rule.

If the `time` parameter is an ambiguous time, the method assumes that it is a standard time. (An ambiguous time is one that can map either to a standard time or to a daylight saving time in the local time zone.) If `time` is an invalid time, the method simply subtracts the local time from the local time zone's UTC offset to return UTC. (An invalid time is one that does not exist because of the application of daylight saving time adjustment rules.)

Because `time` is interpreted in relation to the current time zone on the current system, the date and time returned by this method can differ if an application is run on different computers or on the same computer with different time zones. For cases in which a date and time value must represent a single, unambiguous point in time, use a DateTimeOffset value to represent the local time.

The ToUniversalTime method corresponds to the TimeZoneInfo.ConvertTimeToUtc(DateTime) method overload with a DateTime parameter whose Kind property does not equal DateTimeKind.Utc. Whenever possible, use the TimeZoneInfo.ConvertTimeToUtc(DateTime) method overload.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents any time zone in the world.

C#

```
public sealed class TimeZoneInfo : IEquatable<TimeZoneInfo>,
System.Runtime.Serialization.IDeserializationCallback,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → TimeZoneInfo

Implements IEquatable<TimeZoneInfo> , IDeserializationCallback , ISerializable

Remarks

A time zone is a geographical region in which the same time is used.

The TimeZoneInfo class offers significant enhancements over the TimeZone class, which provides only limited functionality.

The TimeZone class recognizes only the local time zone, and can convert times between Coordinated Universal Time (UTC) and local time. A TimeZoneInfo object can represent any time zone, and methods of the TimeZoneInfo class can be used to convert the time in one time zone to the corresponding time in any other time zone. The members of the TimeZoneInfo class support the following operations:

- Retrieving a time zone that is already defined by the operating system.
- Enumerating the time zones that are available on a system.
- Converting times between different time zones.
- Creating a new time zone that is not already defined by the operating system.
- Serializing a time zone for later retrieval.

> **Note**
>
> An instance of the **TimeZoneInfo** class is immutable. Once an object has been instantiated, its values cannot be modified.

You cannot instantiate a TimeZoneInfo object using the `new` keyword. Instead, you must call one of the static members of the TimeZoneInfo class shown in the following table.

Expand table

Static member name	Description
CreateCustomTimeZone method	Creates a custom time zone from application-supplied data.
FindSystemTimeZoneById method	Instantiates a time zone based on its identifier.
FromSerializedString method	Deserializes a string value to re-create a previously serialized TimeZoneInfo object.
GetSystemTimeZones method	Returns an enumerable ReadOnlyCollection<T> of TimeZoneInfo objects that represents all time zones that are available on the local system.
Local property	Instantiates a TimeZoneInfo object that represents the local time zone.
Utc property	Instantiates a TimeZoneInfo object that represents the UTC zone.

You can use the CreateCustomTimeZone method to create a time zone that is not defined in the local system registry on Windows systems or by the ICU Library's Time Zone Data on Linux or macOS. You can then use the ToSerializedString property to save the time zone object's information as a string, which can be stored in some form that is accessible to the application. You can use the FromSerializedString method to convert a serialized string back to a TimeZoneInfo object.

Properties

Expand table

BaseUtcOffset	Gets the time difference between the current time zone's standard time and Coordinated Universal Time (UTC).

DaylightName	Gets the display name for the current time zone's daylight saving time.
DisplayName	Gets the general display name that represents the time zone.
HasIanaId	Returns `true` if this TimeZoneInfo object has an IANA ID.
Id	Gets the time zone identifier.
Local	Gets a TimeZoneInfo object that represents the local time zone.
StandardName	Gets the display name for the time zone's standard time.
SupportsDaylightSavingTime	Gets a value indicating whether the time zone has any daylight saving time rules.
Utc	Gets a TimeZoneInfo object that represents the Coordinated Universal Time (UTC) zone.

Methods

Expand table

ClearCachedData()	Clears cached time zone data.
ConvertTime(DateTime, TimeZoneInfo)	Converts a time to the time in a particular time zone.
ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo)	Converts a time from one time zone to another.
ConvertTime(DateTimeOffset, TimeZoneInfo)	Converts a time to the time in a particular time zone.
ConvertTimeBySystemTimeZoneId(DateTime, String)	Converts a time to the time in another time zone based on the time zone's identifier.
ConvertTimeBySystemTimeZoneId(DateTime, String, String)	Converts a time from one time zone to another based on time zone identifiers.
ConvertTimeBySystemTimeZoneId(DateTimeOffset, String)	Converts a time to the time in another time zone based on the time zone's identifier.
ConvertTimeFromUtc(DateTime, TimeZoneInfo)	Converts a Coordinated Universal Time (UTC) to the time in a specified time zone.
ConvertTimeToUtc(DateTime)	Converts the specified date and time to Coordinated Universal Time (UTC).
ConvertTimeToUtc(DateTime, Time	Converts the time in a specified time zone to Coordinated

ZoneInfo)	Universal Time (UTC).
CreateCustomTimeZone(String, TimeSpan, String, String)	Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, and a standard time display name.
CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[])	Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, a standard time name, a daylight saving time name, and daylight saving time rules.
CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[], Boolean)	Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, a standard time name, a daylight saving time name, daylight saving time rules, and a value that indicates whether the returned object reflects daylight saving time information.
Equals(Object)	Determines whether the current TimeZoneInfo object and another object are equal.
Equals(TimeZoneInfo)	Determines whether the current TimeZoneInfo object and another TimeZoneInfo object are equal.
FindSystemTimeZoneById(String)	Instantiates a new TimeZoneInfo object based on its identifier.
FromSerializedString(String)	Deserializes a string to re-create an original serialized TimeZoneInfo object.
GetAdjustmentRules()	Retrieves an array of TimeZoneInfo.AdjustmentRule objects that apply to the current TimeZoneInfo object.
GetAmbiguousTimeOffsets(DateTime)	Returns information about the possible dates and times that an ambiguous date and time can be mapped to.
GetAmbiguousTimeOffsets(DateTimeOffset)	Returns information about the possible dates and times that an ambiguous date and time can be mapped to.
GetHashCode()	Serves as a hash function for hashing algorithms and data structures such as hash tables.
GetSystemTimeZones()	Returns a sorted collection of all the time zones about which information is available on the local system.
GetSystemTimeZones(Boolean)	Returns a ReadOnlyCollection<T> containing all valid TimeZone's from the local machine. This method does *not* throw TimeZoneNotFoundException or InvalidTimeZoneException.
GetType()	Gets the Type of the current instance. (Inherited from Object)

GetUtcOffset(DateTime)	Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.
GetUtcOffset(DateTimeOffset)	Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.
HasSameRules(TimeZoneInfo)	Indicates whether the current object and another TimeZoneInfo object have the same adjustment rules.
IsAmbiguousTime(DateTime)	Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.
IsAmbiguousTime(DateTime Offset)	Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.
IsDaylightSavingTime(DateTime)	Indicates whether a specified date and time falls in the range of daylight saving time for the time zone of the current TimeZoneInfo object.
IsDaylightSavingTime(DateTime Offset)	Indicates whether a specified date and time falls in the range of daylight saving time for the time zone of the current TimeZoneInfo object.
IsInvalidTime(DateTime)	Indicates whether a particular date and time is invalid.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToSerializedString()	Converts the current TimeZoneInfo object to a serialized string.
ToString()	Returns the current TimeZoneInfo object's display name.
TryConvertIanaIdToWindows Id(String, String)	Tries to convert an IANA time zone ID to a Windows ID.
TryConvertWindowsIdToIana Id(String, String)	Tries to convert a Windows time zone ID to an IANA ID.
TryConvertWindowsIdToIana Id(String, String, String)	Tries to convert a Windows time zone ID to an IANA ID.
TryFindSystemTimeZone ById(String, TimeZoneInfo)	Retrieves a TimeZoneInfo object by time zone name.

Explicit Interface Implementations

Expand table

IDeserializationCallback.OnDeserialization(Object)	Runs when the deserialization of an object has been completed.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo object with the data needed to serialize the current TimeZoneInfo object.

Applies to

Product	Versions

TimeZoneInfo.BaseUtcOffset Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time difference between the current time zone's standard time and Coordinated Universal Time (UTC).

C#

```
public TimeSpan BaseUtcOffset { get; }
```

Property Value

TimeSpan

An object that indicates the time difference between the current time zone's standard time and Coordinated Universal Time (UTC).

Examples

The following example uses the BaseUtcOffset property to display the difference between the local time and Coordinated Universal Time (UTC).

C#

```
TimeZoneInfo localZone = TimeZoneInfo.Local;
Console.WriteLine("The {0} time zone is {1}:{2} {3} than Coordinated
Universal Time.",
                  localZone.DisplayName,
                  Math.Abs(localZone.BaseUtcOffset.Hours),
                  Math.Abs(localZone.BaseUtcOffset.Minutes),
                  (localZone.BaseUtcOffset >= TimeSpan.Zero) ? "later" :
"earlier");
```

Remarks

The time span returned by the BaseUtcOffset property can range from 14 hours (for a time zone that is 14 hours ahead of Coordinated Universal Time (UTC)) to -14 hours (for a time zone that is 14 hours behind UTC). Time zones that are ahead of UTC have a positive offset; time zones that are behind UTC have a negative offset.

The BaseUtcOffset value is represented as a whole number of minutes. It cannot include a fractional number of minutes.

> ⓘ **Note**
>
> Because **BaseUtcOffset** is a property of the **TimeZoneInfo** object rather than the **TimeZoneInfo.AdjustmentRule** object, the **TimeZoneInfo** class applies a single offset from UTC to all of a time zone's adjustments. To reflect a time zone that has modified its offset from UTC, you must create a new time zone using the **CreateCustomTimeZone** method.

The BaseUtcOffset property differs from the GetUtcOffset method in the following ways:

- The BaseUtcOffset property returns the difference between UTC and the time zone's standard time; the GetUtcOffset method returns the difference between UTC and the time zone's time at a particular point in time.
- The GetUtcOffset method reflects the application of any adjustment rules to the time zone; the BaseUtcOffset property does not.

Applies to

TimeZoneInfo.DaylightName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the display name for the current time zone's daylight saving time.

C#

```
public string DaylightName { get; }
```

Property Value

String

The display name for the time zone's daylight saving time.

Examples

The following example defines a method named `DisplayDateWithTimeZoneName` that uses the IsDaylightSavingTime(DateTime) method to determine whether to display a time zone's standard time name or daylight saving time name.

C#

```
private void DisplayDateWithTimeZoneName(DateTime date1, TimeZoneInfo
timeZone)
{
   Console.WriteLine("The time is {0:t} on {0:d} {1}",
                     date1,
                     timeZone.IsDaylightSavingTime(date1) ?
                         timeZone.DaylightName : timeZone.StandardName);
}
// The example displays output similar to the following:
//    The time is 1:00 AM on 4/2/2006 Pacific Standard Time
```

Remarks

The display name is localized based on the culture installed with the Windows operating system.

A DaylightName property whose value is not String.Empty or `null` does not necessarily indicate that the time zone supports daylight saving time. To determine whether the time zone supports daylight saving time, check the value of its SupportsDaylightSavingTime property.

In most cases, the `DaylightName` property of system-defined time zones is not String.Empty or `null`. However, the DaylightName property of custom time zones can be set to String.Empty. This occurs when custom time zones are created by the TimeZoneInfo.CreateCustomTimeZone(String, TimeSpan, String, String) or the TimeZoneInfo.CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[], Boolean) overload and the `disableDaylightSavingTime` parameter is `true`. Therefore, your code should never assume that the value of the DaylightName property is not `null` or empty.

The DaylightName property is equivalent to the DaylightName property of the TimeZone class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.DisplayName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the general display name that represents the time zone.

C#

```
public string DisplayName { get; }
```

Property Value

String

The time zone's general display name.

Examples

The following example retrieves a TimeZoneInfo object that represents the local time zone and outputs its display name, standard time name, and daylight saving time name. The output is displayed for a system in the U.S. Pacific Standard Time zone.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      TimeZoneInfo localZone = TimeZoneInfo.Local;
      Console.WriteLine("Local Time Zone ID: {0}", localZone.Id);
      Console.WriteLine("   Display Name is: {0}.", localZone.DisplayName);
      Console.WriteLine("   Standard name is: {0}.",
localZone.StandardName);
      Console.WriteLine("   Daylight saving name is: {0}.",
localZone.DaylightName);
   }
}
// The example displays output like the following:
```

```
//     Local Time Zone ID: Pacific Standard Time
//        Display Name is: (UTC-08:00) Pacific Time (US & Canada).
//        Standard name is: Pacific Standard Time.
//        Daylight saving name is: Pacific Daylight Time.
```

Remarks

The display name is localized based on the culture installed with the Windows operating system.

Time zone display names for Windows system time zones follow a fairly standard format. The first portion of the display name is the time zone's base offset from Coordinated Universal Time, which is indicated by the acronym GMT (for Greenwich Mean Time), enclosed in parentheses. For Coordinated Universal Time, the GMT acronym with no offset is enclosed in parentheses. This is followed by a string that identifies the time zone or one or more of the cities, regions, or countries in the time zone. For example:

```
(GMT) Greenwich Mean Time : Dublin, Edinburgh, Lisbon, London
(GMT+02:00) Athens, Beirut, Istanbul, Minsk
(GMT-02:00) Mid-Atlantic
(GMT-07:00) Mountain Time (US & Canada)
```

Applies to

Product	Versions

TimeZoneInfo.Id Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time zone identifier.

```
C#
public string Id { get; }
```

Property Value

String

The time zone identifier.

Examples

The following example lists the identifier of each of the time zones defined on the local computer.

```
C#
ReadOnlyCollection<TimeZoneInfo> zones = TimeZoneInfo.GetSystemTimeZones();
Console.WriteLine("The local system has the following {0} time zones",
zones.Count);
foreach (TimeZoneInfo zone in zones)
   Console.WriteLine(zone.Id);
```

Remarks

The time zone identifier is a key string that uniquely identifies a particular time zone. On Windows systems, it corresponds to the subkeys of the HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Time Zone branch of the registry on Windows systems and from the ICU Library on Linux and

macOS. It can be passed as a parameter to the FindSystemTimeZoneById method to instantiate a TimeZoneInfo object that represents a particular time zone.

> **Important**
>
> Although a key name in the Windows registry can be a maximum of 255 characters, we recommend that an identifier that you assign to a custom time zone be 32 characters or fewer. The longer the identifier, the greater the probability that an incorrect key name will be supplied when retrieving it.

The value of the Id property is usually, but not always, identical to that of the StandardName property. The identifier of the Coordinated Universal Time zone is UTC.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.Local Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a TimeZoneInfo object that represents the local time zone.

C#

```
public static TimeZoneInfo Local { get; }
```

Property Value

TimeZoneInfo

An object that represents the local time zone.

Examples

The following example retrieves a TimeZoneInfo object that represents the local time zone and outputs its display name, standard time name, and daylight saving time name.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      TimeZoneInfo localZone = TimeZoneInfo.Local;
      Console.WriteLine("Local Time Zone ID: {0}", localZone.Id);
      Console.WriteLine("   Display Name is: {0}.", localZone.DisplayName);
      Console.WriteLine("   Standard name is: {0}.",
localZone.StandardName);
      Console.WriteLine("   Daylight saving name is: {0}.",
localZone.DaylightName);
   }
}
// The example displays output like the following:
//     Local Time Zone ID: Pacific Standard Time
```

```
//        Display Name is: (UTC-08:00) Pacific Time (US & Canada).
//        Standard name is: Pacific Standard Time.
//        Daylight saving name is: Pacific Daylight Time.
```

Remarks

The local time zone is the time zone on the computer where the code is executing.

> ⓘ **Important**
>
> You should always access the local time zone through the **TimeZoneInfo.Local** property rather than assigning the local time zone to a **TimeZoneInfo** object variable. This prevents the **TimeZoneInfo** object variable from being invalidated by a call to the **ClearCachedData** method.

On Windows systems, the TimeZoneInfo object returned by the TimeZoneInfo.Local property reflects the setting of the **Automatically adjust clock for Daylight Saving Time** checkbox in the Control Panel **Date and Time** application. If the checkbox is unchecked, the cached copy of the local time zone contains no daylight saving time information. This means that:

- The local time zone's GetAdjustmentRules method returns an array whose length is zero.
- The local time zone's SupportsDaylightSavingTime property returns `false`.
- The local time zone has no ambiguous or invalid times (all calls to IsAmbiguousTime or IsInvalidTime return `false`).
- All calls to IsDaylightSavingTime with individual local times return false.

This is not true, however, if a reference to the local time zone is retrieved using the FindSystemTimeZoneById method.

The Local property corresponds to the CurrentTimeZone property of the TimeZone class.

Applies to

Product	Versions

TimeZoneInfo.StandardName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the display name for the time zone's standard time.

C#

```
public string StandardName { get; }
```

Property Value

String

The display name of the time zone's standard time.

Examples

The following example defines a method named `DisplayDateWithTimeZoneName` that uses the IsDaylightSavingTime(DateTime) method to determine whether to display a time zone's standard time name or daylight saving time name.

C#

```
private void DisplayDateWithTimeZoneName(DateTime date1, TimeZoneInfo
timeZone)
{
   Console.WriteLine("The time is {0:t} on {0:d} {1}",
                     date1,
                     timeZone.IsDaylightSavingTime(date1) ?
                         timeZone.DaylightName : timeZone.StandardName);
}
// The example displays output similar to the following:
//    The time is 1:00 AM on 4/2/2006 Pacific Standard Time
```

Remarks

The display name is localized based on the culture installed with the Windows operating system.

The StandardName property is identical to the StandardName property of the TimeZone class.

If the operating system language is English, the value of the StandardName property is usually, but not always, identical to that of the Id property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.SupportsDaylightSaving Time Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the time zone has any daylight saving time rules.

C#

```
public bool SupportsDaylightSavingTime { get; }
```

Property Value

Boolean

`true` if the time zone supports daylight saving time; otherwise, `false`.

Examples

The following example retrieves a collection of all time zones that are available on a local system and displays the names of those that do not support daylight saving time.

C#

```
ReadOnlyCollection<TimeZoneInfo> zones = TimeZoneInfo.GetSystemTimeZones();
foreach(TimeZoneInfo zone in zones)
{
   if (! zone.SupportsDaylightSavingTime)
      Console.WriteLine(zone.DisplayName);
}
```

Remarks

The value of the SupportsDaylightSavingTime property for the local time zone returned by the TimeZoneInfo.Local property reflects the setting of the Control Panel **Date and Time** application's checkbox that defines whether the system automatically adjusts for

daylight saving time. If it is unchecked, or if no checkbox is displayed for a time zone, the value of this property is `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.Utc Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a TimeZoneInfo object that represents the Coordinated Universal Time (UTC) zone.

C#

```
public static TimeZoneInfo Utc { get; }
```

Property Value

TimeZoneInfo

An object that represents the Coordinated Universal Time (UTC) zone.

Examples

The following example retrieves a TimeZoneInfo object that represents Coordinated Universal Time (UTC) and outputs its display name, standard time name, and daylight saving time name.

C#

```
TimeZoneInfo universalZone = TimeZoneInfo.Utc;
Console.WriteLine("The universal time zone is {0}.",
universalZone.DisplayName);
Console.WriteLine("Its standard name is {0}.", universalZone.StandardName);
Console.WriteLine("Its daylight savings name is {0}.",
universalZone.DaylightName);
```

Remarks

This is a built-in object; information about this TimeZoneInfo object is not retrieved from the registry on Windows systems and from the ICU Library on Linux and macOS.

> **Important**
>
> You should always access the Coordinated Universal Time (UTC) zone through the **TimeZoneInfo.Utc** property rather than assigning the UTC time zone to a **TimeZoneInfo** object variable. This prevents the **TimeZoneInfo** object variable from being invalidated by a call to the **ClearCachedData** method.

Coordinated Universal Time was previously known as Greenwich Mean Time (GMT).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.ClearCachedData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clears cached time zone data.

C#

```
public static void ClearCachedData ();
```

Remarks

Cached time zone data includes data on the local time zone and the Coordinated Universal Time (UTC) zone.

You might call the `ClearCachedData` method to reduce the memory devoted to the application's cache of time zone information or to reflect the fact that the local system's time zone has changed.

Storing references to the local and UTC time zones is not recommended. After the call to the `ClearCachedData` method, these object variables will be undefined TimeZoneInfo objects that are no longer references to TimeZoneInfo.Local or TimeZoneInfo.Utc. For example, in the following code, the second call to the TimeZoneInfo.ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo) method throws an ArgumentException because the `local` variable is no longer considered equal to TimeZoneInfo.Local.

C#

```
TimeZoneInfo cst = TimeZoneInfo.FindSystemTimeZoneById("Central Standard
Time");
TimeZoneInfo local = TimeZoneInfo.Local;
Console.WriteLine(TimeZoneInfo.ConvertTime(DateTime.Now, local, cst));

TimeZoneInfo.ClearCachedData();
try
{
   Console.WriteLine(TimeZoneInfo.ConvertTime(DateTime.Now, local, cst));
```

```
}
catch (ArgumentException e)
{
   Console.WriteLine(e.GetType().Name + "\n   " + e.Message);
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.ConvertTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a time to the time in a particular time zone.

Overloads

Expand table

ConvertTime(DateTime, TimeZoneInfo)	Converts a time to the time in a particular time zone.
ConvertTime(DateTimeOffset, TimeZoneInfo)	Converts a time to the time in a particular time zone.
ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo)	Converts a time from one time zone to another.

ConvertTime(DateTime, TimeZoneInfo)

Converts a time to the time in a particular time zone.

C#

```
public static DateTime ConvertTime (DateTime dateTime, TimeZoneInfo
destinationTimeZone);
```

Parameters

dateTime DateTime

The date and time to convert.

destinationTimeZone TimeZoneInfo

The time zone to convert `dateTime` to.

Returns

DateTime

The date and time in the destination time zone.

Exceptions

ArgumentException

The value of the `dateTime` parameter represents an invalid time.

ArgumentNullException

The value of the `destinationTimeZone` parameter is `null`.

Examples

The following example converts an array of date and time values to times in the Eastern Time zone of the U.S. and Canada. It shows that the source time zone depends on the DateTime.Kind property of the source DateTime value. It also illustrates that the ConvertTime method takes time zone adjustments into account, because a time zone adjustment occurs in both the source and destination time zones at 2:00 A.M. on November 7, 2010.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define times to be converted.
      DateTime[] times = { new DateTime(2010, 1, 1, 0, 1, 0),
                           new DateTime(2010, 1, 1, 0, 1, 0,
DateTimeKind.Utc),
                           new DateTime(2010, 1, 1, 0, 1, 0,
DateTimeKind.Local),
                           new DateTime(2010, 11, 6, 23, 30, 0),
                           new DateTime(2010, 11, 7, 2, 30, 0) };

      // Retrieve the time zone for Eastern Standard Time (U.S. and
Canada).
      TimeZoneInfo est;
      try {
         est = TimeZoneInfo.FindSystemTimeZoneById("Eastern Standard
Time");
      }
      catch (TimeZoneNotFoundException) {
```

```
            Console.WriteLine("Unable to retrieve the Eastern Standard time
zone.");
            return;
        }
        catch (InvalidTimeZoneException) {
            Console.WriteLine("Unable to retrieve the Eastern Standard time
zone.");
            return;
        }

        // Display the current time zone name.
        Console.WriteLine("Local time zone: {0}\n",
TimeZoneInfo.Local.DisplayName);

        // Convert each time in the array.
        foreach (DateTime timeToConvert in times)
        {
            DateTime targetTime = TimeZoneInfo.ConvertTime(timeToConvert,
est);
            Console.WriteLine("Converted {0} {1} to {2}.", timeToConvert,
                              timeToConvert.Kind, targetTime);
        }
    }
}
// The example displays the following output:
//    Local time zone: (GMT-08:00) Pacific Time (US & Canada)
//
//    Converted 1/1/2010 12:01:00 AM Unspecified to 1/1/2010 3:01:00 AM.
//    Converted 1/1/2010 12:01:00 AM Utc to 12/31/2009 7:01:00 PM.
//    Converted 1/1/2010 12:01:00 AM Local to 1/1/2010 3:01:00 AM.
//    Converted 11/6/2010 11:30:00 PM Unspecified to 11/7/2010 1:30:00
AM.
//    Converted 11/7/2010 2:30:00 AM Unspecified to 11/7/2010 5:30:00 AM.
```

Remarks

When performing the conversion, the ConvertTime(DateTimeOffset, TimeZoneInfo) method applies any adjustment rules in effect in the `destinationTimeZone` time zone.

This overload of the ConvertTime(DateTime, TimeZoneInfo) method determines the source time zone from the value of the `dateTime` parameter's Kind property, as the following table shows.

Expand table

Kind property value	Source time zone	Method behavior
DateTimeKind.Local	Local	Converts the local time to the time in

Kind property value	Source time zone	Method behavior
		`destinationTimeZone`.
DateTimeKind.Utc	Utc	Converts Coordinated Universal Time (UTC) to the time in `destinationTimeZone`.
DateTimeKind.Unspecified	Assumed to be Local.	Converts the local time to the time in `destinationTimeZone`.

The Kind property of the returned DateTime value is set as shown in the following table.

Expand table

Condition	Returned Kind property value
The `destinationTimeZone` is TimeZoneInfo.Utc.	DateTimeKind.Utc
The `destinationTimeZone` is TimeZoneInfo.Local.	DateTimeKind.Local
All other date and time values and destination time zones.	DateTimeKind.Unspecified

If the value of the `dateTime` parameter is an ambiguous local time, it is interpreted as a standard time. If the `dateTime` parameter is an invalid local time, this method throws an ArgumentException.

If the conversion of `dateTime` results in a date and time value that is earlier than DateTime.MinValue or later than DateTime.MaxValue, this method returns DateTime.MinValue or DateTime.MaxValue, respectively.

You can also convert to or from UTC by calling the ConvertTimeFromUtc and ConvertTimeToUtc methods.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ConvertTime(DateTimeOffset, TimeZoneInfo)

Converts a time to the time in a particular time zone.

C#

```
public static DateTimeOffset ConvertTime (DateTimeOffset dateTimeOffset,
TimeZoneInfo destinationTimeZone);
```

Parameters

`dateTimeOffset` DateTimeOffset

The date and time to convert.

`destinationTimeZone` TimeZoneInfo

The time zone to convert `dateTime` to.

Returns

DateTimeOffset

The date and time in the destination time zone.

Exceptions

ArgumentNullException

The value of the `destinationTimeZone` parameter is `null`.

Examples

The following example converts an array of DateTimeOffset values to times in the Eastern Time zone of the U.S. and Canada. It illustrates that the ConvertTime method takes time zone adjustments into account, because a time zone adjustment occurs in both the source and destination time zones at 2:00 A.M. on November 7, 2010.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define times to be converted.
      DateTime time1 = new DateTime(2010, 1, 1, 12, 1, 0);
      DateTime time2 = new DateTime(2010, 11, 6, 23, 30, 0);
      DateTimeOffset[] times = { new DateTimeOffset(time1,
TimeZoneInfo.Local.GetUtcOffset(time1)),
                                 new DateTimeOffset(time1,
TimeSpan.Zero),
                                 new DateTimeOffset(time2,
TimeZoneInfo.Local.GetUtcOffset(time2)),
                                 new DateTimeOffset(time2.AddHours(3),
TimeZoneInfo.Local.GetUtcOffset(time2.AddHours(3))) };

      // Retrieve the time zone for Eastern Standard Time (U.S. and
Canada).
      TimeZoneInfo est;
      try {
         est = TimeZoneInfo.FindSystemTimeZoneById("Eastern Standard
Time");
      }
      catch (TimeZoneNotFoundException) {
         Console.WriteLine("Unable to retrieve the Eastern Standard time
zone.");
         return;
      }
      catch (InvalidTimeZoneException) {
         Console.WriteLine("Unable to retrieve the Eastern Standard time
zone.");
         return;
      }

      // Display the current time zone name.
      Console.WriteLine("Local time zone: {0}\n",
TimeZoneInfo.Local.DisplayName);

      // Convert each time in the array.
      foreach (DateTimeOffset timeToConvert in times)
      {
         DateTimeOffset targetTime =
TimeZoneInfo.ConvertTime(timeToConvert, est);
         Console.WriteLine("Converted {0} to {1}.", timeToConvert,
```

```
targetTime);
        }
    }
}
// The example displays the following output:
//    Local time zone: (GMT-08:00) Pacific Time (US & Canada)
//
//    Converted 1/1/2010 12:01:00 AM -08:00 to 1/1/2010 3:01:00 AM
-05:00.
//    Converted 1/1/2010 12:01:00 AM +00:00 to 12/31/2009 7:01:00 PM
-05:00.
//    Converted 11/6/2010 11:30:00 PM -07:00 to 11/7/2010 1:30:00 AM
-05:00.
//    Converted 11/7/2010 2:30:00 AM -08:00 to 11/7/2010 5:30:00 AM
-05:00.
```

Remarks

When performing the conversion, the ConvertTime(DateTimeOffset, TimeZoneInfo) method applies any adjustment rules in effect in the `destinationTimeZone` time zone.

This overload differs from the other overloads of the ConvertTime method by accepting a DateTimeOffset value as its first parameter. This identifies the date and time as an offset from Coordinated Universal Time (UTC) rather than as the date and time in a particular time zone. As a result, the `dateTimeOffset` parameter cannot represent either an ambiguous time or an invalid time.

In converting the `dateTimeOffset` value to the time in the destination time zone, this method takes into account any adjustment rules in effect in the destination time zone.

If the conversion of `dateTimeOffset` results in a date and time value that is earlier than DateTimeOffset.MinValue or later than DateTimeOffset.MaxValue, this method returns DateTimeOffset.MinValue or DateTimeOffset.MaxValue, respectively.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo)

Converts a time from one time zone to another.

C#

```
public static DateTime ConvertTime (DateTime dateTime, TimeZoneInfo
sourceTimeZone, TimeZoneInfo destinationTimeZone);
```

Parameters

`dateTime` DateTime

The date and time to convert.

`sourceTimeZone` TimeZoneInfo

The time zone of `dateTime`.

`destinationTimeZone` TimeZoneInfo

The time zone to convert `dateTime` to.

Returns

DateTime

The date and time in the destination time zone that corresponds to the `dateTime` parameter in the source time zone.

Exceptions

ArgumentException

The Kind property of the `dateTime` parameter is Local, but the `sourceTimeZone` parameter does not equal Local.

-or-

The Kind property of the `dateTime` parameter is Utc, but the `sourceTimeZone` parameter does not equal Utc.

-or-

The `dateTime` parameter is an invalid time (that is, it represents a time that does not exist because of a time zone's adjustment rules).

ArgumentNullException

The `sourceTimeZone` parameter is `null`.

-or-

The `destinationTimeZone` parameter is `null`.

Examples

The following example illustrates the use of the ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo) method to convert from Hawaiian Standard Time to local time.

C#

```
DateTime hwTime = new DateTime(2007, 02, 01, 08, 00, 00);
try
{
   TimeZoneInfo hwZone = TimeZoneInfo.FindSystemTimeZoneById("Hawaiian
Standard Time");
   Console.WriteLine("{0} {1} is {2} local time.",
           hwTime,
           hwZone.IsDaylightSavingTime(hwTime) ? hwZone.DaylightName :
hwZone.StandardName,
           TimeZoneInfo.ConvertTime(hwTime, hwZone, TimeZoneInfo.Local));
}
catch (TimeZoneNotFoundException)
{
   Console.WriteLine("The registry does not define the Hawaiian Standard
Time zone.");
}
catch (InvalidTimeZoneException)
{
   Console.WriteLine("Registry data on the Hawaiian Standard Time zone
```

```
has been corrupted.");
}
```

Remarks

When performing the conversion, the ConvertTime method applies any adjustment rules in effect in the `destinationTimeZone` time zone.

The value of the Kind property of the `dateTime` parameter must correspond to the `sourceTimeZone` parameter, as the following table shows.

Expand table

DateTime.Kind value	sourceTimeZone value	Method behavior
DateTimeKind.Utc	Equals TimeZoneInfo.Utc.	Converts `dateTime` to the destination time zone's time.
DateTimeKind.Utc	Does not equal TimeZoneInfo.Utc.	Throws an ArgumentException.
DateTimeKind.Local	Equals TimeZoneInfo.Local.	Converts `dateTime` to the destination time zone's time.
DateTimeKind.Local	Does not equal TimeZoneInfo.Local.	Throws an ArgumentException.
DateTimeKind.Unspecified	Any.	Converts `dateTime` to the destination time zone's time.

You can also convert to or from Coordinated Universal Time (UTC) by calling the ConvertTimeFromUtc and ConvertTimeToUtc methods.

The Kind property of the returned DateTime value is set as shown in the following table.

Expand table

Condition	Returned Kind property value
The `destinationTimeZone` argument is TimeZoneInfo.Utc.	DateTimeKind.Utc
The `destinationTimeZone` argument is TimeZoneInfo.Local.	DateTimeKind.Local
All other date and time values, source time zones, and	DateTimeKind.Unspecified

Condition	Returned Kind property value
destination time zones.	

If the value of the `dateTime` parameter is an ambiguous time in the source time zone, it is interpreted as a standard time. If the `dateTime` parameter is an invalid time in the source time zone, this method throws an ArgumentException.

If the conversion of `dateTime` results in a date and time value that is earlier than DateTime.MinValue or later than DateTime.MaxValue, this method returns DateTime.MinValue or DateTime.MaxValue, respectively.

The ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo) method throws an ArgumentException exception if the DateTime.Kind property of the `dateTime` argument is DateTimeKind.Local but the `sourceTimeZone` argument is not TimeZoneInfo.Local. To determine whether the source time zone is the local time zone or the universal time zone, the method tests for reference equality instead of testing for value equality with the Equals(TimeZoneInfo) method. Note that TimeZoneInfo objects that represent the local time zone and that are retrieved by calling the FindSystemTimeZoneById method do not have referential equality with TimeZoneInfo.Local. Furthermore, TimeZoneInfo objects that represent the local or universal time zone and that are retrieved by iterating the collection returned by the GetSystemTimeZones method do not have referential equality with TimeZoneInfo.Local or TimeZoneInfo.Utc. As an alternative, you can call the ConvertTimeBySystemTimeZoneId(DateTime, String, String) method.

TimeZoneInfo.ConvertTimeBySystemTimeZoneId Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a time to the time in another time zone based on a time zone identifier.

Overloads

Expand table

ConvertTimeBySystemTimeZoneId(DateTime, String)	Converts a time to the time in another time zone based on the time zone's identifier.
ConvertTimeBySystemTimeZoneId(DateTimeOffset, String)	Converts a time to the time in another time zone based on the time zone's identifier.
ConvertTimeBySystemTimeZoneId(DateTime, String, String)	Converts a time from one time zone to another based on time zone identifiers.

ConvertTimeBySystemTimeZoneId(DateTime, String)

Converts a time to the time in another time zone based on the time zone's identifier.

C#

```
public static DateTime ConvertTimeBySystemTimeZoneId (DateTime dateTime,
string destinationTimeZoneId);
```

Parameters

dateTime DateTime

The date and time to convert.

`destinationTimeZoneId` String

The identifier of the destination time zone.

Returns

DateTime

The date and time in the destination time zone.

Exceptions

ArgumentNullException

`destinationTimeZoneId` is `null`.

InvalidTimeZoneException

The time zone identifier was found, but the registry data is corrupted.

SecurityException

The process does not have the permissions required to read from the registry key that contains the time zone information.

TimeZoneNotFoundException

The `destinationTimeZoneId` identifier was not found on the local system.

Remarks

When performing the conversion, the ConvertTimeBySystemTimeZoneId method applies any adjustment rules in effect in the `destinationTimeZoneId` time zone.

This overload is largely identical to calling the ConvertTime(DateTime, TimeZoneInfo) method, except that it allows you to specify the destination time zone by its identifier rather than by an object reference. This method is most useful when you must convert a time without retrieving the time zone object that corresponds to it and you do not need to know whether the converted time is standard or daylight saving time.

The ConvertTimeBySystemTimeZoneId(DateTime, String) method determines the source time zone from the value of the `dateTime` parameter's Kind property, as the following table shows.

Expand table

Kind property value	Source time zone	Method behavior
DateTimeKind.Local	Local	Converts the local time to the time in `destinationTimeZone`.
DateTimeKind.Utc	Utc	Converts Coordinated Universal Time (UTC) to the time in `destinationTimeZone`.
DateTimeKind.Unspecified	Assumed to be Local.	Converts the local time to the time in `destinationTimeZone`.

The Kind property of the returned DateTime value is set as shown in the following table.

Expand table

Condition	Returned Kind property value
The `destinationTimeZone` is `TimeZoneInfo.Utc.Id`.	DateTimeKind.Utc
Any other `destinationTimeZone` value.	DateTimeKind.Unspecified

If the value of the `dateTime` parameter is an ambiguous local time, it is interpreted as a standard time. If the `dateTime` parameter is an invalid local time, this method throws an ArgumentException.

If the conversion of `dateTime` results in a date and time value that is earlier than DateTime.MinValue or later than DateTime.MaxValue, this method returns DateTime.MinValue or DateTime.MaxValue, respectively.

This method retrieves information on the time zone whose identifier is specified by the `destinationTimeZoneId` parameter from the registry on Windows systems and from the ICU Library on Linux and macOS. It cannot retrieve a time zone object that is created using the CreateCustomTimeZone method. The `destinationTimeZoneId` parameter must correspond exactly to the time zone's identifier in length, but not in case, for a successful match to occur; that is, the comparison of `destinationTimeZoneId` with time zone identifiers is case-insensitive.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ConvertTimeBySystemTimeZoneId(DateTimeOffset, String)

Converts a time to the time in another time zone based on the time zone's identifier.

C#

```
public static DateTimeOffset ConvertTimeBySystemTimeZoneId
(DateTimeOffset dateTimeOffset, string destinationTimeZoneId);
```

Parameters

`dateTimeOffset` DateTimeOffset

The date and time to convert.

`destinationTimeZoneId` String

The identifier of the destination time zone.

Returns

DateTimeOffset

The date and time in the destination time zone.

Exceptions

ArgumentNullException

`destinationTimeZoneId` is `null`.

InvalidTimeZoneException

The time zone identifier was found but the registry data is corrupted.

SecurityException
The process does not have the permissions required to read from the registry key that contains the time zone information.

TimeZoneNotFoundException
The `destinationTimeZoneId` identifier was not found on the local system.

Remarks

When performing the conversion, the ConvertTimeBySystemTimeZoneId method applies any adjustment rules in effect in the `destinationTimeZoneId` time zone.

This overload is identical to calling the ConvertTime(DateTimeOffset, TimeZoneInfo) method, except that it allows you to specify the destination time zone by its identifier rather than by an object reference. This method is most useful when you must convert a time without retrieving the time zone object that corresponds to it and you do not need to know whether the converted time is standard or daylight saving time.

Because the `dateTimeOffset` parameter represents a date and time together with that time's offset from Coordinated Universal Time (UTC), it cannot represent either an ambiguous time or an invalid time.

This method retrieves the time zone whose identifier is specified by the `destinationTimeZoneId` parameter from the registry on Windows systems and from the ICU Library on Linux and macOS. It cannot retrieve a time zone object that is created using the CreateCustomTimeZone method. The `destinationTimeZoneId` parameter must correspond exactly to the time zone's identifier in length, but not in case, for a successful match to occur; that is, the comparison of `destinationTimeZoneId` with time zone identifiers is case-insensitive.

In converting the `dateTimeOffset` value to the time in the destination time zone, the method takes into account any adjustment rules in effect in the destination time zone.

If the conversion of `dateTimeOffset` results in a date and time value that is earlier than DateTimeOffset.MinValue or later than DateTimeOffset.MaxValue, this method returns DateTimeOffset.MinValue or DateTimeOffset.MaxValue, respectively.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ConvertTimeBySystemTimeZoneId(DateTime, String, String)

Converts a time from one time zone to another based on time zone identifiers.

C#

```
public static DateTime ConvertTimeBySystemTimeZoneId (DateTime dateTime,
string sourceTimeZoneId, string destinationTimeZoneId);
```

Parameters

`dateTime` DateTime

The date and time to convert.

`sourceTimeZoneId` String

The identifier of the source time zone.

`destinationTimeZoneId` String

The identifier of the destination time zone.

Returns

DateTime

The date and time in the destination time zone that corresponds to the `dateTime` parameter in the source time zone.

Exceptions

ArgumentException

The Kind property of the `dateTime` parameter does not correspond to the source time zone.

-or-

`dateTime` is an invalid time in the source time zone.

ArgumentNullException

`sourceTimeZoneId` is `null`.

-or-

`destinationTimeZoneId` is `null`.

InvalidTimeZoneException

The time zone identifiers were found, but the registry data is corrupted.

SecurityException

The user does not have the permissions required to read from the registry keys that hold time zone data.

TimeZoneNotFoundException

The `sourceTimeZoneId` identifier was not found on the local system.

-or-

The `destinationTimeZoneId` identifier was not found on the local system.

Examples

The following example uses the TimeZoneInfo.ConvertTimeBySystemTimeZoneId(DateTime, String, String) method to display the time that corresponds to the local system time in eight cities of the world.

```
C#
```

```
DateTime currentTime = DateTime.Now;
Console.WriteLine("Current Times:");
Console.WriteLine();
Console.WriteLine("Los Angeles: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "Pacific Standard Time"));
Console.WriteLine("Chicago: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "Central Standard Time"));
Console.WriteLine("New York: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "Eastern Standard Time"));
Console.WriteLine("London: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "GMT Standard Time"));
Console.WriteLine("Moscow: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "Russian Standard Time"));
Console.WriteLine("New Delhi: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "India Standard Time"));
Console.WriteLine("Beijing: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "China Standard Time"));
Console.WriteLine("Tokyo: {0}",
                  TimeZoneInfo.ConvertTimeBySystemTimeZoneId(currentTime,
TimeZoneInfo.Local.Id, "Tokyo Standard Time"));
```

Remarks

When performing the conversion, the ConvertTimeBySystemTimeZoneId method applies any adjustment rules in effect in the `destinationTimeZoneId` time zone.

Although it is similar to the TimeZoneInfo.ConvertTime(DateTime, TimeZoneInfo, TimeZoneInfo) method, you can use TimeZoneInfo.ConvertTimeBySystemTimeZoneId(DateTime, String, String) to specify the source and destination time zones using their identifiers instead of their TimeZoneInfo objects. This method is most useful when you must convert a time without retrieving the time zone object that corresponds to it and you do not need to know whether the converted time is standard or daylight saving time.

This method retrieves the time zones whose identifiers are the `sourceTimeZoneId` and `destinationTimeZoneId` parameters from the registry on Windows systems and from the ICU Library on Linux and macOS. It cannot retrieve time zone objects that are created using the CreateCustomTimeZone method.

The value of the Kind property of the `dateTime` parameter must correspond to the `sourceTimeZoneId` parameter, as the following table shows.

Expand table

DateTime.Kind value	sourceTimeZone value	Method behavior
DateTimeKind.Utc	Equals `TimeZoneInfo.Utc.Id`.	Converts `dateTime` to the destination time zone's time.
DateTimeKind.Utc	Does not equal `TimeZoneInfo.Utc.Id`.	Throws an ArgumentException.
DateTimeKind.Local	Equals `TimeZoneInfo.Local.Id`.	Converts `dateTime` to the destination time zone's time.
DateTimeKind.Local	Does not equal `TimeZoneInfo.Local.Id`.	Throws an ArgumentException.
DateTimeKind.Unspecified	Any.	Converts `dateTime` to the destination time zone's time.

Because it relies on calls to the FindSystemTimeZoneById method, the ConvertTimeBySystemTimeZoneId method performs a case-insensitive search to locate the time zones that correspond to `sourceTimeZoneId` and `destinationTimeZoneId`.

If the value of the `dateTime` parameter is an ambiguous time in the source time zone, it is interpreted as a standard time. If the `dateTime` parameter is an invalid time in the source time zone, this method throws an ArgumentException.

The Kind property of the returned DateTime value is set to DateTimeKind.Unspecified unless the destination time zone is Coordinated Universal Time (UTC), in which case it is set to DateTimeKind.Utc.

TimeZoneInfo.ConvertTimeFromUtc(DateTime, TimeZoneInfo) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a Coordinated Universal Time (UTC) to the time in a specified time zone.

C#

```
public static DateTime ConvertTimeFromUtc (DateTime dateTime, TimeZoneInfo
destinationTimeZone);
```

Parameters

`dateTime` DateTime

The Coordinated Universal Time (UTC).

`destinationTimeZone` TimeZoneInfo

The time zone to convert `dateTime` to.

Returns

DateTime

The date and time in the destination time zone. Its Kind property is Utc if `destinationTimeZone` is Utc; otherwise, its Kind property is Unspecified.

Exceptions

ArgumentException

The Kind property of `dateTime` is Local.

ArgumentNullException

`destinationTimeZone` is `null`.

Examples

The following example converts Coordinated Universal Time (UTC) to Central Time.

C#

```
DateTime timeUtc = DateTime.UtcNow;
try
{
   TimeZoneInfo cstZone = TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time");
   DateTime cstTime = TimeZoneInfo.ConvertTimeFromUtc(timeUtc, cstZone);
   Console.WriteLine("The date and time are {0} {1}.",
                     cstTime,
                     cstZone.IsDaylightSavingTime(cstTime) ?
                             cstZone.DaylightName : cstZone.StandardName);
}
catch (TimeZoneNotFoundException)
{
   Console.WriteLine("The registry does not define the Central Standard Time
zone.");
}
catch (InvalidTimeZoneException)
{
   Console.WriteLine("Registry data on the Central Standard Time zone has
been corrupted.");
}
```

Remarks

When performing the conversion, the ConvertTimeFromUtc method applies any adjustment rules in effect in the `destinationTimeZone` time zone.

The precise behavior of this method depends on the value of the Kind property of the `dateTime` parameter, as the following table shows.

Expand table

DateTime.Kind property	Conversion
DateTimeKind.Local	Throws an ArgumentException.
DateTimeKind.Unspecified or DateTimeKind.Utc	Converts from Coordinated Universal Time (UTC).

If the conversion of `dateTime` results in a date and time value that is earlier than DateTime.MinValue or later than DateTime.MaxValue, this method returns

DateTime.MinValue or DateTime.MaxValue, respectively.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneInfo.ConvertTimeToUtc Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a date and time to Coordinated Universal Time (UTC).

Overloads

Expand table

ConvertTimeToUtc(DateTime)	Converts the specified date and time to Coordinated Universal Time (UTC).
ConvertTimeToUtc(DateTime, TimeZoneInfo)	Converts the time in a specified time zone to Coordinated Universal Time (UTC).

ConvertTimeToUtc(DateTime)

Converts the specified date and time to Coordinated Universal Time (UTC).

C#

```
public static DateTime ConvertTimeToUtc (DateTime dateTime);
```

Parameters

`dateTime` DateTime

The date and time to convert.

Returns

DateTime

The Coordinated Universal Time (UTC) that corresponds to the `dateTime` parameter. The DateTime value's Kind property is always set to Utc.

Exceptions

ArgumentException

`TimeZoneInfo.Local.IsInvalidDateTime( dateTime )` returns `true`.

Examples

The following example illustrates the conversion of time values whose Kind property is DateTimeKind.Utc, DateTimeKind.Local, and DateTimeKind.Unspecified, respectively. It also illustrates the conversion of ambiguous and invalid times.

C#

```
DateTime datNowLocal = DateTime.Now;
Console.WriteLine("Converting {0}, Kind {1}:", datNowLocal,
datNowLocal.Kind);
Console.WriteLine("   ConvertTimeToUtc: {0}, Kind {1}",
TimeZoneInfo.ConvertTimeToUtc(datNowLocal),
TimeZoneInfo.ConvertTimeToUtc(datNowLocal).Kind);
Console.WriteLine();

DateTime datNowUtc = DateTime.UtcNow;
Console.WriteLine("Converting {0}, Kind {1}", datNowUtc, datNowUtc.Kind);
Console.WriteLine("   ConvertTimeToUtc: {0}, Kind {1}",
TimeZoneInfo.ConvertTimeToUtc(datNowUtc),
TimeZoneInfo.ConvertTimeToUtc(datNowUtc).Kind);
Console.WriteLine();

DateTime datNow = new DateTime(2007, 10, 26, 13, 32, 00);
Console.WriteLine("Converting {0}, Kind {1}", datNow, datNow.Kind);
Console.WriteLine("   ConvertTimeToUtc: {0}, Kind {1}",
TimeZoneInfo.ConvertTimeToUtc(datNow),
TimeZoneInfo.ConvertTimeToUtc(datNow).Kind);
Console.WriteLine();

DateTime datAmbiguous = new DateTime(2007, 11, 4, 1, 30, 00);
Console.WriteLine("Converting {0}, Kind {1}, Ambiguous {2}",
datAmbiguous, datAmbiguous.Kind,
TimeZoneInfo.Local.IsAmbiguousTime(datAmbiguous));
Console.WriteLine("   ConvertTimeToUtc: {0}, Kind {1}",
TimeZoneInfo.ConvertTimeToUtc(datAmbiguous),
TimeZoneInfo.ConvertTimeToUtc(datAmbiguous).Kind);
Console.WriteLine();

DateTime datInvalid = new DateTime(2007, 3, 11, 02, 30, 00);
Console.WriteLine("Converting {0}, Kind {1}, Invalid {2}", datInvalid,
datInvalid.Kind, TimeZoneInfo.Local.IsInvalidTime(datInvalid));
```

```
try
{
   Console.WriteLine("   ConvertTimeToUtc: {0}, Kind {1}",
TimeZoneInfo.ConvertTimeToUtc(datInvalid),
TimeZoneInfo.ConvertTimeToUtc(datInvalid).Kind);
}
catch (ArgumentException e)
{
   Console.WriteLine("   {0}: Cannot convert {1} to UTC.",
e.GetType().Name, datInvalid);
}
Console.WriteLine();

DateTime datNearMax = new DateTime(9999, 12, 31, 22, 00, 00);
Console.WriteLine("Converting {0}, Kind {1}", datNearMax,
datNearMax.Kind);
Console.WriteLine("   ConvertTimeToUtc: {0}, Kind {1}",
TimeZoneInfo.ConvertTimeToUtc(datNearMax),
TimeZoneInfo.ConvertTimeToUtc(datNearMax).Kind);
Console.WriteLine();
//
// This example produces the following output if the local time zone
// is Pacific Standard Time:
//
//    Converting 8/31/2007 2:26:28 PM, Kind Local:
//       ConvertTimeToUtc: 8/31/2007 9:26:28 PM, Kind Utc
//
//    Converting 8/31/2007 9:26:28 PM, Kind Utc
//       ConvertTimeToUtc: 8/31/2007 9:26:28 PM, Kind Utc
//
//    Converting 10/26/2007 1:32:00 PM, Kind Unspecified
//       ConvertTimeToUtc: 10/26/2007 8:32:00 PM, Kind Utc
//
//    Converting 11/4/2007 1:30:00 AM, Kind Unspecified, Ambiguous True
//       ConvertTimeToUtc: 11/4/2007 9:30:00 AM, Kind Utc
//
//    Converting 3/11/2007 2:30:00 AM, Kind Unspecified, Invalid True
//       ArgumentException: Cannot convert 3/11/2007 2:30:00 AM to UTC.
//
//    Converting 12/31/9999 10:00:00 PM, Kind Unspecified
//       ConvertTimeToUtc: 12/31/9999 11:59:59 PM, Kind Utc
//
```

Remarks

The exact conversion performed depends on the value of the Kind property of the `dateTime` parameter, as the following table shows.

Expand table

DateTime.Kind property	Conversion
DateTimeKind.Local	Converts from local time to Coordinated Universal Time (UTC).
DateTimeKind.Unspecified	Assumes `dateTime` is local time and converts from local time to UTC.
DateTimeKind.Utc	Returns `dateTime` unchanged.

If `dateTime` corresponds to an ambiguous local time, this method assumes that it is standard local time. If `dateTime` corresponds to an invalid local time, the method throws an ArgumentException.

> ⓘ **Note**
>
> If the current computer's local time zone includes multiple adjustment rules, this overload of the **ConvertTimeToUtc** method can return results that differ from the **TimeZone.ToUniversalTime** and **DateTime.ToUniversalTime** methods. **TimeZone.ToUniversalTime** always applies the current adjustment rule to time zone conversion, whether or not `dateTime` lies within its date range. And when executing on .NET Framework 3.5, **DateTime.ToUniversalTime** also applies the current adjustment rule to time zone conversion, whether or not `dateTime` lies within its date range.

If the UTC equivalent of `dateTime` is earlier than DateTime.MinValue or later that DateTime.MaxValue, this method returns MinValue or MaxValue, respectively.

See also

- Converting Times Between Time Zones

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ConvertTimeToUtc(DateTime, TimeZoneInfo)

Converts the time in a specified time zone to Coordinated Universal Time (UTC).

```
C#

public static DateTime ConvertTimeToUtc (DateTime dateTime, TimeZoneInfo
sourceTimeZone);
```

Parameters

`dateTime` DateTime

The date and time to convert.

`sourceTimeZone` TimeZoneInfo

The time zone of `dateTime`.

Returns

DateTime

The Coordinated Universal Time (UTC) that corresponds to the `dateTime` parameter. The DateTime object's Kind property is always set to Utc.

Exceptions

ArgumentException

`dateTime.Kind` is Utc and `sourceTimeZone` does not equal Utc.

-or-

`dateTime.Kind` is Local and `sourceTimeZone` does not equal Local.

-or-

`sourceTimeZone.IsInvalidDateTime( dateTime )` returns `true`.

ArgumentNullException

`sourceTimeZone` is `null`.

Examples

The following example retrieves the current date from the local system and converts it to Coordinated Universal Time (UTC), then converts it to Tokyo Standard Time, and finally converts from Tokyo Standard Time back to UTC. Note that the two UTC times are identical.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get time in local time zone
      DateTime thisTime = DateTime.Now;
      Console.WriteLine("Time in {0} zone: {1}",
TimeZoneInfo.Local.IsDaylightSavingTime(thisTime) ?
                        TimeZoneInfo.Local.DaylightName :
TimeZoneInfo.Local.StandardName, thisTime);
      Console.WriteLine("   UTC Time: {0}",
TimeZoneInfo.ConvertTimeToUtc(thisTime, TimeZoneInfo.Local));
      // Get Tokyo Standard Time zone
      TimeZoneInfo tst = TimeZoneInfo.FindSystemTimeZoneById("Tokyo
Standard Time");
      DateTime tstTime = TimeZoneInfo.ConvertTime(thisTime,
TimeZoneInfo.Local, tst);
      Console.WriteLine("Time in {0} zone: {1}",
tst.IsDaylightSavingTime(tstTime) ?
                        tst.DaylightName : tst.StandardName, tstTime);
      Console.WriteLine("   UTC Time: {0}",
TimeZoneInfo.ConvertTimeToUtc(tstTime, tst));
   }
}
// The example displays output like the following when run on a system in
the
// U.S. Pacific Standard Time zone:
//       Time in Pacific Standard Time zone: 12/6/2013 10:57:51 AM
//          UTC Time: 12/6/2013 6:57:51 PM
//       Time in Tokyo Standard Time zone: 12/7/2013 3:57:51 AM
//          UTC Time: 12/6/2013 6:57:51 PM
```

Remarks

If the Kind property of the `dateTime` parameter equals DateTimeKind.Utc and the `sourceTimeZone` parameter equals TimeZoneInfo.Utc, this method returns `dateTime` without performing any conversion.

If `dateTime` corresponds to an ambiguous time, this method assumes that it is the standard time of the source time zone. If `dateTime` corresponds to an invalid time,

this method throws an ArgumentException.

If the Coordinated Universal Time (UTC) equivalent of `dateTime` is earlier than DateTime.MinValue or later that DateTime.MaxValue, this method returns MinValue or MaxValue, respectively.

TimeZoneInfo.CreateCustomTimeZone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a time zone that is not found on the local computer.

Overloads

Expand table

CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[], Boolean)	Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, a standard time name, a daylight saving time name, daylight saving time rules, and a value that indicates whether the returned object reflects daylight saving time information.
CreateCustomTimeZone(String, TimeSpan, String, String)	Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, and a standard time display name.
CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[])	Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, a standard time name, a daylight saving time name, and daylight saving time rules.

CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[], Boolean)

Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, a standard time name, a daylight saving time name, daylight saving time rules, and a value that indicates whether the returned object reflects daylight saving time information.

```
C#

public static TimeZoneInfo CreateCustomTimeZone (string id, TimeSpan
baseUtcOffset, string? displayName, string? standardDisplayName, string?
daylightDisplayName, TimeZoneInfo.AdjustmentRule[]? adjustmentRules, bool
disableDaylightSavingTime);
```

Parameters

`id` String

The time zone's identifier.

`baseUtcOffset` TimeSpan

A TimeSpan object that represents the time difference between this time zone and Coordinated Universal Time (UTC).

`displayName` String

The display name of the new time zone.

`standardDisplayName` String

The standard time name of the new time zone.

`daylightDisplayName` String

The daylight saving time name of the new time zone.

`adjustmentRules` TimeZoneInfo.AdjustmentRule[]

An array of TimeZoneInfo.AdjustmentRule objects that augment the base UTC offset for a particular period.

`disableDaylightSavingTime` Boolean

`true` to discard any daylight saving time-related information present in `adjustmentRules` with the new object; otherwise, `false`.

Returns

TimeZoneInfo

The new time zone. If the `disableDaylightSavingTime` parameter is `true`, the returned object has no daylight saving time data.

Exceptions

ArgumentNullException

The `id` parameter is `null`.

ArgumentException

The `id` parameter is an empty string ("").

-or-

The `baseUtcOffset` parameter does not represent a whole number of minutes.

ArgumentOutOfRangeException

The `baseUtcOffset` parameter is greater than 14 hours or less than -14 hours.

InvalidTimeZoneException

The adjustment rules specified in the `adjustmentRules` parameter overlap.

-or-

The adjustment rules specified in the `adjustmentRules` parameter are not in chronological order.

-or-

One or more elements in `adjustmentRules` are `null`.

-or-

A date can have multiple adjustment rules applied to it.

-or-

The sum of the `baseUtcOffset` parameter and the DaylightDelta value of one or more objects in the `adjustmentRules` array is greater than 14 hours or less than -14 hours.

Examples

The following example creates a custom time zone for the Palmer station and Anvers Island in Antarctica. It sets the `disableDaylightSavingTime` parameter in the call to the TimeZoneInfo.CreateCustomTimeZone method to `true`. It then displays the new time zone's daylight saving time name, if one is present, and the number of adjustment rules to confirm that the new time zone has no daylight saving time information.

C#

```
// Define transition times to/from DST
TimeZoneInfo.TransitionTime startTransition, endTransition;
startTransition = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1, 4, 0, 0),
                                                                    10, 2,
DayOfWeek.Sunday);
endTransition = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1,3, 0, 0),
                                                                  3, 2,
DayOfWeek.Sunday);
// Define adjustment rule
TimeSpan delta = new TimeSpan(1, 0, 0);
TimeZoneInfo.AdjustmentRule adjustment =
TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new DateTime(1999, 10,
1),
                                        DateTime.MaxValue.Date, delta,
startTransition, endTransition);
// Create array for adjustment rules
TimeZoneInfo.AdjustmentRule[] adjustments = {adjustment};
// Define other custom time zone arguments
string displayName = "(GMT-04:00) Antarctica/Palmer Time";
string standardName = "Palmer Standard Time";
string daylightName = "Palmer Daylight Time";
TimeSpan offset = new TimeSpan(-4, 0, 0);
// Create custom time zone without copying DST information
TimeZoneInfo palmer = TimeZoneInfo.CreateCustomTimeZone(standardName,
offset, displayName, standardName,
                                                    daylightName,
adjustments, true);
// Indicate whether new time zone//s adjustment rules are present
Console.WriteLine("{0} {1}has {2} adjustment rules.",
                  palmer.StandardName,
                  ! (string.IsNullOrEmpty(palmer.DaylightName)) ?  "(" +
palmer.DaylightName + ") ": "" ,
                  palmer.GetAdjustmentRules().Length);
// Indicate whether new time zone supports DST
Console.WriteLine("{0} supports DST: {1}", palmer.StandardName,
palmer.SupportsDaylightSavingTime);
```

Remarks

You can use this overload of the TimeZoneInfo.CreateCustomTimeZone method to create a custom time zone whose support for daylight saving time can be determined by conditions at run time.

The following table shows the relationship between the parameters that are provided to the TimeZoneInfo.CreateCustomTimeZone method and the members of the TimeZoneInfo object that are returned by the method call.

Expand table

CreateCustomTimeZone parameter	TimeZoneInfo property
`id`	Id
`baseUtcOffset`	BaseUtcOffset
`displayName`	DisplayName
`standardDisplayName`	StandardName
`daylightDisplayName`	DaylightName if `disableDaylightSavingTime` is `false`; String.Empty if `disableDaylightSavingTime` is `true`.
`adjustmentRules`	An array of TimeZoneInfo.AdjustmentRule objects returned by the GetAdjustmentRules method if `disableDaylightSavingTime` is `false`; an empty array returned by the GetAdjustmentRules method if `disableDaylightSavingTime` is `true`.
`disableDaylightSavingTime`	Not SupportsDaylightSavingTime.

Typically, the time zone's standard time name and its identifier are the same. However, the length of the time zone's identifier should not exceed 32 characters. The string passed to the `displayName` parameter follows a fairly standard format. The first portion of the display name is the time zone's base offset from Coordinated Universal Time, which is indicated by the acronym GMT (for Greenwich Mean Time), enclosed in parentheses. This is followed by a string that identifies the time zone itself, or one or more of the cities, regions, or countries in the time zone, or both. For example:

```
(GMT+02:00) Athens, Beirut, Istanbul, Minsk
(GMT-02:00) Mid-Atlantic
(GMT-07:00) Mountain Time (US & Canada)
```

A time zone's adjustment rules are defined by doing the following:

1. Calling either the CreateFloatingDateRule or the CreateFixedDateRule method to define the starting and ending transition rules for each adjustment rule.
2. Calling the CreateAdjustmentRule method for each adjustment rule.
3. Assigning the adjustment rules to an array that can be passed as the `adjustmentRules` parameter.

If `disableDaylightSavingTime` parameter is `false`, the operation of this method is identical to the TimeZoneInfo.CreateCustomTimeZone overload. If `disableDaylightSavingTime` is `true`, the returned object includes no adjustment rules and a DaylightName property whose value is an empty string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateCustomTimeZone(String, TimeSpan, String, String)

Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, and a standard time display name.

C#

```
public static TimeZoneInfo CreateCustomTimeZone (string id, TimeSpan
baseUtcOffset, string? displayName, string? standardDisplayName);
```

Parameters

`id` String

The time zone's identifier.

`baseUtcOffset` TimeSpan

An object that represents the time difference between this time zone and Coordinated Universal Time (UTC).

`displayName` String

The display name of the new time zone.

`standardDisplayName` String

The name of the new time zone's standard time.

Returns

TimeZoneInfo

The new time zone.

Exceptions

ArgumentNullException

The `id` parameter is `null`.

ArgumentException

The `id` parameter is an empty string ("").

-or-

The `baseUtcOffset` parameter does not represent a whole number of minutes.

ArgumentOutOfRangeException

The `baseUtcOffset` parameter is greater than 14 hours or less than -14 hours.

Examples

The following example creates a custom time zone for the Mawson and Holme Bay regions of Antarctica. It then displays the result of converting the local time to the time in the new time zone.

```C#
string displayName = "(GMT+06:00) Antarctica/Mawson Time";
string standardName = "Mawson Time";
TimeSpan offset = new TimeSpan(06, 00, 00);
TimeZoneInfo mawson = TimeZoneInfo.CreateCustomTimeZone(standardName,
offset, displayName, standardName);
Console.WriteLine("The current time is {0} {1}",
                  TimeZoneInfo.ConvertTime(DateTime.Now,
TimeZoneInfo.Local, mawson),
                  mawson.StandardName);
```

Remarks

This overload of the CreateCustomTimeZone(String, TimeSpan, String, String) method is suitable for creating a time zone that has no adjustments (that is, a time zone that does not support daylight saving time). To define a time zone that includes adjustments for daylight saving time, use either the TimeZoneInfo.CreateCustomTimeZone or the TimeZoneInfo.CreateCustomTimeZone method.

The following table shows the relationship between the parameters that are provided to the TimeZoneInfo.CreateCustomTimeZone method and the properties of the TimeZoneInfo object that are returned by the method call.

Expand table

CreateCustomTimeZone parameter	TimeZoneInfo property
`id`	Id
`baseUtcOffset`	BaseUtcOffset
`displayName`	DisplayName
`standardDisplayName`	StandardName

Typically, the time zone's standard time name and its identifier are the same. However, the length of the time zone's identifier should not exceed 32 characters. The string passed to the `displayName` parameter follows a fairly standard format. The first portion of the display name is the time zone's base offset from Coordinated Universal Time, which is indicated by the acronym GMT (for Greenwich Mean Time), enclosed in parentheses. This is followed by a string that identifies the time zone itself, or one or more of the cities, regions, or countries in the time zone, or both. For example:

```
(GMT+02:00) Athens, Beirut, Istanbul, Minsk
(GMT-02:00) Mid-Atlantic
(GMT-07:00) Mountain Time (US & Canada)
```

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[])

Creates a custom time zone with a specified identifier, an offset from Coordinated Universal Time (UTC), a display name, a standard time name, a daylight saving time name, and daylight saving time rules.

C#

```
public static TimeZoneInfo CreateCustomTimeZone (string id, TimeSpan
baseUtcOffset, string? displayName, string? standardDisplayName, string?
daylightDisplayName, TimeZoneInfo.AdjustmentRule[]? adjustmentRules);
```

Parameters

`id` String

The time zone's identifier.

`baseUtcOffset` TimeSpan

An object that represents the time difference between this time zone and Coordinated Universal Time (UTC).

`displayName` String

The display name of the new time zone.

`standardDisplayName` String

The new time zone's standard time name.

`daylightDisplayName` String

The daylight saving time name of the new time zone.

`adjustmentRules` TimeZoneInfo.AdjustmentRule[]

An array that augments the base UTC offset for a particular period.

Returns

TimeZoneInfo

A TimeZoneInfo object that represents the new time zone.

Exceptions

ArgumentNullException

The `id` parameter is `null`.

ArgumentException

The `id` parameter is an empty string ("").

-or-

The `baseUtcOffset` parameter does not represent a whole number of minutes.

ArgumentOutOfRangeException

The `baseUtcOffset` parameter is greater than 14 hours or less than -14 hours.

InvalidTimeZoneException

The adjustment rules specified in the `adjustmentRules` parameter overlap.

-or-

The adjustment rules specified in the `adjustmentRules` parameter are not in chronological order.

-or-

One or more elements in `adjustmentRules` are `null`.

-or-

A date can have multiple adjustment rules applied to it.

-or-

The sum of the `baseUtcOffset` parameter and the DaylightDelta value of one or more objects in the `adjustmentRules` array is greater than 14 hours or less than -14 hours.

Examples

The following example creates a custom time zone for the Palmer station and Anvers Island in Antarctica. It then converts the local time to the time in the new time zone and displays the result.

C#

```
// Define transition times to/from DST
TimeZoneInfo.TransitionTime startTransition, endTransition;
startTransition = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1, 4, 0, 0),
                                                                    10, 2,
DayOfWeek.Sunday);
endTransition = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1, 3, 0, 0),
                                                                  3, 2,
DayOfWeek.Sunday);
// Define adjustment rule
TimeSpan delta = new TimeSpan(1, 0, 0);
TimeZoneInfo.AdjustmentRule adjustment;
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1999, 10, 1), DateTime.MaxValue.Date, delta, startTransition,
endTransition);
// Create array for adjustment rules
TimeZoneInfo.AdjustmentRule[] adjustments = {adjustment};
// Define other custom time zone arguments
string displayName = "(GMT-04:00) Antarctica/Palmer Time";
string standardName = "Palmer Time";
string daylightName = "Palmer Daylight Time";
TimeSpan offset = new TimeSpan(-4, 0, 0);
TimeZoneInfo palmer = TimeZoneInfo.CreateCustomTimeZone(standardName,
```

```
offset, displayName, standardName, daylightName, adjustments);
Console.WriteLine("The current time is {0} {1}",
                  TimeZoneInfo.ConvertTime(DateTime.Now,
TimeZoneInfo.Local, palmer),
                  palmer.StandardName);
```

Remarks

This overload of the TimeZoneInfo.CreateCustomTimeZone method is suitable for creating a time zone that supports daylight saving time. To define a time zone that does not support daylight saving time, use either the TimeZoneInfo.CreateCustomTimeZone or the TimeZoneInfo.CreateCustomTimeZone method.

The following table shows the relationship between the parameters that are provided to the TimeZoneInfo.CreateCustomTimeZone method and the members of the TimeZoneInfo object that are returned by the method call.

Expand table

CreateCustomTimeZone parameter	TimeZoneInfo member
`id`	Id
`baseUtcOffset`	BaseUtcOffset
`displayName`	DisplayName
`standardDisplayName`	StandardName
`daylightDisplayName`	DaylightName
`adjustmentRules`	An array of System.TimeZoneInfo.AdjustmentRule objects returned by the GetAdjustmentRules method.

Typically, the time zone's standard time name and its identifier are the same. However, the length of the time zone's identifier should not exceed 32 characters. The string passed to the `displayName` parameter follows a fairly standard format. The first portion of the display name is the time zone's base offset from Coordinated Universal Time, which is indicated by the acronym GMT (for Greenwich Mean Time), enclosed in parentheses. This is followed by a string that identifies the time zone itself, or one or more of the cities, regions, or countries in the time zone, or both. For example:

```
(GMT+02:00) Athens, Beirut, Istanbul, Minsk
(GMT-02:00) Mid-Atlantic
(GMT-07:00) Mountain Time (US & Canada)
```

The `baseUtcOffset` parameter defines the custom time zone's offset from Coordinated Universal Time (UTC) for all of the time zone's adjustment rules. In other words, the TimeZoneInfo object model assumes that the time zone's offset from UTC is constant throughout the life of the time zone, and exists independent of particular adjustment rules. To reflect a time zone that has changed its offset from UTC, you must create a new time zone object.

A time zone's adjustment rules are defined by doing the following:

1. Calling either the CreateFloatingDateRule or the CreateFixedDateRule method to define the starting and ending transition time for each adjustment rule.
2. Calling the CreateAdjustmentRule method for each adjustment rule.
3. Assigning the adjustment rules to an array that can be passed as the `adjustmentRules` parameter.

TimeZoneInfo.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two TimeZoneInfo objects are equal.

Overloads

Expand table

Equals(Object)	Determines whether the current TimeZoneInfo object and another object are equal.
Equals(TimeZoneInfo)	Determines whether the current TimeZoneInfo object and another TimeZoneInfo object are equal.

Equals(Object)

Determines whether the current TimeZoneInfo object and another object are equal.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

A second object to compare with the current object.

Returns

Boolean

`true` if `obj` is a TimeZoneInfo object that is equal to the current instance; otherwise, `false`.

Examples

The following example uses the Equals(Object) method to determine whether the local time zone is Pacific Time or Eastern Time.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      TimeZoneInfo thisTimeZone;
      object obj1, obj2;

      thisTimeZone = TimeZoneInfo.Local;
      obj1 = TimeZoneInfo.FindSystemTimeZoneById("Pacific Standard
Time");
      obj2 = TimeZoneInfo.FindSystemTimeZoneById("Eastern Standard
Time");
      Console.WriteLine(thisTimeZone.Equals(obj1));
      Console.WriteLine(thisTimeZone.Equals(obj2));
   }
}
// The example displays the following output:
//      True
//      False
```

Remarks

This method converts or casts `obj` to a TimeZoneInfo object and compares it with the current instance. The test for equality is based on a comparison of values. The current TimeZoneInfo instance and `obj` are considered to be equal under the following conditions:

- The run-time type of `obj` is TimeZoneInfo.
- The two objects have the same Id property value.
- The two objects have the same adjustment rules.

If `obj` is `null`, this method returns `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(TimeZoneInfo)

Determines whether the current TimeZoneInfo object and another TimeZoneInfo object are equal.

C#

```
public bool Equals (TimeZoneInfo? other);
```

Parameters

`other` TimeZoneInfo

A second object to compare with the current object.

Returns

Boolean

`true` if the two TimeZoneInfo objects are equal; otherwise, `false`.

Implements

Equals(T)

Examples

The following example uses the Equals(TimeZoneInfo) method to determine whether the local time zone is Pacific Time or Eastern Time.

C#

```
    TimeZoneInfo thisTimeZone, zone1, zone2;

    thisTimeZone = TimeZoneInfo.Local;
    zone1 = TimeZoneInfo.FindSystemTimeZoneById("Pacific Standard Time");
```

```
    zone2 = TimeZoneInfo.FindSystemTimeZoneById("Eastern Standard Time");
    Console.WriteLine(thisTimeZone.Equals(zone1));
    Console.WriteLine(thisTimeZone.Equals(zone2));
```

Remarks

Equality is based on a comparison of values. Two TimeZoneInfo objects are considered to be equal under the following conditions:

- The value of their Id property is the same.
- They have the same adjustment rules.

TimeZoneInfo.Equals(TimeZoneInfo) returns the Boolean value that results from evaluating the following expression:

```C#
other.Id == this.Id && HasSameRules(other);
```

If the `other` parameter is an uninitialized TimeZoneInfo object, this method returns `false`.

TimeZoneInfo.FindSystemTimeZoneById(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Instantiates a new TimeZoneInfo object based on its identifier.

C#

```
public static TimeZoneInfo FindSystemTimeZoneById (string id);
```

Parameters

id String

The time zone identifier, which corresponds to the Id property.

Returns

TimeZoneInfo

An object whose identifier is the value of the `id` parameter.

Exceptions

OutOfMemoryException

The system does not have enough memory to hold information about the time zone.

ArgumentNullException

The `id` parameter is `null`.

TimeZoneNotFoundException

The time zone identifier specified by `id` was not found. This means that a time zone identifier whose name matches `id` does not exist, or that the identifier exists but does not contain any time zone data.

SecurityException

The process does not have the permissions required to read from the registry key that contains the time zone information.

InvalidTimeZoneException

The time zone identifier was found, but the registry data is corrupted.

Examples

The following example uses the FindSystemTimeZoneById method to retrieve the Tokyo Standard Time zone. This TimeZoneInfo object is then used to convert the local time to the time in Tokyo and to determine whether it is Tokyo Standard Time or Tokyo Daylight Time.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get time in local time zone
      DateTime thisTime = DateTime.Now;
      Console.WriteLine("Time in {0} zone: {1}",
TimeZoneInfo.Local.IsDaylightSavingTime(thisTime) ?
                        TimeZoneInfo.Local.DaylightName :
TimeZoneInfo.Local.StandardName, thisTime);
      Console.WriteLine("   UTC Time: {0}",
TimeZoneInfo.ConvertTimeToUtc(thisTime, TimeZoneInfo.Local));
      // Get Tokyo Standard Time zone
      TimeZoneInfo tst = TimeZoneInfo.FindSystemTimeZoneById("Tokyo Standard
Time");
      DateTime tstTime = TimeZoneInfo.ConvertTime(thisTime,
TimeZoneInfo.Local, tst);
      Console.WriteLine("Time in {0} zone: {1}",
tst.IsDaylightSavingTime(tstTime) ?
                        tst.DaylightName : tst.StandardName, tstTime);
      Console.WriteLine("   UTC Time: {0}",
TimeZoneInfo.ConvertTimeToUtc(tstTime, tst));
   }
}
// The example displays output like the following when run on a system in
the
// U.S. Pacific Standard Time zone:
//       Time in Pacific Standard Time zone: 12/6/2013 10:57:51 AM
//          UTC Time: 12/6/2013 6:57:51 PM
```

```
//       Time in Tokyo Standard Time zone: 12/7/2013 3:57:51 AM
//          UTC Time: 12/6/2013 6:57:51 PM
```

Remarks

The `id` parameter must correspond exactly to the time zone's identifier in length, but not in case, for a successful match to occur; that is, the comparison of `id` with time zone identifiers is case-insensitive. If you want to retrieve time zone objects based on partial matches, you can write custom procedures that work with the read-only collection of TimeZoneInfo objects returned by the GetSystemTimeZones method.

On Windows systems, `FindSystemTimeZoneById` tries to match `id` to the subkey names of the HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Time Zones branch of the registry. On Linux and macOS, it uses time zone information available in the ICU Library. If the registry or the library does not have the information for the time zone you desire, you can create a particular time zone either by calling one of the overloads of the CreateCustomTimeZone method or by calling FromSerializedString to deserialize a TimeZoneInfo object that represents the required time zone. However, time zones created by these method calls are not system-defined time and cannot be retrieved using the FindSystemTimeZoneById method. These custom time zones can be accessed only through the object reference returned by the CreateCustomTimeZone or FromSerializedString method call.

This method returns a new TimeZoneInfo instance for each method call; it does not return cached objects. This may impact performance in applications that call the `FindSystemTimeZoneById` method repeatedly with the same identifier.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.FromSerializedString(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Deserializes a string to re-create an original serialized TimeZoneInfo object.

```
C#
public static TimeZoneInfo FromSerializedString (string source);
```

Parameters

`source` String

The string representation of the serialized TimeZoneInfo object.

Returns

TimeZoneInfo

The original serialized object.

Exceptions

ArgumentException

The `source` parameter is Empty.

ArgumentNullException

The `source` parameter is a null string.

SerializationException

The source parameter cannot be deserialized back into a TimeZoneInfo object.

Examples

The following example tries to retrieve the Antarctica/South Pole time zone from the local system. If it fails, the code tries to retrieve information about the time zone from a text file in the application directory. If this attempt fails, the code creates the time zone and writes information about the time zone to the text file.

C#

```
private TimeZoneInfo InitializeTimeZone()
{
   TimeZoneInfo southPole = null;
   // Determine if South Pole time zone is defined in system
   try
   {
      southPole = TimeZoneInfo.FindSystemTimeZoneById("Antarctica/South Pole
Standard Time");
   }
   // Time zone does not exist; create it, store it in a text file, and
return it
   catch
   {
      const string filename = @".\TimeZoneInfo.txt";
      bool found = false;

      if (File.Exists(filename))
      {
         StreamReader reader = new StreamReader(filename);
         string timeZoneInfo;
         while (reader.Peek() >= 0)
         {
            timeZoneInfo = reader.ReadLine();
            if (timeZoneInfo.Contains("Antarctica/South Pole"))
            {
               southPole = TimeZoneInfo.FromSerializedString(timeZoneInfo);
               reader.Close();
               found = true;
               break;
            }
         }
      }
      if (! found)
      {
         // Define transition times to/from DST
         TimeZoneInfo.TransitionTime startTransition =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1, 2,
0, 0), 10, 1, DayOfWeek.Sunday);
         TimeZoneInfo.TransitionTime endTransition =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1, 2,
0, 0), 3, 3, DayOfWeek.Sunday);
         // Define adjustment rule
         TimeSpan delta = new TimeSpan(1, 0, 0);
         TimeZoneInfo.AdjustmentRule adjustment =
TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new DateTime(1989, 10, 1),
DateTime.MaxValue.Date, delta, startTransition, endTransition);
```

```
            // Create array for adjustment rules
            TimeZoneInfo.AdjustmentRule[] adjustments = {adjustment};
            // Define other custom time zone arguments
            string displayName = "(GMT+12:00) Antarctica/South Pole";
            string standardName = "Antarctica/South Pole Standard Time";
            string daylightName = "Antarctica/South Pole Daylight Time";
            TimeSpan offset = new TimeSpan(12, 0, 0);
            southPole = TimeZoneInfo.CreateCustomTimeZone(standardName, offset,
displayName, standardName, daylightName, adjustments);
            // Write time zone to the file
            StreamWriter writer = new StreamWriter(filename, true);
            writer.WriteLine(southPole.ToSerializedString());
            writer.Close();
        }
    }
    return southPole;
}
```

Remarks

There is an alternative to providing all the code required to create a time zone that is not found in the registry on Windows or in the ICU Library on Linux and macOS. You can define a custom time zone and either use the ToSerializedString method in a standalone executable or use an application's setup program to save the time zone as a string. The application can then retrieve this string from its storage location and instantiate it using the FromSerializedString method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneInfo.GetAdjustmentRules Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves an array of TimeZoneInfo.AdjustmentRule objects that apply to the current TimeZoneInfo object.

C#

```
public TimeZoneInfo.AdjustmentRule[] GetAdjustmentRules ();
```

Returns

AdjustmentRule[]

An array of objects for this time zone.

Exceptions

OutOfMemoryException

The system does not have enough memory to make an in-memory copy of the adjustment rules.

Examples

The following example retrieves all time zones that are defined on the local system and displays complete information about their adjustment rules to the console.

C#

```
private enum WeekOfMonth
{
   First = 1,
   Second = 2,
   Third = 3,
   Fourth = 4,
```

```
   Last = 5,
}

private static void ShowStartAndEndDates()
{
   // Get all time zones from system
   ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
   string[] monthNames =
CultureInfo.CurrentCulture.DateTimeFormat.MonthNames;
   // Get each time zone
   foreach (TimeZoneInfo timeZone in timeZones)
   {
      TimeZoneInfo.AdjustmentRule[] adjustments =
timeZone.GetAdjustmentRules();
      // Display message for time zones with no adjustments
      if (adjustments.Length == 0)
      {
         Console.WriteLine("{0} has no adjustment rules",
timeZone.StandardName);
      }
      else
      {
         // Handle time zones with 1 or 2+ adjustments differently
         bool showCount = false;
         int ctr = 0;
         string spacer = "";

         Console.WriteLine("{0} Adjustment rules", timeZone.StandardName);
         if (adjustments.Length > 1)
         {
            showCount = true;
            spacer = "   ";
         }
         // Iterate adjustment rules
         foreach (TimeZoneInfo.AdjustmentRule adjustment in adjustments)
         {
            if (showCount)
            {
               Console.WriteLine("   Adjustment rule #{0}", ctr+1);
               ctr++;
            }
            // Display general adjustment information
            Console.WriteLine("{0}   Start Date: {1:D}", spacer,
adjustment.DateStart);
            Console.WriteLine("{0}   End Date: {1:D}", spacer,
adjustment.DateEnd);
            Console.WriteLine("{0}   Time Change: {1}:{2:00} hours", spacer,
                              adjustment.DaylightDelta.Hours,
adjustment.DaylightDelta.Minutes);
            // Get transition start information
            TimeZoneInfo.TransitionTime transitionStart =
adjustment.DaylightTransitionStart;
            Console.Write("{0}   Annual Start: ", spacer);
            if (transitionStart.IsFixedDateRule)
```

```
            {
               Console.WriteLine("On {0} {1} at {2:t}",
                                 monthNames[transitionStart.Month - 1],
                                 transitionStart.Day,
                                 transitionStart.TimeOfDay);
            }
            else
            {
               Console.WriteLine("The {0} {1} of {2} at {3:t}",

((WeekOfMonth)transitionStart.Week).ToString(),
                                 transitionStart.DayOfWeek.ToString(),
                                 monthNames[transitionStart.Month - 1],
                                 transitionStart.TimeOfDay);
            }
            // Get transition end information
            TimeZoneInfo.TransitionTime transitionEnd =
adjustment.DaylightTransitionEnd;
            Console.Write("{0}   Annual End: ", spacer);
            if (transitionEnd.IsFixedDateRule)
            {
               Console.WriteLine("On {0} {1} at {2:t}",
                                 monthNames[transitionEnd.Month - 1],
                                 transitionEnd.Day,
                                 transitionEnd.TimeOfDay);
            }
            else
            {
               Console.WriteLine("The {0} {1} of {2} at {3:t}",

((WeekOfMonth)transitionEnd.Week).ToString(),
                                 transitionEnd.DayOfWeek.ToString(),
                                 monthNames[transitionEnd.Month - 1],
                                 transitionEnd.TimeOfDay);
            }
         }
      }
      Console.WriteLine();
   }
}
```

Remarks

The GetAdjustmentRules method retrieves an array of System.TimeZoneInfo.AdjustmentRule objects. Each object in the array defines the effective start and end date of that time zone adjustment, as well as its delta (the exact amount by which the adjustment causes the time to change). In addition, two properties return System.TimeZoneInfo.TransitionTime objects that define when each annual transition to and from standard time occurs.

If a time zone has multiple adjustment rules, they are generally ordered from earliest (at index 0) to latest (at index Length - 1).

If a time zone has no adjustment rules, the GetAdjustmentRules method returns an empty array (an array whose Length is zero).

Any modifications to the elements of the array returned by the GetAdjustmentRules method are not reflected in the adjustment rules that belong to a particular time zone. To modify a time zone's adjustment rules (such as to reflect its historical transition to and from daylight saving time) you must create a new time zone with the appropriate adjustment rules, rather than modify the existing one.

TimeZoneInfo.GetAmbiguousTime Offsets Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns information about the possible dates and times that an ambiguous date and time can be mapped to.

Overloads

Expand table

GetAmbiguousTimeOffsets(DateTime)	Returns information about the possible dates and times that an ambiguous date and time can be mapped to.
GetAmbiguousTimeOffsets(DateTimeOffset)	Returns information about the possible dates and times that an ambiguous date and time can be mapped to.

GetAmbiguousTimeOffsets(DateTime)

Returns information about the possible dates and times that an ambiguous date and time can be mapped to.

C#

```
public TimeSpan[] GetAmbiguousTimeOffsets (DateTime dateTime);
```

Parameters

`dateTime` DateTime

A date and time.

Returns

TimeSpan[]

An array of objects that represents possible Coordinated Universal Time (UTC) offsets that a particular date and time can be mapped to.

Exceptions

ArgumentException

`dateTime` is not an ambiguous time.

Examples

The following example defines a method named `ShowPossibleUtcTimes` that uses the GetAmbiguousTimeOffsets(DateTime) method to map an ambiguous time to its possible corresponding Coordinated Universal Time (UTC) times.

C#

```
private void ShowPossibleUtcTimes(DateTime ambiguousTime, TimeZoneInfo
timeZone)
{
   // Determine if time is ambiguous in target time zone
   if (! timeZone.IsAmbiguousTime(ambiguousTime))
   {
      Console.WriteLine("{0} is not ambiguous in time zone {1}.",
                        ambiguousTime,
                        timeZone.DisplayName);
   }
   else
   {
      // Display time and its time zone (local, UTC, or indicated by
timeZone argument)
      string originalTimeZoneName;
      if (ambiguousTime.Kind == DateTimeKind.Utc)
         originalTimeZoneName = "UTC";
      else if (ambiguousTime.Kind == DateTimeKind.Local)
         originalTimeZoneName = "local time";
      else
         originalTimeZoneName = timeZone.DisplayName;

      Console.WriteLine("{0} {1} maps to the following possible times:",
                        ambiguousTime, originalTimeZoneName);
      // Get ambiguous offsets
      TimeSpan[] offsets =
timeZone.GetAmbiguousTimeOffsets(ambiguousTime);
      // Handle times not in time zone of timeZone argument
      // Local time where timeZone is not local zone
      if ((ambiguousTime.Kind == DateTimeKind.Local) && !
```

```
timeZone.Equals(TimeZoneInfo.Local))
         ambiguousTime = TimeZoneInfo.ConvertTime(ambiguousTime,
TimeZoneInfo.Local, timeZone);
      // UTC time where timeZone is not UTC zone
      else if ((ambiguousTime.Kind == DateTimeKind.Utc) && !
timeZone.Equals(TimeZoneInfo.Utc))
         ambiguousTime = TimeZoneInfo.ConvertTime(ambiguousTime,
TimeZoneInfo.Utc, timeZone);

      // Display each offset and its mapping to UTC
      foreach (TimeSpan offset in offsets)
      {
         if (offset.Equals(timeZone.BaseUtcOffset))
            Console.WriteLine("If {0} is {1}, {2} UTC", ambiguousTime,
timeZone.StandardName, ambiguousTime - offset);
         else
            Console.WriteLine("If {0} is {1}, {2} UTC", ambiguousTime,
timeZone.DaylightName, ambiguousTime - offset);
      }
   }
}
```

The method can then be called using code such as the following:

C#

```
Console.WriteLine();
ShowPossibleUtcTimes(new DateTime(2007, 11, 4, 1, 0, 0),
                     TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time"));
Console.WriteLine();
ShowPossibleUtcTimes(new DateTime(2007, 11, 4, 01, 00, 00,
DateTimeKind.Local),
                     TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time"));
Console.WriteLine();
ShowPossibleUtcTimes(new DateTime(2007, 11, 4, 00, 00, 00,
DateTimeKind.Local),
                     TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time"));
Console.WriteLine();
ShowPossibleUtcTimes(new DateTime(2007, 11, 4, 01, 00, 00,
DateTimeKind.Unspecified),
                     TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time"));
Console.WriteLine();
ShowPossibleUtcTimes(new DateTime(2007, 11, 4, 07, 00, 00,
DateTimeKind.Utc),
                     TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time"));
//
// This example produces the following output if run in the Pacific time
zone:
```

```
//
//    11/4/2007 1:00:00 AM (GMT-06:00) Central Time (US & Canada) maps to
the following possible times:
//    If 11/4/2007 1:00:00 AM is Central Standard Time, 11/4/2007 7:00:00
AM UTC
//    If 11/4/2007 1:00:00 AM is Central Daylight Time, 11/4/2007 6:00:00
AM UTC
//
//    11/4/2007 1:00:00 AM Pacific Standard Time is not ambiguous in time
zone (GMT-06:00) Central Time (US & Canada).
//
//    11/4/2007 12:00:00 AM local time maps to the following possible
times:
//    If 11/4/2007 1:00:00 AM is Central Standard Time, 11/4/2007 7:00:00
AM UTC
//    If 11/4/2007 1:00:00 AM is Central Daylight Time, 11/4/2007 6:00:00
AM UTC
//
//    11/4/2007 1:00:00 AM (GMT-06:00) Central Time (US & Canada) maps to
the following possible times:
//    If 11/4/2007 1:00:00 AM is Central Standard Time, 11/4/2007 7:00:00
AM UTC
//    If 11/4/2007 1:00:00 AM is Central Daylight Time, 11/4/2007 6:00:00
AM UTC
//
//    11/4/2007 7:00:00 AM UTC maps to the following possible times:
//    If 11/4/2007 1:00:00 AM is Central Standard Time, 11/4/2007 7:00:00
AM UTC
//    If 11/4/2007 1:00:00 AM is Central Daylight Time, 11/4/2007 6:00:00
AM UTC
//
```

Remarks

The precise behavior of this method depends on the relationship between the Kind property and the TimeZoneInfo object, as the following table shows.

Expand table

TimeZoneInfo object type	Kind property value	Behavior
TimeZoneInfo.Local	DateTimeKind.Local or DateTimeKind.Unspecified	Returns ambiguous time offsets for `dateTime`.
TimeZoneInfo.Local	DateTimeKind.Utc	Converts `dateTime` to the local time, and then returns ambiguous time offsets for that time.
TimeZoneInfo.Utc	Any value.	Throws an ArgumentException.

TimeZoneInfo object type	Kind property value	Behavior
Any other time zone.	Local or DateTimeKind.Utc	Converts `dateTime` to the specified time zone, and then determines whether that time is ambiguous.
Any other time zone.	DateTimeKind.Unspecified	Determines whether `dateTime` is ambiguous in the specified time zone.

The order of TimeSpan objects in the array returned by this method is undefined. However, you can determine which element represents an offset from the time zone's standard time by comparing its value with the time zone's BaseUtcOffset property. To map an ambiguous time to a time zone's standard time, see How to: Resolve Ambiguous Times.

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetAmbiguousTimeOffsets(DateTimeOffset)

Returns information about the possible dates and times that an ambiguous date and time can be mapped to.

```C#
public TimeSpan[] GetAmbiguousTimeOffsets (DateTimeOffset
dateTimeOffset);
```

Parameters

`dateTimeOffset` DateTimeOffset

A date and time.

Returns

TimeSpan[]

An array of objects that represents possible Coordinated Universal Time (UTC) offsets that a particular date and time can be mapped to.

Exceptions

ArgumentException

`dateTimeOffset` is not an ambiguous time.

Remarks

The precise behavior of this method depends on the relationship between the Offset property of the `dateTimeOffset` parameter and the TimeZoneInfo object. If the value of the Offset property corresponds to the current time zone's possible offsets from Coordinated Universal Time (UTC) for that date and time, the method returns the possible offsets. Otherwise, it converts `dateTimeOffset` to the time in the current time zone, and then returns the possible offsets of that date and time.

The order of TimeSpan objects in the array returned by this method is undefined. However, you can determine which element represents an offset from the time zone's standard time by comparing its value with the time zone's BaseUtcOffset property. To map an ambiguous time to a time zone's standard time, see How to: Resolve Ambiguous Times.

TimeZoneInfo.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as a hash function for hashing algorithms and data structures such as hash tables.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer that serves as the hash code for this TimeZoneInfo object.

Remarks

For additional detail about the GetHashCode method, see GetHashCode.

TimeZoneInfo.GetSystemTimeZones Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetSystemTimeZones()	Returns a sorted collection of all the time zones about which information is available on the local system.
GetSystemTimeZones(Boolean)	Returns a ReadOnlyCollection<T> containing all valid TimeZone's from the local machine. This method does *not* throw TimeZoneNotFoundException or InvalidTimeZoneException.

GetSystemTimeZones()

Returns a sorted collection of all the time zones about which information is available on the local system.

C#

```
public static
System.Collections.ObjectModel.ReadOnlyCollection<TimeZoneInfo>
GetSystemTimeZones ();
```

Returns

ReadOnlyCollection<TimeZoneInfo>

A read-only collection of TimeZoneInfo objects.

Exceptions

OutOfMemoryException

There is insufficient memory to store all time zone information.

SecurityException

The user does not have permission to read from the registry keys that contain time zone information.

Examples

The following example retrieves a collection of time zone objects that represent the time zones defined on a computer and writes information about them to a text file.

C#

```
using System;
using System.Globalization;
using System.IO;
using System.Collections.ObjectModel;

public class Example
{
   public static void Main()
   {
      const string OUTPUTFILENAME = @"C:\Temp\TimeZoneInfo.txt";

      DateTimeFormatInfo dateFormats =
CultureInfo.CurrentCulture.DateTimeFormat;
      ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
      StreamWriter sw = new StreamWriter(OUTPUTFILENAME, false);

      foreach (TimeZoneInfo timeZone in timeZones)
      {
         bool hasDST = timeZone.SupportsDaylightSavingTime;
         TimeSpan offsetFromUtc = timeZone.BaseUtcOffset;
         TimeZoneInfo.AdjustmentRule[] adjustRules;
         string offsetString;

         sw.WriteLine("ID: {0}", timeZone.Id);

```

```
#         Begins at 02:00 on Sunday of week 2 of March
#         Ends at 02:00 on Sunday of week 1 of November
```

Remarks

The GetSystemTimeZones method retrieves all available time zone information from the subkeys of the registry's HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Time Zones key on Windows systems and from the ICU Library on Linux and macOS. If it is unable to successfully retrieve and parse values for particular string properties of individual TimeZoneInfo objects, this method sets their value to an empty string ("").

> **Important**
>
> The **GetSystemTimeZones** method returns a collection of **TimeZoneInfo** objects only for time zones defined in the Windows registry or the ICU library. It does not include time zones created using the overloads of the **CreateCustomTimeZone** method. These are accessible only through the object reference returned by the time zone creation method.

The collection returned by this method is sorted by UTC offset and, for time zones that have the same UTC offset, by the display name using the current culture. For information about the display name, see DisplayName.

The ReadOnlyCollection<T> object returned by this method supports the IEnumerable<T> interface, which means that it can be iterated using the `foreach` (in C#) or `For Each…Next` (in Visual Basic) statements. Each iteration of the loop provides the next TimeZoneInfo object in the collection.

The collection of TimeZoneInfo objects represents time zones defined on the local computer; it does not necessarily provide complete information for all time zones during all time periods. If your application requires time zones not found on the local computer, you can create custom time zones using the overloads of the CreateCustomTimeZone method. For more information, see How to: Create Time Zones Without Adjustment Rules and How to: Create Time Zones with Adjustment Rules.

You can also determine whether an individual time zone is defined on the local computer by calling the FindSystemTimeZoneById method and providing the identifier of the time zone you want to retrieve as a parameter.

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetSystemTimeZones(Boolean)

Returns a ReadOnlyCollection<T> containing all valid TimeZone's from the local machine. This method does *not* throw TimeZoneNotFoundException or InvalidTimeZoneException.

C#

```
public static
System.Collections.ObjectModel.ReadOnlyCollection<TimeZoneInfo>
GetSystemTimeZones (bool skipSorting);
```

Parameters

`skipSorting` Boolean

If `true`, The collection returned may not necessarily be sorted.

Returns

ReadOnlyCollection<TimeZoneInfo>

Remarks

By setting the skipSorting parameter to `true`, the method will attempt to avoid sorting the returned collection. This option can be beneficial when the caller does not require a sorted list and aims to enhance the performance.

TimeZoneInfo.GetUtcOffset Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.

Overloads

Expand table

GetUtcOffset(DateTime)	Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.
GetUtcOffset(DateTimeOffset)	Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.

GetUtcOffset(DateTime)

Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.

C#

```
public TimeSpan GetUtcOffset (DateTime dateTime);
```

Parameters

`dateTime` DateTime

The date and time to determine the offset for.

Returns

TimeSpan

An object that indicates the time difference between the two time zones.

Examples

The following example illustrates the use of the GetUtcOffset(DateTime) method with different time zones and with date values that have different Kind property values.

C#

```
using System;

[assembly:CLSCompliant(true)]
namespace TimeZoneInfoCode
{
   public class TimeOffsets
   {
      public static void Main()
      {
         TimeOffsets timeoff = new TimeOffsets();
         TimeZoneInfo cst = TimeZoneInfo.FindSystemTimeZoneById("Central
Standard Time");

         timeoff.ShowOffset(new DateTime(2006, 6, 12, 11, 0, 0),
TimeZoneInfo.Local);
         timeoff.ShowOffset(new DateTime(2007, 11, 4, 1, 0, 0),
TimeZoneInfo.Local);
         timeoff.ShowOffset(new DateTime(2006, 12, 10, 15, 0, 0),
TimeZoneInfo.Local);
         timeoff.ShowOffset(new DateTime(2007, 3, 11, 2, 30, 0),
TimeZoneInfo.Local);
         timeoff.ShowOffset(DateTime.UtcNow, TimeZoneInfo.Local);
         timeoff.ShowOffset(new DateTime(2006, 6, 12, 11, 0, 0),
TimeZoneInfo.Utc);
         timeoff.ShowOffset(new DateTime(2007, 11, 4, 1, 0, 0),
TimeZoneInfo.Utc);
         timeoff.ShowOffset(new DateTime(2006, 12, 10, 3, 0, 0),
TimeZoneInfo.Utc);
         timeoff.ShowOffset(new DateTime(2007, 3, 11, 2, 30, 0),
TimeZoneInfo.Utc);
         timeoff.ShowOffset(DateTime.Now, TimeZoneInfo.Utc);
         timeoff.ShowOffset(new DateTime(2006, 6, 12, 11, 0, 0), cst);
         timeoff.ShowOffset(new DateTime(2007, 11, 4, 1, 0, 0), cst);
         timeoff.ShowOffset(new DateTime(2006, 12, 10, 15, 0, 0), cst);
         timeoff.ShowOffset(new DateTime(2007, 3, 11, 2, 30, 0, 0), cst);
         timeoff.ShowOffset(new DateTime(2007, 11, 14, 00, 00, 00,
DateTimeKind.Local), cst);
      }

      private void ShowOffset(DateTime time, TimeZoneInfo timeZone)
      {
```

```
         DateTime convertedTime = time;
         TimeSpan offset;

         if (time.Kind == DateTimeKind.Local && !
timeZone.Equals(TimeZoneInfo.Local))
            convertedTime = TimeZoneInfo.ConvertTime(time,
TimeZoneInfo.Local, timeZone);
         else if (time.Kind == DateTimeKind.Utc && !
timeZone.Equals(TimeZoneInfo.Utc))
            convertedTime = TimeZoneInfo.ConvertTime(time,
TimeZoneInfo.Utc, timeZone);

         offset = timeZone.GetUtcOffset(time);
         if (time == convertedTime)
         {
            Console.WriteLine("{0} {1} ", time,
                              timeZone.IsDaylightSavingTime(time) ?
timeZone.DaylightName : timeZone.StandardName);
            Console.WriteLine("   It differs from UTC by {0} hours, {1}
minutes.",
                               offset.Hours,
                               offset.Minutes);
         }
         else
         {
            Console.WriteLine("{0} {1} ", time,
                              time.Kind == DateTimeKind.Utc ? "UTC" :
TimeZoneInfo.Local.Id);
            Console.WriteLine("   converts to {0} {1}.",
                              convertedTime,
                              timeZone.Id);
            Console.WriteLine("   It differs from UTC by {0} hours, {1}
minutes.",
                              offset.Hours, offset.Minutes);
         }
         Console.WriteLine();
      }
   }
}
// The example produces the following output:
//
//       6/12/2006 11:00:00 AM Pacific Daylight Time
//          It differs from UTC by -7 hours, 0 minutes.
//
//       11/4/2007 1:00:00 AM Pacific Standard Time
//          It differs from UTC by -8 hours, 0 minutes.
//
//       12/10/2006 3:00:00 PM Pacific Standard Time
//          It differs from UTC by -8 hours, 0 minutes.
//
//       3/11/2007 2:30:00 AM Pacific Standard Time
//          It differs from UTC by -8 hours, 0 minutes.
//
//       2/2/2007 8:35:46 PM UTC
//          converts to 2/2/2007 12:35:46 PM Pacific Standard Time.
```

```
//          It differs from UTC by -8 hours, 0 minutes.
//
//       6/12/2006 11:00:00 AM UTC
//          It differs from UTC by 0 hours, 0 minutes.
//
//       11/4/2007 1:00:00 AM UTC
//          It differs from UTC by 0 hours, 0 minutes.
//
//       12/10/2006 3:00:00 AM UTC
//          It differs from UTC by 0 hours, 0 minutes.
//
//       3/11/2007 2:30:00 AM UTC
//          It differs from UTC by 0 hours, 0 minutes.
//
//       2/2/2007 12:35:46 PM Pacific Standard Time
//          converts to 2/2/2007 8:35:46 PM UTC.
//          It differs from UTC by 0 hours, 0 minutes.
//
//       6/12/2006 11:00:00 AM Central Daylight Time
//          It differs from UTC by -5 hours, 0 minutes.
//
//       11/4/2007 1:00:00 AM Central Standard Time
//          It differs from UTC by -6 hours, 0 minutes.
//
//       12/10/2006 3:00:00 PM Central Standard Time
//          It differs from UTC by -6 hours, 0 minutes.
//
//       3/11/2007 2:30:00 AM Central Standard Time
//          It differs from UTC by -6 hours, 0 minutes.
//
//       11/14/2007 12:00:00 AM Pacific Standard Time
//          converts to 11/14/2007 2:00:00 AM Central Standard Time.
//          It differs from UTC by -6 hours, 0 minutes.
```

Remarks

The returned time span includes any differences due to the application of adjustment rules to the current time zone. It differs from the BaseUtcOffset property, which returns the difference between Coordinated Universal Time (UTC) and the time zone's standard time and, therefore, does not take adjustment rules into account.

If the `dateTime` parameter's Kind property does not correspond to the time zone object, this method performs the necessary conversion before returning a result. For example, this can occur if the Kind property is DateTimeKind.Local but the time zone object is not the local time zone. If `dateTime` is ambiguous, or if the converted time is ambiguous, this method interprets the ambiguous time as a standard time. If `dateTime` is invalid, this method returns a TimeSpan object that reflects the difference between UTC and the time zone's standard time.

The TimeZoneInfo.GetUtcOffset(DateTime) method is similar in operation to the GetUtcOffset method of the TimeZone class.

GetUtcOffset(DateTimeOffset)

Calculates the offset or difference between the time in this time zone and Coordinated Universal Time (UTC) for a particular date and time.

C#

```
public TimeSpan GetUtcOffset (DateTimeOffset dateTimeOffset);
```

Parameters

`dateTimeOffset` DateTimeOffset

The date and time to determine the offset for.

Returns

TimeSpan

An object that indicates the time difference between Coordinated Universal Time (UTC) and the current time zone.

Remarks

The returned time span includes any differences due to the application of adjustment rules to the current time zone. It differs from the BaseUtcOffset property, which returns the difference between Coordinated Universal Time (UTC) and the time zone's standard time and, therefore, does not take adjustment rules into account.

TimeZoneInfo.HasSameRules(TimeZoneInfo) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the current object and another TimeZoneInfo object have the same adjustment rules.

```
C#

public bool HasSameRules (TimeZoneInfo other);
```

Parameters

other TimeZoneInfo

A second object to compare with the current TimeZoneInfo object.

Returns

Boolean

`true` if the two time zones have identical adjustment rules and an identical base offset; otherwise, `false`.

Exceptions

ArgumentNullException

The `other` parameter is `null`.

Examples

Typically, a number of time zones defined in the registry on Windows and the ICU Library on Linux and macOS have the same offset from Coordinated Universal Time (UTC) and the same adjustment rules. The following example displays a list of these time zones to the console.

C#

```
ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
TimeZoneInfo[] timeZoneArray = new TimeZoneInfo[timeZones.Count];
timeZones.CopyTo(timeZoneArray, 0);
// Iterate array from top to bottom
for (int ctr = timeZoneArray.GetUpperBound(0); ctr >= 1; ctr--)
{
   // Get next item from top
   TimeZoneInfo thisTimeZone = timeZoneArray[ctr];
   for (int compareCtr = 0; compareCtr <= ctr - 1; compareCtr++)
   {
      // Determine if time zones have the same rules
      if (thisTimeZone.HasSameRules(timeZoneArray[compareCtr]))
      {
         Console.WriteLine("{0} has the same rules as {1}",
                           thisTimeZone.StandardName,
                           timeZoneArray[compareCtr].StandardName);
      }
   }
}
```

Remarks

Like the TimeZoneInfo.Equals(TimeZoneInfo) method, the HasSameRules method indicates whether two time zones have the same base offset (as defined by the BaseUtcOffset property) and the same adjustment rules. Unlike the TimeZoneInfo.Equals(TimeZoneInfo) method, HasSameRules does not compare time zone identifiers (as defined by the Id property).

TimeZoneInfo.IsAmbiguousTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.

Overloads

Expand table

IsAmbiguousTime(DateTime)	Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.
IsAmbiguousTime(DateTimeOffset)	Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.

IsAmbiguousTime(DateTime)

Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.

C#

```
public bool IsAmbiguousTime (DateTime dateTime);
```

Parameters

`dateTime` DateTime

A date and time value.

Returns

Boolean

`true` if the `dateTime` parameter is ambiguous; otherwise, `false`.

Exceptions

ArgumentException

The Kind property of the `dateTime` value is Local and `dateTime` is an invalid time.

Examples

In the Pacific Time zone, daylight saving time ends at 2:00 A.M. on November 4, 2007. The following example passes the time at one-minute intervals from 12:59 A.M. on November 4, 2007, to 2:01 A.M. on November 4, 2007, to the IsAmbiguousTime(DateTime) method of a TimeZoneInfo object that represents the Pacific Time zone. The console output indicates that all times from 1:00 A.M. on November 4, 2007, to 1:59 A.M. on November 4, 2007, are ambiguous.

C#

```
   // Specify DateTimeKind in Date constructor
   DateTime baseTime = new DateTime(2007, 11, 4, 0, 59, 00,
DateTimeKind.Unspecified);
   DateTime newTime;

   // Get Pacific Standard Time zone
   TimeZoneInfo pstZone = TimeZoneInfo.FindSystemTimeZoneById("Pacific
Standard Time");

   // List possible ambiguous times for 63-minute interval, from 12:59 AM
to 2:01 AM
   for (int ctr = 0; ctr < 63; ctr++)
   {
      // Because of assignment, newTime.Kind is also
DateTimeKind.Unspecified
      newTime = baseTime.AddMinutes(ctr);
      Console.WriteLine("{0} is ambiguous: {1}", newTime,
pstZone.IsAmbiguousTime(newTime));
   }
```

Remarks

An ambiguous time falls within a range of times for the current time zone. This means it can be either a standard time or a time that results from the application of

an adjustment rule. Typically, ambiguous times result when the clock is set to return to standard time from daylight saving time. See the Example section for an illustration.

Coordinated Universal Time (UTC) has no ambiguous times; neither do time zones that do not support daylight saving time. Therefore, these time zones have no adjustment rules and calls to the IsAmbiguousTime method always return `false`.

For time zones that do observe daylight saving time, the precise behavior of this method depends on the relationship between the Kind property and the TimeZoneInfo object, as the following table shows.

Expand table

TimeZoneInfo object type	Kind property value	Behavior
TimeZoneInfo.Local	DateTimeKind.Local or DateTimeKind.Unspecified	Determines whether the `dateTime` parameter is ambiguous.
TimeZoneInfo.Local	DateTimeKind.Utc	Converts `dateTime` to the local time and then determines whether that time is ambiguous.
TimeZoneInfo.Utc	DateTimeKind.Utc or DateTimeKind.Unspecified	Returns `false`.
TimeZoneInfo.Utc	DateTimeKind.Local	If `dateTime` is ambiguous, assumes it is a standard time, converts it to UTC, and returns `false`.
Any other time zone.	DateTimeKind.Local or DateTimeKind.Utc	Converts `dateTime` to the time in the specified time zone and then determines whether that time is ambiguous.
Any other time zone.	DateTimeKind.Unspecified	Determines whether `dateTime` is ambiguous.

UWP	10.0

IsAmbiguousTime(DateTimeOffset)

Determines whether a particular date and time in a particular time zone is ambiguous and can be mapped to two or more Coordinated Universal Time (UTC) times.

```
C#

public bool IsAmbiguousTime (DateTimeOffset dateTimeOffset);
```

Parameters

`dateTimeOffset` DateTimeOffset

A date and time.

Returns

Boolean

`true` if the `dateTimeOffset` parameter is ambiguous in the current time zone; otherwise, `false`.

Remarks

An ambiguous time falls within a range of times for the current time zone. This means that it can be either a standard time or a time that results from the application of an adjustment rule. Typically, ambiguous times result when the clock is set to return to standard time from daylight saving time. Coordinated Universal Time (UTC) has no ambiguous times; neither do time zones that do not support daylight saving time.

The precise behavior of the method depends on the relationship between the Offset property of the `dateTimeOffset` parameter and the current time zone. If the value of the Offset property is a possible offset from the UTC of the current time zone, the method determines whether that date and time is ambiguous. Otherwise, it converts `dateTimeOffset` to the time in the current time zone, and then determines whether that date and time is ambiguous.

TimeZoneInfo.IsDaylightSavingTime Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a specified date and time falls in the range of daylight saving time for the current TimeZoneInfo object's time zone.

Overloads

Expand table

IsDaylightSavingTime(DateTime)	Indicates whether a specified date and time falls in the range of daylight saving time for the time zone of the current TimeZoneInfo object.
IsDaylightSavingTime(DateTimeOffset)	Indicates whether a specified date and time falls in the range of daylight saving time for the time zone of the current TimeZoneInfo object.

IsDaylightSavingTime(DateTime)

Indicates whether a specified date and time falls in the range of daylight saving time for the time zone of the current TimeZoneInfo object.

C#

```
public bool IsDaylightSavingTime (DateTime dateTime);
```

Parameters

dateTime DateTime

A date and time value.

Returns

Boolean

`true` if the `dateTime` parameter is a daylight saving time; otherwise, `false`.

Exceptions

ArgumentException

The Kind property of the `dateTime` value is Local and `dateTime` is an invalid time.

Examples

The following example defines a method named `DisplayDateWithTimeZoneName` that uses the TimeZoneInfo.IsDaylightSavingTime method to determine whether to display a time zone's standard time name or daylight saving time name.

C#

```
private void DisplayDateWithTimeZoneName(DateTime date1, TimeZoneInfo
timeZone)
{
   Console.WriteLine("The time is {0:t} on {0:d} {1}",
                     date1,
                     timeZone.IsDaylightSavingTime(date1) ?
                         timeZone.DaylightName : timeZone.StandardName);
}
// The example displays output similar to the following:
//    The time is 1:00 AM on 4/2/2006 Pacific Standard Time
```

Remarks

The return value of TimeZoneInfo.IsDaylightSavingTime is affected by the relationship between the time zone represented by the TimeZoneInfo object and the Kind property of the `dateTime` parameter, as the following table shows.

Expand table

TimeZoneInfo object	DateTime.Kind property	Result
TimeZoneInfo.Local	`DateTimeKind.Local`	Determines whether `dateTime` is daylight saving time.
TimeZoneInfo.Local	`DateTimeKind.Utc`	Converts `dateTime` from Coordinated Universal Time (UTC)

TimeZoneInfo object	DateTime.Kind property	Result
		to local time and determines whether it is daylight saving time.
TimeZoneInfo.Local	`DateTimeKind.Unspecified`	Assumes that `dateTime` represents local time and determines whether it is daylight saving time.
TimeZoneInfo.Utc	`DateTimeKind.Local`, `DateTimeKind.Unspecified`, or `DateTimeKind.Utc`	Returns `false` (UTC does not support daylight saving time).
Any other TimeZoneInfo object.	`DateTimeKind.Local`	Converts the local time to the equivalent time of the TimeZoneInfo object and then determines whether the latter is daylight saving time.
Any other TimeZoneInfo object.	`DateTimeKind.Utc`	Converts UTC to the equivalent time of the TimeZoneInfo object and then determines whether the latter is daylight saving time.
Any other TimeZoneInfo object.	`DateTimeKind.Unspecified`	Determines whether `dateTime` is daylight saving time.

If the time zone represented by the TimeZoneInfo object does not support daylight saving time, the method always returns `false`. A number of time zones, including Utc, do not observe daylight saving time. To determine whether a time zone supports daylight saving time, retrieve the value of its SupportsDaylightSavingTime property.

If the `dateTime` parameter specifies an ambiguous time in the current object's time zone, the TimeZoneInfo.IsDaylightSavingTime method interprets `dateTime` as standard time and returns `false` if its Kind property is DateTimeKind.Local or DateTimeKind.Unspecified. If the Kind property is DateTimeKind.Utc, this method will select the correct ambiguous time and indicate whether it is a daylight saving time.

Because the TimeZoneInfo.IsDaylightSavingTime(DateTime) method can return `false` for a date and time that is ambiguous (that is, a date and time that can represent either a standard time or a daylight saving time in a particular time zone), the TimeZoneInfo.IsAmbiguousTime(DateTime) method can be paired with the IsDaylightSavingTime(DateTime) method to determine whether a time may be a daylight saving time. Because an ambiguous time is one that can be both a daylight

saving time and a standard time, the IsAmbiguousTime(DateTime) method can be called first to determine whether a date and time may be a daylight saving time. If the method returns `false`, the IsDaylightSavingTime(DateTime) method can be called to determine whether the DateTime value is a daylight saving time. The following example illustrates this technique.

C#

```
DateTime unclearDate = new DateTime(2007, 11, 4, 1, 30, 0);
// Test if time is ambiguous.
Console.WriteLine("In the {0}, {1} is {2}ambiguous.",
                  TimeZoneInfo.Local.DisplayName,
                  unclearDate,
                  TimeZoneInfo.Local.IsAmbiguousTime(unclearDate) ? "" :
"not ");
// Test if time is DST.
Console.WriteLine("In the {0}, {1} is {2}daylight saving time.",
                  TimeZoneInfo.Local.DisplayName,
                  unclearDate,
                  TimeZoneInfo.Local.IsDaylightSavingTime(unclearDate) ?
"" : "not ");
Console.WriteLine();
// Report time as DST if it is either ambiguous or DST.
if (TimeZoneInfo.Local.IsAmbiguousTime(unclearDate) ||
    TimeZoneInfo.Local.IsDaylightSavingTime(unclearDate))
    Console.WriteLine("{0} may be daylight saving time in {1}.",
                      unclearDate, TimeZoneInfo.Local.DisplayName);
// The example displays the following output:
//    In the (GMT-08:00) Pacific Time (US & Canada), 11/4/2007 1:30:00 AM
is ambiguous.
//    In the (GMT-08:00) Pacific Time (US & Canada), 11/4/2007 1:30:00 AM
is not daylight saving time.
//
//    11/4/2007 1:30:00 AM may be daylight saving time in (GMT-08:00)
Pacific Time (US & Canada).
```

If the `dateTime` parameter specifies an invalid time, the method call throws an ArgumentException if the value of the `dateTime` parameter's Kind property is DateTimeKind.Local; otherwise, the method returns `false`.

Call the TimeZoneInfo.IsDaylightSavingTime method to determine whether to use a time zone's StandardName value or its DaylightName value when displaying the time zone name. See the Example section for an illustration.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

IsDaylightSavingTime(DateTimeOffset)

Indicates whether a specified date and time falls in the range of daylight saving time for the time zone of the current TimeZoneInfo object.

C#

```
public bool IsDaylightSavingTime (DateTimeOffset dateTimeOffset);
```

Parameters

`dateTimeOffset` DateTimeOffset

A date and time value.

Returns

Boolean

`true` if the `dateTimeOffset` parameter is a daylight saving time; otherwise, `false`.

Remarks

The return value of TimeZoneInfo.IsDaylightSavingTime is affected by the relationship between the time zone represented by the TimeZoneInfo object and the Offset property of the `dateTimeOffset` parameter. If `dateTimeOffset` does not correspond to the current time zone's offset from Coordinated Universal Time (UTC),

the method converts that time to the time in the current time zone. It then determines whether that date and time is a daylight saving time.

If the time zone represented by the TimeZoneInfo object does not support daylight saving time, the method always returns `false`. To determine whether a time zone supports daylight saving time, retrieve the value of its SupportsDaylightSavingTime property.

TimeZoneInfo.IsInvalidTime(DateTime) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a particular date and time is invalid.

```
C#

public bool IsInvalidTime (DateTime dateTime);
```

Parameters

dateTime DateTime

A date and time value.

Returns

Boolean

`true` if `dateTime` is invalid; otherwise, `false`.

Examples

In the Pacific Time zone, daylight saving time begins at 2:00 A.M. on April 2, 2006. The following code passes the time at one-minute intervals from 1:59 A.M. on April 2, 2006, to 3:01 A.M. on April 2, 2006, to the IsInvalidTime method of a TimeZoneInfo object that represents the Pacific Time zone. The console output indicates that all times from 2:00 A.M. on April 2, 2006, to 2:59 A.M. on April 2, 2006, are invalid.

```
C#

// Specify DateTimeKind in Date constructor
DateTime baseTime = new DateTime(2007, 3, 11, 1, 59, 0,
DateTimeKind.Unspecified);
DateTime newTime;
```

```
// Get Pacific Standard Time zone
TimeZoneInfo pstZone = TimeZoneInfo.FindSystemTimeZoneById("Pacific Standard
Time");

// List possible invalid times for a 63-minute interval, from 1:59 AM to
3:01 AM
for (int ctr = 0; ctr < 63; ctr++)
{
   // Because of assignment, newTime.Kind is also DateTimeKind.Unspecified
   newTime = baseTime.AddMinutes(ctr);
   Console.WriteLine("{0} is invalid: {1}", newTime,
pstZone.IsInvalidTime(newTime));
}
```

Remarks

An invalid time falls within a range of times for the current time zone that cannot be mapped to Coordinated Universal Time (UTC) due to the application of an adjustment rule. Typically, invalid times occur when the time moves ahead for daylight saving time. See the Example section for an illustration.

The value of the Kind property of the `dateTime` parameter affects whether `dateTime` represents an invalid time, as the following table shows.

Expand table

DateTime.Kind property	TimeZoneInfo object (if applicable)	Behavior
DateTimeKind.Local	TimeZoneInfo.Local	Determines whether the time is invalid.
DateTimeKind.Local	TimeZoneInfo.Utc or a non-local time zone.	Converts `dateTime` to the time of the TimeZoneInfo object and returns `false`.
DateTimeKind.Unspecified	Not applicable.	Assumes `dateTime` is the time of the TimeZoneInfo object and determines whether it is invalid.
DateTimeKind.Utc	Not applicable.	Returns `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TimeZoneInfo.ToSerializedString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the current TimeZoneInfo object to a serialized string.

C#

```
public string ToSerializedString ();
```

Returns

String

A string that represents the current TimeZoneInfo object.

Examples

The following example tries to retrieve the Antarctica/South Pole time zone from the local system. If it fails, the code tries to retrieve information about the time zone from a text file in the application directory. If this attempt fails, the code creates the time zone and writes information about it to the text file.

C#

```
private TimeZoneInfo InitializeTimeZone()
{
   TimeZoneInfo southPole = null;
   // Determine if South Pole time zone is defined in system
   try
   {
      southPole = TimeZoneInfo.FindSystemTimeZoneById("Antarctica/South Pole
Standard Time");
   }
   // Time zone does not exist; create it, store it in a text file, and
return it
   catch
```

```
    {
        const string filename = @".\TimeZoneInfo.txt";
        bool found = false;

        if (File.Exists(filename))
        {
            StreamReader reader = new StreamReader(filename);
            string timeZoneInfo;
            while (reader.Peek() >= 0)
            {
                timeZoneInfo = reader.ReadLine();
                if (timeZoneInfo.Contains("Antarctica/South Pole"))
                {
                    southPole = TimeZoneInfo.FromSerializedString(timeZoneInfo);
                    reader.Close();
                    found = true;
                    break;
                }
            }
        }
        if (! found)
        {
            // Define transition times to/from DST
            TimeZoneInfo.TransitionTime startTransition =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1, 2,
0, 0), 10, 1, DayOfWeek.Sunday);
            TimeZoneInfo.TransitionTime endTransition =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1, 2,
0, 0), 3, 3, DayOfWeek.Sunday);
            // Define adjustment rule
            TimeSpan delta = new TimeSpan(1, 0, 0);
            TimeZoneInfo.AdjustmentRule adjustment =
TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new DateTime(1989, 10, 1),
DateTime.MaxValue.Date, delta, startTransition, endTransition);
            // Create array for adjustment rules
            TimeZoneInfo.AdjustmentRule[] adjustments = {adjustment};
            // Define other custom time zone arguments
            string displayName = "(GMT+12:00) Antarctica/South Pole";
            string standardName = "Antarctica/South Pole Standard Time";
            string daylightName = "Antarctica/South Pole Daylight Time";
            TimeSpan offset = new TimeSpan(12, 0, 0);
            southPole = TimeZoneInfo.CreateCustomTimeZone(standardName, offset,
displayName, standardName, daylightName, adjustments);
            // Write time zone to the file
            StreamWriter writer = new StreamWriter(filename, true);
            writer.WriteLine(southPole.ToSerializedString());
            writer.Close();
        }
    }
    return southPole;
}
```

Remarks

Applications that rely on time zones that are not typically defined in the registry of Windows systems or the ICU Library on Linux and macOScan can use the CreateCustomTimeZone method to instantiate the necessary time zones as TimeZoneInfo objects. The application can then call the ToSerializedString method to convert the time zone object to a string.

The TimeZoneInfo object should also be stored in a location where the application can retrieve it when needed. Possible locations include:

- The registry on Windows systems.
- An application resource file.
- An external file, such as a text file.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneInfo.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the current TimeZoneInfo object's display name.

C#

```
public override string ToString ();
```

Returns

String

The value of the DisplayName property of the current TimeZoneInfo object.

Remarks

When assigning a collection that contains TimeZoneInfo objects to a list control such as the ListBox control, the control automatically calls the ToString method to extract a string that describes each object to be represented in the list. As a result, you do not need to store a meaningful description of the object as a string, and the user does not need to use that string to extract the object from the collection. See How to: Enumerate Time Zones Present on a Computer for more detail.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TimeZoneInfo.TryConvertIanaIdToWindowsId(String, String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an IANA time zone ID to a Windows ID.

```
C#

public static bool TryConvertIanaIdToWindowsId (string ianaId, out string?
windowsId);
```

Parameters

`ianaId` String

The IANA time zone ID.

`windowsId` String

When this method returns, contains the Windows ID that corresponds to the specified IANA ID.

Returns

Boolean

`true` if the ID conversion succeeded, `false` otherwise.

Remarks

This API is exclusively supported on .NET 6 and later versions, and only when the application utilizes the ICU library. However, in .NET, the ICU library is not always used by default, particularly in the following scenarios:

- When the application runs on an operating system that does not have the ICU library, and the app does not utilize the app-local ICU feature.

- When the globalization invariant mode or NLS mode is enabled on Windows.

If the application is running on a Windows OS version that lacks the ICU library, it has the option to opt-in and enable the usage of the ICU library through the app-local ICU feature.

Applies to

TimeZoneInfo.TryConvertWindowsIdToIanaId Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryConvertWindowsIdToIanaId(String, String)	Tries to convert a Windows time zone ID to an IANA ID.
TryConvertWindowsIdToIanaId(String, String, String)	Tries to convert a Windows time zone ID to an IANA ID.

TryConvertWindowsIdToIanaId(String, String)

Tries to convert a Windows time zone ID to an IANA ID.

C#

```
public static bool TryConvertWindowsIdToIanaId (string windowsId, out
string? ianaId);
```

Parameters

`windowsId` String

The Windows time zone ID.

`ianaId` String

When this method returns, contains the IANA ID that corresponds to the specified Windows ID.

Returns

Boolean

`true` if the ID conversion succeeded, `false` otherwise.

Remarks

This API is exclusively supported on .NET 6.0 and later versions. It is also supported when the application utilizes the ICU library, otherwise the API will fail. However, in .NET, the ICU library is not always used by default, particularly in the following scenarios:

- When the application runs on an operating system that does not have the ICU library, and the app does not utilize the APP-Local ICU feature.
- When the Globalization Invariant Mode or NLS mode is enabled on Windows OS.

If the application is running on a Windows OS version that lacks the ICU library, it has the option to opt-in and enable the usage of the ICU library through the App-Local ICU feature.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryConvertWindowsIdToIanaId(String, String, String)

Tries to convert a Windows time zone ID to an IANA ID.

C#

```
public static bool TryConvertWindowsIdToIanaId (string windowsId, string?
region, out string? ianaId);
```

Parameters

`windowsId` String

The Windows time zone ID.

`region` String

The ISO 3166 code for the country/region.

`ianaId` String

When this method returns, contains the IANA ID that corresponds to the specified Windows ID.

Returns

Boolean

`true` if the ID conversion succeeded, `false` otherwise.

Remarks

This API is exclusively supported on .NET 6.0 and later versions. It is also supported when the application utilizes the ICU library, otherwise the API will fail. However, in .NET, the ICU library is not always used by default, particularly in the following scenarios:

- When the application runs on an operating system that does not have the ICU library, and the app does not utilize the App-local ICU feature.
- When the Globalization Invariant Mode or NLS mode is enabled on Windows OS.

If the application is running on a Windows OS version that lacks the ICU library, it has the option to opt-in and enable the usage of the ICU library through the App-Local ICU feature.

TimeZoneInfo.TryFindSystemTimeZoneById(String, TimeZoneInfo) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves a TimeZoneInfo object by time zone name.

C#

```
public static bool TryFindSystemTimeZoneById (string id, out TimeZoneInfo?
timeZoneInfo);
```

Parameters

id String

The time zone name.

timeZoneInfo TimeZoneInfo

When this method returns, contains the retrieved TimeZoneInfo or `null` if no valid time zone was found.

Returns

Boolean

`true` if the TimeZoneInfo object was successfully retrieved; otherwise, `false`.

Remarks

This function wraps the logic necessary to keep the private SystemTimeZones cache in working order.

Applies to

Product	Versions
.NET	8, 9

TimeZoneInfo.IDeserializationCallback.OnDeserialization(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Runs when the deserialization of an object has been completed.

C#

```
void IDeserializationCallback.OnDeserialization (object sender);
```

Parameters

sender Object

The object that initiated the callback. The functionality for this parameter is not currently implemented.

Implements

OnDeserialization(Object)

Exceptions

SerializationException

The TimeZoneInfo object contains invalid or corrupted data.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data needed to serialize the current TimeZoneInfo object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo object to populate with data.

`context` StreamingContext

The destination for this serialization (see StreamingContext).

Implements

GetObjectData(SerializationInfo, StreamingContext)

Exceptions

ArgumentNullException

The `info` parameter is `null`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.AdjustmentRule Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides information about a time zone adjustment, such as the transition to and from daylight saving time.

C#

```
public sealed class TimeZoneInfo.AdjustmentRule :
IEquatable<TimeZoneInfo.AdjustmentRule>,
System.Runtime.Serialization.IDeserializationCallback,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → TimeZoneInfo.AdjustmentRule

Implements IEquatable<TimeZoneInfo.AdjustmentRule> , IDeserializationCallback , ISerializable

Examples

The following example retrieves all time zones defined on the local system and displays complete information about their adjustment rules.

C#

```
private enum WeekOfMonth
{
   First = 1,
   Second = 2,
   Third = 3,
   Fourth = 4,
   Last = 5,
}

private static void ShowStartAndEndDates()
{
   // Get all time zones from system
   ReadOnlyCollection<TimeZoneInfo> timeZones =
```

```
TimeZoneInfo.GetSystemTimeZones();
   string[] monthNames =
CultureInfo.CurrentCulture.DateTimeFormat.MonthNames;
   // Get each time zone
   foreach (TimeZoneInfo timeZone in timeZones)
   {
      TimeZoneInfo.AdjustmentRule[] adjustments =
timeZone.GetAdjustmentRules();
      // Display message for time zones with no adjustments
      if (adjustments.Length == 0)
      {
         Console.WriteLine("{0} has no adjustment rules",
timeZone.StandardName);
      }
      else
      {
         // Handle time zones with 1 or 2+ adjustments differently
         bool showCount = false;
         int ctr = 0;
         string spacer = "";

         Console.WriteLine("{0} Adjustment rules", timeZone.StandardName);
         if (adjustments.Length > 1)
         {
            showCount = true;
            spacer = "   ";
         }
         // Iterate adjustment rules
         foreach (TimeZoneInfo.AdjustmentRule adjustment in adjustments)
         {
            if (showCount)
            {
               Console.WriteLine("   Adjustment rule #{0}", ctr+1);
               ctr++;
            }
            // Display general adjustment information
            Console.WriteLine("{0}   Start Date: {1:D}", spacer,
adjustment.DateStart);
            Console.WriteLine("{0}   End Date: {1:D}", spacer,
adjustment.DateEnd);
            Console.WriteLine("{0}   Time Change: {1}:{2:00} hours", spacer,
                              adjustment.DaylightDelta.Hours,
adjustment.DaylightDelta.Minutes);
            // Get transition start information
            TimeZoneInfo.TransitionTime transitionStart =
adjustment.DaylightTransitionStart;
            Console.Write("{0}   Annual Start: ", spacer);
            if (transitionStart.IsFixedDateRule)
            {
               Console.WriteLine("On {0} {1} at {2:t}",
                                 monthNames[transitionStart.Month - 1],
                                 transitionStart.Day,
                                 transitionStart.TimeOfDay);
            }
            else
```

```
            {
               Console.WriteLine("The {0} {1} of {2} at {3:t}",

((WeekOfMonth)transitionStart.Week).ToString(),
                                 transitionStart.DayOfWeek.ToString(),
                                 monthNames[transitionStart.Month - 1],
                                 transitionStart.TimeOfDay);
            }
            // Get transition end information
            TimeZoneInfo.TransitionTime transitionEnd =
adjustment.DaylightTransitionEnd;
            Console.Write("{0}   Annual End: ", spacer);
            if (transitionEnd.IsFixedDateRule)
            {
               Console.WriteLine("On {0} {1} at {2:t}",
                                 monthNames[transitionEnd.Month - 1],
                                 transitionEnd.Day,
                                 transitionEnd.TimeOfDay);
            }
            else
            {
               Console.WriteLine("The {0} {1} of {2} at {3:t}",

((WeekOfMonth)transitionEnd.Week).ToString(),
                                 transitionEnd.DayOfWeek.ToString(),
                                 monthNames[transitionEnd.Month - 1],
                                 transitionEnd.TimeOfDay);
            }
         }
      }
      Console.WriteLine();
   }
}
```

The following is a small portion of the output that is generated by the example. The exact output will vary depending on the operating system and the date on which the example is run.

```
Morocco Standard Time Adjustment rules
   Adjustment rule #1
      Start Date: Tuesday, January 01, 2008
      End Date: Wednesday, December 31, 2008
      Time Change: 1:00 hours
      Annual Start: The Last Saturday of May at 11:59 PM
      Annual End: The Last Sunday of August at 11:59 PM
   Adjustment rule #2
      Start Date: Thursday, January 01, 2009
      End Date: Thursday, December 31, 2009
      Time Change: 1:00 hours
      Annual Start: The Last Sunday of May at 11:59 PM
```

```
      Annual End: The Third Thursday of August at 11:59 PM

Coordinated Universal Time has no adjustment rules

GMT Standard Time Adjustment rules
   Start Date: Monday, January 01, 0001
   End Date: Friday, December 31, 9999
   Time Change: 1:00 hours
   Annual Start: The Last Sunday of March at 1:00 AM
   Annual End: The Last Sunday of October at 2:00 AM

Greenwich Standard Time has no adjustment rules

W. Europe Standard Time Adjustment rules
   Start Date: Monday, January 01, 0001
   End Date: Friday, December 31, 9999
   Time Change: 1:00 hours
   Annual Start: The Last Sunday of March at 2:00 AM
   Annual End: The Last Sunday of October at 3:00 AM

Central Europe Standard Time Adjustment rules
   Start Date: Monday, January 01, 0001
   End Date: Friday, December 31, 9999
   Time Change: 1:00 hours
   Annual Start: The Last Sunday of March at 2:00 AM
   Annual End: The Last Sunday of October at 3:00 AM

Romance Standard Time Adjustment rules
   Start Date: Monday, January 01, 0001
   End Date: Friday, December 31, 9999
   Time Change: 1:00 hours
   Annual Start: The Last Sunday of March at 2:00 AM
   Annual End: The Last Sunday of October at 3:00 AM

Central European Standard Time Adjustment rules
   Start Date: Monday, January 01, 0001
   End Date: Friday, December 31, 9999
   Time Change: 1:00 hours
   Annual Start: The Last Sunday of March at 2:00 AM
   Annual End: The Last Sunday of October at 3:00 AM

W. Central Africa Standard Time has no adjustment rules
```

Remarks

The TimeZoneInfo.AdjustmentRule class defines the effective start and end dates of a particular time change to and from daylight saving time, respectively, as well as its delta (the exact amount by which the adjustment causes the time zone's standard time to change). In addition, two properties return TimeZoneInfo.TransitionTime objects that define when each transition to and from standard time occurs.

> **Note**
>
> An instance of the **TimeZoneInfo.AdjustmentRule** class is immutable. Once an object has been created, its values cannot be modified.

To create a TimeZoneInfo.AdjustmentRule object, call the `static` (`Shared` in Visual Basic) TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule method. You can then supply an array of TimeZoneInfo.AdjustmentRule objects to two of the overloads of the TimeZoneInfo.CreateCustomTimeZone method. To retrieve the adjustment rules of a particular time zone, call its TimeZoneInfo.GetAdjustmentRules method, which returns an array of TimeZoneInfo.AdjustmentRule objects.

Properties

Expand table

BaseUtcOffsetDelta	Gets the time difference with the base UTC offset for the time zone during the adjustment-rule period.
DateEnd	Gets the date when the adjustment rule ceases to be in effect.
DateStart	Gets the date when the adjustment rule takes effect.
DaylightDelta	Gets the amount of time that is required to form the time zone's daylight saving time. This amount of time is added to the time zone's offset from Coordinated Universal Time (UTC).
DaylightTransitionEnd	Gets information about the annual transition from daylight saving time back to standard time.
DaylightTransitionStart	Gets information about the annual transition from standard time to daylight saving time.

Methods

Expand table

CreateAdjustmentRule(DateTime, DateTime, TimeSpan, TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime)	Creates a new adjustment rule for a particular time zone.
CreateAdjustmentRule(DateTime, DateTime, TimeSpan, TimeZoneInfo+TransitionTime, TimeZone	Creates a new adjustment rule for a particular time zone.

Info+TransitionTime, TimeSpan)	
Equals(Object)	Indicates whether the current instance is equal to another instance.
Equals(TimeZoneInfo+AdjustmentRule)	Determines whether the current TimeZoneInfo.AdjustmentRule object is equal to a second TimeZoneInfo.AdjustmentRule object.
GetHashCode()	Serves as a hash function for hashing algorithms and data structures such as hash tables.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Explicit Interface Implementations

Expand table

IDeserializationCallback.OnDeserialization(Object)	Runs when the deserialization of a TimeZoneInfo.AdjustmentRule object is completed.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo object with the data that is required to serialize this object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneInfo.AdjustmentRule.BaseUtcOffsetDelta Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the time difference with the base UTC offset for the time zone during the adjustment-rule period.

C#

```
public TimeSpan BaseUtcOffsetDelta { get; }
```

Property Value

TimeSpan

A TimeSpan instance representing the time difference.

Applies to

Product	Versions
.NET	6, 7, 8, 9

TimeZoneInfo.AdjustmentRule.DateEnd Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the date when the adjustment rule ceases to be in effect.

C#

```
public DateTime DateEnd { get; }
```

Property Value

DateTime

A DateTime value that indicates the end date of the adjustment rule.

Examples

The following example displays information about all of the time zones defined in the local computer's system registry, including the starting and ending dates of their adjustment rules.

C#

```
using System;
using System.Collections.ObjectModel;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
      DateTimeFormatInfo dateInfo =
CultureInfo.CurrentCulture.DateTimeFormat;

      foreach (var zone in timeZones)
```

```
      {
         Console.WriteLine("{0} transition time information:",
zone.StandardName);
         Console.WriteLine("   Time zone information: ");
         Console.WriteLine("      Base UTC Offset: {0}",
zone.BaseUtcOffset);
         Console.WriteLine("      Supports DST: {0}",
zone.SupportsDaylightSavingTime);

         TimeZoneInfo.AdjustmentRule[] adjustmentRules=
zone.GetAdjustmentRules();

         // Indicate that time zone has no adjustment rules
         if (adjustmentRules.Length == 0) {
            Console.WriteLine("      No adjustment rules defined.");
         }
         else {
            Console.WriteLine("      Adjustment Rules: {0}",
adjustmentRules.Length);
            // Iterate adjustment rules
            foreach (var adjustmentRule in adjustmentRules) {
               Console.WriteLine("   Adjustment rule from {0:d} to {1:d}:",
                                 adjustmentRule.DateStart,
                                 adjustmentRule.DateEnd);
               Console.WriteLine("      Delta: {0}",
adjustmentRule.DaylightDelta);
               // Get start of transition
               TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
               // Display information on floating date rule
               if (! daylightStart.IsFixedDateRule)
                  Console.WriteLine("      Begins at {0:t} on the {1} {2} of
{3}",
                                 daylightStart.TimeOfDay,
                                 (WeekOfMonth) daylightStart.Week,
                                 daylightStart.DayOfWeek,

dateInfo.GetMonthName(daylightStart.Month));
               // Display information on fixed date rule
               else
                  Console.WriteLine("      Begins at {0:t} on {1} {2}",
                                    daylightStart.TimeOfDay,

dateInfo.GetMonthName(daylightStart.Month),
                                    daylightStart.Day);

               // Get end of transition.
              TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
               // Display information on floating date rule.
               if (!daylightEnd.IsFixedDateRule)
                  Console.WriteLine("      Ends at {0:t} on the {1} {2} of
{3}",
                                 daylightEnd.TimeOfDay,
                                 (WeekOfMonth) daylightEnd.Week,
```

```
                                 daylightEnd.DayOfWeek,
                                 dateInfo.GetMonthName(daylightEnd.Month));

   }
}
// A portion of the output from the example might appear as follows:
//       Tonga Standard Time transition time information:
//          Time zone information:
//             Base UTC Offset: 13:00:00
//             Supports DST: False
//             No adjustment rules defined.
//       Samoa Standard Time transition time information:
//          Time zone information:
//             Base UTC Offset: 13:00:00
//             Supports DST: True
//             Adjustment Rules: 4
//          Adjustment rule from 1/1/0001 to 12/31/2009:
//             Delta: 00:00:00
//             Begins at 12:00 AM on January 1
//             Ends at 12:00 AM on January 1
//          Adjustment rule from 1/1/2010 to 12/31/2010:
//             Delta: 01:00:00
//             Begins at 11:59 PM on the Last Saturday of September
//             Ends at 12:00 AM on the First Friday of January
//          Adjustment rule from 1/1/2011 to 12/31/2011:
//             Delta: 01:00:00
//             Begins at 3:00 AM on the Fourth Saturday of September
//             Ends at 4:00 AM on the First Saturday of April
//          Adjustment rule from 1/1/2012 to 12/31/9999:
//             Delta: 01:00:00
//             Begins at 12:00 AM on the Last Sunday of September
//             Ends at 1:00 AM on the First Sunday of April
//       Line Islands Standard Time transition time information:
//          Time zone information:
//             Base UTC Offset: 14:00:00
//             Supports DST: False
//             No adjustment rules defined.
```

Remarks

The value of the DateEnd property is a date value without a time component.

Because the end date of the current adjustment rule is typically not known, you can assign `DateTime.MaxValue.Date` to the DateEnd property when you create a custom adjustment rule.

> **Important**
>
> Unless there is a compelling reason to do otherwise, you should define the adjustment rule's end date to occur within the time interval during which the time zone observes standard time. Unless there is a compelling reason to do so, you should not define the adjustment rule's end date to occur within the time interval during which the time zone observes daylight saving time. For example, if a time zone's transition from daylight saving time occurs on the third Sunday of March and its transition to daylight saving time occurs on the first Sunday of October, the effective end date of the adjustment rule should not be December 31 of a particular year, since that date occurs within the period of daylight saving time.

By default, the registry in Windows XP defines a single adjustment rule whose end date is Friday, December 31, 9999 (the value of `DateTime.MaxValue.Date`), for each time zone. For time zones in the United States, the registry in Windows Vista defines two adjustment rules:

- Monday, January 01, 0001, to Sunday, December 31, 2006.
- Monday, January 01, 2007, to Friday, December 31, 9999.

This means that, although time zone adjustment rules stored in the registry are useful for performing current time zone-related operations, they cannot be reliably used for retrieving historical time zone information. For information about defining a custom time zone with multiple adjustment rules that can be used in a historical time zone-aware application, see How to: Create Time Zones with Adjustment Rules.

TimeZoneInfo.AdjustmentRule.DateStart Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the date when the adjustment rule takes effect.

C#

```
public DateTime DateStart { get; }
```

Property Value

DateTime

A DateTime value that indicates when the adjustment rule takes effect.

Examples

The following example displays information about all of the time zones defined in the local computer's system registry, including the starting and ending dates of their adjustment rules.

C#

```
using System;
using System.Collections.ObjectModel;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
      DateTimeFormatInfo dateInfo =
CultureInfo.CurrentCulture.DateTimeFormat;

      foreach (var zone in timeZones)
```

```
      {
         Console.WriteLine("{0} transition time information:",
zone.StandardName);
         Console.WriteLine("   Time zone information: ");
         Console.WriteLine("      Base UTC Offset: {0}",
zone.BaseUtcOffset);
         Console.WriteLine("      Supports DST: {0}",
zone.SupportsDaylightSavingTime);

         TimeZoneInfo.AdjustmentRule[] adjustmentRules=
zone.GetAdjustmentRules();

         // Indicate that time zone has no adjustment rules
         if (adjustmentRules.Length == 0) {
            Console.WriteLine("      No adjustment rules defined.");
         }
         else {
            Console.WriteLine("      Adjustment Rules: {0}",
adjustmentRules.Length);
            // Iterate adjustment rules
            foreach (var adjustmentRule in adjustmentRules) {
               Console.WriteLine("   Adjustment rule from {0:d} to {1:d}:",
                                 adjustmentRule.DateStart,
                                 adjustmentRule.DateEnd);
               Console.WriteLine("      Delta: {0}",
adjustmentRule.DaylightDelta);
               // Get start of transition
               TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
               // Display information on floating date rule
               if (! daylightStart.IsFixedDateRule)
                  Console.WriteLine("      Begins at {0:t} on the {1} {2} of
{3}",
                                 daylightStart.TimeOfDay,
                                 (WeekOfMonth) daylightStart.Week,
                                 daylightStart.DayOfWeek,

dateInfo.GetMonthName(daylightStart.Month));
               // Display information on fixed date rule
               else
                  Console.WriteLine("      Begins at {0:t} on {1} {2}",
                                    daylightStart.TimeOfDay,

dateInfo.GetMonthName(daylightStart.Month),
                                    daylightStart.Day);

               // Get end of transition.
              TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
               // Display information on floating date rule.
               if (!daylightEnd.IsFixedDateRule)
                  Console.WriteLine("      Ends at {0:t} on the {1} {2} of
{3}",
                                 daylightEnd.TimeOfDay,
                                 (WeekOfMonth) daylightEnd.Week,
```

```
                                 daylightEnd.DayOfWeek,
                                 dateInfo.GetMonthName(daylightEnd.Month));
               // Display information on fixed date rule.
               else
                  Console.WriteLine("      Ends at {0:t} on {1} {2}",
                                    daylightEnd.TimeOfDay,

dateInfo.GetMonthName(daylightEnd.Month),
                                    daylightEnd.Day);
            }
         }
      }
   }

   private enum WeekOfMonth
   {
      First = 1,
      Second = 2,
      Third = 3,
      Fourth = 4,
      Last = 5,
   }
}
// A portion of the output from the example might appear as follows:
//       Tonga Standard Time transition time information:
//          Time zone information:
//             Base UTC Offset: 13:00:00
//             Supports DST: False
//             No adjustment rules defined.
//       Samoa Standard Time transition time information:
//          Time zone information:
//             Base UTC Offset: 13:00:00
//             Supports DST: True
//             Adjustment Rules: 4
//          Adjustment rule from 1/1/0001 to 12/31/2009:
//             Delta: 00:00:00
//             Begins at 12:00 AM on January 1
//             Ends at 12:00 AM on January 1
//          Adjustment rule from 1/1/2010 to 12/31/2010:
//             Delta: 01:00:00
//             Begins at 11:59 PM on the Last Saturday of September
//             Ends at 12:00 AM on the First Friday of January
//          Adjustment rule from 1/1/2011 to 12/31/2011:
//             Delta: 01:00:00
//             Begins at 3:00 AM on the Fourth Saturday of September
//             Ends at 4:00 AM on the First Saturday of April
//          Adjustment rule from 1/1/2012 to 12/31/9999:
//             Delta: 01:00:00
//             Begins at 12:00 AM on the Last Sunday of September
//             Ends at 1:00 AM on the First Sunday of April
//       Line Islands Standard Time transition time information:
//          Time zone information:
//             Base UTC Offset: 14:00:00
//             Supports DST: False
//             No adjustment rules defined.
```

Remarks

The value of the DateStart property is a date value without a time component. It defines the date on which a particular adjustment rule goes into effect. This is the date in which a set of transitions (which typically are defined by one transition to daylight savings time and one transition back to standard time) go into effect. For example, an adjustment rule might go into effect on January 1, 2017, that provides for a transition to daylight savings time on the second Sunday of March and for a transition back to standard time on the first Sunday of November. Note that the starting date of the adjustment rule is not tied to the date of the first transition.

You can assign `DateTime.MinValue.Date` to the DateEnd property when you create a custom adjustment rule for use in a time zone-aware application that does not have to work with historic time zone information.

> **ⓘ Important**
>
> Unless there is a compelling reason to do otherwise, you should define the adjustment rule's start date to occur within the time interval during which the time zone observes standard time. Unless there is a compelling reason to do so, you should not define the adjustment rule's start date to occur within the time interval during which the time zone observes daylight saving time. For example, if a time zone's transition from daylight saving time occurs on the third Sunday of March and its transition to daylight saving time occurs on the first Sunday of October, the effective start date of the adjustment rule should not be January 1 of a particular year, since that date occurs within the period of daylight saving time.

By default, the registry in Windows XP defines a single adjustment rule whose start date is Monday, January 01, 0001 (the value of `DateTime.MinValue.Date`), for each time zone. For time zones in the United States, the registry in Windows Vista defines two adjustment rules:

- Monday, January 01, 0001, to Sunday, December 31, 2006.
- Monday, January 01, 2007, to Friday, December 31, 9999.

This means that, although time zone adjustment rules stored in the registry are useful for performing current time zone-related operations, they cannot be reliably used for retrieving historical time zone information. For information about defining a custom

time zone with multiple adjustment rules that can be used in a historical time zone-aware application, see How to: Create Time Zones with Adjustment Rules.

TimeZoneInfo.AdjustmentRule.DaylightDelta Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the amount of time that is required to form the time zone's daylight saving time. This amount of time is added to the time zone's offset from Coordinated Universal Time (UTC).

```
C#
public TimeSpan DaylightDelta { get; }
```

Property Value

TimeSpan

A TimeSpan object that indicates the amount of time to add to the standard time changes as a result of the adjustment rule.

Remarks

The following formula defines a time zone's daylight saving time:

```
TimeZoneTime = BaseUtcOffset + DaylightDelta + UtcTime
```

The value of the DaylightDelta property can range from 14 hours to -14 hours.

> **Note**
>
> The **DaylightDelta** property measures the difference between the time zone's standard time and its daylight saving time. It does not apply to changes in a time zone's standard offset from Coordinated Universal Time (UTC). To represent a time

zone that has changed its standard time offset from UTC, you must call the **CreateCustomTimeZone** method to create a new time zone.

The most common value of the DaylightDelta property is 1.0 hours. The application of the daylight saving time adjustment rule increases the time zone's offset from Coordinated Universal Time (UTC) by one hour.

TimeZoneInfo.AdjustmentRule.DaylightTransitionEnd Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets information about the annual transition from daylight saving time back to standard time.

C#

```
public TimeZoneInfo.TransitionTime DaylightTransitionEnd { get; }
```

Property Value

TimeZoneInfo.TransitionTime

A TimeZoneInfo.TransitionTime object that defines the annual transition from daylight saving time back to the time zone's standard time.

Remarks

The TimeZoneInfo.TransitionTime object returned by the DaylightTransitionEnd property defines either a fixed-date rule or a floating-date rule for the return to standard time. A fixed-date rule provides the month, day, and time of day on which the transition occurs. A floating-date rule provides the month, week, day of the week, and time of day on which the transition occurs.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.AdjustmentRule.DaylightTransitionStart Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets information about the annual transition from standard time to daylight saving time.

C#

```
public TimeZoneInfo.TransitionTime DaylightTransitionStart { get; }
```

Property Value

TimeZoneInfo.TransitionTime

A TimeZoneInfo.TransitionTime object that defines the annual transition from a time zone's standard time to daylight saving time.

Remarks

The TimeZoneInfo.TransitionTime object returned by the DaylightTransitionStart property defines either a fixed-date rule or a floating-date rule for the transition to daylight saving time. A fixed-date rule provides the month, day, and time of day on which the transition occurs. A floating-date rule provides the month, the week, the day of the week, and the time of day on which the transition occurs.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CreateAdjustmentRule(DateTime, DateTime, TimeSpan, TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime)	Creates a new adjustment rule for a particular time zone.
CreateAdjustmentRule(DateTime, DateTime, TimeSpan, TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime, TimeSpan)	Creates a new adjustment rule for a particular time zone.

CreateAdjustmentRule(DateTime, DateTime, TimeSpan, TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime)

Creates a new adjustment rule for a particular time zone.

C#

```
public static TimeZoneInfo.AdjustmentRule CreateAdjustmentRule (DateTime
dateStart, DateTime dateEnd, TimeSpan daylightDelta,
TimeZoneInfo.TransitionTime daylightTransitionStart,
TimeZoneInfo.TransitionTime daylightTransitionEnd);
```

Parameters

`dateStart` DateTime

The effective date of the adjustment rule. If the value of the `dateStart` parameter is `DateTime.MinValue.Date`, this is the first adjustment rule in effect for a time zone.

`dateEnd` DateTime

The last date that the adjustment rule is in force. If the value of the `dateEnd` parameter is `DateTime.MaxValue.Date`, the adjustment rule has no end date.

`daylightDelta` TimeSpan

The time change that results from the adjustment. This value is added to the time zone's BaseUtcOffset property to obtain the correct daylight offset from Coordinated Universal Time (UTC). This value can range from -14 to 14.

`daylightTransitionStart` TimeZoneInfo.TransitionTime

An object that defines the start of daylight saving time.

`daylightTransitionEnd` TimeZoneInfo.TransitionTime

An object that defines the end of daylight saving time.

Returns

TimeZoneInfo.AdjustmentRule

An object that represents the new adjustment rule.

Exceptions

ArgumentException

The Kind property of the `dateStart` or `dateEnd` parameter does not equal Unspecified.

-or-

The `daylightTransitionStart` parameter is equal to the `daylightTransitionEnd` parameter.

-or-

The `dateStart` or `dateEnd` parameter includes a time of day value.

ArgumentOutOfRangeException

`dateEnd` is earlier than `dateStart`.

-or-

`daylightDelta` is less than -14 or greater than 14.

-or-

The Milliseconds property of the `daylightDelta` parameter is not equal to 0.

-or-

The Ticks property of the `daylightDelta` parameter does not equal a whole number of seconds.

Examples

The following example creates an alternate Central Standard Time zone and defines three adjustment rules for the periods 1976-1986, 1987-2006, and 2007 and beyond. These rules are added to a generic List<T> object whose elements are then copied to a TimeZoneInfo.AdjustmentRule array. This array is then used in the call to the TimeZoneInfo.CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[]) method.

C#

```
// Create alternate Central Standard Time to include historical time zone
information
//
// Declare necessary TimeZoneInfo.AdjustmentRule objects for time zone
TimeSpan delta = new TimeSpan(1, 0, 0);
TimeZoneInfo.AdjustmentRule adjustment;
List<TimeZoneInfo.AdjustmentRule> adjustmentList = new
List<TimeZoneInfo.AdjustmentRule>();
// Declare transition time variables to hold transition time information
TimeZoneInfo.TransitionTime transitionRuleStart, transitionRuleEnd;

// Define end rule (for 1976-2006)
transitionRuleEnd =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
2, 0, 0), 10, 5, DayOfWeek.Sunday);
// Define rule (1976-1986)
transitionRuleStart =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
2, 0, 0), 04, 05, DayOfWeek.Sunday);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1976, 1, 1), new DateTime(1986, 12, 31), delta,
transitionRuleStart, transitionRuleEnd);
adjustmentList.Add(adjustment);
// Define rule (1987-2006)
transitionRuleStart =
```

```
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
2, 0, 0), 04, 01, DayOfWeek.Sunday);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1987, 1, 1), new DateTime(2006, 12, 31), delta,
transitionRuleStart, transitionRuleEnd);
adjustmentList.Add(adjustment);
// Define rule (2007- )
transitionRuleStart =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
2, 0, 0), 03, 02, DayOfWeek.Sunday);
transitionRuleEnd =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
2, 0, 0), 11, 01, DayOfWeek.Sunday);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(2007, 01, 01), DateTime.MaxValue.Date, delta,
transitionRuleStart, transitionRuleEnd);
adjustmentList.Add(adjustment);

// Create custom U.S. Central Standard Time zone
TimeZoneInfo.CreateCustomTimeZone("Central Standard Time", new
TimeSpan(-6, 0, 0),
                "(GMT-06:00) Central Time (US Only)", "Central Standard
Time",
                "Central Daylight Time", adjustmentList.ToArray());
```

Remarks

You can use this method to create one or more adjustment rules for a custom time zone. An array of the TimeZoneInfo.AdjustmentRule objects returned by calls to this method can then be passed as the `adjustmentRules` parameter to two overloads of the CreateCustomTimeZone method. The example illustrates this procedure.

> **Note**
>
> The **CreateAdjustmentRule** method can be used only to define an adjustment rule for a new time zone; it cannot be used to modify an adjustment rule for an existing time zone.

The `dateStart` and `dateEnd` parameters must be date values without a time component or an ArgumentException is thrown. The time component can be removed by retrieving a DateTime value from the date and time's Date property as shown in the following statements:

```

DateTime.MinValue.Date
DateTime.MaxValue.Date
```

```
DateTime.Now.Date
dateVariable.Date
```

The Kind property of the `dateStart` and `dateEnd` parameters must also be DateTimeKind.Unspecified.

The value of the `daylightDelta` parameter can range from -14 to 14. The sum of the `daylightDelta` parameter and the `baseUtcOffset` parameter used in the call to the TimeZoneInfo.CreateCustomTimeZone method must also range from -14 to 14 or an InvalidTimeZoneException is thrown.

> **Note**
>
> The `daylightDelta` parameter defines the difference between a time zone's standard time and its daylight saving time. It is not intended to define the time zone's standard time offset from Coordinated Universal Time (UTC). The **TimeZoneInfo** class assumes that this offset from UTC is constant throughout the life of the time zone. To reflect a change in a time zone's offset from UTC that is not caused by the application of an adjustment rule, you must use the **CreateCustomTimeZone** method to create a new custom time zone.

.NET Standard	2.0, 2.1

CreateAdjustmentRule(DateTime, DateTime, TimeSpan, TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime, TimeSpan)

Creates a new adjustment rule for a particular time zone.

```
C#
```

```
public static TimeZoneInfo.AdjustmentRule CreateAdjustmentRule (DateTime
dateStart, DateTime dateEnd, TimeSpan daylightDelta,
TimeZoneInfo.TransitionTime daylightTransitionStart,
TimeZoneInfo.TransitionTime daylightTransitionEnd, TimeSpan
baseUtcOffsetDelta);
```

Parameters

`dateStart` DateTime

The effective date of the adjustment rule. If the value is `DateTime.MinValue.Date`, this is the first adjustment rule in effect for a time zone.

`dateEnd` DateTime

The last date that the adjustment rule is in force. If the value is `DateTime.MaxValue.Date`, the adjustment rule has no end date.

`daylightDelta` TimeSpan

The time change that results from the adjustment. This value is added to the time zone's BaseUtcOffset and BaseUtcOffsetDelta properties to obtain the correct daylight offset from Coordinated Universal Time (UTC). This value can range from -14 to 14.

`daylightTransitionStart` TimeZoneInfo.TransitionTime

The start of daylight saving time.

`daylightTransitionEnd` TimeZoneInfo.TransitionTime

The end of daylight saving time.

`baseUtcOffsetDelta` TimeSpan

The time difference with the base UTC offset for the time zone during the adjustment-rule period.

Returns

TimeZoneInfo.AdjustmentRule

The new adjustment rule.

Applies to

TimeZoneInfo.AdjustmentRule.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Object)	Indicates whether the current instance is equal to another instance.
Equals(TimeZoneInfo+AdjustmentRule)	Determines whether the current TimeZoneInfo.AdjustmentRule object is equal to a second TimeZoneInfo.AdjustmentRule object.

Equals(Object)

Indicates whether the current instance is equal to another instance.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An instance to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the other instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Equals(TimeZoneInfo+AdjustmentRule)

Determines whether the current TimeZoneInfo.AdjustmentRule object is equal to a second TimeZoneInfo.AdjustmentRule object.

```
C#
public bool Equals (TimeZoneInfo.AdjustmentRule? other);
```

Parameters

`other` TimeZoneInfo.AdjustmentRule

The object to compare with the current object.

Returns

Boolean

`true` if both TimeZoneInfo.AdjustmentRule objects have equal values; otherwise, `false`.

Implements

Equals(T)

Examples

The following example calls the TimeZoneInfo.AdjustmentRule.Equals(TimeZoneInfo+AdjustmentRule) method to compare the adjustment rules for Central Standard Time with those for Canada Central Standard Time and Mexico Standard Time.

```
C#
```

```
   string timeZoneName = "";
   // Get CST, Canadian CST, and Mexican CST adjustment rules
   TimeZoneInfo.AdjustmentRule[] usCstAdjustments = null;
   TimeZoneInfo.AdjustmentRule[] canCstAdjustments = null;
   TimeZoneInfo.AdjustmentRule[] mexCstAdjustments = null;
   try
   {
      timeZoneName = "Central Standard Time";
      usCstAdjustments =
TimeZoneInfo.FindSystemTimeZoneById(timeZoneName).GetAdjustmentRules();
   }
   catch (TimeZoneNotFoundException)
   {
      Console.WriteLine("The {0} time zone is not defined in the
registry.",
                        timeZoneName);
   }
   catch (InvalidTimeZoneException)
   {
      Console.WriteLine("Data for the {0} time zone is invalid.",
                        timeZoneName);
   }
   try
   {
      timeZoneName = "Canada Central Standard Time";
      canCstAdjustments =
TimeZoneInfo.FindSystemTimeZoneById(timeZoneName).GetAdjustmentRules();
   }
   catch (TimeZoneNotFoundException)
   {
      Console.WriteLine("The {0} time zone is not defined in the
registry.",
                        timeZoneName);
   }
   catch (InvalidTimeZoneException)
   {
      Console.WriteLine("Data for the {0} time zone is invalid.",
                        timeZoneName);
   }
   try
   {
      timeZoneName = "Central Standard Time (Mexico)";
      mexCstAdjustments =
TimeZoneInfo.FindSystemTimeZoneById(timeZoneName).GetAdjustmentRules();
   }
   catch (TimeZoneNotFoundException)
   {
      Console.WriteLine("The {0} time zone is not defined in the
registry.",
                        timeZoneName);
   }
   catch (InvalidTimeZoneException)
   {
      Console.WriteLine("Data for the {0} time zone is invalid.",
```

```
                        timeZoneName);
    }
    // Determine if CST and other time zones have the same rules
    foreach(TimeZoneInfo.AdjustmentRule rule in usCstAdjustments)
    {
       Console.WriteLine("Comparing Central Standard Time rule for {0:d}
to {1:d} with:",
                        rule.DateStart, rule.DateEnd);
       // Compare with Canada Central Standard Time
       if (canCstAdjustments.Length == 0)
       {
          Console.WriteLine("   Canada Central Standard Time has no
adjustment rules.");
       }
       else
       {
          foreach (TimeZoneInfo.AdjustmentRule canRule in
canCstAdjustments)
          {
             Console.WriteLine("   Canadian CST for {0:d} to {1:d}: {2}",
                               canRule.DateStart, canRule.DateEnd,
                               rule.Equals(canRule) ? "Equal" : "Not
Equal");
          }
       }

       // Compare with Mexico Central Standard Time
       if (mexCstAdjustments.Length == 0)
       {
          Console.WriteLine("   Mexican Central Standard Time has no
adjustment rules.");
       }
       else
       {
          foreach (TimeZoneInfo.AdjustmentRule mexRule in
mexCstAdjustments)
          {
             Console.WriteLine("   Mexican CST for {0:d} to {1:d}: {2}",
                               mexRule.DateStart, mexRule.DateEnd,
                               rule.Equals(mexRule) ? "Equal" : "Not
Equal");
          }
       }
    }
    // This code displays the following output to the console:
    //
    // Comparing Central Standard Time rule for 1/1/0001 to 12/31/9999
with:
    //    Canada Central Standard Time has no adjustment rules.
    //    Mexican CST for 1/1/0001 to 12/31/9999: Equal
```

This code displays the following output to the console:

```
Comparing Central Standard Time rule for 1/1/0001 to 12/31/9999 with:
   Canada Central Standard Time has no adjustment rules.
   Mexican CST for 1/1/0001 to 12/31/9999: Equal
```

Remarks

To determine whether two TimeZoneInfo.AdjustmentRule objects are equal, the Equals(TimeZoneInfo+AdjustmentRule) method compares the member values of each object. Two adjustment rules are equal if they have the same effective dates, the same delta, and identical values for the TimeZoneInfo.TransitionTime objects returned by their DaylightTransitionStart and DaylightTransitionEnd properties.

TimeZoneInfo.AdjustmentRule.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as a hash function for hashing algorithms and data structures such as hash tables.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer that serves as the hash code for the current TimeZoneInfo.AdjustmentRule object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.AdjustmentRule.IDeserializationCallback.OnDeserialization Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Runs when the deserialization of a TimeZoneInfo.AdjustmentRule object is completed.

```
C#
void IDeserializationCallback.OnDeserialization (object sender);
```

Parameters

`sender` Object

The object that initiated the callback. The functionality for this parameter is not currently implemented.

Implements

OnDeserialization(Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.AdjustmentRule.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data that is required to serialize this object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to populate with data.

`context` StreamingContext

The destination for this serialization (see StreamingContext).

Implements

GetObjectData(SerializationInfo, StreamingContext)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.TransitionTime Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides information about a specific time change, such as the change from daylight saving time to standard time or vice versa, in a particular time zone.

C#

```
public readonly struct TimeZoneInfo.TransitionTime :
IEquatable<TimeZoneInfo.TransitionTime>,
System.Runtime.Serialization.IDeserializationCallback,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → ValueType → TimeZoneInfo.TransitionTime

Implements IEquatable<TimeZoneInfo.TransitionTime> , IDeserializationCallback , ISerializable

Remarks

You can use the TimeZoneInfo.TransitionTime structure to indicate when a transition from standard time to daylight saving time, or from daylight saving time back to standard time, occurs. This structure supports both fixed-date rules and floating-date rules. Use fixed-date rules for time transitions that occur on a specific day of a specific month (such as 2:00 A.M. on November 3). Use floating-date rules for time transitions that occur on a specific day of a specific week of a specific month (such as 2:00 A.M. on the first Sunday of November).

The following table compares the properties used in fixed-date and floating-date transitions:

Expand table

	Month	Week	Day	Time
Fixed-date rule	Month	N/A	Day	TimeOfDay
Floating-date rule	Month	Week	DayOfWeek	TimeOfDay

For both fixed-date and floating-date transitions, the TimeOfDay property gets the time at which the time change occurs. For transitions from standard to daylight saving time, this is the time zone's standard time value. For transitions from daylight saving to standard time, this is the time zone's daylight saving time value. This is a DateTime value whose date component is ignored; its year, month, and day value must always equal 1.

> **Note**
>
> An instance of the **TimeZoneInfo.TransitionTime** structure is immutable. Once an object has been created, its values cannot be modified.

A TimeZoneInfo.TransitionTime object can be created by calling the `static` (`Shared` in Visual Basic) CreateFixedDateRule and CreateFloatingDateRule methods to create a fixed or floating-date rule, respectively. The starting and ending TimeZoneInfo.TransitionTime objects are then supplied as parameters to the CreateAdjustmentRule method to create a new adjustment rule that includes this transition time information.

The DaylightTransitionStart and DaylightTransitionEnd properties of an TimeZoneInfo.AdjustmentRule object return a TimeZoneInfo.TransitionTime object.

Properties

Expand table

Day	Gets the day on which the time change occurs.
DayOfWeek	Gets the day of the week on which the time change occurs.
IsFixedDateRule	Gets a value indicating whether the time change occurs at a fixed date and time (such as November 1) or a floating date and time (such as the last Sunday of October).
Month	Gets the month in which the time change occurs.
TimeOfDay	Gets the hour, minute, and second at which the time change occurs.
Week	Gets the week of the month in which a time change occurs.

Methods

Expand table

CreateFixedDateRule(DateTime, Int32, Int32)	Defines a time change that uses a fixed-date rule (that is, a time change that occurs on a specific day of a specific month).
CreateFloatingDateRule(DateTime, Int32, Int32, DayOfWeek)	Defines a time change that uses a floating-date rule (that is, a time change that occurs on a specific day of a specific week of a specific month).
Equals(Object)	Determines whether an object has identical values to the current TimeZoneInfo.TransitionTime object.
Equals(TimeZoneInfo+TransitionTime)	Determines whether the current TimeZoneInfo.TransitionTime object has identical values to a second TimeZoneInfo.TransitionTime object.
GetHashCode()	Serves as a hash function for hashing algorithms and data structures such as hash tables.

Operators

Expand table

Equality(TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime)	Determines whether two specified TimeZoneInfo.TransitionTime objects are equal.
Inequality(TimeZoneInfo+TransitionTime, TimeZoneInfo+TransitionTime)	Determines whether two specified TimeZoneInfo.TransitionTime objects are not equal.

Explicit Interface Implementations

Expand table

IDeserializationCallback.OnDeserialization(Object)	Runs when the deserialization of an object has been completed.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo object with the data that is required to serialize this object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneInfo.TransitionTime.Day Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day on which the time change occurs.

C#

```
public int Day { get; }
```

Property Value

Int32

The day on which the time change occurs.

Examples

The following example enumerates the time zones found on the local computer and displays transition time information for all fixed-date transitions. The time information includes the day on which the time change occurs.

C#

```
private void GetFixedTransitionTimes()
{
   ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
   DateTimeFormatInfo dateInfo = CultureInfo.CurrentCulture.DateTimeFormat;
   foreach (TimeZoneInfo zone in timeZones)
   {
      TimeZoneInfo.AdjustmentRule[] adjustmentRules =
zone.GetAdjustmentRules();
      foreach (TimeZoneInfo.AdjustmentRule adjustmentRule in
adjustmentRules)
      {
         TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
```

```
         if (daylightStart.IsFixedDateRule)
            Console.WriteLine("For {0}, daylight savings time begins at
{1:t} on {2} {3} from {4:d} to {5:d}.",
                              zone.StandardName,
                              daylightStart.TimeOfDay,
                              dateInfo.GetMonthName(daylightStart.Month),
                              daylightStart.Day,
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd);
         TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
         if (daylightEnd.IsFixedDateRule)
            Console.WriteLine("For {0}, daylight savings time ends at {1:t}
on {2} {3} from {4:d} to {5:d}.",
                              zone.StandardName,
                              daylightEnd.TimeOfDay,
                              dateInfo.GetMonthName(daylightEnd.Month),
                              daylightEnd.Day,
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd);
      }
   }
}
```

Remarks

The Day property returns a valid value only if the IsFixedDateRule property is `true`.

The Day property value corresponds to the value of the `day` parameter of the CreateFixedDateRule method. If its value is greater than the number of days in the month of the transition, the transition occurs on the last day of the month.

The Day property indicates the day of the month on which a fixed-date rule is applied (for example, April 15). In contrast, the DayOfWeek property indicates the day of the week on which a floating-date rule is applied (for example, the second Sunday of November).

Applies to

TimeZoneInfo.TransitionTime.DayOfWeek Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the day of the week on which the time change occurs.

C#

```
public DayOfWeek DayOfWeek { get; }
```

Property Value

DayOfWeek

The day of the week on which the time change occurs.

Examples

The following example enumerates the time zones found on the local computer and displays transition time information for all floating-date transitions. The time information includes the day of the week on which the time change occurs.

C#

```
private enum WeekOfMonth
{
   First = 1,
   Second = 2,
   Third = 3,
   Fourth = 4,
   Last = 5
}

private void GetFloatingTransitionTimes()
{
   ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
   foreach (TimeZoneInfo zone in timeZones)
```

```
    {
        TimeZoneInfo.AdjustmentRule[] adjustmentRules =
zone.GetAdjustmentRules();
        DateTimeFormatInfo dateInfo =
CultureInfo.CurrentCulture.DateTimeFormat;
        foreach (TimeZoneInfo.AdjustmentRule adjustmentRule in
adjustmentRules)
        {
            TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
            if (! daylightStart.IsFixedDateRule)
                Console.WriteLine("{0}, {1:d}-{2:d}: Begins at {3:t} on the {4}
{5} of {6}.",
                                  zone.StandardName,
                                  adjustmentRule.DateStart,
                                  adjustmentRule.DateEnd,
                                  daylightStart.TimeOfDay,
                                  ((WeekOfMonth)daylightStart.Week).ToString(),
                                  daylightStart.DayOfWeek.ToString(),
                                  dateInfo.GetMonthName(daylightStart.Month));

            TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
            if (! daylightEnd.IsFixedDateRule)
                Console.WriteLine("{0}, {1:d}-{2:d}: Ends at {3:t} on the {4}
{5} of {6}.",
                                  zone.StandardName,
                                  adjustmentRule.DateStart,
                                  adjustmentRule.DateEnd,
                                  daylightEnd.TimeOfDay,
                                  ((WeekOfMonth)daylightEnd.Week).ToString(),
                                  daylightEnd.DayOfWeek.ToString(),
                                  dateInfo.GetMonthName(daylightEnd.Month));
        }
    }
}
```

Remarks

The DayOfWeek property returns a valid value only if the IsFixedDateRule property is `false`.

The DayOfWeek property indicates the day of the week on which a floating-date rule is applied (for example, the second Sunday of November). In contrast, the Day property indicates the day of the month on which a fixed-date rule is applied (for example, April 15).

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the time change occurs at a fixed date and time (such as November 1) or a floating date and time (such as the last Sunday of October).

C#

```
public bool IsFixedDateRule { get; }
```

Property Value

Boolean

`true` if the time change rule is fixed-date; `false` if the time change rule is floating-date.

Examples

The following example lists the transition times to and from daylight saving time for all time zones that are available on the local system. For time zones with fixed-date rules, it displays transition time information from the properties of the TimeZoneInfo.TransitionTime object. For time zones without fixed-date rules, it uses a Calendar object that represents the current system calendar to determine the actual start and end dates of the transition. The example displays the results to the console.

C#

```
private void GetTransitionTimes(int year)
{
   // Instantiate DateTimeFormatInfo object for month names
   DateTimeFormatInfo dateFormat =
CultureInfo.CurrentCulture.DateTimeFormat;

   // Get and iterate time zones on local computer
   ReadOnlyCollection<TimeZoneInfo> timeZones =
```

```
TimeZoneInfo.GetSystemTimeZones();
   foreach (TimeZoneInfo timeZone in timeZones)
   {
      Console.WriteLine("{0}:", timeZone.StandardName);
      TimeZoneInfo.AdjustmentRule[] adjustments =
timeZone.GetAdjustmentRules();
      int startYear = year;
      int endYear = startYear;

      if (adjustments.Length == 0)
      {
         Console.WriteLine("   No adjustment rules.");
      }
      else
      {
         TimeZoneInfo.AdjustmentRule adjustment = GetAdjustment(adjustments,
year);
         if (adjustment == null)
         {
            Console.WriteLine("   No adjustment rules available for this
year.");
            continue;
         }
         TimeZoneInfo.TransitionTime startTransition, endTransition;

         // Determine if starting transition is fixed
         startTransition = adjustment.DaylightTransitionStart;
         // Determine if starting transition is fixed and display transition
info for year
         if (startTransition.IsFixedDateRule)
            Console.WriteLine("   Begins on {0} {1} at {2:t}",

dateFormat.GetMonthName(startTransition.Month),
                              startTransition.Day,
                              startTransition.TimeOfDay);
         else
            DisplayTransitionInfo(startTransition, startYear, "Begins on");

         // Determine if ending transition is fixed and display transition
info for year
         endTransition = adjustment.DaylightTransitionEnd;

         // Does the transition back occur in an earlier month (i.e.,
         // the following year) than the transition to DST? If so, make
         // sure we have the right adjustment rule.
         if (endTransition.Month < startTransition.Month)
         {
            endTransition = GetAdjustment(adjustments, year +
1).DaylightTransitionEnd;
            endYear++;
         }

         if (endTransition.IsFixedDateRule)
            Console.WriteLine("   Ends on {0} {1} at {2:t}",
                              dateFormat.GetMonthName(endTransition.Month),
```

```
                                endTransition.Day,
                                endTransition.TimeOfDay);
         else
            DisplayTransitionInfo(endTransition, endYear, "Ends on");
      }
   }
}

private static TimeZoneInfo.AdjustmentRule
GetAdjustment(TimeZoneInfo.AdjustmentRule[] adjustments,
                                                    int year)
{
   // Iterate adjustment rules for time zone
   foreach (TimeZoneInfo.AdjustmentRule adjustment in adjustments)
   {
      // Determine if this adjustment rule covers year desired
      if (adjustment.DateStart.Year <= year && adjustment.DateEnd.Year >=
year)
         return adjustment;
   }
   return null;
}

private void DisplayTransitionInfo(TimeZoneInfo.TransitionTime transition,
int year, string label)
{
   // For non-fixed date rules, get local calendar
   Calendar cal = CultureInfo.CurrentCulture.Calendar;
   // Get first day of week for transition
   // For example, the 3rd week starts no earlier than the 15th of the month
   int startOfWeek = transition.Week * 7 - 6;
   // What day of the week does the month start on?
   int firstDayOfWeek = (int) cal.GetDayOfWeek(new DateTime(year,
transition.Month, 1));
   // Determine how much start date has to be adjusted
   int transitionDay;
   int changeDayOfWeek = (int) transition.DayOfWeek;

   if (firstDayOfWeek <= changeDayOfWeek)
      transitionDay = startOfWeek + (changeDayOfWeek - firstDayOfWeek);
   else
      transitionDay = startOfWeek + (7 - firstDayOfWeek + changeDayOfWeek);

   // Adjust for months with no fifth week
   if (transitionDay > cal.GetDaysInMonth(year, transition.Month))
      transitionDay -= 7;

   Console.WriteLine("   {0} {1}, {2:d} at {3:t}",
                     label,
                     transition.DayOfWeek,
                     new DateTime(year, transition.Month, transitionDay),
                     transition.TimeOfDay);
}
```

Remarks

A fixed-date rule indicates that the transition occurs on the same date and time of each year to which the adjustment rule applies. For example, a time change that occurs every November 3 follows a fixed-date rule. A floating-date rule indicates that the transition occurs on a specific day of a specific week of a specific month for each year to which the adjustment rule applies. For example, a time change that occurs on the first Sunday of November follows a floating-date rule.

The value of the IsFixedDateRule property determines which properties of a TimeZoneInfo.TransitionTime object have valid values. The following table indicates which properties are affected by the value of the IsFixedDateRule property.

Expand table

TransitionTime property	IsFixedDateRule = true	IsFixedDateRule = false
`Day`	Valid	Unused
`DayOfWeek`	Unused	Valid
`Week`	Unused	Valid
`Month`	Valid	Valid
`TimeOfDay`	Valid	Valid

TimeZoneInfo.TransitionTime.Month Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the month in which the time change occurs.

C#

```
public int Month { get; }
```

Property Value

Int32

The month in which the time change occurs.

Examples

The following example enumerates the time zones found on the local computer and displays transition time information for all floating-date transitions. The time information includes the month in which the time change occurs.

C#

```
private enum WeekOfMonth
{
   First = 1,
   Second = 2,
   Third = 3,
   Fourth = 4,
   Last = 5
}

private void GetFloatingTransitionTimes()
{
   ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
   foreach (TimeZoneInfo zone in timeZones)
```

```
   {
      TimeZoneInfo.AdjustmentRule[] adjustmentRules =
zone.GetAdjustmentRules();
      DateTimeFormatInfo dateInfo =
CultureInfo.CurrentCulture.DateTimeFormat;
      foreach (TimeZoneInfo.AdjustmentRule adjustmentRule in
adjustmentRules)
      {
         TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
         if (! daylightStart.IsFixedDateRule)
            Console.WriteLine("{0}, {1:d}-{2:d}: Begins at {3:t} on the {4}
{5} of {6}.",
                              zone.StandardName,
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd,
                              daylightStart.TimeOfDay,
                              ((WeekOfMonth)daylightStart.Week).ToString(),
                              daylightStart.DayOfWeek.ToString(),
                              dateInfo.GetMonthName(daylightStart.Month));

         TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
         if (! daylightEnd.IsFixedDateRule)
            Console.WriteLine("{0}, {1:d}-{2:d}: Ends at {3:t} on the {4}
{5} of {6}.",
                              zone.StandardName,
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd,
                              daylightEnd.TimeOfDay,
                              ((WeekOfMonth)daylightEnd.Week).ToString(),
                              daylightEnd.DayOfWeek.ToString(),
                              dateInfo.GetMonthName(daylightEnd.Month));
      }
   }
}
```

Remarks

Valid values for the Month property range from 1 to 12.

The Month property is used for both fixed-date and floating-date rules.

TimeZoneInfo.TransitionTime.TimeOfDay Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the hour, minute, and second at which the time change occurs.

C#

```
public DateTime TimeOfDay { get; }
```

Property Value

DateTime

The time of day at which the time change occurs.

Examples

The following example enumerates the time zones found on the local computer and displays transition time information for those time zones that have adjustment rules. The time information includes the time of day at which the time change occurs.

C#

```
private enum WeekOfMonth
{
   First = 1,
   Second = 2,
   Third = 3,
   Fourth = 4,
   Last = 5,
}

public void GetAllTransitionTimes()
{
   ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
   DateTimeFormatInfo dateInfo = CultureInfo.CurrentCulture.DateTimeFormat;
```

```
   foreach (TimeZoneInfo zone in timeZones)
   {
      Console.WriteLine("{0} transition time information:",
zone.StandardName);
      TimeZoneInfo.AdjustmentRule[] adjustmentRules=
zone.GetAdjustmentRules();

      // Indicate that time zone has no adjustment rules
      if (adjustmentRules.Length == 0)
      {
         Console.WriteLine("   No adjustment rules defined.");
      }
      else
      {
         // Iterate adjustment rules
         foreach (TimeZoneInfo.AdjustmentRule adjustmentRule in
adjustmentRules)
         {
            Console.WriteLine("   Adjustment rule from {0:d} to {1:d}:",
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd);

            // Get start of transition
            TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
            // Display information on fixed date rule
            if (! daylightStart.IsFixedDateRule)
               Console.WriteLine("      Begins at {0:t} on the {1} {2} of
{3}.",
                              daylightStart.TimeOfDay,
                              ((WeekOfMonth)daylightStart.Week).ToString(),
                              daylightStart.DayOfWeek.ToString(),
                              dateInfo.GetMonthName(daylightStart.Month));
            // Display information on floating date rule
            else
               Console.WriteLine("      Begins at {0:t} on the {1} {2} of
{3}.",
                                 daylightStart.TimeOfDay,

((WeekOfMonth)daylightStart.Week).ToString(),
                                 daylightStart.DayOfWeek.ToString(),

dateInfo.GetMonthName(daylightStart.Month));

            // Get end of transition
            TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
            // Display information on fixed date rule
            if (! daylightEnd.IsFixedDateRule)
               Console.WriteLine("      Ends at {0:t} on the {1} {2} of
{3}.",
                              daylightEnd.TimeOfDay,
                              ((WeekOfMonth)daylightEnd.Week).ToString(),
                              daylightEnd.DayOfWeek.ToString(),
```

```
                                dateInfo.GetMonthName(daylightEnd.Month));
            // Display information on floating date rule
            else
               Console.WriteLine("      Ends at {0:t} on the {1} {2} of
{3}.",
                                  daylightStart.TimeOfDay,

((WeekOfMonth)daylightStart.Week).ToString(),
                                  daylightStart.DayOfWeek.ToString(),

dateInfo.GetMonthName(daylightStart.Month));
         }
      }
   }
}
```

Remarks

For transitions from standard time to daylight saving time, the TimeOfDay value represents the time of the transition in the time zone's standard time. For transitions from daylight saving time to standard time, it represents the time of the transition in the time zone's daylight saving time.

The TimeOfDay property defines only the time of a time change, but not its date. The date is determined by the Month and Day properties for fixed-rule changes, and by the Month, Week, and DayOfWeek properties for floating-rule changes. The date component of this DateTime value is ignored; the value of the year, month, and day is always 1.

The TimeOfDay property is used for both fixed-date and floating-date transitions.

TimeZoneInfo.TransitionTime.Week Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the week of the month in which a time change occurs.

C#

```
public int Week { get; }
```

Property Value

Int32

The week of the month in which the time change occurs.

Examples

The following example enumerates the time zones found on the local computer and displays transition time information for all floating-date transitions. The time information includes the week of the month in which the time change occurs. The example also defines a `WeekOfMonth` enumeration to display a string that represents the ordinal value of the Week property rather than an integer.

C#

```
private enum WeekOfMonth
{
   First = 1,
   Second = 2,
   Third = 3,
   Fourth = 4,
   Last = 5
}

private void GetFloatingTransitionTimes()
{
```

```
   ReadOnlyCollection<TimeZoneInfo> timeZones =
TimeZoneInfo.GetSystemTimeZones();
   foreach (TimeZoneInfo zone in timeZones)
   {
      TimeZoneInfo.AdjustmentRule[] adjustmentRules =
zone.GetAdjustmentRules();
      DateTimeFormatInfo dateInfo =
CultureInfo.CurrentCulture.DateTimeFormat;
      foreach (TimeZoneInfo.AdjustmentRule adjustmentRule in
adjustmentRules)
      {
         TimeZoneInfo.TransitionTime daylightStart =
adjustmentRule.DaylightTransitionStart;
         if (! daylightStart.IsFixedDateRule)
            Console.WriteLine("{0}, {1:d}-{2:d}: Begins at {3:t} on the {4}
{5} of {6}.",
                              zone.StandardName,
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd,
                              daylightStart.TimeOfDay,
                              ((WeekOfMonth)daylightStart.Week).ToString(),
                              daylightStart.DayOfWeek.ToString(),
                              dateInfo.GetMonthName(daylightStart.Month));

         TimeZoneInfo.TransitionTime daylightEnd =
adjustmentRule.DaylightTransitionEnd;
         if (! daylightEnd.IsFixedDateRule)
            Console.WriteLine("{0}, {1:d}-{2:d}: Ends at {3:t} on the {4}
{5} of {6}.",
                              zone.StandardName,
                              adjustmentRule.DateStart,
                              adjustmentRule.DateEnd,
                              daylightEnd.TimeOfDay,
                              ((WeekOfMonth)daylightEnd.Week).ToString(),
                              daylightEnd.DayOfWeek.ToString(),
                              dateInfo.GetMonthName(daylightEnd.Month));
      }
   }
}
```

Remarks

The value of the Week property is used only for time changes with floating-date rules. Valid values can range from 1 to 5.

The Month property defines the month in which the time change occurs. The Week property determines the week on which the transition occurs. The DayOfWeek property defines the day of the week on which the transition occurs. The value of the Week property is determined as shown in the following table.

Expand table

If the Week property value is	The transition occurs on
1	The first occurrence of the DayOfWeek value in Month.
2	The second occurrence of the DayOfWeek value in Month.
3	The third occurrence of the DayOfWeek value in Month.
4	The fourth occurrence of the DayOfWeek value in Month.
5	The last occurrence of the DayOfWeek value in Month.

For example, if a transition occurs on the first Sunday of March, the value of the Week property is 1. If it occurs on the last Sunday of March, the value of the Week property is 5.

TimeZoneInfo.TransitionTime.CreateFixedDateRule Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a time change that uses a fixed-date rule (that is, a time change that occurs on a specific day of a specific month).

C#

```
public static TimeZoneInfo.TransitionTime CreateFixedDateRule (DateTime
timeOfDay, int month, int day);
```

Parameters

timeOfDay DateTime

The time at which the time change occurs. This parameter corresponds to the TimeOfDay property.

month Int32

The month in which the time change occurs. This parameter corresponds to the Month property.

day Int32

The day of the month on which the time change occurs. This parameter corresponds to the Day property.

Returns

TimeZoneInfo.TransitionTime

Data about the time change.

Exceptions

ArgumentException

The `timeOfDay` parameter has a non-default date component.

-or-

The `timeOfDay` parameter's Kind property is not Unspecified.

-or-

The `timeOfDay` parameter does not represent a whole number of milliseconds.

ArgumentOutOfRangeException

The `month` parameter is less than 1 or greater than 12.

-or-

The `day` parameter is less than 1 or greater than 31.

Examples

The following example creates time zone transitions for an imaginary time zone by using both a fixed-date rule and a floating-date rule. The fixed-date rule defines a time zone adjustment that starts at 2:00 A.M. on March 15 and ends at 3:00 A.M. on November 15 for the years 1900 to 1955.

C#

```
// Declare necessary TimeZoneInfo.AdjustmentRule objects for time zone
TimeZoneInfo imaginaryTZ;
TimeSpan delta = new TimeSpan(1, 0, 0);
TimeZoneInfo.AdjustmentRule adjustment;
List<TimeZoneInfo.AdjustmentRule> adjustmentList = new
List<TimeZoneInfo.AdjustmentRule>();
// Declare transition time variables to hold transition time information
TimeZoneInfo.TransitionTime transitionRuleStart, transitionRuleEnd;

// Define a fictitious new time zone consisting of fixed and floating
adjustment rules
// Define fixed rule (for 1900-1955)
transitionRuleStart = TimeZoneInfo.TransitionTime.CreateFixedDateRule(new
DateTime(1, 1, 1, 2, 0, 0), 3, 15);
transitionRuleEnd = TimeZoneInfo.TransitionTime.CreateFixedDateRule(new
DateTime(1, 1, 1, 3, 0, 0), 11, 15);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1900, 1, 1), new DateTime(1955, 12, 31),
             delta, transitionRuleStart, transitionRuleEnd);
adjustmentList.Add(adjustment);
// Define floating rule (for 1956- )
transitionRuleStart = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
```

```
DateTime(1, 1, 1, 2, 0, 0), 3, 5, DayOfWeek.Sunday);
transitionRuleEnd = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1, 3, 0, 0), 10, 4, DayOfWeek.Sunday);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1956, 1, 1), DateTime.MaxValue.Date, delta, transitionRuleStart,
transitionRuleEnd);
adjustmentList.Add(adjustment);

// Create fictitious time zone
imaginaryTZ = TimeZoneInfo.CreateCustomTimeZone("Fictitious Standard Time",
new TimeSpan(-9, 0, 0),
                "(GMT-09:00) Fictitious Time", "Fictitious Standard Time",
                "Fictitious Daylight Time", adjustmentList.ToArray());
```

Remarks

This method creates a fixed-date rule (that is, a time change that occurs on a specific day of a specific month). For example, a time change that always occurs on October 28 follows a fixed-date rule.

For transitions from standard time to daylight saving time, the `timeOfDay` argument represents the time of the transition in the time zone's standard time. For transitions from daylight saving time to standard time, it represents the time of the transition in the time zone's daylight saving time. Note that this is a DateTime value whose year, month, and date values must all equal 1.

TimeZoneInfo.TransitionTime.CreateFloatingDateRule Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines a time change that uses a floating-date rule (that is, a time change that occurs on a specific day of a specific week of a specific month).

C#

```
public static TimeZoneInfo.TransitionTime CreateFloatingDateRule (DateTime
timeOfDay, int month, int week, DayOfWeek dayOfWeek);
```

Parameters

timeOfDay DateTime

The time at which the time change occurs. This parameter corresponds to the TimeOfDay property.

month Int32

The month in which the time change occurs. This parameter corresponds to the Month property.

week Int32

The week of the month in which the time change occurs. Its value can range from 1 to 5, with 5 representing the last week of the month. This parameter corresponds to the Week property.

dayOfWeek DayOfWeek

The day of the week on which the time change occurs. This parameter corresponds to the DayOfWeek property.

Returns

TimeZoneInfo.TransitionTime

Data about the time change.

Exceptions

ArgumentException

The `timeOfDay` parameter has a non-default date component.

-or-

The `timeOfDay` parameter does not represent a whole number of milliseconds.

-or-

The `timeOfDay` parameter's Kind property is not Unspecified.

ArgumentOutOfRangeException

`month` is less than 1 or greater than 12.

-or-

`week` is less than 1 or greater than 5.

-or-

The `dayOfWeek` parameter is not a member of the DayOfWeek enumeration.

Examples

The following example creates time zone transitions for an imaginary time zone by using both a fixed-date rule and a floating-date rule. The floating-date rule defines a time zone adjustment that starts at 2:00 A.M. on the last Sunday of March and ends at 3:00 A.M. on the fourth Sunday in October for the years 1956 onward.

C#

```
// Declare necessary TimeZoneInfo.AdjustmentRule objects for time zone
TimeZoneInfo imaginaryTZ;
TimeSpan delta = new TimeSpan(1, 0, 0);
TimeZoneInfo.AdjustmentRule adjustment;
List<TimeZoneInfo.AdjustmentRule> adjustmentList = new
List<TimeZoneInfo.AdjustmentRule>();
// Declare transition time variables to hold transition time information
TimeZoneInfo.TransitionTime transitionRuleStart, transitionRuleEnd;

// Define a fictitious new time zone consisting of fixed and floating
adjustment rules
```

```
// Define fixed rule (for 1900-1955)
transitionRuleStart = TimeZoneInfo.TransitionTime.CreateFixedDateRule(new
DateTime(1, 1, 1, 2, 0, 0), 3, 15);
transitionRuleEnd = TimeZoneInfo.TransitionTime.CreateFixedDateRule(new
DateTime(1, 1, 1, 3, 0, 0), 11, 15);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1900, 1, 1), new DateTime(1955, 12, 31),
             delta, transitionRuleStart, transitionRuleEnd);
adjustmentList.Add(adjustment);
// Define floating rule (for 1956- )
transitionRuleStart = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1, 2, 0, 0), 3, 5, DayOfWeek.Sunday);
transitionRuleEnd = TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new
DateTime(1, 1, 1, 3, 0, 0), 10, 4, DayOfWeek.Sunday);
adjustment = TimeZoneInfo.AdjustmentRule.CreateAdjustmentRule(new
DateTime(1956, 1, 1), DateTime.MaxValue.Date, delta, transitionRuleStart,
transitionRuleEnd);
adjustmentList.Add(adjustment);

// Create fictitious time zone
imaginaryTZ = TimeZoneInfo.CreateCustomTimeZone("Fictitious Standard Time",
new TimeSpan(-9, 0, 0),
                "(GMT-09:00) Fictitious Time", "Fictitious Standard Time",
                "Fictitious Daylight Time", adjustmentList.ToArray());
```

Remarks

This method creates a floating-date rule (that is, a time change that occurs on a specific day of a specific week of a specific month). For example, a time change that occurs on the last Sunday of October follows a floating-date rule.

For transitions from standard time to daylight saving time, the `timeOfDay` argument represents the time of the transition in the time zone's standard time. For transitions from daylight saving time to standard time, it represents the time of the transition in the time zone's daylight saving time. Note that this is a DateTime value whose year, month, and date values must all equal 1.

TimeZoneInfo.TransitionTime.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two TimeZoneInfo.TransitionTime objects have identical values.

Overloads

Expand table

Equals(Object)	Determines whether an object has identical values to the current TimeZoneInfo.TransitionTime object.
Equals(TimeZoneInfo+TransitionTime)	Determines whether the current TimeZoneInfo.TransitionTime object has identical values to a second TimeZoneInfo.TransitionTime object.

Equals(Object)

Determines whether an object has identical values to the current TimeZoneInfo.TransitionTime object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with the current TimeZoneInfo.TransitionTime object.

Returns

Boolean

`true` if the two objects are equal; otherwise, `false`.

Examples

The following example illustrates calls to the Equals method.

```C#
TimeZoneInfo.TransitionTime tt1 =
TimeZoneInfo.TransitionTime.CreateFixedDateRule(new DateTime(1, 1, 1, 02,
00, 00), 11, 03);
TimeZoneInfo.TransitionTime tt2 =
TimeZoneInfo.TransitionTime.CreateFixedDateRule(new DateTime(1, 1, 1, 02,
00, 00), 11, 03);
TimeZoneInfo.TransitionTime tt3 =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
02, 00, 00), 10, 05, DayOfWeek.Sunday);
TimeZoneInfo tz = TimeZoneInfo.Local;
Console.WriteLine(tt1.Equals(tz));         // Returns False (overload
with argument of type Object)
Console.WriteLine(tt1.Equals(tt1));        // Returns True (an object
always equals itself)
Console.WriteLine(tt1.Equals(tt2));        // Returns True (identical
property values)
Console.WriteLine(tt1.Equals(tt3));        // Returns False (different
property values)
```

Remarks

Equality is defined as follows: The `obj` parameter must be a TimeZoneInfo.TransitionTime object and must have property values identical to the current TimeZoneInfo.TransitionTime object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(TimeZoneInfo+TransitionTime)

Determines whether the current TimeZoneInfo.TransitionTime object has identical values to a second TimeZoneInfo.TransitionTime object.

```
C#

public bool Equals (TimeZoneInfo.TransitionTime other);
```

Parameters

`other` TimeZoneInfo.TransitionTime

An object to compare to the current instance.

Returns

Boolean

`true` if the two objects have identical property values; otherwise, `false`.

Implements

Equals(T)

Examples

The following example illustrates calls to the Equals method.

```
C#

TimeZoneInfo.TransitionTime tt1 =
TimeZoneInfo.TransitionTime.CreateFixedDateRule(new DateTime(1, 1, 1, 02,
00, 00), 11, 03);
TimeZoneInfo.TransitionTime tt2 =
TimeZoneInfo.TransitionTime.CreateFixedDateRule(new DateTime(1, 1, 1, 02,
00, 00), 11, 03);
TimeZoneInfo.TransitionTime tt3 =
TimeZoneInfo.TransitionTime.CreateFloatingDateRule(new DateTime(1, 1, 1,
02, 00, 00), 10, 05, DayOfWeek.Sunday);
Console.WriteLine(tt1.Equals(tt1));        // Returns True (an object
always equals itself)
Console.WriteLine(tt1.Equals(tt2));        // Returns True (identical
property values)
Console.WriteLine(tt1.Equals(tt3));        // Returns False (different
property values)
```

Remarks

To determine whether the two TimeZoneInfo.TransitionTime objects are equal, this method performs a property-by-property comparison. The method returns `true` only if the current TimeZoneInfo.TransitionTime object and the `other` object have identical values for each of the TimeZoneInfo.TransitionTime object's six property values.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TimeZoneInfo.TransitionTime.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as a hash function for hashing algorithms and data structures such as hash tables.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer that serves as the hash code for this TimeZoneInfo.TransitionTime object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.TransitionTime.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified TimeZoneInfo.TransitionTime objects are equal.

C#

```
public static bool operator == (TimeZoneInfo.TransitionTime t1,
TimeZoneInfo.TransitionTime t2);
```

Parameters

t1 TimeZoneInfo.TransitionTime

The first object to compare.

t2 TimeZoneInfo.TransitionTime

The second object to compare.

Returns

Boolean

`true` if `t1` and `t2` have identical values; otherwise, `false`.

Remarks

Two TimeZoneInfo.TransitionTime objects are equal if they have identical values for each of their six properties. Otherwise, they are unequal.

The equivalent method for this operator is TimeZoneInfo.TransitionTime.Equals(TimeZoneInfo+TransitionTime).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.TransitionTime.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified TimeZoneInfo.TransitionTime objects are not equal.

C#

```
public static bool operator != (TimeZoneInfo.TransitionTime t1,
TimeZoneInfo.TransitionTime t2);
```

Parameters

t1 TimeZoneInfo.TransitionTime

The first object to compare.

t2 TimeZoneInfo.TransitionTime

The second object to compare.

Returns

Boolean

`true` if `t1` and `t2` have any different member values; otherwise, `false`.

Remarks

Two TimeZoneInfo.TransitionTime objects are unequal if they have different values for any of their six properties. Otherwise, they are equal.

The equivalent method for this operator is TimeZoneInfo.TransitionTime.Equals(TimeZoneInfo+TransitionTime).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.TransitionTime.IDeserializationCallback.OnDeserialization Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Runs when the deserialization of an object has been completed.

C#

```
void IDeserializationCallback.OnDeserialization (object sender);
```

Parameters

`sender` Object

The object that initiated the callback. The functionality for this parameter is not currently implemented.

Implements

OnDeserialization(Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TimeZoneInfo.TransitionTime.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data that is required to serialize this object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object to populate with data.

`context` StreamingContext

The destination for this serialization (see StreamingContext).

Implements

GetObjectData(SerializationInfo, StreamingContext)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneNotFoundException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a time zone cannot be found.

C#

```
public class TimeZoneNotFoundException : Exception
```

Inheritance Object → Exception → TimeZoneNotFoundException

Remarks

This exception is thrown by the ConvertTimeBySystemTimeZoneId and FindSystemTimeZoneById methods when a time zone identifier cannot be found on the local system, or when there is no data associated with a particular time zone identifier.

Because the registry serves as the repository of time zone information in Windows XP and Windows Vista, this exception indicates that the registry contains no information about a particular time zone. Time zone information is stored in the subkeys of HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Time Zones.

If an application depends on the presence of a particular time zone and the attempt to retrieve it throws a TimeZoneNotFoundException, the application can handle the exception in either of two ways:

- By calling the FromSerializedString method to deserialize a saved TimeZoneInfo object.
- By calling one of the overloads of the CreateCustomTimeZone method to create a time zone.

See the examples for the TimeZoneInfo.CreateCustomTimeZone(String, TimeSpan, String, String, String, TimeZoneInfo+AdjustmentRule[], Boolean) and FromSerializedString methods.

Constructors

Expand table

TimeZoneNotFoundException()	Initializes a new instance of the TimeZoneNotFoundException class with a system-supplied message.
TimeZoneNotFound Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TimeZoneNotFoundException class from serialized data.
TimeZoneNotFoundException(String)	Initializes a new instance of the TimeZoneNotFoundException class with the specified message string.
TimeZoneNotFoundException(String, Exception)	Initializes a new instance of the TimeZoneNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)

TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneNotFoundException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the TimeZoneNotFoundException class.

Overloads

Expand table

TimeZoneNotFoundException()	Initializes a new instance of the TimeZoneNotFoundException class with a system-supplied message.
TimeZoneNotFoundException(String)	Initializes a new instance of the TimeZoneNotFoundException class with the specified message string.
TimeZoneNotFoundException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TimeZoneNotFoundException class from serialized data.
TimeZoneNotFoundException(String, Exception)	Initializes a new instance of the TimeZoneNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

TimeZoneNotFoundException()

Initializes a new instance of the TimeZoneNotFoundException class with a system-supplied message.

```
C#
```

```
public TimeZoneNotFoundException ();
```

Remarks

This is the parameterless constructor of the TimeZoneNotFoundException class. This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "The time zone '*timeZoneName*' was not found on the local computer." This message is localized for the current system culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneNotFoundException(String)

Initializes a new instance of the TimeZoneNotFoundException class with the specified message string.

C#

```
public TimeZoneNotFoundException (string? message);
```

Parameters

`message` String

A string that describes the exception.

Remarks

The `message` string is assigned to the Message property. The string should be localized for the current culture.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneNotFoundException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the TimeZoneNotFoundException class from serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected TimeZoneNotFoundException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that contains the serialized data.

`context` StreamingContext

The stream that contains the serialized data.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` parameter is `null`.

-or-

The `context` parameter is `null`.

Remarks

This constructor is not called directly by your code to instantiate the TimeZoneNotFoundException object. Instead, it is called by the IFormatter object's Deserialize method when deserializing the TimeZoneNotFoundException object from a stream.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TimeZoneNotFoundException(String, Exception)

Initializes a new instance of the TimeZoneNotFoundException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public TimeZoneNotFoundException (string? message, Exception?
innerException);
```

Parameters

`message` String

A string that describes the exception.

`innerException` Exception

The exception that is the cause of the current exception.

Examples

The following example tries to retrieve a nonexistent time zone, which throws a TimeZoneNotFoundException. The exception handler wraps the exception in a new TimeZoneNotFoundException object, which the exception handler returns to the caller. The caller's exception handler then displays information about both the outer and inner exception.

C#

```
private void HandleInnerException()
{
   string timeZoneName = "Any Standard Time";
   TimeZoneInfo tz;
   try
   {
      tz = RetrieveTimeZone(timeZoneName);
      Console.WriteLine("The time zone display name is {0}.",
tz.DisplayName);
   }
   catch (TimeZoneNotFoundException e)
   {
      Console.WriteLine("{0} thrown by application", e.GetType().Name);
      Console.WriteLine("   Message: {0}", e.Message);
      if (e.InnerException != null)
      {
         Console.WriteLine("   Inner Exception Information:");
         Exception innerEx = e.InnerException;
         while (innerEx != null)
         {
            Console.WriteLine("      {0}: {1}", innerEx.GetType().Name,
innerEx.Message);
            innerEx = innerEx.InnerException;
         }
      }
   }
}

private TimeZoneInfo RetrieveTimeZone(string tzName)
{
   try
   {
```

```
        return TimeZoneInfo.FindSystemTimeZoneById(tzName);
    }
    catch (TimeZoneNotFoundException ex1)
    {
        throw new TimeZoneNotFoundException(
              String.Format("The time zone '{0}' cannot be found.",
tzName),
              ex1);
    }
    catch (InvalidTimeZoneException ex2)
    {
        throw new InvalidTimeZoneException(
              String.Format("The time zone {0} contains invalid data.",
tzName),
              ex2);
    }
}
```

Remarks

Typically, you use this TimeZoneNotFoundException overload to handle an exception in a `try`...`catch` block. The `innerException` parameter should be a reference to the exception object handled in the `catch` block, or it can be `null`. This value is then assigned to the TimeZoneNotFoundException object's InnerException property.

The `message` string is assigned to the Message property. The string should be localized for the current culture.

Tuple Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides static methods for creating tuple objects.

C#

```
public static class Tuple
```

Inheritance Object → Tuple

Examples

The following example creates an 8-tuple (octuple) that contains prime numbers that are less than 20.

C#

```
var primes = Tuple.Create(2, 3, 5, 7, 11, 13, 17, 19);
Console.WriteLine("Prime numbers less than 20: " +
                  "{0}, {1}, {2}, {3}, {4}, {5}, {6}, and {7}",
                  primes.Item1, primes.Item2, primes.Item3,
                  primes.Item4, primes.Item5, primes.Item6,
                  primes.Item7, primes.Rest.Item1);
// The example displays the following output:
//    Prime numbers less than 20: 2, 3, 5, 7, 11, 13, 17, and 19
```

Remarks

A tuple is a data structure that has a specific number and sequence of elements. An example of a tuple is a data structure with three elements (known as a 3-tuple or triple) that is used to store an identifier such as a person's name in the first element, a year in the second element, and the person's income for that year in the third element. The .NET Framework directly supports tuples with one to seven elements. In addition, you

can create tuples of eight or more elements by nesting tuple objects in the Rest property of a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Tuples are commonly used in four ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set.
- To return multiple values from a method without using `out` parameters (in C#) or `ByRef` parameters (in Visual Basic).
- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup time. If you supply a Tuple<T1,T2,T3> object as the method argument, you can supply the thread's startup routine with three items of data.

The Tuple class does not itself represent a tuple. Instead, it is a class that provides static methods for creating instances of the tuple types that are supported by the .NET Framework. It provides helper methods that you can call to instantiate tuple objects without having to explicitly specify the type of each tuple component.

Although you can create an instance of a tuple class by calling its class constructor, the code to do so can be cumbersome. The following example uses a class constructor to create a 7-tuple or septuple that contains population data for New York City for each census from 1950 through 2000.

C#

```
// Create a 7-tuple.
var population = new Tuple<string, int, int, int, int, int, int>(
                           "New York", 7891957, 7781984,
                           7894862, 7071639, 7322564, 8008278);
// Display the first and last elements.
Console.WriteLine("Population of {0} in 2000: {1:N0}",
                  population.Item1, population.Item7);
// The example displays the following output:
//       Population of New York in 2000: 8,008,278
```

Creating the same tuple object by using a helper method is more straightforward, as the following example shows.

C#

```
// Create a 7-tuple.
var population = Tuple.Create("New York", 7891957, 7781984, 7894862,
7071639, 7322564, 8008278);
// Display the first and last elements.
Console.WriteLine("Population of {0} in 2000: {1:N0}",
                  population.Item1, population.Item7);
// The example displays the following output:
//       Population of New York in 2000: 8,008,278
```

The Create helper methods directly support the creation of tuple objects that have from one to eight components (that is, singletons through octuples). Although there is no practical limit to the number of components a tuple may have, helper methods are not available to create a tuple with nine or more components. To create such a tuple, you must call the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> constructor.

> **Note**
>
> For additional information and examples that use tuples, see the documentation for the individual tuple types in the .NET Framework. These are listed in the See Also section at the end of this topic.

Methods

Expand table

Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)	Creates a new 8-tuple, or octuple.
Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Creates a new 7-tuple, or septuple.
Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Creates a new 6-tuple, or sextuple.
Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Creates a new 5-tuple, or quintuple.
Create<T1,T2,T3,T4>(T1, T2, T3, T4)	Creates a new 4-tuple, or quadruple.
Create<T1,T2,T3>(T1, T2, T3)	Creates a new 3-tuple, or triple.
Create<T1,T2>(T1, T2)	Creates a new 2-tuple, or pair.
Create<T1>(T1)	Creates a new 1-tuple, or singleton.

Tuple.Create Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new tuple object.

Overloads

Expand table

Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)	Creates a new 8-tuple, or octuple.
Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Creates a new 7-tuple, or septuple.
Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Creates a new 6-tuple, or sextuple.
Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Creates a new 5-tuple, or quintuple.
Create<T1,T2,T3,T4>(T1, T2, T3, T4)	Creates a new 4-tuple, or quadruple.
Create<T1,T2,T3>(T1, T2, T3)	Creates a new 3-tuple, or triple.
Create<T1,T2>(T1, T2)	Creates a new 2-tuple, or pair.
Create<T1>(T1)	Creates a new 1-tuple, or singleton.

Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)

Creates a new 8-tuple, or octuple.

C#

```
public static Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>
Create<T1,T2,T3,T4,T5,T6,T7,T8> (T1 item1, T2 item2, T3 item3, T4 item4,
```

```
  T5 item5, T6 item6, T7 item7, T8 item8);
```

Type Parameters

`T1`

The type of the first component of the tuple.

`T2`

The type of the second component of the tuple.

`T3`

The type of the third component of the tuple.

`T4`

The type of the fourth component of the tuple.

`T5`

The type of the fifth component of the tuple.

`T6`

The type of the sixth component of the tuple.

`T7`

The type of the seventh component of the tuple.

`T8`

The type of the eighth component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

`item3` T3

The value of the third component of the tuple.

`item4` T4

The value of the fourth component of the tuple.

`item5` T5

The value of the fifth component of the tuple.

`item6` T6

The value of the sixth component of the tuple.

`item7` T7

The value of the seventh component of the tuple.

`item8` T8

The value of the eighth component of the tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>

An 8-tuple (octuple) whose value is (`item1`, `item2`, `item3`, `item4`, `item5`, `item6`, `item7`, `item8`).

Examples

The following example creates an 8-tuple whose components are prime numbers that are less than 20.

C#

```
var primes = Tuple.Create(2, 3, 5, 7, 11, 13, 17, 19);
Console.WriteLine("Prime numbers less than 20: " +
                  "{0}, {1}, {2}, {3}, {4}, {5}, {6}, and {7}",
                  primes.Item1, primes.Item2, primes.Item3,
                  primes.Item4, primes.Item5, primes.Item6,
                  primes.Item7, primes.Rest.Item1);
// The example displays the following output:
//    Prime numbers less than 20: 2, 3, 5, 7, 11, 13, 17, and 19
```

This is equivalent to the following example, which uses the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> class constructor instead of the Create factory creation method. Note that instantiating a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object in this way involves considerably more code, because you must declare a nested Tuple<T1> object as the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's eighth component to produce an octuple.

```C#
var primes = new Tuple<int, int, int, int, int, int, int,
                 Tuple<int>>(2, 3, 5, 7, 11, 13, 16,
                 new Tuple<int>(19));
```

Remarks

Create is a helper method that you can call to instantiate an 8-tuple without having to explicitly specify the types of its components.

> **Note**
>
> You must call the **Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>** constructor to create a tuple with nine or more components unless your language provides a special syntax for this purpose. The static (`Shared` in Visual Basic) methods of the **Tuple** class cannot be used to create a tuple with nine or more components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)

Creates a new 7-tuple, or septuple.

```
C#

public static Tuple<T1,T2,T3,T4,T5,T6,T7> Create<T1,T2,T3,T4,T5,T6,T7>
(T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6, T7 item7);
```

Type Parameters

`T1`

The type of the first component of the tuple.

`T2`

The type of the second component of the tuple.

`T3`

The type of the third component of the tuple.

`T4`

The type of the fourth component of the tuple.

`T5`

The type of the fifth component of the tuple.

`T6`

The type of the sixth component of the tuple.

`T7`

The type of the seventh component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

`item3` T3

The value of the third component of the tuple.

`item4` T4

The value of the fourth component of the tuple.

`item5` T5

The value of the fifth component of the tuple.

`item6` T6

The value of the sixth component of the tuple.

`item7` T7

The value of the seventh component of the tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7>

A 7-tuple whose value is (`item1`, `item2`, `item3`, `item4`, `item5`, `item6`, `item7`).

Remarks

Create is a helper method that you can call to instantiate a 7-tuple object without having to explicitly specify the types of its components. The following example uses the Create method to instantiate a 7-tuple.

C#

```
var tuple7 = Tuple.Create("Jane", 90, 87, 93, 67, 100, 92);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}, {6}",
                  tuple7.Item1, tuple7.Item2, tuple7.Item3,
                  tuple7.Item4, tuple7.Item5, tuple7.Item6,
                  tuple7.Item7);
// Displays Test scores for Jane: 90, 87, 93, 67, 100, 92
```

This code is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5,T6,T7> class constructor.

C#

```
var tuple7 = new Tuple<string, int, int, int, int, int, int>
                      ("Jane", 90, 87, 93, 67, 100, 92);
```

```
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}, {6}",
                  tuple7.Item1, tuple7.Item2, tuple7.Item3,
                  tuple7.Item4, tuple7.Item5, tuple7.Item6,
                  tuple7.Item7);
// Displays Test scores for Jane: 90, 87, 93, 67, 100, 92
```

UWP	10.0

Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)

Creates a new 6-tuple, or sextuple.

C#

```
public static Tuple<T1,T2,T3,T4,T5,T6> Create<T1,T2,T3,T4,T5,T6> (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6);
```

Type Parameters

T1

The type of the first component of the tuple.

T2

The type of the second component of the tuple.

`T3`

The type of the third component of the tuple.

`T4`

The type of the fourth component of the tuple.

`T5`

The type of the fifth component of the tuple.

`T6`

The type of the sixth component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

`item3` T3

The value of the third component of the tuple.

`item4` T4

The value of the fourth component of the tuple.

`item5` T5

The value of the fifth component of the tuple.

`item6` T6

The value of the sixth component of the tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6>

A 6-tuple whose value is (`item1`, `item2`, `item3`, `item4`, `item5`, `item6`).

Remarks

Create is a helper method that you can call to instantiate a 6-tuple object without having to explicitly specify the types of its components. The following example uses the Create method to instantiate a 6-tuple.

```
C#

var tuple6 = Tuple.Create("Jane", 90, 87, 93, 67, 100);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}",
                  tuple6.Item1, tuple6.Item2, tuple6.Item3,
                  tuple6.Item4, tuple6.Item5, tuple6.Item6);
// Displays Test scores for Jane: 90, 87, 93, 67, 100
```

This code is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5,T6> class constructor.

```
C#

var tuple6 = new Tuple<string, int, int, int, int, int>
                     ("Jane", 90, 87, 93, 67, 100);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}",
                  tuple6.Item1, tuple6.Item2, tuple6.Item3,
                  tuple6.Item4, tuple6.Item5, tuple6.Item6);
// Displays Test scores for Jane: 90, 87, 93, 67, 100
```

.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)

Creates a new 5-tuple, or quintuple.

```
C#

public static Tuple<T1,T2,T3,T4,T5> Create<T1,T2,T3,T4,T5> (T1 item1, T2
item2, T3 item3, T4 item4, T5 item5);
```

Type Parameters

`T1`

The type of the first component of the tuple.

`T2`

The type of the second component of the tuple.

`T3`

The type of the third component of the tuple.

`T4`

The type of the fourth component of the tuple.

`T5`

The type of the fifth component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

`item3` T3

The value of the third component of the tuple.

`item4` T4

The value of the fourth component of the tuple.

`item5` T5

The value of the fifth component of the tuple.

Returns

Tuple<T1,T2,T3,T4,T5>

A 5-tuple whose value is (`item1`, `item2`, `item3`, `item4`, `item5`).

Remarks

Create is a helper method that you can call to instantiate a 5-tuple object without having to explicitly specify the types of its components. The following example uses the Create method to instantiate a 5-tuple.

```
C#

var tuple5 = Tuple.Create("New York", 1990, 7322564, 2000, 8008278);
Console.WriteLine("{0}: {1:N0} in {2}, {3:N0} in {4}",
                  tuple5.Item1, tuple5.Item3, tuple5.Item2,
                  tuple5.Item5, tuple5.Item4);
// Displays New York: 7,322,564 in 1990, 8,008,278 in 2000
```

This code is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5> class constructor.

```
C#

var tuple5 = new Tuple<string, int, int, int, int>
                      ("New York", 1990, 7322564, 2000, 8008278);
Console.WriteLine("{0}: {1:N0} in {2}, {3:N0} in {4}",
                  tuple5.Item1, tuple5.Item3, tuple5.Item2,
                  tuple5.Item5, tuple5.Item4);
// Displays New York: 7,322,564 in 1990, 8,008,278 in 2000
```

See also

- Tuple<T1,T2,T3,T4,T5>

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Create<T1,T2,T3,T4>(T1, T2, T3, T4)

Creates a new 4-tuple, or quadruple.

C#

```
public static Tuple<T1,T2,T3,T4> Create<T1,T2,T3,T4> (T1 item1, T2 item2,
T3 item3, T4 item4);
```

Type Parameters

`T1`

The type of the first component of the tuple.

`T2`

The type of the second component of the tuple.

`T3`

The type of the third component of the tuple.

`T4`

The type of the fourth component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

`item3` T3

The value of the third component of the tuple.

`item4` T4

The value of the fourth component of the tuple.

Returns

Tuple<T1,T2,T3,T4>

A 4-tuple whose value is (`item1`, `item2`, `item3`, `item4`).

Remarks

Create is a helper method that you can call to instantiate a 4-tuple object without having to explicitly specify the types of its components. The following example uses the Create method to instantiate a 4-tuple.

C#

```
var tuple4 = Tuple.Create("New York", 32.68, 51.87, 76.3);
Console.WriteLine("{0}: Hi {1}, Lo {2}, Ave {3}",
                  tuple4.Item1, tuple4.Item4, tuple4.Item2,
                  tuple4.Item3);
// Displays New York: Hi 76.3, Lo 32.68, Ave 51.87
```

This code is equivalent to the following call to the Tuple<T1,T2,T3,T4>.Tuple<T1,T2,T3,T4> class constructor.

C#

```
var tuple4 = new Tuple<string, double, double, double>
                      ("New York", 32.68, 51.87, 76.3);
Console.WriteLine("{0}: Hi {1}, Lo {2}, Ave {3}",
                  tuple4.Item1, tuple4.Item4, tuple4.Item2,
                  tuple4.Item3);
// Displays New York: Hi 76.3, Lo 32.68, Ave 51.87
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Create<T1,T2,T3>(T1, T2, T3)

Creates a new 3-tuple, or triple.

C#

```
public static Tuple<T1,T2,T3> Create<T1,T2,T3> (T1 item1, T2 item2, T3
item3);
```

Type Parameters

`T1`

The type of the first component of the tuple.

`T2`

The type of the second component of the tuple.

`T3`

The type of the third component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

`item3` T3

The value of the third component of the tuple.

Returns

Tuple<T1,T2,T3>

A 3-tuple whose value is (`item1`, `item2`, `item3`).

Remarks

Create is a helper method that you can call to instantiate a 3-tuple object without having to explicitly specify the types of its components. The following example uses the Create method to instantiate a 3-tuple.

```
C#

var tuple3 = Tuple.Create("New York", 32.68, 51.87);
Console.WriteLine("{0}: lo {1}, hi {2}",
                  tuple3.Item1, tuple3.Item2, tuple3.Item3);
// Displays New York: lo 32.68, hi 51.87
```

This code is equivalent to the following call to the Tuple<T1,T2,T3>.Tuple<T1,T2,T3> class constructor.

```
C#

var tuple3 = new Tuple<string, double, double>
                      ("New York", 32.68, 51.87);
Console.WriteLine("{0}: lo {1}, hi {2}",
                  tuple3.Item1, tuple3.Item2, tuple3.Item3);
// Displays New York: lo 32.68, hi 51.87
```

See also

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Create<T1,T2>(T1, T2)

Creates a new 2-tuple, or pair.

```
C#

public static Tuple<T1,T2> Create<T1,T2> (T1 item1, T2 item2);
```

Type Parameters

`T1`

The type of the first component of the tuple.

`T2`

The type of the second component of the tuple.

Parameters

`item1` T1

The value of the first component of the tuple.

`item2` T2

The value of the second component of the tuple.

Returns

Tuple<T1,T2>

A 2-tuple whose value is (`item1`, `item2`).

Remarks

Create is a helper method that you can call to instantiate a 2-tuple object without having to explicitly specify the types of its components. The following example uses the Create method to instantiate a 2-tuple.

```C#
var tuple2 = Tuple.Create("New York", 32.68);
Console.WriteLine("{0}: {1}", tuple2.Item1, tuple2.Item2);
// Displays New York: 32.68
```

This code is equivalent to the following call to the Tuple<T1,T2> class constructor.

```C#
var tuple2 = new Tuple<string, double>("New York", 32.68);
Console.WriteLine("{0}: {1}", tuple2.Item1, tuple2.Item2);
// Displays New York: 32.68
```

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Create<T1>(T1)

Creates a new 1-tuple, or singleton.

```C#
public static Tuple<T1> Create<T1> (T1 item1);
```

Type Parameters

T1

The type of the only component of the tuple.

Parameters

item1 T1

The value of the only component of the tuple.

Returns

Tuple<T1>

A tuple whose value is (`item1`).

Remarks

Create is a helper method that you can call to instantiate a 1-tuple object without having to explicitly specify the type of its component. The following example uses the Create method to instantiate a 1-tuple whose component is of type Int32.

```C#
var tuple1 = Tuple.Create(12);
Console.WriteLine(tuple1.Item1);     // Displays 12
```

This code is equivalent to the following call to the Tuple<T1> class constructor.

```C#
var tuple1 = new Tuple<int>(12);
Console.WriteLine(tuple1.Item1);     // Displays 12
```

Tuple<T1> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 1-tuple, or singleton.

C#

```
public class Tuple<T1> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's only component.

Inheritance Object → Tuple<T1>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1> class represents a 1-tuple, or singleton, which is a tuple that has a single component. A singleton is used comparatively rarely in application development.

You can instantiate a Tuple<T1> object by calling either the Tuple<T1> constructor or the static Tuple.Create method. You can retrieve the value of the tuple's single component by using the read-only Item1 instance property.

Constructors

Expand table

Tuple<T1>(T1)	Initializes a new instance of the Tuple<T1> class.

Properties

Expand table

Item1	Gets the value of the Tuple<T1> object's single component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1> instance.

Explicit Interface Implementations

Expand table

IComparable.Compare To(Object)	Compares the current Tuple<T1> object to a specified object, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable. CompareTo(Object, IComparer)	Compares the current Tuple<T1> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable. Equals(Object, IEquality Comparer)	Returns a value that indicates whether the current Tuple<T1> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.Get HashCode(IEquality	Calculates the hash code for the current Tuple<T1> object by using a specified computation method.

Comparer)	
ITuple.Item[Int32]	Gets the value of the `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1>(Tuple<T1>, T1)	Deconstructs a tuple with 1 element into a separate variable.
ToValueTuple<T1>(Tuple<T1>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Applies to

Product	Versions

Tuple<T1>(T1) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1> class.

```
C#

public Tuple (T1 item1);
```

Parameters

item1 T1

The value of the tuple's only component.

Remarks

You can also use the static Tuple.Create method to instantiate a 1-tuple object without having to explicitly specify the type of its component. The following example uses the Create method to instantiate a 1-tuple whose component is of type Int32.

```
C#

var tuple1 = Tuple.Create(12);
Console.WriteLine(tuple1.Item1);     // Displays 12
```

This is equivalent to the following call to the Tuple<T1> class constructor.

```
C#

var tuple1 = new Tuple<int>(12);
Console.WriteLine(tuple1.Item1);     // Displays 12
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the Tuple<T1> object's single component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1> object's single component.

Examples

The following example displays information about two singletons and their components.

C#

```
using System;
using System.Numerics;

public class Example
{
   public static void Main()
   {
      var tuple1 = Tuple.Create(-1.23445e-32);
      // Display information about this singleton.
      Type tuple1Type = tuple1.GetType();
      Console.WriteLine("First 1-Tuple:");
      Console.WriteLine("   Type: {0}", tuple1Type.Name);
      Console.WriteLine("   Generic Parameter Type: {0}",
                        tuple1Type.GetGenericArguments()[0]);
      Console.WriteLine("   Component Value: {0}", tuple1.Item1);
      Console.WriteLine("   Component Value Type: {0}",
                        tuple1.Item1.GetType().Name);
      Console.WriteLine();
```

```
        var tuple2 =
 Tuple.Create((BigInteger)1.83789322281780983781356676e103);
        // Display information about this singleton.
        Type tuple2Type = tuple2.GetType();
        Console.WriteLine("Second 1-Tuple:");
        Console.WriteLine("   Type: {0}", tuple2Type.Name);
        Console.WriteLine("   Generic Parameter Type: {0}",
                          tuple2Type.GetGenericArguments()[0]);
        Console.WriteLine("   Component Value: {0}", tuple2.Item1);
        Console.WriteLine("   Component Value Type: {0}",
                          tuple2.Item1.GetType().Name);
    }
 }
 // The example displays the following output:
 //       First 1-Tuple:
 //          Type: Tuple`1
 //          Generic Parameter Type: System.Double
 //          Component Value: -1.23445E-32
 //          Component Value Type: Double
 //
 //       Second 1-Tuple:
 //          Type: Tuple`1
 //          Generic Parameter Type: System.Numerics.BigInteger
 //          Component Value: 1.83789322281780981688589094 92E+103
 //          Component Value Type: BigInteger
```

Remarks

You can determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

The example illustrates both approaches.

Applies to

Tuple<T1>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1> object is equal to a specified object.

```
C#

public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example calls the Tuple<T1>.Equals(Object) method to compare a Tuple<T1> object whose component is a Double value with three Tuple<T1> objects whose components have the following characteristics:

- Same type (Double) and same value.
- Same type (Double), but different value.
- Different type (Single), but same value.

```
C#

using System;
```

```
public class Example
{
   public static void Main()
   {
      var doubleTuple1 = Tuple.Create(12.3455);
      var doubleTuple2 = Tuple.Create(16.8912);
      var doubleTuple3 = Tuple.Create(12.3455);
      var singleTuple1 = Tuple.Create(12.3455f);
      var tuple2 = Tuple.Create("James", 97.3);

      // Compare first tuple with a Tuple(Of Double) with a different value.
      TestEquality(doubleTuple1, doubleTuple2);
      // Compare first tuple with a Tuple(Of Double) with the same value.
      TestEquality(doubleTuple1, doubleTuple3);
      // Compare first tuple with a Tuple(Of Single) with the same value.
      TestEquality(doubleTuple1, singleTuple1);
      // Compare a 1-tuple with a 2-tuple.
      TestEquality(doubleTuple1, tuple2);
   }

   private static void TestEquality(Tuple<double> tuple, object obj)
   {
      Console.WriteLine("{0} = {1}: {2}", tuple.ToString(),
                                          obj.ToString(),
                                          tuple.Equals(obj));
   }
}
// The example displays the following output:
//       (12.3455) = (16.8912): False
//       (12.3455) = (12.3455): True
//       (12.3455) = (12.3455): False
//       (12.3455) = (James, 97.3): False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1> object.
- Its single component is of the same type as the current instance.
- Its single component is equal to that of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions

Tuple<T1>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1> object.

Examples

The following example illustrates the ToString method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      var tuple1Double = Tuple.Create(3.456e-18);
      DisplayTuple(tuple1Double);

      var tuple1String = Tuple.Create("Australia");
      DisplayTuple(tuple1String);

      var tuple1Bool = Tuple.Create(true);
      DisplayTuple(tuple1Bool);

      var tuple1Char = Tuple.Create('a');
      DisplayTuple(tuple1Char);
   }
```

```
    private static void DisplayTuple(object obj)
    {
        Console.WriteLine(obj.ToString());
    }
}
// The example displays the following output:
//       (3.456E-18)
//       (Australia)
//       (True)
//       (a)
```

Remarks

The string returned by this method takes the form (*Item1*), where *Item1* represents the value of the Item1 property. If the value of Item1 is `null`, it is represented as String.Empty.

Applies to

Product	Versions

Tuple<T1>.IStructuralComparable.CompareTo(Object, IComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

An object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1> object.

Examples

The following example defines a generic class named `DescendingComparer` that implements the IComparer<T> interface. `DescendingComparer` sorts objects in descending rather than ascending order by reversing the value returned by the default comparer for a particular type. An instance of the generic `DescendingComparer` class is then passed to the Array.Sort(Array, IComparer) method to sort an array of Tuple<T1> objects in descending order. Note that the example does not directly call the IStructuralComparable.CompareTo method. This method is called implicitly by the Array.Sort(Array, IComparer) method for each element in the array.

C#

```
using System;
using System.Collections.Generic;

public class DescendingComparer<T> : IComparer<T>
{
    public int Compare(T x, T y)
    {
        return -1 * Comparer<T>.Default.Compare(x, y);
    }
}

class CompareTo2
{
   static void Main()
   {
       Tuple<Double>[] values = { Tuple.Create(13.54),
                                  Tuple.Create(Double.NaN),
                                  Tuple.Create(-189.42993),
                                  Tuple.Create(Double.PositiveInfinity),
                                  Tuple.Create(Double.Epsilon),
```

```
                                    Tuple.Create(1.934E-17),
                                    Tuple.Create(Double.NegativeInfinity),
                                    Tuple.Create(-0.000000000003588),
                                    null };
        Console.WriteLine("The values in unsorted order:");
        foreach (var value in values)
            if (value != null)
                Console.WriteLine("   {0}", value.Item1);
            else
                Console.WriteLine("   <null>");
        Console.WriteLine();

        Array.Sort(values, new DescendingComparer<Tuple<Double>>());

        Console.WriteLine("The values sorted in descending order:");
        foreach (var value in values)
            if (value != null)
                Console.WriteLine("   {0}", value.Item1);
            else
                Console.WriteLine("   <null>");
    }
}
// The example displays the following output:
//      The values in unsorted order:
//         13.54
//         NaN
//         -189.42993
//         Infinity
//         4.94065645841247E-324
//         1.934E-17
//         -Infinity
//         -3.588E-12
//
//      The values sorted in descending order:
//         Infinity
//         13.54
//         1.934E-17
//         4.94065645841247E-324
//         -3.588E-12
//         -189.42993
//         -Infinity
//         NaN
```

Remarks

Although this method can be called directly, it is most commonly called by collection sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

⊗ **Caution**

The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals** method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1>.IStructuralEquatable.Equals(Object, IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines an IEqualityComparer implementation that considers two floating-point values to be equal if they are approximately equal to each other (that is, if one value is within .01 percent of the other).

C#

```
using System;
using System.Collections;

public class Tuple1Comparer : IEqualityComparer
{
   new public bool Equals(object x, object y)
   {
      // Check if x is a floating point type. If x is, then y is.
      if (x is double | x is float)
      {
         // Convert to Double values.
         double dblX = (double) x;
         double dblY = (double) y;
         if (Double.IsNaN(dblX) | Double.IsInfinity(dblX) |
             Double.IsNaN(dblY) | Double.IsInfinity(dblY))
            return dblX.Equals(dblY);
         else
            return Math.Abs(dblX - dblY) <= dblX * .0001;
      }
      else
      {
         return x.Equals(y);
      }
   }

   public int GetHashCode(object obj)
   {
      return obj.GetHashCode();
   }
}

public class Example
{
   public static void Main()
   {
      var doubleTuple1 = Tuple.Create(12.3455);

      var doubleTuple2 = Tuple.Create(16.8912);
      var doubleTuple3 = Tuple.Create(12.3449599);

      // Compare first tuple with a Tuple<double> with a different value.
      TestEquality(doubleTuple1, doubleTuple2);
      //Compare first tuple with a Tuple<double> with the same value.
      TestEquality(doubleTuple1, doubleTuple3);
   }

   private static void TestEquality(Tuple<double> tuple, object obj)
```

```
    {
       Console.WriteLine("{0} = {1}: {2}", tuple.ToString(),
                                           obj.ToString(),

((IStructuralEquatable)tuple).Equals(obj, new Tuple1Comparer()));
    }
}
// The example displays the following output:
//       (12.3455) = (16.8912): False
//       (12.3455) = (12.3449599): True
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1> object whose single component is of the same type as the current instance. The method is passed the Item1 component of the current instance and the Item1 component of the Tuple<T1> object represented by the `other` parameter.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1>.IStructuralEquatable.GetHashCode(IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

comparer IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1> objects that are considered to be equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1> object to a specified object, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1> object.

Examples

The following example creates an array of singletons whose component is a Double value. It displays the value of each tuple component in unsorted order, sorts the array, and then displays the values in sorted order. Note that the example does not directly call the Tuple<T1>.IComparable.CompareTo method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;

class Example
{
   static void Main()
   {
      Tuple<Double>[] values = { Tuple.Create(13.54),
                                 Tuple.Create(Double.NaN),
                                 Tuple.Create(-189.42993),
                                 Tuple.Create(Double.PositiveInfinity),
                                 Tuple.Create(Double.Epsilon),
                                 Tuple.Create(1.934E-17),
                                 Tuple.Create(Double.NegativeInfinity),
                                 Tuple.Create(-0.000000000003588),
                                 null };
      Console.WriteLine("The values in unsorted order:");
      foreach (var value in values)
         if (value != null)
            Console.WriteLine("   {0}", value.Item1);
         else
            Console.WriteLine("   <null>");
      Console.WriteLine();

      Array.Sort(values);

      Console.WriteLine("The values in sorted order:");
      foreach (var value in values)
         if (value != null)
            Console.WriteLine("   {0}", value.Item1);
         else
            Console.WriteLine("   <null>");
   }
```

```
}
// The example displays the following output:
//      The values in unsorted order:
//         13.54
//         NaN
//         -189.42993
//         Infinity
//         4.94065645841247E-324
//         1.934E-17
//         -Infinity
//         -3.588E-12
//
//      The values in sorted order:
//         NaN
//         -Infinity
//         -189.42993
//         -3.588E-12
//         4.94065645841247E-324
//         1.934E-17
//         13.54
//         Infinity
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1> class. Although the method can be called directly, it is most commonly called by the default overloads of collection sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **Tuple<T1>.IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Equals** method.

The Tuple<T1>.IComparable.CompareTo method uses the default object comparer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the `Tuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the `Tuple` element. `index` must be 0.

Property Value

Object

The value of the `Tuple` element.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 0.

Remarks

The Tuple<T1>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

1, the number of elements in a Tuple<T1> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 2-tuple, or pair.

C#

```
public class Tuple<T1,T2> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

Inheritance Object → Tuple<T1,T2>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2> class represents a 2-tuple, or pair, which is a tuple that has two components. A 2-tuple is similar to a KeyValuePair<TKey,TValue> structure.

You can instantiate a Tuple<T1,T2> object by calling either the Tuple<T1,T2> constructor or the static Tuple.Create<T1,T2>(T1, T2) method. You can retrieve the values of the tuple's components by using the read-only Item1 and Item2 instance properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a record in a database, and its components can represent that record's fields.

- To provide easy access to, and manipulation of, a data set. The following example defines an array of Tuple<T1,T2> objects that contain the names of students and their corresponding test scores. It then iterates the array to calculate the mean test score.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, Nullable<int>>[] scores =
                    { new Tuple<string, Nullable<int>>("Jack", 78),
                      new Tuple<string, Nullable<int>>("Abbey", 92),
                      new Tuple<string, Nullable<int>>("Dave", 88),
                      new Tuple<string, Nullable<int>>("Sam", 91),
                      new Tuple<string, Nullable<int>>("Ed", null),
                      new Tuple<string, Nullable<int>>("Penelope", 82),
                      new Tuple<string, Nullable<int>>("Linda", 99),
                      new Tuple<string, Nullable<int>>("Judith", 84) };
      int number;
      double mean = ComputeMean(scores, out number);
      Console.WriteLine("Average test score: {0:N2} (n={1})", mean,
number);
   }

   private static double ComputeMean(Tuple<string, Nullable<int>>[]
scores, out int n)
   {
      n = 0;
      int sum = 0;
      foreach (var score in scores)
      {
         if (score.Item2.HasValue)
         {
            n += 1;
            sum += score.Item2.Value;
         }
      }
      if (n > 0)
         return sum / (double) n;
      else
         return 0;
   }
}
```

```
// The example displays the following output:
//       Average test score: 87.71 (n=7)
```

- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the following example uses a Tuple<T1,T2> object to return the quotient and the remainder that result from integer division.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      int dividend, divisor;
      Tuple<int, int> result;

      dividend = 136945; divisor = 178;
      result = IntegerDivide(dividend, divisor);
      if (result != null)
         Console.WriteLine(@"{0} \ {1} = {2}, remainder {3}",
                           dividend, divisor, result.Item1,
result.Item2);
      else
         Console.WriteLine(@"{0} \ {1} = <Error>", dividend, divisor);

      dividend = Int32.MaxValue; divisor = -2073;
      result = IntegerDivide(dividend, divisor);
      if (result != null)
         Console.WriteLine(@"{0} \ {1} = {2}, remainder {3}",
                           dividend, divisor, result.Item1,
result.Item2);
      else
         Console.WriteLine(@"{0} \ {1} = <Error>", dividend, divisor);
   }

   private static Tuple<int, int> IntegerDivide(int dividend, int
divisor)
   {
      try {
         int remainder;
         int quotient = Math.DivRem(dividend, divisor, out remainder);
         return new Tuple<int, int>(quotient, remainder);
      }
      catch (DivideByZeroException) {
         return null;
      }
   }
}
// The example displays the following output:
```

```
//        136945 \ 178 = 769, remainder 63
//        2147483647 \ -2073 = -1035930, remainder 757
```

- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a Tuple<T1,T2> object as the method argument, you can supply the thread's startup routine with two items of data.

Constructors

Expand table

Tuple<T1,T2>(T1, T2)	Initializes a new instance of the Tuple<T1,T2> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2> object's first component.
Item2	Gets the value of the current Tuple<T1,T2> object's second component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1,T2> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current Tuple<T1,T2> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current Tuple<T1,T2> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current Tuple<T1,T2> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1,T2>(Tuple<T1,T2>, T1, T2)	Deconstructs a tuple with 2 elements into separate variables.
ToValueTuple<T1,T2>(Tuple<T1,T2>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Tuple<T1,T2>(T1, T2) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2> class.

```
C#

public Tuple (T1 item1, T2 item2);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

Remarks

You can also use the static Tuple.Create<T1,T2>(T1, T2) method to instantiate a 2-tuple object without having to explicitly specify the types of its components. The following example uses the Tuple.Create<T1,T2>(T1, T2) method to instantiate a 2-tuple whose components are of type String and Double.

```
C#

var tuple2 = Tuple.Create("New York", 32.68);
Console.WriteLine("{0}: {1}", tuple2.Item1, tuple2.Item2);
// Displays New York: 32.68
```

This is equivalent to the following call to the Tuple<T1,T2> class constructor.

```
C#

var tuple2 = new Tuple<string, double>("New York", 32.68);
Console.WriteLine("{0}: {1}", tuple2.Item1, tuple2.Item2);
```

```
// Displays New York: 32.68
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2> object's first component.

Examples

The example illustrates the use of the Item1 and Item2 properties to define a method that returns multiple values in the form of a 2-tuple.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      int dividend, divisor;
      Tuple<int, int> result;

      dividend = 136945; divisor = 178;
      result = IntegerDivide(dividend, divisor);
      if (result != null)
         Console.WriteLine(@"{0} \ {1} = {2}, remainder {3}",
                           dividend, divisor, result.Item1, result.Item2);
      else
         Console.WriteLine(@"{0} \ {1} = <Error>", dividend, divisor);
```

```
        dividend = Int32.MaxValue; divisor = -2073;
        result = IntegerDivide(dividend, divisor);
        if (result != null)
           Console.WriteLine(@"{0} \ {1} = {2}, remainder {3}",
                             dividend, divisor, result.Item1, result.Item2);
        else
           Console.WriteLine(@"{0} \ {1} = <Error>", dividend, divisor);
     }

     private static Tuple<int, int> IntegerDivide(int dividend, int divisor)
     {
        try {
           int remainder;
           int quotient = Math.DivRem(dividend, divisor, out remainder);
           return new Tuple<int, int>(quotient, remainder);
        }
        catch (DivideByZeroException) {
           return null;
        }
     }
  }
  // The example displays the following output:
  //       136945 \ 178 = 769, remainder 63
  //       2147483647 \ -2073 = -1035930, remainder 757
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Tuple<T1,T2>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2> object's second component.

Examples

The example illustrates the use of the Item1 and Item2 properties to define a method that returns multiple values in the form of a 2-tuple.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      int dividend, divisor;
      Tuple<int, int> result;

      dividend = 136945; divisor = 178;
      result = IntegerDivide(dividend, divisor);
      if (result != null)
         Console.WriteLine(@"{0} \ {1} = {2}, remainder {3}",
                           dividend, divisor, result.Item1, result.Item2);
      else
         Console.WriteLine(@"{0} \ {1} = <Error>", dividend, divisor);
```

```
        dividend = Int32.MaxValue; divisor = -2073;
        result = IntegerDivide(dividend, divisor);
        if (result != null)
           Console.WriteLine(@"{0} \ {1} = {2}, remainder {3}",
                             dividend, divisor, result.Item1, result.Item2);
        else
           Console.WriteLine(@"{0} \ {1} = <Error>", dividend, divisor);
     }

     private static Tuple<int, int> IntegerDivide(int dividend, int divisor)
     {
        try {
           int remainder;
           int quotient = Math.DivRem(dividend, divisor, out remainder);
           return new Tuple<int, int>(quotient, remainder);
        }
        catch (DivideByZeroException) {
           return null;
        }
     }
  }
  // The example displays the following output:
  //       136945 \ 178 = 769, remainder 63
  //       2147483647 \ -2073 = -1035930, remainder 757
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2> object is equal to a specified object.

```
C#

public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example calls the Tuple<T1,T2>.Equals(Object) method to determine whether any of the objects in an array of Tuple<T1,T2> objects are equal to one another. The output reflects the fact that the Equals(Object) method returns `true` when comparing Tuple<T1,T2> objects whose components have equal values.

```
C#

using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, Nullable<int>>[] scores =
```

```
                        { new Tuple<string, Nullable<int>>("Dan", 90),
                          new Tuple<string, Nullable<int>>("Ernie", null),
                          new Tuple<string, Nullable<int>>("Jill", 88),
                          new Tuple<string, Nullable<int>>("Ernie", null),
                          new Tuple<string, Nullable<int>>("Nancy", 88),
                          new Tuple<string, Nullable<int>>("Dan", 90) };

      // Compare the Tuple objects
      for (int ctr = 0; ctr < scores.Length; ctr++)
      {
         for (int innerCtr = ctr + 1; innerCtr < scores.Length; innerCtr++)
         {
            Console.WriteLine("{0} = {1}: {2}",
                              scores[ctr], scores[innerCtr],
                              scores[ctr].Equals(scores[innerCtr]));
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       (Dan, 90) = (Ernie, ): False
//       (Dan, 90) = (Jill, 88): False
//       (Dan, 90) = (Ernie, ): False
//       (Dan, 90) = (Nancy, 88): False
//       (Dan, 90) = (Dan, 90): True
//
//       (Ernie, ) = (Jill, 88): False
//       (Ernie, ) = (Ernie, ): True
//       (Ernie, ) = (Nancy, 88): False
//       (Ernie, ) = (Dan, 90): False
//
//       (Jill, 88) = (Ernie, ): False
//       (Jill, 88) = (Nancy, 88): False
//       (Jill, 88) = (Dan, 90): False
//
//       (Ernie, ) = (Nancy, 88): False
//       (Ernie, ) = (Dan, 90): False
//
//       (Nancy, 88) = (Dan, 90): False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1,T2> object.
- Its two components are of the same types as the current instance.

- Its two components are equal to those of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1,T2>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1,T2> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2> object.

Examples

The following example illustrates the ToString method.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      Tuple<string, Nullable<int>>[] scores =
                      { new Tuple<string, Nullable<int>>("Abbey", 92),
                        new Tuple<string, Nullable<int>>("Dave", 88),
                        new Tuple<string, Nullable<int>>("Ed", null),
                        new Tuple<string, Nullable<int>>("Jack", 78),
                        new Tuple<string, Nullable<int>>("Linda", 99),
                        new Tuple<string, Nullable<int>>("Judith", 84),
                        new Tuple<string, Nullable<int>>("Penelope", 82),
                        new Tuple<string, Nullable<int>>("Sam", 91) };
      foreach (var score in scores)
         Console.WriteLine(score.ToString());
   }
}
```

```
// The example displays the following output:
//       (Abbey, 92)
//       (Dave, 88)
//       (Ed, )
//       (Jack, 78)
//       (Linda, 99)
//       (Judith, 84)
//       (Penelope, 82)
//       (Sam, 91)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*), where *Item1* and *Item2* represent the values of the Item1 and Item2 properties. If either property value is `null`, it is represented as String.Empty.

Applies to

Product	Versions

Tuple<T1,T2>.IStructuralComparable.CompareTo(Object, IComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

An object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2> object.

Examples

The following example creates an array of Tuple<T1,T2> objects that consist of a student's name and test score. It displays the component of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display the value of each tuple in sorted order. To sort the array, the example defines a generic `ScoreComparer` class that implements the IComparer interface and sorts the Tuple<T1,T2> objects in ascending order by the value of their second component rather than their first component. Note that the example does not directly call the IStructuralComparable.CompareTo method. This method is called implicitly by the Array.Sort(Array, IComparer) method for each element in the array.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class ScoreComparer<T1, T2> : IComparer
{
   public int Compare(object x, object y)
   {
      Tuple<T1, T2> tX = x as Tuple<T1,T2>;
      if (tX == null)
      {
         return 0;
      }
      else
      {
         Tuple<T1, T2> tY = y as Tuple<T1, T2>;
         return Comparer<T2>.Default.Compare(tX.Item2, tY.Item2);
      }
   }
```

```
}

public class Example
{
   public static void Main()
   {
      Tuple<string, Nullable<int>>[] scores =
                    { new Tuple<string, Nullable<int>>("Jack", 78),
                      new Tuple<string, Nullable<int>>("Abbey", 92),
                      new Tuple<string, Nullable<int>>("Dave", 88),
                      new Tuple<string, Nullable<int>>("Sam", 91),
                      new Tuple<string, Nullable<int>>("Ed", null),
                      new Tuple<string, Nullable<int>>("Penelope", 82),
                      new Tuple<string, Nullable<int>>("Linda", 99),
                      new Tuple<string, Nullable<int>>("Judith", 84) };

      Console.WriteLine("The values in unsorted order:");
      foreach (var score in scores)
         Console.WriteLine(score.ToString());

      Console.WriteLine();

      Array.Sort(scores, new ScoreComparer<string, Nullable<int>>());

      Console.WriteLine("The values in sorted order:");
      foreach (var score in scores)
         Console.WriteLine(score.ToString());
   }
}
// The example displays the following output;
//       The values in unsorted order:
//       (Jack, 78)
//       (Abbey, 92)
//       (Dave, 88)
//       (Sam, 91)
//       (Ed, )
//       (Penelope, 82)
//       (Linda, 99)
//       (Judith, 84)
//
//       The values in sorted order:
//       (Ed, )
//       (Jack, 78)
//       (Penelope, 82)
//       (Judith, 84)
//       (Dave, 88)
//       (Sam, 91)
//       (Abbey, 92)
//       (Linda, 99)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2> instance is cast to an IStructuralComparable interface.

Although this method can be called directly, it is most commonly called by collection sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals** method.

Tuple<T1,T2>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines an `Item2Comparer` class that implements the IEqualityComparer interface and changes the way in which Tuple<T1,T2> objects are

evaluated for equality. The method always returns `true` when it is passed the Item1 property values of two Tuple<T1,T2> objects, and it calls the IStructuralEquatable.Equals method to evaluate their Item2 property values. As a result, the method tests for equality based only on the value of the Item2 property. The output illustrates the result for a data set of Tuple<T1,T2> objects that record the names of runners and the distances that they ran.

C#

```
using System;
using System.Collections;

public class Item2Comparer<T1, T2> : IEqualityComparer
{
   new public bool Equals(object x, object y)
   {
      // Return true for all values of Item1.
      if (x is T1)
      //if (typeof(x) is string)
         return true;
      else
         return x.Equals(y);
   }

   public int GetHashCode(object obj)
   {
      if (obj is T1)
         return ((T1) obj).GetHashCode();
      else
         return ((T2) obj).GetHashCode();
   }
}

public class Example
{
   public static void Main()
   {
      Tuple<string, double>[] distancesWalked = {
                        Tuple.Create("Jan", Double.NaN),
                        Tuple.Create("Joe", Double.NaN),
                        Tuple.Create("Adam", 1.36),
                        Tuple.Create("Selena", 2.01),
                        Tuple.Create("Jake", 1.36) };
      for (int ctr = 0; ctr < distancesWalked.Length; ctr++)
      {
         Tuple<string, double> distanceWalked = distancesWalked[ctr];
         for (int ctr2 = ctr + 1; ctr2 < distancesWalked.Length; ctr2++)
         {
            Console.WriteLine("{0} = {1}: {2}", distanceWalked,
                              distancesWalked[ctr2],

((IStructuralEquatable)distanceWalked).Equals(distancesWalked[ctr2],
```

```
                                                        new
Item2Comparer<string, double>()));
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//       (Jan, NaN) = (Joe, NaN): True
//       (Jan, NaN) = (Adam, 1.36): False
//       (Jan, NaN) = (Selena, 2.01): False
//       (Jan, NaN) = (Jake, 1.36): False
//
//       (Joe, NaN) = (Adam, 1.36): False
//       (Joe, NaN) = (Selena, 2.01): False
//       (Joe, NaN) = (Jake, 1.36): False
//
//       (Adam, 1.36) = (Selena, 2.01): False
//       (Adam, 1.36) = (Jake, 1.36): True
//
//       (Selena, 2.01) = (Jake, 1.36): False
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2> instance is cast to an IStructuralEquatable interface.

The IStructuralEquatable.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2> object whose components are of the same types as the current instance. The IStructuralEquatable.Equals method first passes the Item1 values of the Tuple<T1,T2> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two Tuple<T1,T2> objects.

Tuple<T1,T2>.IStructuralEquatable.GetHashCode(IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2> objects that are considered to be equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2> object.

Examples

The following example creates an array of Tuple<T1,T2> objects that consist of a student's name and test score. It displays the component of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display the value of each tuple in sorted order. The output shows that the array has been sorted by its first component. Note that the example does not directly call the IComparable.CompareTo(Object) method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, Nullable<int>>[] scores =
                    { new Tuple<string, Nullable<int>>("Jack", 78),
                      new Tuple<string, Nullable<int>>("Abbey", 92),
                      new Tuple<string, Nullable<int>>("Dave", 88),
                      new Tuple<string, Nullable<int>>("Sam", 91),
                      new Tuple<string, Nullable<int>>("Ed", null),
                      new Tuple<string, Nullable<int>>("Penelope", 82),
                      new Tuple<string, Nullable<int>>("Linda", 99),
                      new Tuple<string, Nullable<int>>("Judith", 84) };

      Console.WriteLine("The values in unsorted order:");
      foreach (Tuple<string, Nullable<int>> score in scores)
         Console.WriteLine(score.ToString());

      Console.WriteLine();

      Array.Sort(scores);

      Console.WriteLine("The values in sorted order:");
      foreach (Tuple<string, Nullable<int>> score in scores)
         Console.WriteLine(score.ToString());
   }
}
```

```
// The example displays the following output;
//       The values in unsorted order:
//       (Jack, 78)
//       (Abbey, 92)
//       (Dave, 88)
//       (Sam, 91)
//       (Ed, )
//       (Penelope, 82)
//       (Linda, 99)
//       (Judith, 84)
//
//       The values in sorted order:
//       (Abbey, 92)
//       (Dave, 88)
//       (Ed, )
//       (Jack, 78)
//       (Judith, 84)
//       (Linda, 99)
//       (Penelope, 82)
//       (Sam, 91)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2> class. Although the method can be called directly, it is most commonly called by the default overloads of collection sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **Tuple<T1,T2>.IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Equals** method.

The Tuple<T1,T2>.IComparable.CompareTo method uses the default object comparer to compare each component.

Applies to

Product	Versions

Tuple<T1,T2>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 to 1.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 1.

Remarks

The Tuple<T1,T2>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

C#

```
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

2, the number of elements in a Tuple<T1,T2> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1,T2,T3> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 3-tuple, or triple.

C#

```
public class Tuple<T1,T2,T3> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

T3

The type of the tuple's third component.

Inheritance Object → Tuple<T1,T2,T3>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2,T3> class represents a 3-tuple, or triple, which is a tuple that has three components.

You can instantiate a Tuple<T1,T2,T3> object by calling either the Tuple<T1,T2,T3> constructor or the static Tuple.Create<T1,T2,T3>(T1, T2, T3) method. You can retrieve

the values of the tuple's components by using the read-only Item1, Item2, and Item3 instance properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set. The following example defines an array of Tuple<T1,T2,T3> objects that contain the names of students, their average test scores, and the number of tests taken. The array is passed to the `ComputeStatistics` method, which calculates the mean and standard deviation of the test scores.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                    { Tuple.Create("Jack", 78.8, 8),
                      Tuple.Create("Abbey", 92.1, 9),
                      Tuple.Create("Dave", 88.3, 9),
                      Tuple.Create("Sam", 91.7, 8),
                      Tuple.Create("Ed", 71.2, 5),
                      Tuple.Create("Penelope", 82.9, 8),
                      Tuple.Create("Linda", 99.0, 9),
                      Tuple.Create("Judith", 84.3, 9) };
      var result = ComputeStatistics(scores);
      Console.WriteLine("Mean score: {0:N2} (SD={1:N2}) (n={2})",
                        result.Item2, result.Item3, result.Item1);
   }

   private static Tuple<int, double, double>
ComputeStatistics(Tuple<string, double, int>[] scores)
   {
      int n = 0;
      double sum = 0;

      // Compute the mean.
      foreach (var score in scores)
      {
         n += score.Item3;
         sum += score.Item2 * score.Item3;
      }
      double mean = sum / n;

      // Compute the standard deviation.
```

```
        double ss = 0;
        foreach (var score in scores)
        {
            ss = Math.Pow(score.Item2 - mean, 2);
        }
        double sd = Math.Sqrt(ss/scores.Length);
        return Tuple.Create(scores.Length, mean, sd);
    }
}
// The example displays the following output:
//       Mean score: 87.02 (SD=0.96) (n=8)
```

- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the previous example returns its summary test score statistics in a Tuple<T1,T2,T3> object.
- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a Tuple<T1,T2,T3> object as the method argument, you can supply the thread's startup routine with three items of data.

Constructors

Expand table

Tuple<T1,T2,T3>(T1, T2, T3)	Initializes a new instance of the Tuple<T1,T2,T3> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2,T3> object's first component.
Item2	Gets the value of the current Tuple<T1,T2,T3> object's second component.
Item3	Gets the value of the current Tuple<T1,T2,T3> object's third component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2,T3> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1,T2,T3> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2,T3> instance.

Explicit Interface Implementations

Expand table

IComparable.Compare To(Object)	Compares the current Tuple<T1,T2,T3> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable. CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2,T3> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable. Equals(Object, IEquality Comparer)	Returns a value that indicates whether the current Tuple<T1,T2,T3> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.Get HashCode(IEquality Comparer)	Calculates the hash code for the current Tuple<T1,T2,T3> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1,T2,T3>(Tuple<T1,T2,T3>, T1, T2, T3)	Deconstructs a tuple with 3 elements into separate variables.

ToValueTuple<T1,T2,T3> (Tuple<T1,T2,T3>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Tuple<T1,T2,T3>(T1, T2, T3) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2,T3> class.

C#

```
public Tuple (T1 item1, T2 item2, T3 item3);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

item3 T3

The value of the tuple's third component.

Remarks

You can also use the static Tuple.Create<T1,T2,T3>(T1, T2, T3) method to instantiate a 3-tuple object without having to explicitly specify the types of its components. The following example uses the Tuple.Create<T1,T2,T3>(T1, T2, T3) method to instantiate a 3-tuple whose components are of type String, Double, and Double.

C#

```
var tuple3 = Tuple.Create("New York", 32.68, 51.87);
Console.WriteLine("{0}: lo {1}, hi {2}",
                  tuple3.Item1, tuple3.Item2, tuple3.Item3);
// Displays New York: lo 32.68, hi 51.87
```

This is equivalent to the following call to the Tuple<T1,T2,T3> class constructor.

C#

```
var tuple3 = new Tuple<string, double, double>
                      ("New York", 32.68, 51.87);
Console.WriteLine("{0}: lo {1}, hi {2}",
                  tuple3.Item1, tuple3.Item2, tuple3.Item3);
// Displays New York: lo 32.68, hi 51.87
```

Applies to

Product	Versions

Tuple<T1,T2,T3>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2,T3> object's first component.

Examples

The following example defines an array of Tuple<T1,T2,T3> objects that contain the names of students, their average test scores, and the number of tests taken. The array is passed to the `ComputeStatistics` method, which calculates the mean score, standard deviation, and number of cases from which the statistics are calculated. These values are stored in the Tuple<T1,T2,T3> object that is returned by the `ComputeStatistics` method. The Item1 property contains the number of cases.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                    { Tuple.Create("Jack", 78.8, 8),
                      Tuple.Create("Abbey", 92.1, 9),
                      Tuple.Create("Dave", 88.3, 9),
                      Tuple.Create("Sam", 91.7, 8),
                      Tuple.Create("Ed", 71.2, 5),
```

```
                        Tuple.Create("Penelope", 82.9, 8),
                        Tuple.Create("Linda", 99.0, 9),
                        Tuple.Create("Judith", 84.3, 9) };
      var result = ComputeStatistics(scores);
      Console.WriteLine("Mean score: {0:N2} (SD={1:N2}) (n={2})",
                          result.Item2, result.Item3, result.Item1);
   }

   private static Tuple<int, double, double> ComputeStatistics(Tuple<string,
double, int>[] scores)
   {
      int n = 0;
      double sum = 0;

      // Compute the mean.
      foreach (var score in scores)
      {
         n += score.Item3;
         sum += score.Item2 * score.Item3;
      }
      double mean = sum / n;

      // Compute the standard deviation.
      double ss = 0;
      foreach (var score in scores)
      {
         ss = Math.Pow(score.Item2 - mean, 2);
      }
      double sd = Math.Sqrt(ss/scores.Length);
      return Tuple.Create(scores.Length, mean, sd);
   }
}
// The example displays the following output:
//       Mean score: 87.02 (SD=0.96) (n=8)
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Applies to

Tuple<T1,T2,T3>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2,T3> object's second component.

Examples

The following example defines an array of Tuple<T1,T2,T3> objects that contain the names of students, their average test scores, and the number of tests taken. The array is passed to the `ComputeStatistics` method, which calculates the mean score, standard deviation, and number of cases from which the statistics are calculated. These values are stored in the Tuple<T1,T2,T3> object that is returned by the `ComputeStatistics` method. The Item2 property contains the mean test score.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                    { Tuple.Create("Jack", 78.8, 8),
                      Tuple.Create("Abbey", 92.1, 9),
                      Tuple.Create("Dave", 88.3, 9),
                      Tuple.Create("Sam", 91.7, 8),
                      Tuple.Create("Ed", 71.2, 5),
```

```
                        Tuple.Create("Penelope", 82.9, 8),
                        Tuple.Create("Linda", 99.0, 9),
                        Tuple.Create("Judith", 84.3, 9) };
      var result = ComputeStatistics(scores);
      Console.WriteLine("Mean score: {0:N2} (SD={1:N2}) (n={2})",
                          result.Item2, result.Item3, result.Item1);
   }

   private static Tuple<int, double, double> ComputeStatistics(Tuple<string,
double, int>[] scores)
   {
      int n = 0;
      double sum = 0;

      // Compute the mean.
      foreach (var score in scores)
      {
         n += score.Item3;
         sum += score.Item2 * score.Item3;
      }
      double mean = sum / n;

      // Compute the standard deviation.
      double ss = 0;
      foreach (var score in scores)
      {
         ss = Math.Pow(score.Item2 - mean, 2);
      }
      double sd = Math.Sqrt(ss/scores.Length);
      return Tuple.Create(scores.Length, mean, sd);
   }
}
// The example displays the following output:
//       Mean score: 87.02 (SD=0.96) (n=8)
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3>.Item3 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3> object's third component.

C#

```
public T3 Item3 { get; }
```

Property Value

T3

The value of the current Tuple<T1,T2,T3> object's third component.

Examples

The following example defines an array of Tuple<T1,T2,T3> objects that contain the names of students, their average test scores, and the number of tests taken. The array is passed to the `ComputeStatistics` method, which calculates the mean score, standard deviation, and number of cases from which the statistics are calculated. These values are stored in the Tuple<T1,T2,T3> object that is returned by the `ComputeStatistics` method. The Item3 property contains the standard deviation.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                    { Tuple.Create("Jack", 78.8, 8),
                      Tuple.Create("Abbey", 92.1, 9),
                      Tuple.Create("Dave", 88.3, 9),
                      Tuple.Create("Sam", 91.7, 8),
                      Tuple.Create("Ed", 71.2, 5),
```

```
                        Tuple.Create("Penelope", 82.9, 8),
                        Tuple.Create("Linda", 99.0, 9),
                        Tuple.Create("Judith", 84.3, 9) };
      var result = ComputeStatistics(scores);
      Console.WriteLine("Mean score: {0:N2} (SD={1:N2}) (n={2})",
                          result.Item2, result.Item3, result.Item1);
   }

   private static Tuple<int, double, double> ComputeStatistics(Tuple<string,
double, int>[] scores)
   {
      int n = 0;
      double sum = 0;

      // Compute the mean.
      foreach (var score in scores)
      {
         n += score.Item3;
         sum += score.Item2 * score.Item3;
      }
      double mean = sum / n;

      // Compute the standard deviation.
      double ss = 0;
      foreach (var score in scores)
      {
         ss = Math.Pow(score.Item2 - mean, 2);
      }
      double sd = Math.Sqrt(ss/scores.Length);
      return Tuple.Create(scores.Length, mean, sd);
   }
}
// The example displays the following output:
//       Mean score: 87.02 (SD=0.96) (n=8)
```

Remarks

You can dynamically determine the type of the Item3 component in one of two ways:

- By calling the `GetType` method on the value returned by the Item3 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3> object, and retrieving the third element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3> object is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example calls the Tuple<T1,T2,T3>.Equals(Object) method to determine whether any of the objects in an array of Tuple<T1,T2,T3> objects are equal to one another. The output reflects the fact that the Equals(Object) method returns `true` when comparing Tuple<T1,T2,T3> objects whose components have equal values.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
```

```
                        { Tuple.Create("Ed", 78.8, 8),
                          Tuple.Create("Abbey", 92.1, 9),
                          Tuple.Create("Ed", 71.2, 9),
                          Tuple.Create("Sam", 91.7, 8),
                          Tuple.Create("Ed", 71.2, 5),
                          Tuple.Create("Penelope", 82.9, 8),
                          Tuple.Create("Ed", 71.2, 9),
                          Tuple.Create("Judith", 84.3, 9) };

      // Test each tuple object for equality with every other tuple.
      for (int ctr = 0; ctr < scores.Length; ctr++)
      {
         var currentTuple = scores[ctr];
         for (int ctr2 = ctr + 1; ctr2 < scores.Length; ctr2++)
            Console.WriteLine("{0} = {1}: {2}", currentTuple, scores[ctr2],

currentTuple.Equals(scores[ctr2]));

         Console.WriteLine();
      }
   }
}
// The example displays the following output;
//    (Ed, 78.8, 8) = (Abbey, 92.1, 9): False
//    (Ed, 78.8, 8) = (Ed, 71.2, 9): False
//    (Ed, 78.8, 8) = (Sam, 91.7, 8): False
//    (Ed, 78.8, 8) = (Ed, 71.2, 5): False
//    (Ed, 78.8, 8) = (Penelope, 82.9, 8): False
//    (Ed, 78.8, 8) = (Ed, 71.2, 9): False
//    (Ed, 78.8, 8) = (Judith, 84.3, 9): False
//
//    (Abbey, 92.1, 9) = (Ed, 71.2, 9): False
//    (Abbey, 92.1, 9) = (Sam, 91.7, 8): False
//    (Abbey, 92.1, 9) = (Ed, 71.2, 5): False
//    (Abbey, 92.1, 9) = (Penelope, 82.9, 8): False
//    (Abbey, 92.1, 9) = (Ed, 71.2, 9): False
//    (Abbey, 92.1, 9) = (Judith, 84.3, 9): False
//
//    (Ed, 71.2, 9) = (Sam, 91.7, 8): False
//    (Ed, 71.2, 9) = (Ed, 71.2, 5): False
//    (Ed, 71.2, 9) = (Penelope, 82.9, 8): False
//    (Ed, 71.2, 9) = (Ed, 71.2, 9): True
//    (Ed, 71.2, 9) = (Judith, 84.3, 9): False
//
//    (Sam, 91.7, 8) = (Ed, 71.2, 5): False
//    (Sam, 91.7, 8) = (Penelope, 82.9, 8): False
//    (Sam, 91.7, 8) = (Ed, 71.2, 9): False
//    (Sam, 91.7, 8) = (Judith, 84.3, 9): False
//
//    (Ed, 71.2, 5) = (Penelope, 82.9, 8): False
//    (Ed, 71.2, 5) = (Ed, 71.2, 9): False
//    (Ed, 71.2, 5) = (Judith, 84.3, 9): False
//
//    (Penelope, 82.9, 8) = (Ed, 71.2, 9): False
//    (Penelope, 82.9, 8) = (Judith, 84.3, 9): False
```

```
//
//    (Ed, 71.2, 9) = (Judith, 84.3, 9): False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1,T2,T3> object.
- Its three components are of the same types as the current instance.
- Its three components are equal to those of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1,T2,T3>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1,T2,T3> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions

Tuple<T1,T2,T3>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2,T3> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2,T3> object.

Examples

The following example illustrates the ToString method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                    { Tuple.Create("Jack", 78.8, 8),
                      Tuple.Create("Abbey", 92.1, 9),
                      Tuple.Create("Dave", 88.3, 9),
                      Tuple.Create("Sam", 91.7, 8),
                      Tuple.Create("Ed", 71.2, 5),
                      Tuple.Create("Penelope", 82.9, 8),
                      Tuple.Create("Linda", 99.0, 9),
                      Tuple.Create("Judith", 84.3, 9) };
      Array.Sort(scores);
      foreach (var score in scores)
         Console.WriteLine(score.ToString());
   }
```

```
}
// The example displays the following output;
//    (Abbey, 92.1, 9)
//    (Dave, 88.3, 9)
//    (Ed, 71.2, 5)
//    (Jack, 78.8, 8)
//    (Judith, 84.3, 9)
//    (Linda, 99, 9)
//    (Penelope, 82.9, 8)
//    (Sam, 91.7, 8)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*), where *Item1*, *Item2*, and *Item3* represent the values of the Item1, Item2, and Item3 properties, respectively. If any of the property values is `null`, it is represented as String.Empty.

Applies to

Tuple<T1,T2,T3>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

An object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2,T3> object.

Examples

The following example creates an array of Tuple<T1,T2,T3> objects that consist of a student's name, mean test score, and number of tests. It displays the component of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display the value of each tuple in sorted order. To sort the array, the example defines a generic `ScoreComparer` class that implements the IComparer interface and sorts the Tuple<T1,T2,T3> objects in ascending order by the value of their second component rather than their first component. Note that the example does not directly call the Tuple<T1,T2,T3>.IStructuralComparable.CompareTo method. This method is called implicitly by the Array.Sort(Array, IComparer) method for each element in the array.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class ScoreComparer<T1, T2, T3> : IComparer
{
   public int Compare(object x, object y)
   {
      Tuple<T1, T2, T3> tX = x as Tuple<T1,T2, T3>;
      if (tX == null)
      {
         return 0;
      }
      else
      {
         Tuple<T1, T2, T3> tY = y as Tuple<T1, T2, T3>;
         return Comparer<T2>.Default.Compare(tX.Item2, tY.Item2);
      }
   }
```

```
}

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                { Tuple.Create("Jack", 78.8, 8),
                  Tuple.Create("Abbey", 92.1, 9),
                  Tuple.Create("Dave", 88.3, 9),
                  Tuple.Create("Sam", 91.7, 8),
                  Tuple.Create("Ed", 71.2, 5),
                  Tuple.Create("Penelope", 82.9, 8),
                  Tuple.Create("Linda", 99.0, 9),
                  Tuple.Create("Judith", 84.3, 9) };

      Console.WriteLine("The values in unsorted order:");
      foreach (var score in scores)
         Console.WriteLine(score.ToString());

      Console.WriteLine();

      Array.Sort(scores, new ScoreComparer<string, double, int>());

      Console.WriteLine("The values in sorted order:");
      foreach (var score in scores)
         Console.WriteLine(score.ToString());
   }
}
// The example displays the following output;
//       The values in unsorted order:
//       (Jack, 78.8, 8)
//       (Abbey, 92.1, 9)
//       (Dave, 88.3, 9)
//       (Sam, 91.7, 8)
//       (Ed, 71.2, 5)
//       (Penelope, 82.9, 8)
//       (Linda, 99, 9)
//       (Judith, 84.3, 9)
//
//       The values in sorted order:
//       (Ed, 71.2, 5)
//       (Jack, 78.8, 8)
//       (Penelope, 82.9, 8)
//       (Judith, 84.3, 9)
//       (Dave, 88.3, 9)
//       (Sam, 91.7, 8)
//       (Abbey, 92.1, 9)
//       (Linda, 99, 9)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3> instance is cast to an IStructuralComparable interface.

Although this method can be called directly, it is most commonly called by collection sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **Tuple<T1,T2,T3>.IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Tuple<T1,T2,T3>.IStructuralEquatable.Equals** method.

Tuple<T1,T2,T3>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines an `Item2Comparer` class that implements the IEqualityComparer interface and changes the way in which Tuple<T1,T2,T3> objects are

evaluated for equality. The method always returns `true` when it is passed the Item1 property values of two Tuple<T1,T2,T3> objects, and it calls the Tuple<T1,T2,T3>.IStructuralEquatable.Equals method to evaluate their Item2 property values. If this method call returns `true`, their Item3 property values are passed to the method, which always returns `true`. As a result, the method tests for equality based only on the value of the Item2 property. The output illustrates the result for a data set of Tuple<T1,T2,T3> objects that record the names, mean test score, and number of tests of students in a class.

C#

```
using System;
using System.Collections;

public class Item2Comparer<T1, T2, T3> : IEqualityComparer
{
   new public bool Equals(object x, object y)
   {
      // Return true for all values of Item1.
      if (x is T1)
         return true;
      else if (x is T2)
         return x.Equals(y);
      else
         return true;
   }

   public int GetHashCode(object obj)
   {
      if (obj is T1)
         return ((T1) obj).GetHashCode();
      else if (obj is T2)
         return ((T2) obj).GetHashCode();
      else
         return ((T3) obj).GetHashCode();
   }
}

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
           { Tuple.Create("Ed", 78.8, 8),
             Tuple.Create("Abbey", 92.1, 9),
             Tuple.Create("Jim", 71.2, 9),
             Tuple.Create("Sam", 91.7, 8),
             Tuple.Create("Sandy", 71.2, 5),
             Tuple.Create("Penelope", 82.9, 8),
             Tuple.Create("Serena", 71.2, 9),
             Tuple.Create("Judith", 84.3, 9) };
```

```
      for (int ctr = 0; ctr < scores.Length; ctr++)
      {
         IStructuralEquatable score = scores[ctr];
         for (int ctr2 = ctr + 1; ctr2 < scores.Length; ctr2++)
         {
            Console.WriteLine("{0} = {1}: {2}", score,
                              scores[ctr2],
                              score.Equals(scores[ctr2],
                                           new Item2Comparer<string, double,
int>()));
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//      (Ed, 78.8, 8) = (Abbey, 92.1, 9): False
//      (Ed, 78.8, 8) = (Jim, 71.2, 9): False
//      (Ed, 78.8, 8) = (Sam, 91.7, 8): False
//      (Ed, 78.8, 8) = (Sandy, 71.2, 5): False
//      (Ed, 78.8, 8) = (Penelope, 82.9, 8): False
//      (Ed, 78.8, 8) = (Serena, 71.2, 9): False
//      (Ed, 78.8, 8) = (Judith, 84.3, 9): False
//
//      (Abbey, 92.1, 9) = (Jim, 71.2, 9): False
//      (Abbey, 92.1, 9) = (Sam, 91.7, 8): False
//      (Abbey, 92.1, 9) = (Sandy, 71.2, 5): False
//      (Abbey, 92.1, 9) = (Penelope, 82.9, 8): False
//      (Abbey, 92.1, 9) = (Serena, 71.2, 9): False
//      (Abbey, 92.1, 9) = (Judith, 84.3, 9): False
//
//      (Jim, 71.2, 9) = (Sam, 91.7, 8): False
//      (Jim, 71.2, 9) = (Sandy, 71.2, 5): True
//      (Jim, 71.2, 9) = (Penelope, 82.9, 8): False
//      (Jim, 71.2, 9) = (Serena, 71.2, 9): True
//      (Jim, 71.2, 9) = (Judith, 84.3, 9): False
//
//      (Sam, 91.7, 8) = (Sandy, 71.2, 5): False
//      (Sam, 91.7, 8) = (Penelope, 82.9, 8): False
//      (Sam, 91.7, 8) = (Serena, 71.2, 9): False
//      (Sam, 91.7, 8) = (Judith, 84.3, 9): False
//
//      (Sandy, 71.2, 5) = (Penelope, 82.9, 8): False
//      (Sandy, 71.2, 5) = (Serena, 71.2, 9): True
//      (Sandy, 71.2, 5) = (Judith, 84.3, 9): False
//
//      (Penelope, 82.9, 8) = (Serena, 71.2, 9): False
//      (Penelope, 82.9, 8) = (Judith, 84.3, 9): False
//
//      (Serena, 71.2, 9) = (Judith, 84.3, 9): False
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2,T3> object whose components are of the same types as the current instance. The Tuple<T1,T2,T3>.IStructuralEquatable.Equals method first passes the Item1 values of the Tuple<T1,T2,T3> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two Tuple<T1,T2,T3> objects. If this method call returns `true` again, the method is called a third time and passed the Item3 values of the two Tuple<T1,T2,T3> objects.

Tuple<T1,T2,T3>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

comparer IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2,T3> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2,T3> objects that are considered to be equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2,T3>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2,T3> object.

Examples

The following example creates an array of Tuple<T1,T2,T3> objects whose components consist of a student's name, mean test score, and number of tests. It displays the components of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display each tuple in sorted order. The output shows that the array has been sorted by its first component. Note that the example does not directly call the Tuple<T1,T2,T3>.IComparable.CompareTo method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, double, int>[] scores =
                    { Tuple.Create("Jack", 78.8, 8),
                      Tuple.Create("Abbey", 92.1, 9),
                      Tuple.Create("Dave", 88.3, 9),
                      Tuple.Create("Sam", 91.7, 8),
                      Tuple.Create("Ed", 71.2, 5),
                      Tuple.Create("Penelope", 82.9, 8),
                      Tuple.Create("Linda", 99.0, 9),
                      Tuple.Create("Judith", 84.3, 9) };

      Console.WriteLine("The values in unsorted order:");
      foreach (var score in scores)
         Console.WriteLine(score.ToString());

      Console.WriteLine();

      Array.Sort(scores);

      Console.WriteLine("The values in sorted order:");
      foreach (var score in scores)
         Console.WriteLine(score.ToString());
   }
}
```

```
// The example displays the following output;
//    The values in unsorted order:
//    (Jack, 78.8, 8)
//    (Abbey, 92.1, 9)
//    (Dave, 88.3, 9)
//    (Sam, 91.7, 8)
//    (Ed, 71.2, 5)
//    (Penelope, 82.9, 8)
//    (Linda, 99, 9)
//    (Judith, 84.3, 9)
//
//    The values in sorted order:
//    (Abbey, 92.1, 9)
//    (Dave, 88.3, 9)
//    (Ed, 71.2, 5)
//    (Jack, 78.8, 8)
//    (Judith, 84.3, 9)
//    (Linda, 99, 9)
//    (Penelope, 82.9, 8)
//    (Sam, 91.7, 8)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2,T3> class. Although the method can be called directly, it is most commonly called by the default overloads of collection sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **Tuple<T1,T2,T3>.IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Equals** method.

The Tuple<T1,T2,T3>.IComparable.CompareTo method uses the default object comparer to compare each component.

Tuple<T1,T2,T3>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 to 2.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 2.

Remarks

The Tuple<T1,T2,T3>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

C#

```
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

3, the number of elements in a Tuple<T1,T2,T3> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3,T4> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 4-tuple, or quadruple.

C#

```
public class Tuple<T1,T2,T3,T4> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

T3

The type of the tuple's third component.

T4

The type of the tuple's fourth component.

Inheritance Object → Tuple<T1,T2,T3,T4>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2,T3,T4> class represents a 4-tuple, or quadruple, which is a tuple that has

four components.

You can instantiate a Tuple<T1,T2,T3,T4> object by calling either the Tuple<T1,T2,T3,T4> constructor or the static Tuple.Create<T1,T2,T3,T4>(T1, T2, T3, T4) method. You can retrieve the value of the tuple's components by using the read-only Item1, Item2, Item3, and Item4 instance properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set. The following example defines an array of Tuple<T1,T2,T3,T4> objects that contain the names of baseball pitchers, the number of innings they pitched, and the number of earned runs (runs that scored without fielding errors), and hits that they gave up. The array is passed to the `ComputeStatistics` method, which calculates each pitcher's earned run average (the average number of runs given up in a nine-inning game), and the average number of hits given up per inning. The method also uses these two averages to compute a hypothetical effectiveness average.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Tuple<string, decimal, int, int>[] pitchers  =
           { Tuple.Create("McHale, Joe", 240.1m, 221, 96),
             Tuple.Create("Paul, Dave", 233.1m, 231, 84),
             Tuple.Create("Williams, Mike", 193.2m, 183, 86),
             Tuple.Create("Blair, Jack", 168.1m, 146, 65),
             Tuple.Create("Henry, Walt", 140.1m, 96, 30),
             Tuple.Create("Lee, Adam", 137.2m, 109, 45),
             Tuple.Create("Rohr, Don", 101.0m, 110, 42) };
      Tuple<string, double, double, double>[] results=
ComputeStatistics(pitchers);

      // Display the results.
      Console.WriteLine("{0,-20} {1,9} {2,11} {3,15}\n",
                        "Pitcher", "ERA", "Hits/Inn.",
"Effectiveness");
      foreach (var result in results)
         Console.WriteLine("{0,-20} {1,9:F2} {2,11:F2} {3,15:F2}",
                        result.Item1, result.Item2, result.Item3,
result.Item4);
```

```
    }

    private static Tuple<string, double, double, double>[]
ComputeStatistics(Tuple<string, decimal, int, int>[] pitchers)
    {
        var list = new List<Tuple<string, double, double, double>>();
        Tuple<string, double, double, double> result;

        foreach (var pitcher in pitchers)
        {
            // Decimal portion of innings pitched represents 1/3 of an
inning
            double innings = (double) Math.Truncate(pitcher.Item2);
            innings = innings + (((double)pitcher.Item2 - innings) * .33);

            double ERA = pitcher.Item4/innings * 9;
            double hitsPerInning = pitcher.Item3/innings;
            double EI = (ERA * 2 + hitsPerInning * 9)/3;
            result = new Tuple<string, double, double, double>
                                (pitcher.Item1, ERA, hitsPerInning, EI);
            list.Add(result);
        }
        return list.ToArray();
    }
}
// The example displays the following output;
//       Pitcher                     ERA   Hits/Inn.   Effectiveness
//
//       McHale, Joe               3.60        0.92            5.16
//       Paul, Dave                3.24        0.99            5.14
//       Williams, Mike            4.01        0.95            5.52
//       Blair, Jack               3.48        0.87            4.93
//       Henry, Walt               1.93        0.69            3.34
//       Lee, Adam                 2.95        0.80            4.36
//       Rohr, Don                 3.74        1.09            5.76
```

- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the previous example returns its computed statistics, along with the name of the pitcher, in an array of Tuple<T1,T2,T3,T4> objects.

- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a Tuple<T1,T2,T3,T4> object as the method argument, you can supply the thread's startup routine with four items of data.

Constructors

Expand table

Tuple<T1,T2,T3,T4>(T1, T2, T3, T4)	Initializes a new instance of the Tuple<T1,T2,T3,T4> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2,T3,T4> object's first component.
Item2	Gets the value of the current Tuple<T1,T2,T3,T4> object's second component.
Item3	Gets the value of the current Tuple<T1,T2,T3,T4> object's third component.
Item4	Gets the value of the current Tuple<T1,T2,T3,T4> object's fourth component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1,T2,T3,T4> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2,T3,T4> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current Tuple<T1,T2,T3,T4> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

IStructuralComparable.CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2,T3,T4> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current Tuple<T1,T2,T3,T4> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>, T1, T2, T3, T4)	Deconstructs a tuple with 4 elements into separate variables.
ToValueTuple<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Tuple<T1,T2,T3,T4>(T1, T2, T3, T4) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2,T3,T4> class.

C#

```
public Tuple (T1 item1, T2 item2, T3 item3, T4 item4);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

item3 T3

The value of the tuple's third component.

item4 T4

The value of the tuple's fourth component.

Remarks

You can also use the static Tuple.Create<T1,T2,T3,T4>(T1, T2, T3, T4) method to instantiate a 4-tuple object without having to explicitly specify the types of its components. The following example uses the Tuple.Create<T1,T2,T3,T4>(T1, T2, T3, T4) method to instantiate a 4-tuple whose components are of type String, Double, Double, and Double.

C#

```
var tuple4 = Tuple.Create("New York", 32.68, 51.87, 76.3);
Console.WriteLine("{0}: Hi {1}, Lo {2}, Ave {3}",
                  tuple4.Item1, tuple4.Item4, tuple4.Item2,
                  tuple4.Item3);
// Displays New York: Hi 76.3, Lo 32.68, Ave 51.87
```

This is equivalent to the following call to the Tuple<T1,T2,T3,T4> class constructor.

C#

```
var tuple4 = new Tuple<string, double, double, double>
                      ("New York", 32.68, 51.87, 76.3);
Console.WriteLine("{0}: Hi {1}, Lo {2}, Ave {3}",
                  tuple4.Item1, tuple4.Item4, tuple4.Item2,
                  tuple4.Item3);
// Displays New York: Hi 76.3, Lo 32.68, Ave 51.87
```

Applies to

Product	Versions

Tuple<T1,T2,T3,T4>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2,T3,T4> object's first component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4> objects whose components contain the name of a city, a month of the year, and the average high and low temperatures for that month. It then retrieves and displays the value of each component.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      Tuple<string, int, double, double>[] temperatures =
            { Tuple.Create("New York, NY", 4, 61.0, 43.0),
              Tuple.Create("Chicago, IL", 2, 34.0, 18.0),
              Tuple.Create("Newark, NJ", 4, 61.0, 43.0),
              Tuple.Create("Boston, MA", 6, 77.0, 59.0),
              Tuple.Create("Detroit, MI", 9, 74.0, 53.0),
              Tuple.Create("Minneapolis, MN", 8, 81.0, 61.0) };
      // Display the array of 4-tuple objects.
```

```
      Console.WriteLine("{0,41}", "Temperatures");
      Console.WriteLine("{0,-20} {1,5}    {2,4}  {3,4}\n",
                        "City", "Month", "High", "Low");
      foreach (var temperature in temperatures)
         Console.WriteLine("{0,-20} {1,5}    {2,4:N1}  {3,4:N1}",
                           temperature.Item1,

DateTimeFormatInfo.CurrentInfo.GetAbbreviatedMonthName(temperature.Item2 -
1),
                           temperature.Item3, temperature.Item4);
   }
}
// The example displays the following output:
//                                     Temperatures
//       City                 Month    High   Low
//
//       New York, NY           Mar    61.0  43.0
//       Chicago, IL            Jan    34.0  18.0
//       Newark, NJ             Mar    61.0  43.0
//       Boston, MA             May    77.0  59.0
//       Detroit, MI            Aug    74.0  53.0
//       Minneapolis, MN        Jul    81.0  61.0
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2,T3,T4> object's second component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4> objects whose components contain the name of a city, a month of the year, and the average high and low temperatures for that month. It then retrieves and displays the value of each component.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      Tuple<string, int, double, double>[] temperatures =
            { Tuple.Create("New York, NY", 4, 61.0, 43.0),
              Tuple.Create("Chicago, IL", 2, 34.0, 18.0),
              Tuple.Create("Newark, NJ", 4, 61.0, 43.0),
              Tuple.Create("Boston, MA", 6, 77.0, 59.0),
              Tuple.Create("Detroit, MI", 9, 74.0, 53.0),
              Tuple.Create("Minneapolis, MN", 8, 81.0, 61.0) };
      // Display the array of 4-tuple objects.
```

```
      Console.WriteLine("{0,41}", "Temperatures");
      Console.WriteLine("{0,-20} {1,5}    {2,4}  {3,4}\n",
                        "City", "Month", "High", "Low");
      foreach (var temperature in temperatures)
         Console.WriteLine("{0,-20} {1,5}    {2,4:N1}  {3,4:N1}",
                           temperature.Item1,

DateTimeFormatInfo.CurrentInfo.GetAbbreviatedMonthName(temperature.Item2 -
1),
                           temperature.Item3, temperature.Item4);
   }
}
// The example displays the following output:
//                                     Temperatures
//       City                 Month    High   Low
//
//       New York, NY           Mar    61.0  43.0
//       Chicago, IL            Jan    34.0  18.0
//       Newark, NJ             Mar    61.0  43.0
//       Boston, MA             May    77.0  59.0
//       Detroit, MI            Aug    74.0  53.0
//       Minneapolis, MN        Jul    81.0  61.0
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4>.Item3 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4> object's third component.

C#

```
public T3 Item3 { get; }
```

Property Value

T3

The value of the current Tuple<T1,T2,T3,T4> object's third component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4> objects whose components contain the name of a city, a month of the year, and the average high and low temperatures for that month. It then retrieves and displays the value of each component.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      Tuple<string, int, double, double>[] temperatures =
            { Tuple.Create("New York, NY", 4, 61.0, 43.0),
              Tuple.Create("Chicago, IL", 2, 34.0, 18.0),
              Tuple.Create("Newark, NJ", 4, 61.0, 43.0),
              Tuple.Create("Boston, MA", 6, 77.0, 59.0),
              Tuple.Create("Detroit, MI", 9, 74.0, 53.0),
              Tuple.Create("Minneapolis, MN", 8, 81.0, 61.0) };
      // Display the array of 4-tuple objects.
```

```
      Console.WriteLine("{0,41}", "Temperatures");
      Console.WriteLine("{0,-20} {1,5}    {2,4}  {3,4}\n",
                        "City", "Month", "High", "Low");
      foreach (var temperature in temperatures)
         Console.WriteLine("{0,-20} {1,5}    {2,4:N1}  {3,4:N1}",
                           temperature.Item1,

DateTimeFormatInfo.CurrentInfo.GetAbbreviatedMonthName(temperature.Item2 -
1),
                           temperature.Item3, temperature.Item4);
   }
}
// The example displays the following output:
//                                     Temperatures
//       City                  Month    High   Low
//
//       New York, NY            Mar    61.0  43.0
//       Chicago, IL             Jan    34.0  18.0
//       Newark, NJ              Mar    61.0  43.0
//       Boston, MA              May    77.0  59.0
//       Detroit, MI             Aug    74.0  53.0
//       Minneapolis, MN         Jul    81.0  61.0
```

Remarks

You can dynamically determine the type of the Item3 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item3 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4> object, and retrieving the third element from the array that is returned by its Type.GetGenericArguments method.

Applies to

Tuple<T1,T2,T3,T4>.Item4 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4> object's fourth component.

C#

```
public T4 Item4 { get; }
```

Property Value

T4

The value of the current Tuple<T1,T2,T3,T4> object's fourth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4> objects whose components contain the name of a city, a month of the year, and the average high and low temperatures for that month. It then retrieves and displays the value of each component.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      Tuple<string, int, double, double>[] temperatures =
            { Tuple.Create("New York, NY", 4, 61.0, 43.0),
              Tuple.Create("Chicago, IL", 2, 34.0, 18.0),
              Tuple.Create("Newark, NJ", 4, 61.0, 43.0),
              Tuple.Create("Boston, MA", 6, 77.0, 59.0),
              Tuple.Create("Detroit, MI", 9, 74.0, 53.0),
              Tuple.Create("Minneapolis, MN", 8, 81.0, 61.0) };
      // Display the array of 4-tuple objects.
```

```
      Console.WriteLine("{0,41}", "Temperatures");
      Console.WriteLine("{0,-20} {1,5}    {2,4}  {3,4}\n",
                        "City", "Month", "High", "Low");
      foreach (var temperature in temperatures)
         Console.WriteLine("{0,-20} {1,5}    {2,4:N1}  {3,4:N1}",
                           temperature.Item1,

DateTimeFormatInfo.CurrentInfo.GetAbbreviatedMonthName(temperature.Item2 -
1),
                           temperature.Item3, temperature.Item4);
   }
}
// The example displays the following output:
//                                     Temperatures
//       City                  Month    High   Low
//
//       New York, NY            Mar    61.0  43.0
//       Chicago, IL             Jan    34.0  18.0
//       Newark, NJ              Mar    61.0  43.0
//       Boston, MA              May    77.0  59.0
//       Detroit, MI             Aug    74.0  53.0
//       Minneapolis, MN         Jul    81.0  61.0
```

Remarks

You can dynamically determine the type of the Item4 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item4 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4> object, and retrieving the fourth element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4> object is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4> objects that provide data on temperatures at three times during a particular day. The Equals(Object) method is called to compare every Tuple<T1,T2,T3,T4> object with every other Tuple<T1,T2,T3,T4> object. The output illustrates that the Equals(Object) method returns `true` only when all four components of the Tuple<T1,T2,T3,T4> objects have equal values.

C#

```
using System;

public class Class1
```

```
{
   public static void Main()
   {
      Tuple<DateTime, double, double, double>[] temperatures =
            { Tuple.Create(new DateTime(2009, 1, 16), 3.0, 5.0, 4.0),
              Tuple.Create(new DateTime(2009, 4, 22), 9.0, 14.0, 11.0),
              Tuple.Create(new DateTime(2009, 4, 22), 9.0, 14.0, 10.0),
              Tuple.Create(new DateTime(2009, 6, 1), 23.0, 28.0, 21.0),
              Tuple.Create(new DateTime(2009, 4, 22), 9.0, 14.0, 11.0),
              Tuple.Create(new DateTime(2009, 9, 6), 25.0, 30.0, 25.0) };
      // Compare each item with every other item for equality.
      for (int ctr = 0; ctr < temperatures.Length; ctr++)
      {
         var temperatureInfo = temperatures[ctr];
         for (int ctr2 = ctr + 1; ctr2 < temperatures.Length; ctr2++)
            Console.WriteLine("{0} = {1}: {2}", temperatureInfo,
temperatures[ctr2],

temperatureInfo.Equals(temperatures[ctr2]));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    (1/16/2009 12:00:00 AM, 3, 5, 4) = (4/22/2009 12:00:00 AM, 9, 14, 11):
False
//    (1/16/2009 12:00:00 AM, 3, 5, 4) = (4/22/2009 12:00:00 AM, 9, 14, 10):
False
//    (1/16/2009 12:00:00 AM, 3, 5, 4) = (6/1/2009 12:00:00 AM, 23, 28, 21):
False
//    (1/16/2009 12:00:00 AM, 3, 5, 4) = (4/22/2009 12:00:00 AM, 9, 14, 11):
False
//    (1/16/2009 12:00:00 AM, 3, 5, 4) = (9/6/2009 12:00:00 AM, 25, 30, 25):
False
//
//    (4/22/2009 12:00:00 AM, 9, 14, 11) = (4/22/2009 12:00:00 AM, 9, 14,
10): False
//    (4/22/2009 12:00:00 AM, 9, 14, 11) = (6/1/2009 12:00:00 AM, 23, 28,
21): False
//    (4/22/2009 12:00:00 AM, 9, 14, 11) = (4/22/2009 12:00:00 AM, 9, 14,
11): True
//    (4/22/2009 12:00:00 AM, 9, 14, 11) = (9/6/2009 12:00:00 AM, 25, 30,
25): False
//
//    (4/22/2009 12:00:00 AM, 9, 14, 10) = (6/1/2009 12:00:00 AM, 23, 28,
21): False
//    (4/22/2009 12:00:00 AM, 9, 14, 10) = (4/22/2009 12:00:00 AM, 9, 14,
11): False
//    (4/22/2009 12:00:00 AM, 9, 14, 10) = (9/6/2009 12:00:00 AM, 25, 30,
25): False
//
//    (6/1/2009 12:00:00 AM, 23, 28, 21) = (4/22/2009 12:00:00 AM, 9, 14,
11): False
//    (6/1/2009 12:00:00 AM, 23, 28, 21) = (9/6/2009 12:00:00 AM, 25, 30,
25): False
```

```
//
//    (4/22/2009 12:00:00 AM, 9, 14, 11) = (9/6/2009 12:00:00 AM, 25, 30,
25): False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1,T2,T3,T4> object.
- Its four components are of the same types as the current instance.
- Its four components are equal to those of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1,T2,T3,T4>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1,T2,T3,T4> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2,T3,T4>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2,T3,T4> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2,T3,T4> object.

Examples

The following example illustrates the ToString method. It displays the components of an array of 4-tuple objects that contain the name of a city, a month of the year, and the high and low average temperature for that month.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      Tuple<string, int, int, int>[] temperatures =
            { Tuple.Create("New York, NY", 4, 61, 43),
              Tuple.Create("Chicago, IL", 2, 34, 18),
              Tuple.Create("Newark, NJ", 4, 61, 43),
              Tuple.Create("Boston, MA", 6, 77, 59),
              Tuple.Create("Detroit, MI", 9, 74, 53),
              Tuple.Create("Minneapolis, MN", 8, 81, 61) };
      // Display the array of 4-tuple objects.
      foreach (var temperature in temperatures)
         Console.WriteLine(temperature.ToString());
```

```
    }
}
// The example displays the following output:
//       (New York, NY, 4, 61, 43)
//       (Chicago, IL, 2, 34, 18)
//       (Newark, NJ, 4, 61, 43)
//       (Boston, MA, 6, 77, 59)
//       (Detroit, MI, 9, 74, 53)
//       (Minneapolis, MN, 8, 81, 61)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*), where *Item1*, *Item2*, *Item3*, and *Item4* represent the values of the Item1, Item2, Item3, and Item4 properties, respectively. If any of the property values is `null`, it is represented as String.Empty.

Tuple<T1,T2,T3,T4>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

An object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2,T3,T4> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4> objects that contain statistical data about baseball pitchers. The data items include the name of the pitcher, the number of innings pitched, the pitcher's earned run average (the average number of runs a pitcher allows per game), and the number of hits the pitcher has given up. The example displays the component of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display the value of each tuple in sorted order. To sort the array, the example defines a generic `PitcherComparer` class that implements the IComparer interface and sorts the Tuple<T1,T2,T3,T4> objects in ascending order by the value of their third component (the earned run average) rather than their first component. Note that the example does not directly call the IStructuralComparable.CompareTo(Object, IComparer) method. This method is called implicitly by the Array.Sort(Array, IComparer) method for each element in the array.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class PitcherComparer<T1, T2, T3, T4> : IComparer
{
   public int Compare(object x, object y)
   {
      Tuple<T1, T2, T3, T4> tX = x as Tuple<T1, T2, T3, T4>;
      if (tX == null)
      {
         return 0;
      }
      else
      {
```

```
            Tuple<T1, T2, T3, T4> tY = y as Tuple<T1, T2, T3, T4>;
            return Comparer<T3>.Default.Compare(tX.Item3, tY.Item3);
         }
      }
   }

   public class Example
   {
      public static void Main()
      {
         Tuple<string, double, double, int>[] pitchers =
                       { Tuple.Create("McHale, Joe", 240.1, 3.60, 221),
                         Tuple.Create("Paul, Dave", 233.1, 3.24, 231),
                         Tuple.Create("Williams, Mike", 193.2, 4.00, 183),
                         Tuple.Create("Blair, Jack", 168.1, 3.48, 146),
                         Tuple.Create("Henry, Walt", 140.1, 1.92, 96),
                         Tuple.Create("Lee, Adam", 137.2, 2.94, 109),
                         Tuple.Create("Rohr, Don", 101.0, 3.74, 110) };

         Console.WriteLine("The values in unsorted order:");
         foreach (var pitcher in pitchers)
            Console.WriteLine(pitcher.ToString());

         Console.WriteLine();

         Array.Sort(pitchers, new PitcherComparer<string, double, double, int>
());

         Console.WriteLine("The values sorted by earned run average (component
3):");
         foreach (var pitcher in pitchers)
            Console.WriteLine(pitcher.ToString());
      }
   }
   // The example displays the following output;
   //       The values in unsorted order:
   //       (McHale, Joe, 240.1, 3.6, 221)
   //       (Paul, Dave, 233.1, 3.24, 231)
   //       (Williams, Mike, 193.2, 4, 183)
   //       (Blair, Jack, 168.1, 3.48, 146)
   //       (Henry, Walt, 140.1, 1.92, 96)
   //       (Lee, Adam, 137.2, 2.94, 109)
   //       (Rohr, Don, 101, 3.74, 110)
   //
   //       The values sorted by earned run average (component 3):
   //       (Henry, Walt, 140.1, 1.92, 96)
   //       (Lee, Adam, 137.2, 2.94, 109)
   //       (Rohr, Don, 101, 3.74, 110)
   //       (Blair, Jack, 168.1, 3.48, 146)
   //       (McHale, Joe, 240.1, 3.6, 221)
   //       (Paul, Dave, 233.1, 3.24, 231)
   //       (Williams, Mike, 193.2, 4, 183)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4> instance is cast to an IStructuralComparable interface.

Although this method can be called directly, it is most commonly called by collection sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo(Object, IComparer)** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals(Object, IEqualityComparer)** method.

Tuple<T1,T2,T3,T4>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

`other` Object

The object to compare with this instance.

`comparer` IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines an `Item3And4Comparer` class that implements the IEqualityComparer interface and changes the way in which Tuple<T1,T2,T3,T4> objects

are evaluated for equality. The method always returns `true` when it is passed the Item1 and Item2 property values of two Tuple<T1,T2,T3,T4> objects, and it calls the `obj.Equals` method to evaluate their Item3 property values. It this method call returns true, it also calls the `obj.Equals` method to evaluate the tuples' Item4 property values. As a result, the method tests for equality based only on the values of the Item3 and Item4 properties. The output illustrates the result for a data set of Tuple<T1,T2,T3,T4> objects that record the name of a U.S. city, the month of a year, and the average high and low temperature for that month.

C#

```
using System;
using System.Collections;

public class Item3And4Comparer<T1, T2, T3, T4> : IEqualityComparer
{
   private int argument = 0;

   new public bool Equals(object x, object y)
   {
      argument++;

      // Return true for all values of Item1, Item2.
      if (argument <= 2)
         return true;
      else
         return x.Equals(y);
   }

   public int GetHashCode(object obj)
   {
      if (obj is T1)
         return ((T1) obj).GetHashCode();
      else if (obj is T2)
         return ((T2) obj).GetHashCode();
      else if (obj is T3)
         return ((T3) obj).GetHashCode();
      else
         return ((T4) obj).GetHashCode();
   }
}

public class Example
{
   public static void Main()
   {
      Tuple<string, int, double, double>[] temperatures =
            { Tuple.Create("New York, NY", 4, 61.0, 43.0),
              Tuple.Create("Chicago, IL", 2, 34.0, 18.0),
              Tuple.Create("Newark, NJ", 4, 61.0, 43.0),
              Tuple.Create("Boston, MA", 6, 77.0, 59.0),
```

```
                Tuple.Create("Detroit, MI", 9, 74.0, 53.0),
                Tuple.Create("Minneapolis, MN", 8, 81.0, 61.0) };
        // Compare each item with every other item for equality.
        for (int ctr = 0; ctr < temperatures.Length; ctr++)
        {
           IStructuralEquatable temperatureInfo = temperatures[ctr];
           for (int ctr2 = ctr + 1; ctr2 < temperatures.Length; ctr2++)
              Console.WriteLine("{0} = {1}: {2}",
                                temperatureInfo, temperatures[ctr2],
                                temperatureInfo.Equals(temperatures[ctr2],
                                                       new Item3And4Comparer<string,
int, double, double>()));

           Console.WriteLine();
        }
    }
}
// The example displays the following output:
//    (New York, NY, 4, 61, 43) = (Chicago, IL, 2, 34, 18): False
//    (New York, NY, 4, 61, 43) = (Newark, NJ, 4, 61, 43): True
//    (New York, NY, 4, 61, 43) = (Boston, MA, 6, 77, 59): False
//    (New York, NY, 4, 61, 43) = (Detroit, MI, 9, 74, 53): False
//    (New York, NY, 4, 61, 43) = (Minneapolis, MN, 8, 81, 61): False
//
//    (Chicago, IL, 2, 34, 18) = (Newark, NJ, 4, 61, 43): False
//    (Chicago, IL, 2, 34, 18) = (Boston, MA, 6, 77, 59): False
//    (Chicago, IL, 2, 34, 18) = (Detroit, MI, 9, 74, 53): False
//    (Chicago, IL, 2, 34, 18) = (Minneapolis, MN, 8, 81, 61): False
//
//    (Newark, NJ, 4, 61, 43) = (Boston, MA, 6, 77, 59): False
//    (Newark, NJ, 4, 61, 43) = (Detroit, MI, 9, 74, 53): False
//    (Newark, NJ, 4, 61, 43) = (Minneapolis, MN, 8, 81, 61): False
//
//    (Boston, MA, 6, 77, 59) = (Detroit, MI, 9, 74, 53): False
//    (Boston, MA, 6, 77, 59) = (Minneapolis, MN, 8, 81, 61): False
//
//    (Detroit, MI, 9, 74, 53) = (Minneapolis, MN, 8, 81, 61): False
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2,T3,T4> object whose components are of the same types as the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the Tuple<T1,T2,T3,T4> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method

is called again and passed the Item2 values of the two Tuple<T1,T2,T3,T4> objects. If this method call returns `true` again, the method is called a third time and passed the Item3 values of the two Tuple<T1,T2,T3,T4> objects. If this method call returns `true` again, the method is called for the fourth and final time and passed the Item4 values of the two Tuple<T1,T2,T3,T4> objects.

Tuple<T1,T2,T3,T4>.IStructural Equatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3,T4> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2,T3,T4> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2,T3,T4> objects that are considered to be equal.

Applies to

Product	Versions

Tuple<T1,T2,T3,T4>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2,T3,T4> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4> objects whose components consist of a baseball pitcher's name, number of innings pitched, and number of hits and earned runs given up. It displays the components of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display each tuple in sorted order. The output shows that the array has been sorted by name, which is the first component. Note that the example does not directly call the IComparable.CompareTo(Object) method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Tuple<string, decimal, int, int>[] pitchers  =
                        { Tuple.Create("McHale, Joe", 240.1m, 221, 96),
                          Tuple.Create("Paul, Dave", 233.1m, 231, 84),
                          Tuple.Create("Williams, Mike", 193.2m, 183, 86),
                          Tuple.Create("Blair, Jack", 168.1m, 146, 65),
                          Tuple.Create("Henry, Walt", 140.1m, 96, 30),
                          Tuple.Create("Lee, Adam", 137.2m, 109, 45),
                          Tuple.Create("Rohr, Don", 101.0m, 110, 42) };

      // Display the array in unsorted order.
      Console.WriteLine("The values in unsorted order:");
      foreach (var pitcher in pitchers)
         Console.WriteLine(pitcher.ToString());
      Console.WriteLine();

      // Sort the array
      Array.Sort(pitchers);

      // Display the array in sorted order.
      Console.WriteLine("The values in sorted order:");
      foreach (var pitcher in pitchers)
```

```
        Console.WriteLine(pitcher.ToString());
    }
}
// The example displays the following output;
//       The values in unsorted order:
//       (McHale, Joe, 240.1, 221, 96)
//       (Paul, Dave, 233.1, 231, 84)
//       (Williams, Mike, 193.2, 183, 86)
//       (Blair, Jack, 168.1, 146, 65)
//       (Henry, Walt, 140.1, 96, 30)
//       (Lee, Adam, 137.2, 109, 45)
//       (Rohr, Don, 101, 110, 42)
//
//       The values in sorted order:
//       (Blair, Jack, 168.1, 146, 65)
//       (Henry, Walt, 140.1, 96, 30)
//       (Lee, Adam, 137.2, 109, 45)
//       (McHale, Joe, 240.1, 221, 96)
//       (Paul, Dave, 233.1, 231, 84)
//       (Rohr, Don, 101, 110, 42)
//       (Williams, Mike, 193.2, 183, 86)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2,T3,T4> class. Although the method can be called directly, it is most commonly called by the default overloads of collection sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Equals** method.

The IComparable.CompareTo method uses the default object comparer to compare each component.

Tuple<T1,T2,T3,T4>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 to 3.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 3.

Remarks

The Tuple<T1,T2,T3,T4>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4> object to an ITuple interface

object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3,T4>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

4, the number of elements in a Tuple<T1,T2,T3,T4> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3,T4,T5> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 5-tuple, or quintuple.

C#

```
public class Tuple<T1,T2,T3,T4,T5> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

T3

The type of the tuple's third component.

T4

The type of the tuple's fourth component.

T5

The type of the tuple's fifth component.

Inheritance Object → Tuple<T1,T2,T3,T4,T5>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2,T3,T4,T5> class represents a 5-tuple, or quintuple, which is a tuple that has five components.

You can instantiate a Tuple<T1,T2,T3,T4,T5> object by calling either the Tuple<T1,T2,T3,T4,T5> constructor or the static Tuple.Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5) method. You can retrieve the value of the tuple's components by using the read-only Item1, Item2, Item3, Item4, and Item5 instance properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set. The following example defines an array of Tuple<T1,T2,T3,T4,T5> objects that contain the names of running backs in American football, the number of games in which they played, and the number of carries, total yards gained, and touchdowns scored during those games. The array is passed to the `ComputeStatistics` method, which calculates each running back's number of carries per game, average yards per game, average yards per carry, and average number of touchdowns per attempt.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      // Organization of runningBacks 5-tuple:
      //    Component 1: Player name
      //    Component 2: Number of games played
      //    Component 3: Number of attempts (carries)
      //    Component 4: Number of yards gained
      //    Component 5: Number of touchdowns
      Tuple<string, int, int, int, int>[] runningBacks =
           { Tuple.Create("Payton, Walter", 190, 3838, 16726, 110),
             Tuple.Create("Sanders, Barry", 153, 3062, 15269, 99),
             Tuple.Create("Brown, Jim", 118, 2359, 12312, 106),
             Tuple.Create("Dickerson, Eric", 144, 2996, 13259, 90),
             Tuple.Create("Faulk, Marshall", 176, 2836, 12279, 100) };
      // Calculate statistics.
      // Organization of runningStats 5-tuple:
      //    Component 1: Player name
      //    Component 2: Number of attempts per game
      //    Component 3: Number of yards per game
      //    Component 4: Number of yards per attempt
```

```
      //    Component 5: Number of touchdowns per attempt
      Tuple<string, double, double, double, double>[] runningStats  =
          ComputeStatistics(runningBacks);

      // Display the result.
      Console.WriteLine("{0,-16} {1,5} {2,6} {3,7} {4,7} {5,7} {6,7}
{7,5} {8,7}\n",
                        "Name", "Games", "Att", "Att/Gm", "Yards",
"Yds/Gm",
                        "Yds/Att", "TD", "TD/Att");
      for (int ctr = 0; ctr < runningBacks.Length; ctr++)
         Console.WriteLine("{0,-16} {1,5} {2,6:N0} {3,7:N1} {4,7:N0}
{5,7:N1} {6,7:N2} {7,5} {8,7:N3}\n",
                           runningBacks[ctr].Item1,
runningBacks[ctr].Item2, runningBacks[ctr].Item3,
                           runningStats[ctr].Item2,
runningBacks[ctr].Item4, runningStats[ctr].Item3,
                           runningStats[ctr].Item4,
runningBacks[ctr].Item5, runningStats[ctr].Item5);
   }

   private static Tuple<string, double, double, double, double>[]
ComputeStatistics(
                Tuple<string, int, int, int, int>[] players)
   {
      Tuple<string, double, double, double, double> result;
      var list = new List<Tuple<string, double, double, double,
double>>();

      foreach (var player in players)
      {
         // Create result object containing player name and statistics.
         result = Tuple.Create(player.Item1,
                               player.Item3/((double)player.Item2),
                               player.Item4/((double)player.Item2),
                               player.Item4/((double)player.Item3),
                               player.Item5/((double)player.Item3));
         list.Add(result);
      }
      return list.ToArray();
   }
}
// The example displays the following output:
//    Name             Games    Att  Att/Gm   Yards  Yds/Gm Yds/Att
TD  TD/Att
//
//    Payton, Walter     190  3,838    20.2  16,726    88.0    4.36
110   0.029
//
//    Sanders, Barry     153  3,062    20.0  15,269    99.8    4.99
99   0.032
//
//    Brown, Jim         118  2,359    20.0  12,312   104.3    5.22
106   0.045
//
```

```
//    Dickerson, Eric    144  2,996    20.8  13,259    92.1    4.43
90   0.030
//
//    Faulk, Marshall    176  2,836    16.1  12,279    69.8    4.33
100   0.035
```

- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the previous example returns its computed statistics, along with the name of the player, in an array of Tuple<T1,T2,T3,T4,T5> objects.
- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a Tuple<T1,T2,T3,T4,T5> object as the method argument, you can supply the thread's startup routine with five items of data.

Constructors

Expand table

Tuple<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Initializes a new instance of the Tuple<T1,T2,T3,T4,T5> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's first component.
Item2	Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's second component.
Item3	Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's third component.
Item4	Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's fourth component.
Item5	Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's fifth component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1,T2,T3,T4,T5> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5> instance.

Explicit Interface Implementations

Expand table

IComparable.Compare To(Object)	Compares the current Tuple<T1,T2,T3,T4,T5> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable. CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2,T3,T4,T5> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable. Equals(Object, IEquality Comparer)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.Get HashCode(IEquality Comparer)	Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1,T2,T3,T4,T5> (Tuple<T1,T2,T3,T4,T5>, T1, T2, T3, T4, T5)	Deconstructs a tuple with 5 elements into separate variables.

ToValueTuple<T1,T2,T3,T4,T5>(Tuple<T1,T2,T3,T4,T5>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Tuple<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2,T3,T4,T5> class.

C#

```
public Tuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

item3 T3

The value of the tuple's third component.

item4 T4

The value of the tuple's fourth component.

item5 T5

The value of the tuple's fifth component.

Remarks

You can also use the static Tuple.Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5) method to instantiate a 5-tuple object without having to explicitly specify the types of its components. The following example uses the Tuple.Create<T1,T2,T3,T4,T5>(T1, T2, T3,

T4, T5) method to instantiate a 5-tuple whose first component is of type String and its remaining four components are of type Int32.

C#

```
var tuple5 = Tuple.Create("New York", 1990, 7322564, 2000, 8008278);
Console.WriteLine("{0}: {1:N0} in {2}, {3:N0} in {4}",
                  tuple5.Item1, tuple5.Item3, tuple5.Item2,
                  tuple5.Item5, tuple5.Item4);
// Displays New York: 7,322,564 in 1990, 8,008,278 in 2000
```

This is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5> class constructor.

C#

```
var tuple5 = new Tuple<string, int, int, int, int>
                      ("New York", 1990, 7322564, 2000, 8008278);
Console.WriteLine("{0}: {1:N0} in {2}, {3:N0} in {4}",
                  tuple5.Item1, tuple5.Item3, tuple5.Item2,
                  tuple5.Item5, tuple5.Item4);
// Displays New York: 7,322,564 in 1990, 8,008,278 in 2000
```

Tuple<T1,T2,T3,T4,T5>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2,T3,T4,T5> object's first component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5> objects whose components contain the name of a state in the United States, its population in 1990 and 2000, its population change in this 10-year period, and the percentage change in its population. It then iterates through the array and displays the value of each component in a tuple.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define array of tuples reflecting population change by state, 1990-
2000.
      Tuple<string, int, int, int, double>[] statesData =
         { Tuple.Create("California", 29760021, 33871648, 4111627, 13.8),
           Tuple.Create("Illinois", 11430602, 12419293, 988691, 8.6),
           Tuple.Create("Washington", 4866692, 5894121, 1027429, 21.1) };
```

```
      // Display the items of each tuple
      Console.WriteLine("{0,-12}{1,18}{2,18}{3,15}{4,12}\n", "State",
                        "Population 1990", "Population 2000", "Change",
                        "% Change");
      foreach(Tuple<string, int, int, int, double> stateData in statesData)
         Console.WriteLine("{0,-12}{1,18:N0}{2,18:N0}{3,15:N0}{4,12:P1}",
                           stateData.Item1, stateData.Item2,
                           stateData.Item3, stateData.Item4,
stateData.Item5/100);
   }
}
// The example displays the following output:
//    State          Population 1990   Population 2000         Change    %
Change
//
//    California          29,760,021        33,871,648      4,111,627
13.8 %
//    Illinois            11,430,602        12,419,293        988,691
8.6 %
//    Washington           4,866,692         5,894,121      1,027,429
21.1 %
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2,T3,T4,T5> object's second component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5> objects whose components contain the name of a state in the United States, its population in 1990 and 2000, its population change in this 10-year period, and the percentage change in its population. It then iterates through the array and displays the value of each component in a tuple.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define array of tuples reflecting population change by state, 1990-
2000.
      Tuple<string, int, int, int, double>[] statesData =
         { Tuple.Create("California", 29760021, 33871648, 4111627, 13.8),
           Tuple.Create("Illinois", 11430602, 12419293, 988691, 8.6),
           Tuple.Create("Washington", 4866692, 5894121, 1027429, 21.1) };
```

```
      // Display the items of each tuple
      Console.WriteLine("{0,-12}{1,18}{2,18}{3,15}{4,12}\n", "State",
                        "Population 1990", "Population 2000", "Change",
                        "% Change");
      foreach(Tuple<string, int, int, int, double> stateData in statesData)
         Console.WriteLine("{0,-12}{1,18:N0}{2,18:N0}{3,15:N0}{4,12:P1}",
                           stateData.Item1, stateData.Item2,
                           stateData.Item3, stateData.Item4,
stateData.Item5/100);
   }
}
// The example displays the following output:
//    State          Population 1990   Population 2000         Change    %
Change
//
//    California          29,760,021        33,871,648      4,111,627
13.8 %
//    Illinois            11,430,602        12,419,293        988,691
8.6 %
//    Washington           4,866,692         5,894,121      1,027,429
21.1 %
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5>.Item3 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's third component.

C#

```
public T3 Item3 { get; }
```

Property Value

T3

The value of the current Tuple<T1,T2,T3,T4,T5> object's third component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5> objects whose components contain the name of a state in the United States, its population in 1990 and 2000, its population change in this 10-year period, and the percentage change in its population. It then iterates through the array and displays the value of each component in a tuple.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define array of tuples reflecting population change by state, 1990-
2000.
      Tuple<string, int, int, int, double>[] statesData =
         { Tuple.Create("California", 29760021, 33871648, 4111627, 13.8),
           Tuple.Create("Illinois", 11430602, 12419293, 988691, 8.6),
           Tuple.Create("Washington", 4866692, 5894121, 1027429, 21.1) };
```

```
      // Display the items of each tuple
      Console.WriteLine("{0,-12}{1,18}{2,18}{3,15}{4,12}\n", "State",
                        "Population 1990", "Population 2000", "Change",
                        "% Change");
      foreach(Tuple<string, int, int, int, double> stateData in statesData)
         Console.WriteLine("{0,-12}{1,18:N0}{2,18:N0}{3,15:N0}{4,12:P1}",
                           stateData.Item1, stateData.Item2,
                           stateData.Item3, stateData.Item4,
stateData.Item5/100);
   }
}
// The example displays the following output:
//    State          Population 1990   Population 2000         Change    %
Change
//
//    California          29,760,021        33,871,648      4,111,627
13.8 %
//    Illinois            11,430,602        12,419,293        988,691

Tuple<T1,T2,T3,T4,T5>.Item4 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's fourth component.

C#

```
public T4 Item4 { get; }
```

Property Value

T4

The value of the current Tuple<T1,T2,T3,T4,T5> object's fourth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5> objects whose components contain the name of a state in the United States, its population in 1990 and 2000, its population change in this 10-year period, and the percentage change in its population. It then iterates through the array and displays the value of each component in a tuple.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define array of tuples reflecting population change by state, 1990-
2000.
      Tuple<string, int, int, int, double>[] statesData =
         { Tuple.Create("California", 29760021, 33871648, 4111627, 13.8),
           Tuple.Create("Illinois", 11430602, 12419293, 988691, 8.6),
           Tuple.Create("Washington", 4866692, 5894121, 1027429, 21.1) };
```

```
      // Display the items of each tuple
      Console.WriteLine("{0,-12}{1,18}{2,18}{3,15}{4,12}\n", "State",
                        "Population 1990", "Population 2000", "Change",
                        "% Change");
      foreach(Tuple<string, int, int, int, double> stateData in statesData)
         Console.WriteLine("{0,-12}{1,18:N0}{2,18:N0}{3,15:N0}{4,12:P1}",
                           stateData.Item1, stateData.Item2,
                           stateData.Item3, stateData.Item4,
stateData.Item5/100);
   }
}
// The example displays the following output:
//    State          Population 1990   Population 2000         Change    %
Change
//
//    California          29,760,021        33,871,648      4,111,627
13.8 %
//    Illinois            11,430,602        12,419,293        988,691
8.6 %
//    Washington           4,866,692         5,894,121      1,027,429
21.1 %
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5>.Item5 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5> object's fifth component.

C#

```
public T5 Item5 { get; }
```

Property Value

T5

The value of the current Tuple<T1,T2,T3,T4,T5> object's fifth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5> objects whose components contain the name of a state in the United Dates, its population in 1990 and 2000, its population change in this 10-year period, and the percentage change in its population. It then iterates through the array and displays the value of each component in a tuple.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define array of tuples reflecting population change by state, 1990-
2000.
      Tuple<string, int, int, int, double>[] statesData =
         { Tuple.Create("California", 29760021, 33871648, 4111627, 13.8),
           Tuple.Create("Illinois", 11430602, 12419293, 988691, 8.6),
           Tuple.Create("Washington", 4866692, 5894121, 1027429, 21.1) };
```

```
      // Display the items of each tuple
      Console.WriteLine("{0,-12}{1,18}{2,18}{3,15}{4,12}\n", "State",
                        "Population 1990", "Population 2000", "Change",
                        "% Change");
      foreach(Tuple<string, int, int, int, double> stateData in statesData)
         Console.WriteLine("{0,-12}{1,18:N0}{2,18:N0}{3,15:N0}{4,12:P1}",
                           stateData.Item1, stateData.Item2,
                           stateData.Item3, stateData.Item4,
stateData.Item5/100);
   }
}
// The example displays the following output:
//    State          Population 1990   Population 2000         Change    %
Change
//
//    California          29,760,021        33,871,648      4,111,627
13.8 %
//    Illinois            11,430,602        12,419,293        988,691
8.6 %
//    Washington           4,866,692         5,894,121      1,027,429
21.1 %
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.

Tuple<T1,T2,T3,T4,T5>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5> object is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example defines an array of 5-tuple objects that contain data about the temperatures of patients in two test groups. The first component of the array provides the number of the test group, and the second through fifth components provide the temperatures of a patient at hourly intervals. The Tuple<T1,T2,T3,T4,T5>.Equals(Object) method is called to compare every Tuple<T1,T2,T3,T4,T5> object with every other Tuple<T1,T2,T3,T4,T5> object. The output illustrates that the Equals method returns `true` only when all five components of the Tuple<T1,T2,T3,T4,T5> objects have equal values.

C#

```
using System;

public class Class1
{
   public static void Main()
   {
      Tuple<int, double, double, double, double>[] temperatureInfos =
                              { Tuple.Create(2, 97.9, 97.8, 98.0, 98.2),
                                Tuple.Create(1, 98.6, 98.8, 98.8, 99.0),
                                Tuple.Create(2, 98.6, 98.6, 98.6, 98.4),
                                Tuple.Create(1, 98.4, 98.6, 99.0, 99.2),
                                Tuple.Create(2, 98.6, 98.6, 98.6, 98.4),
                                Tuple.Create(1, 98.6, 98.8, 98.8, 99.0) };
      // Compare each item with every other item for equality.
      for (int ctr = 0; ctr < temperatureInfos.Length; ctr++)
      {
         var temperatureInfo = temperatureInfos[ctr];
         for (int ctr2 = ctr + 1; ctr2 < temperatureInfos.Length; ctr2++)
            Console.WriteLine("{0} = {1}: {2}", temperatureInfo,
temperatureInfos[ctr2],

temperatureInfo.Equals(temperatureInfos[ctr2]));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    (2, 97.9, 97.8, 98, 98.2) = (1, 98.6, 98.8, 98.8, 99): False
//    (2, 97.9, 97.8, 98, 98.2) = (2, 98.6, 98.6, 98.6, 98.4): False
//    (2, 97.9, 97.8, 98, 98.2) = (1, 98.4, 98.6, 99, 99.2): False
//    (2, 97.9, 97.8, 98, 98.2) = (2, 98.6, 98.6, 98.6, 98.4): False
//    (2, 97.9, 97.8, 98, 98.2) = (1, 98.6, 98.8, 98.8, 99): False
//
//    (1, 98.6, 98.8, 98.8, 99) = (2, 98.6, 98.6, 98.6, 98.4): False
//    (1, 98.6, 98.8, 98.8, 99) = (1, 98.4, 98.6, 99, 99.2): False
//    (1, 98.6, 98.8, 98.8, 99) = (2, 98.6, 98.6, 98.6, 98.4): False
//    (1, 98.6, 98.8, 98.8, 99) = (1, 98.6, 98.8, 98.8, 99): True
//
//    (2, 98.6, 98.6, 98.6, 98.4) = (1, 98.4, 98.6, 99, 99.2): False
//    (2, 98.6, 98.6, 98.6, 98.4) = (2, 98.6, 98.6, 98.6, 98.4): True
//    (2, 98.6, 98.6, 98.6, 98.4) = (1, 98.6, 98.8, 98.8, 99): False
//
//    (1, 98.4, 98.6, 99, 99.2) = (2, 98.6, 98.6, 98.6, 98.4): False
//    (1, 98.4, 98.6, 99, 99.2) = (1, 98.6, 98.8, 98.8, 99): False
//
//    (2, 98.6, 98.6, 98.6, 98.4) = (1, 98.6, 98.8, 98.8, 99): False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1,T2,T3,T4,T5> object.
- Its five components are of the same types as the current instance.
- Its five components are equal to those of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1,T2,T3,T4,T5>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1,T2,T3,T4,T5> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2,T3,T4,T5>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2,T3,T4,T5> object.

Examples

The following example illustrates the ToString method. It displays an array of 5-tuple objects that contain the name of a state in the United States, its population in 1990 and 2000, its population change in this 10-year period, and the annual rate of population change.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Define array of tuples reflecting population change by state, 1990-
2000.
      Tuple<string, int, int, int, double>[] populationChanges =
           { Tuple.Create("California", 29760021, 33871648, 4111627, 13.8),
             Tuple.Create("Illinois", 11430602, 12419293, 988691, 8.6),
             Tuple.Create("Washington", 4866692, 5894121, 1027429, 21.1) };
      // Display each tuple.
      foreach (var item in populationChanges)
         Console.WriteLine(item.ToString());
```

```
    }
}
// The example displays the following output:
//       (California, 29760021, 33871648, 4111627, 13.8)
//       (Illinois, 11430602, 12419293, 988691, 8.6)
//       (Washington, 4866692, 5894121, 1027429, 21.1)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, `Item5`), where *Item1*, *Item2*, *Item3*, *Item4*, and `Item5` represent the values of the Item1, Item2, Item3, Item4, and Item5 properties, respectively. If any of the property values is `null`, it is represented as String.Empty.

Tuple<T1,T2,T3,T4,T5>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

An object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2,T3,T4,T5> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5> objects that contain career statistical data for running backs in American professional football. The 5-tuple's components consist of the player's name, the number of games in which he played, the number of carries or attempts, the total number of yards gained, and the number of touchdowns scored. The example displays the components of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display each tuple in sorted order. To sort the array, the example defines a generic `YardsGained` class that implements the IComparer interface and sorts the Tuple<T1,T2,T3,T4,T5> objects in descending order by the value of their fourth component (yards gained) rather than by their first component. Note that the example does not directly call the IStructuralComparable.CompareTo method. This method is called implicitly by the Array.Sort(Array, IComparer) method for each element in the array.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class YardsGained<T1, T2, T3, T4, T5> : IComparer
{
   public int Compare(object x, object y)
   {
      Tuple<T1, T2, T3, T4, T5> tX = x as Tuple<T1, T2, T3, T4, T5>;
      if (tX == null)
      {
         return 0;
      }
      else
      {
```

```
         Tuple<T1, T2, T3, T4, T5> tY = y as Tuple<T1, T2, T3, T4, T5>;
         return -1 * Comparer<T4>.Default.Compare(tX.Item4, tY.Item4);
      }
   }
}

public class Example
{
   public static void Main()
   {
      // Organization of runningBacks 5-tuple:
      //    Component 1: Player name
      //    Component 2: Number of games played
      //    Component 3: Number of attempts (carries)
      //    Component 4: Number of yards gained
      //    Component 5: Number of touchdowns
      Tuple<string, int, int, int, int>[] runningBacks =
           { Tuple.Create("Payton, Walter", 190, 3838, 16726, 110),
             Tuple.Create("Sanders, Barry", 153, 3062, 15269, 99),
             Tuple.Create("Brown, Jim", 118, 2359, 12312, 106),
             Tuple.Create("Dickerson, Eric", 144, 2996, 13259, 90),
             Tuple.Create("Faulk, Marshall", 176, 2836, 12279, 100) };

      // Display the array in unsorted order.
      Console.WriteLine("The values in unsorted order:");
      foreach (var runningBack in runningBacks)
         Console.WriteLine(runningBack.ToString());
      Console.WriteLine();

      // Sort the array
      Array.Sort(runningBacks, new YardsGained<string, int, int, int, int>
());

      // Display the array in sorted order.
      Console.WriteLine("The values in sorted order:");
      foreach (var runningBack in runningBacks)
         Console.WriteLine(runningBack.ToString());
   }
}
// The example displays the following output:
//       The values in unsorted order:
//       (Payton, Walter, 190, 3838, 16726, 110)
//       (Sanders, Barry, 153, 3062, 15269, 99)
//       (Brown, Jim, 118, 2359, 12312, 106)
//       (Dickerson, Eric, 144, 2996, 13259, 90)
//       (Faulk, Marshall, 176, 2836, 12279, 100)
//
//       The values in sorted order:
//       (Brown, Jim, 118, 2359, 12312, 106)
//       (Dickerson, Eric, 144, 2996, 13259, 90)
//       (Faulk, Marshall, 176, 2836, 12279, 100)
//       (Payton, Walter, 190, 3838, 16726, 110)
//       (Sanders, Barry, 153, 3062, 15269, 99)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5> instance is cast to an IStructuralComparable interface.

Although this method can be called directly, it is most commonly called by collection-sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals(Object, IEqualityComparer)** method.

Tuple<T1,T2,T3,T4,T5>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines a `DoubleComparer` class that implements the IEqualityComparer interface. The example instantiates two Tuple<T1,T2,T3,T4,T5>

objects by using a random number generator to populate their second through fifth components, casts the first instance to an IStructuralEquatable interface, and then uses a `DoubleComparer` object to test the two Tuple<T1,T2,T3,T4,T5> objects for approximate equality.

C#

```
using System;
using System.Collections;

public class DoubleComparer<T1, T2, T3, T4, T5> : IEqualityComparer
{
   private double difference;
   private int argument = 0;

   public DoubleComparer(double difference)
   {
      this.difference = difference;
   }

   new public bool Equals(object x, object y)
   {
      argument += 1;

      // Return true for Item1.
      if (argument == 1) return true;

      double d1 = (double) x;
      double d2 = (double) y;

      if (d1 - d2 < d1 * difference)
         return true;
      else
         return false;
   }

   public int GetHashCode(object obj)
   {
      if (obj is T1)
         return ((T1) obj).GetHashCode();
      else if (obj is T2)
         return ((T2) obj).GetHashCode();
      else if (obj is T3)
         return ((T3) obj).GetHashCode();
      else if (obj is T4)
         return ((T4) obj).GetHashCode();
      else
         return ((T5) obj).GetHashCode();
   }
}

public class Example
{
```

```
    public static void Main()
    {
       var value1 = GetValues(1);
       var value2 = GetValues(2);
       IStructuralEquatable iValue1 = value1;
       Console.WriteLine("{0} =\n{1} :\n{2}", value1, value2,
                         iValue1.Equals(value2,
                         new DoubleComparer<int, double, double, double,
double>(.01)));
    }

    private static Tuple<int, double, double, double, double> GetValues(int
ctr)
    {
       // Generate four random numbers between 0 and 1
       Random rnd = new Random((int)DateTime.Now.Ticks >> 32 >> ctr);
       return Tuple.Create(ctr, rnd.NextDouble(), rnd.NextDouble(),
                           rnd.NextDouble(), rnd.NextDouble());
    }
}
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2,T3,T4,T5> object whose components are of the same types as the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the Tuple<T1,T2,T3,T4,T5> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two Tuple<T1,T2,T3,T4,T5> objects. This continues until the method call returns `false` when it compares a specific pair of `Item` values, or the two Item5 values are passed to the method.

Tuple<T1,T2,T3,T4,T5>.IStructural Equatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer
comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2,T3,T4,T5> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2,T3,T4,T5> objects that are considered to be equal.

Applies to

Tuple<T1,T2,T3,T4,T5>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2,T3,T4,T5> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5> objects that contain career statistics for running backs in American professional football. The five components consist of the player's name, the number of games in which he played, the number of carries or attempts, the total number of yards gained, and the number of touchdowns scored. The example displays the components of each tuple in the array in unsorted order, sorts the array, and then calls ToString to display each tuple in sorted order. The output shows that the array has been sorted by name, which is the first component. Note that the example does not directly call the IComparable.CompareTo method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      // Organization of runningBacks 5-tuple:
      //    Component 1: Player name
      //    Component 2: Number of games played
      //    Component 3: Number of attempts (carries)
      //    Component 4: Number of yards gained
      //    Component 5: Number of touchdowns
      Tuple<string, int, int, int, int>[] runningBacks =
           { Tuple.Create("Payton, Walter", 190, 3838, 16726, 110),
             Tuple.Create("Sanders, Barry", 153, 3062, 15269, 99),
             Tuple.Create("Brown, Jim", 118, 2359, 12312, 106),
             Tuple.Create("Dickerson, Eric", 144, 2996, 13259, 90),
             Tuple.Create("Faulk, Marshall", 176, 2836, 12279, 100) };

      // Display the array in unsorted order.
      Console.WriteLine("The values in unsorted order:");
      foreach (var runningBack in runningBacks)
         Console.WriteLine(runningBack.ToString());
      Console.WriteLine();
```

```
      // Sort the array
      Array.Sort(runningBacks);

      // Display the array in sorted order.
      Console.WriteLine("The values in sorted order:");
      foreach (var runningBack in runningBacks)
         Console.WriteLine(runningBack.ToString());
   }
}
// The example displays the following output:
//       The values in unsorted order:
//       (Payton, Walter, 190, 3838, 16726, 110)
//       (Sanders, Barry, 153, 3062, 15269, 99)
//       (Brown, Jim, 118, 2359, 12312, 106)
//       (Dickerson, Eric, 144, 2996, 13259, 90)
//       (Faulk, Marshall, 176, 2836, 12279, 100)
//
//       The values in sorted order:
//       (Brown, Jim, 118, 2359, 12312, 106)
//       (Dickerson, Eric, 144, 2996, 13259, 90)
//       (Faulk, Marshall, 176, 2836, 12279, 100)
//       (Payton, Walter, 190, 3838, 16726, 110)
//       (Sanders, Barry, 153, 3062, 15269, 99)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2,T3,T4,T5> class. Although the method can be called directly, it is most commonly called by the default overloads of collection-sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Tuple<T1,T2,T3,T4,T5>.Equals(Object)** method.

The IComparable.CompareTo(Object) method uses the default object comparer to compare each component.

Tuple<T1,T2,T3,T4,T5>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 to 4.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 4.

Remarks

The Tuple<T1,T2,T3,T4,T5>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5> object to an ITuple

interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1,T2,T3,T4,T5>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

5, the number of elements in a Tuple<T1,T2,T3,T4,T5> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1,T2,T3,T4,T5,T6> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 6-tuple, or sextuple.

C#

```
public class Tuple<T1,T2,T3,T4,T5,T6> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

T3

The type of the tuple's third component.

T4

The type of the tuple's fourth component.

T5

The type of the tuple's fifth component.

T6

The type of the tuple's sixth component.

Inheritance Object → Tuple<T1,T2,T3,T4,T5,T6>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2,T3,T4,T5,T6> class represents a 6-tuple, or sextuple, which is a tuple that has six components.

You can instantiate a Tuple<T1,T2,T3,T4,T5,T6> object by calling either the Tuple<T1,T2,T3,T4,T5,T6> or the static Tuple.Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6) method. You can retrieve the value of the tuple's components by using the read-only Item1, Item2, Item3, Item4, Item5, and Item6 instance properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set. The following example defines a Tuple<T1,T2,T3,T4,T5,T6> object that contains population data for New York City for each census from 1960 through 2000. The sextuple is passed to the `ComputePopulationChange` method, which calculates the annual rate of change between censuses, as well as the annual rate of change for the entire 50 year period.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get population data for New York City, 1960-2000.
      var population =
           Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
8008278);
      var rate = ComputePopulationChange(population);
      // Display results.
      Console.WriteLine("Population Change, {0}, 1960-2000\n",
population.Item1);
      Console.WriteLine("Year      {0,10} {1,9}", "Population", "Annual
Rate");
      Console.WriteLine("1960      {0,10:N0} {1,11}", population.Item2,
"NA");
      Console.WriteLine("1970      {0,10:N0} {1,11:P2}",
population.Item3, rate.Item2/10);
```

```
      Console.WriteLine("1980      {0,10:N0} {1,11:P2}",
population.Item4, rate.Item3/10);
      Console.WriteLine("1990      {0,10:N0} {1,11:P2}",
population.Item5, rate.Item4/10);
      Console.WriteLine("2000      {0,10:N0} {1,11:P2}",
population.Item6, rate.Item5/10);
      Console.WriteLine("1960-2000 {0,10:N0} {1,11:P2}", "",
rate.Item6/50);
   }

   private static Tuple<string, double, double, double, double, double>
ComputePopulationChange(
           Tuple<string, int, int, int, int, int> data)
   {
      var rate = Tuple.Create(data.Item1,
                              (double)(data.Item3 -
data.Item2)/data.Item2,
                              (double)(data.Item4 -
data.Item3)/data.Item3,
                              (double)(data.Item5 -
data.Item4)/data.Item4,
                              (double)(data.Item6 -
data.Item5)/data.Item5,
                              (double)(data.Item6 -
data.Item2)/data.Item2 );
      return rate;
   }
}
// The example displays the following output:
//       Population Change, New York, 1960-2000
//
//       Year      Population Annual Rate
//       1960       7,781,984          NA
//       1970       7,894,862      0.15 %
//       1980       7,071,639     -1.04 %
//       1990       7,322,564      0.35 %
//       2000       8,008,278      0.94 %
//       1960-2000                 0.06 %
```

- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the previous example returns its computed statistics, along with the city name, in a Tuple<T1,T2,T3,T4,T5,T6> object.

- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a Tuple<T1,T2,T3,T4,T5,T6> object as the method argument, you can supply the thread's startup routine with six items of data.

Constructors

Expand table

Tuple<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Initializes a new instance of the Tuple<T1,T2,T3,T4,T5,T6> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's first component.
Item2	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's second component.
Item3	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's third component.
Item4	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's fourth component.
Item5	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's fifth component.
Item6	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's sixth component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1,T2,T3,T4,T5,T6> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5,T6> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current Tuple<T1,T2,T3,T4,T5,T6> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2,T3,T4,T5,T6> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>, T1, T2, T3, T4, T5, T6)	Deconstructs a tuple with 6 elements into separate variables.
ToValueTuple<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Tuple<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2,T3,T4,T5,T6> class.

C#

```
public Tuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

item3 T3

The value of the tuple's third component.

item4 T4

The value of the tuple's fourth component.

item5 T5

The value of the tuple's fifth component.

item6 T6

The value of the tuple's sixth component.

Remarks

You can also use the static Tuple.Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6) method to instantiate a 6-tuple object without having to explicitly specify the types of its components. The following example uses the Tuple.Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6) method to instantiate a 6-tuple whose first component is of type String and whose remaining components are of type Int32.

C#

```
var tuple6 = Tuple.Create("Jane", 90, 87, 93, 67, 100);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}",
                  tuple6.Item1, tuple6.Item2, tuple6.Item3,
                  tuple6.Item4, tuple6.Item5, tuple6.Item6);
// Displays Test scores for Jane: 90, 87, 93, 67, 100
```

This is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5,T6> class constructor.

C#

```
var tuple6 = new Tuple<string, int, int, int, int, int>
                     ("Jane", 90, 87, 93, 67, 100);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}",
                  tuple6.Item1, tuple6.Item2, tuple6.Item3,
                  tuple6.Item4, tuple6.Item5, tuple6.Item6);
// Displays Test scores for Jane: 90, 87, 93, 67, 100
```

Tuple<T1,T2,T3,T4,T5,T6>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2,T3,T4,T5,T6> object's first component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1960 through 2000. It then displays a table that lists the data. To display the city name, it retrieves the value of the Item1 property for each Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
```

```
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,60}",
                        "City", new String('-',(60-header.Length)/2) +
header +
                                new String('-', (60-header.Length)/2));
      Console.WriteLine("{0,25}{1,12}{2,12}{3,12}{4,12}\n",
                        "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,12:N0}{2,12:N0}{3,12:N0}{4,12:N0}
{5,12:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6);
   }
}
// The example displays the following output:
//    City          ----------------------Population in--------------------
---
//                         1960        1970        1980        1990
2000
//
//    New York        7,781,984   7,894,862   7,071,639   7,322,564
8,008,278
//    Los Angeles     2,479,015   2,816,061   2,966,850   3,485,398
3,694,820
//    Chicago         3,550,904   3,366,957   3,005,072   2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2,T3,T4,T5,T6> object's second component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1960 through 2000. It then displays a table that lists the data. To display the population in 1960, it retrieves the value of the Item2 property for each Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
```

```
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,60}",
                        "City", new String('-',(60-header.Length)/2) +
header +
                                new String('-', (60-header.Length)/2));
      Console.WriteLine("{0,25}{1,12}{2,12}{3,12}{4,12}\n",
                        "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,12:N0}{2,12:N0}{3,12:N0}{4,12:N0}
{5,12:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6);
   }
}
// The example displays the following output:
//    City          ----------------------Population in--------------------
---
//                         1960        1970        1980        1990
2000
//
//    New York        7,781,984   7,894,862   7,071,639   7,322,564
8,008,278
//    Los Angeles     2,479,015   2,816,061   2,966,850   3,485,398
3,694,820
//    Chicago         3,550,904   3,366,957   3,005,072   2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6>.Item3 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's third component.

C#

```
public T3 Item3 { get; }
```

Property Value

T3

The value of the current Tuple<T1,T2,T3,T4,T5,T6> object's third component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1960 through 2000. It then displays a table that lists the data. To display the population in 1970, it retrieves the value of the Item3 property for each Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
```

```
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,60}",
                        "City", new String('-',(60-header.Length)/2) +
header +
                                new String('-', (60-header.Length)/2));
      Console.WriteLine("{0,25}{1,12}{2,12}{3,12}{4,12}\n",
                        "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,12:N0}{2,12:N0}{3,12:N0}{4,12:N0}
{5,12:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6);
   }
}
// The example displays the following output:
//    City          ----------------------Population in--------------------
---
//                         1960        1970        1980        1990
2000
//
//    New York        7,781,984   7,894,862   7,071,639   7,322,564
8,008,278
//    Los Angeles     2,479,015   2,816,061   2,966,850   3,485,398
3,694,820
//    Chicago         3,550,904   3,366,957   3,005,072   2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item3 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item3 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6>.Item4 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's fourth component.

C#

```
public T4 Item4 { get; }
```

Property Value

T4

The value of the current Tuple<T1,T2,T3,T4,T5,T6> object's fourth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1960 through 2000. It then displays a table that lists the data. To display the population in 1980, it retrieves the value of the Item4 property for each Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
```

```
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,60}",
                        "City", new String('-',(60-header.Length)/2) +
header +
                                new String('-', (60-header.Length)/2));
      Console.WriteLine("{0,25}{1,12}{2,12}{3,12}{4,12}\n",
                        "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,12:N0}{2,12:N0}{3,12:N0}{4,12:N0}
{5,12:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6);
   }
}
// The example displays the following output:
//    City          ----------------------Population in--------------------
---
//                         1960        1970        1980        1990
2000
//
//    New York        7,781,984   7,894,862   7,071,639   7,322,564
8,008,278
//    Los Angeles     2,479,015   2,816,061   2,966,850   3,485,398
3,694,820
//    Chicago         3,550,904   3,366,957   3,005,072   2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item4 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item4 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6>.Item5 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's fifth component.

C#

```
public T5 Item5 { get; }
```

Property Value

T5

The value of the current Tuple<T1,T2,T3,T4,T5,T6> object's fifth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1960 through 2000. It then displays a table that lists the data. To display the population in 1990, it retrieves the value of the Item5 property for each Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
```

```
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,60}",
                        "City", new String('-',(60-header.Length)/2) +
header +
                                new String('-', (60-header.Length)/2));
      Console.WriteLine("{0,25}{1,12}{2,12}{3,12}{4,12}\n",
                        "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,12:N0}{2,12:N0}{3,12:N0}{4,12:N0}
{5,12:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6);
   }
}
// The example displays the following output:
//    City          ----------------------Population in--------------------
---
//                         1960        1970        1980        1990
2000
//
//    New York        7,781,984   7,894,862   7,071,639   7,322,564
8,008,278
//    Los Angeles     2,479,015   2,816,061   2,966,850   3,485,398
3,694,820
//    Chicago         3,550,904   3,366,957   3,005,072   2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item5 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item5 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6>.Item6 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6> object's sixth component.

C#

```
public T6 Item6 { get; }
```

Property Value

T6

The value of the current Tuple<T1,T2,T3,T4,T5,T6> object's sixth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1960 through 2000. It then displays a table that lists the data. To display the population in 2000, it retrieves the value of the Item6 property for each Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
```

```
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,60}",
                        "City", new String('-',(60-header.Length)/2) +
header +
                                new String('-', (60-header.Length)/2));
      Console.WriteLine("{0,25}{1,12}{2,12}{3,12}{4,12}\n",
                        "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,12:N0}{2,12:N0}{3,12:N0}{4,12:N0}
{5,12:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6);
   }
}
// The example displays the following output:
//    City          ----------------------Population in--------------------
---
//                         1960        1970        1980        1990
2000
//
//    New York        7,781,984   7,894,862   7,071,639   7,322,564
8,008,278
//    Los Angeles     2,479,015   2,816,061   2,966,850   3,485,398
3,694,820
//    Chicago         3,550,904   3,366,957   3,005,072   2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item6 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item6 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6> object is equal to a specified object.

```
C#

public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example defines an array of sextuples that contain population data for Los Angeles and New York from 1960 to 2000. The first component of each sextuple identifies the city. The first, third, and fourth sextuples contain data for New York. The first sextuple is a duplicate of the fourth sextuple. The third sextuple identifies the city as "New York City" instead of "New York". As the example shows, only the fourth sextuple is equal to the first sextuple.

```
C#

using System;
```

```
public class Example
{
   public static void Main()
   {
      // Get population data for New York City and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int>[] urbanPopulations =
           { Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
8008278),
             Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
             Tuple.Create("New York City", 7781984, 7894862, 7071639,
7322564, 8008278),
             Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
8008278) };
      // Compare each tuple with every other tuple for equality.
      for (int ctr = 0; ctr <= urbanPopulations.Length - 2; ctr++)
      {
         var urbanPopulation = urbanPopulations[ctr];
         Console.WriteLine(urbanPopulation.ToString() + " = ");
         for (int innerCtr = ctr +1; innerCtr <= urbanPopulations.Length -
1; innerCtr++)
            Console.WriteLine("   {0}: {1}", urbanPopulations[innerCtr],

urbanPopulation.Equals(urbanPopulations[innerCtr]));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278) =
//       (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820): False
//       (New York City, 7781984, 7894862, 7071639, 7322564, 8008278): False
//       (New York, 7781984, 7894862, 7071639, 7322564, 8008278): True
//
//    (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820) =
//       (New York City, 7781984, 7894862, 7071639, 7322564, 8008278): False
//       (New York, 7781984, 7894862, 7071639, 7322564, 8008278): False
//
//    (New York City, 7781984, 7894862, 7071639, 7322564, 8008278) =
//       (New York, 7781984, 7894862, 7071639, 7322564, 8008278): False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1,T2,T3,T4,T5,T6> object.
- Its six components are of the same types as the current instance.

- Its six components are equal to those of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1,T2,T3,T4,T5,T6>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1,T2,T3,T4,T5,T6> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions

Tuple<T1,T2,T3,T4,T5,T6>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5,T6> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2,T3,T4,T5,T6> object.

Examples

The following example defines a Tuple<T1,T2,T3,T4,T5,T6> object that contains population data for New York City for each census from 1960 through 2000. The components of the sextuple are then displayed by a call to the ToString method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get population data for New York City, 1960-2000.
      var population = Tuple.Create("New York", 7781984, 7894862,
                                    7071639, 7322564, 8008278);
      Console.WriteLine(population.ToString());
   }
}
```

```
// The example displays the following output:
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, `Item5`, `Item6`), where *Item1*, *Item2*, *Item3*, *Item4*, *Item5*, and *Item6* represent the values of the Item1, Item2, Item3, Item4, Item5, and Item6 properties, respectively. If any of the property values is `null`, it is represented as String.Empty.

Applies to

Tuple<T1,T2,T3,T4,T5,T6>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5,T6> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

An object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2,T3,T4,T5,T6> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5,T6> objects that contains population data for three U.S. cities from 1960 to 2000. The sextuple's first component is the city name. The remaining five components represent the population at 10-year intervals from 1960 to 2000.

The `PopulationComparer` class provides an IComparer implementation that allows the array of sextuples to be sorted by any one of its components. Two values are provided to the `PopulationComparer` class in its constructor: The position of the component that defines the sort order, and a Boolean value that indicates whether the tuple objects should be sorted in ascending or descending order.

The example then displays the elements in the array in unsorted order, sorts them by the third component (the population in 1970) and displays them, and then sorts them by the sixth component (the population in 2000) and displays them.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class PopulationComparer<T1, T2, T3, T4, T5, T6> : IComparer
{
   private int itemPosition;
   private int multiplier = -1;

   public PopulationComparer(int component) : this(component, true)
   { }

   public PopulationComparer(int component, bool descending)
```

```
   {
      if (! descending) multiplier = 1;

      if (component <= 0 || component > 6)

         Console.WriteLine(city.ToString());
   }
}
// The example displays the following output:
//    In unsorted order:
//    (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Chicago, 3550904, 3366957, 3005072, 2783726, 2896016)
//
//    Sorted by population in 1970:
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Chicago, 3550904, 3366957, 3005072, 2783726, 2896016)
//    (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820)
//
//    Sorted by population in 2000:
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (Chicago, 3550904, 3366957, 3005072, 2783726, 2896016)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6> instance is cast to an IStructuralComparable interface.

This method lets you define customized comparisons of Tuple<T1,T2,T3,T4,T5,T6> objects. For example, you can use this method to order Tuple<T1,T2,T3,T4,T5,T6> objects based on the value of a specific component.

Although this method can be called directly, it is most commonly called by collection-sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals(Object, IEqualityComparer)** method.

Tuple<T1,T2,T3,T4,T5,T6>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines a `RateComparer` class that performs a custom test for equality. If the values that are passed to its IStructuralEquatable.Equals method are of

type Single or Double, the method tests for equality by using only up to three fractional digits. Otherwise, it simply calls the `x` parameter's `Equals` method. The example uses this IEqualityComparer implementation to determine whether four Tuple<T1,T2,T3,T4,T5,T6> objects that contain data on the rate of population change between 1960 and 2000 are equal.

C#

```
using System;
using System.Collections;

public class RateComparer<T1, T2, T3, T4, T5, T6> : IEqualityComparer
{
   private int argument = 0;

   public new bool Equals(object x, object y)
   {
      argument++;
      if (argument == 1) return true;

      double fx, fy;
      if (x is Double || x is Single)
      {
            fx = (double) x;
            fy = (double) y;
            return Math.Round(fx * 1000).Equals(Math.Round(fy * 1000));
      }
      else
      {
         return x.Equals(y);
      }
   }

   public int GetHashCode(object obj)
   {
      if (obj is Single || obj is Double)
         return Math.Round(((double) obj) * 1000).GetHashCode();
      else
         return obj.GetHashCode();
   }
}

public class Example
{
   public static void Main()
   {
      var rate1 = Tuple.Create("New York", .014505, -.1042733,
                               .0354833, .093644, .0290792);
      var rate2 = Tuple.Create("Unknown City", .014505, -.1042733,
                               .0354833, .093644, .0290792);
      var rate3 = Tuple.Create("Unknown City", .014505, -.1042733,
                               .0354833, .093644, .029079);
```

```
        var rate4 = Tuple.Create("San Francisco", -.0332858, -.0512803,
                                 .0662544, .0728964, .0491912);
        IStructuralEquatable eq = rate1;
        // Compare first tuple with remaining two tuples.
        Console.WriteLine("{0} = ", rate1.ToString());
        Console.WriteLine("   {0} : {1}", rate2,
                          eq.Equals(rate2, new RateComparer<string, double,
double, double, double, double>()));
        Console.WriteLine("   {0} : {1}", rate3,
                          eq.Equals(rate3, new RateComparer<string, double,
double, double, double, double>()));
        Console.WriteLine("   {0} : {1}", rate4,
                          eq.Equals(rate4, new RateComparer<string, double,
double, double, double, double>()));
    }
}
// The example displays the following output:
//    (New York, 0.014505, -0.1042733, 0.0354833, 0.093644, 0.0290792) =
//       (Unknown City, 0.014505, -0.1042733, 0.0354833, 0.093644,
0.0290792) : True
//       (Unknown City, 0.014505, -0.1042733, 0.0354833, 0.093644, 0.029079)
: True
//       (San Francisco, -0.0332858, -0.0512803, 0.0662544, 0.0728964,
0.0491912) : False
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2,T3,T4,T5,T6> object whose components are of the same types as the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the Tuple<T1,T2,T3,T4,T5,T6> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two Tuple<T1,T2,T3,T4,T5,T6> objects. This continues until the method call returns `false` when it compares a specific pair of `Item` values, or the two Item6 values are passed to the method.

Tuple<T1,T2,T3,T4,T5,T6>.IStructural Equatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer
comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2,T3,T4,T5,T6> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2,T3,T4,T5,T6> objects that are considered to be equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2,T3,T4,T5,T6>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5,T6> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

```
C#

int IComparable.CompareTo (object obj);
```

Parameters

`obj` Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2,T3,T4,T5,T6> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5,T6> objects that contain population data for three cities in the United States from 1960 to 2000. The six components consist of the city name followed by the city's population at 10-year intervals from 1960 to 2000. The example displays the components of each tuple in the array in unsorted order, sorts the array, and then calls the ToString method to display each tuple in sorted order. The output shows that the array has been sorted by name, which is the first component. Note that the example does not directly call the IComparable.CompareTo(Object) method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Create array of sextuple with population data for three U.S.
      // cities, 1960-2000.
      Tuple<string, int, int, int, int, int>[] cities =
          { Tuple.Create("Los Angeles", 2479015, 2816061, 2966850, 3485398,
3694820),
            Tuple.Create("New York", 7781984, 7894862, 7071639, 7322564,
8008278),
            Tuple.Create("Chicago", 3550904, 3366957, 3005072, 2783726,
2896016) };

      // Display array in unsorted order.
      Console.WriteLine("In unsorted order:");
      foreach (var city in cities)
         Console.WriteLine(city.ToString());

      Console.WriteLine();

      Array.Sort(cities);

      // Display array in sorted order.
```

```
        Console.WriteLine("In sorted order:");
        foreach (var city in cities)
           Console.WriteLine(city.ToString());
    }
}
// The example displays the following output:
//    In unsorted order:
//    (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Chicago, 3550904, 3366957, 3005072, 2783726, 2896016)
//
//    In sorted order:
//    (Chicago, 3550904, 3366957, 3005072, 2783726, 2896016)
//    (Los Angeles, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (New York, 7781984, 7894862, 7071639, 7322564, 8008278)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2,T3,T4,T5,T6> class. Although the method can be called directly, it is most commonly called by the default overloads of collection-sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Tuple<T1,T2,T3,T4,T5,T6>.Equals(Object)** method.

The IComparable.CompareTo(Object) method uses the default object comparer to compare each component.

Tuple<T1,T2,T3,T4,T5,T6>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 to 5.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 5.

Remarks

The Tuple<T1,T2,T3,T4,T5,T6>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5,T6> object

to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1,T2,T3,T4,T5,T6>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

6, the number of elements in a Tuple<T1,T2,T3,T4,T5,T6> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5,T6> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3,T4,T5,T6,T7> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a 7-tuple, or septuple.

C#

```
public class Tuple<T1,T2,T3,T4,T5,T6,T7> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

T3

The type of the tuple's third component.

T4

The type of the tuple's fourth component.

T5

The type of the tuple's fifth component.

T6

The type of the tuple's sixth component.

T7

The type of the tuple's seventh component.

Inheritance Object → Tuple<T1,T2,T3,T4,T5,T6,T7>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2,T3,T4,T5,T6,T7> class represents a 7-tuple, or septuple, which is a tuple that has seven components.

You can instantiate a Tuple<T1,T2,T3,T4,T5,T6,T7> object by calling either the Tuple<T1,T2,T3,T4,T5,T6,T7> or the static Tuple.Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) method. You can retrieve the value of the tuple's components by using the read-only Item1, Item2, Item3, Item4, Item5, Item6, and Item7 instance properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set. The following example defines a Tuple<T1,T2,T3,T4,T5,T6,T7> object that contains population data for New York City for each census from 1950 through 2000. The septuple is passed to the `ComputePopulationChange` method, which calculates the annual rate of change between censuses, as well as the annual rate of change for the entire 60 year period.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get population data for New York City, 1950-2000.
      var population = Tuple.Create("New York", 7891957, 7781984,
                                    7894862, 7071639, 7322564,
8008278);
      var rate = ComputePopulationChange(population);
      // Display results.
      Console.WriteLine("Population Change, {0}, 1950-2000\n",
population.Item1);
      Console.WriteLine("Year      {0,10} {1,9}", "Population", "Annual
Rate");
      Console.WriteLine("1950      {0,10:N0} {1,11}", population.Item2,
```

```
"NA");
      Console.WriteLine("1960      {0,10:N0} {1,11:P2}",
population.Item3, rate.Item2/10);
      Console.WriteLine("1970      {0,10:N0} {1,11:P2}",
population.Item4, rate.Item3/10);
      Console.WriteLine("1980      {0,10:N0} {1,11:P2}",
population.Item5, rate.Item4/10);
      Console.WriteLine("1990      {0,10:N0} {1,11:P2}",
population.Item6, rate.Item5/10);
      Console.WriteLine("2000      {0,10:N0} {1,11:P2}",
population.Item7, rate.Item6/10);
      Console.WriteLine("1950-2000 {0,10:N0} {1,11:P2}", "",
rate.Item7/50);
   }

   private static Tuple<string, double, double, double, double, double,
double>
        ComputePopulationChange(
           Tuple<string, int, int, int, int, int, int> data)
   {
      var rate = Tuple.Create(data.Item1,
                        (double)(data.Item3 - data.Item2)/data.Item2,
                        (double)(data.Item4 - data.Item3)/data.Item3,
                        (double)(data.Item5 - data.Item4)/data.Item4,
                        (double)(data.Item6 - data.Item5)/data.Item5,
                        (double)(data.Item7 - data.Item6)/data.Item6,
                        (double)(data.Item7 - data.Item2)/data.Item2 );
      return rate;
   }
}
// The example displays the following output:
//       Population Change, New York, 1950-2000
//
//       Year      Population Annual Rate
//       1950       7,891,957          NA
//       1960       7,781,984     -0.14 %
//       1970       7,894,862      0.15 %
//       1980       7,071,639     -1.04 %
//       1990       7,322,564      0.35 %
//       2000       8,008,278      0.94 %
//       1950-2000                 0.03 %
```

- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the previous example returns its computed statistics, along with the city name, in a Tuple<T1,T2,T3,T4,T5,T6,T7> object.

- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a

Tuple<T1,T2,T3,T4,T5,T6,T7> object as the method argument, you can supply the thread's startup routine with seven items of data.

Constructors

Expand table

Tuple<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Initializes a new instance of the Tuple<T1,T2,T3,T4,T5,T6,T7> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's first component.
Item2	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's second component.
Item3	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's third component.
Item4	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's fourth component.
Item5	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's fifth component.
Item6	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's sixth component.
Item7	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's seventh component.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7> object is equal to a specified object.
GetHashCode()	Returns the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5,T6,T7>

	instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.
ITuple.Length	Gets the number of elements in the `Tuple`.

Extension Methods

Expand table

Deconstruct<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>, T1, T2, T3, T4, T5, T6, T7)	Deconstructs a tuple with 7 elements into separate variables.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

Tuple<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2,T3,T4,T5,T6,T7> class.

C#

```
public Tuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6, T7
item7);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

item3 T3

The value of the tuple's third component.

item4 T4

The value of the tuple's fourth component.

item5 T5

The value of the tuple's fifth component.

item6 T6

The value of the tuple's sixth component.

item7 T7

The value of the tuple's seventh component.

Remarks

You can use the static Tuple.Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) method to instantiate a 7-tuple object without having to explicitly specify the types of its components. The following example uses the Tuple.Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) method to instantiate a 7-tuple whose first component is of type String and whose remaining components are of type Int32.

C#

```
var tuple7 = Tuple.Create("Jane", 90, 87, 93, 67, 100, 92);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}, {6}",
                  tuple7.Item1, tuple7.Item2, tuple7.Item3,
                  tuple7.Item4, tuple7.Item5, tuple7.Item6,
                  tuple7.Item7);
// Displays Test scores for Jane: 90, 87, 93, 67, 100, 92
```

This is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5,T6,T7> class constructor.

C#

```
var tuple7 = new Tuple<string, int, int, int, int, int, int>
                      ("Jane", 90, 87, 93, 67, 100, 92);
Console.WriteLine("Test scores for {0}: {1}, {2}, {3}, {4}, {5}, {6}",
                  tuple7.Item1, tuple7.Item2, tuple7.Item3,
                  tuple7.Item4, tuple7.Item5, tuple7.Item6,
                  tuple7.Item7);
// Displays Test scores for Jane: 90, 87, 93, 67, 100, 92
```

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's first component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the city name, it retrieves the value of the Item1 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398
3,694,820
//   Chicago        3,620,962  3,550,904  3,366,957  3,005,072  2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's second component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the population in 1950, it retrieves the value of the Item2 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398
3,694,820
//   Chicago        3,620,962  3,550,904  3,366,957  3,005,072  2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item3 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's third component.

C#

```
public T3 Item3 { get; }
```

Property Value

T3

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's third component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the population in 1960, it retrieves the value of the Item3 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398
3,694,820
//   Chicago        3,620,962  3,550,904  3,366,957  3,005,072  2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item3 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item3 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7> object, and retrieving the third element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item4 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's fourth component.

C#

```
public T4 Item4 { get; }
```

Property Value

T4

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's fourth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the population in 1970, it retrieves the value of the Item4 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398
3,694,820
//   Chicago        3,620,962  3,550,904  3,366,957  3,005,072  2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item4 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item4 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7> object, and retrieving the fourth element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item5 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's fifth component.

C#

```
public T5 Item5 { get; }
```

Property Value

T5

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's fifth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the population in 1980, it retrieves the value of the Item5 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item6 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's sixth component.

C#

```
public T6 Item6 { get; }
```

Property Value

T6

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's sixth component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the population in 1990, it retrieves the value of the Item6 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398
3,694,820
//   Chicago        3,620,962  3,550,904  3,366,957  3,005,072  2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item6 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item6 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7> object, and retrieving the sixth element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.Item7 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's seventh component.

C#

```
public T7 Item7 { get; }
```

Property Value

T7

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object's seventh component.

Examples

The following example defines an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects whose components contain population data for three U.S. cities (New York, Chicago, and Los Angeles) from 1950 through 2000. It then displays a table that lists the data. To display the population in 2000, it retrieves the value of the Item7 property for each Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
using System;
using System.Text.RegularExpressions;

public class Class1
{
   public static void Main()
   {
      // Create tuples containing population data for New York, Chicago,
      // and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
```

```
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display tuple data in table.
      string header = "Population in";
      Console.WriteLine("{0,-12} {1,66}",
                        "City", new String('-',(66-header.Length)/2) +
header +
                                new String('-', (66-header.Length)/2));
      Console.WriteLine("{0,24}{1,11}{2,11}{3,11}{4,11}{5,11}\n",
                        "1950", "1960", "1970", "1980", "1990", "2000");

      foreach (var city in cities)
         Console.WriteLine("{0,-12} {1,11:N0}{2,11:N0}{3,11:N0}{4,11:N0}
{5,11:N0}{6,11:N0}",
                           city.Item1, city.Item2, city.Item3, city.Item4,
                           city.Item5, city.Item6, city.Item7);
   }
}
// The example displays the following output:
//   City          -------------------------Population in-----------------
--------
//                       1950       1960       1970       1980       1990
2000
//
//   New York       7,891,957  7,781,984  7,894,862  7,071,639  7,322,564
8,008,278
//   Los Angeles    1,970,358  2,479,015  2,816,061  2,966,850  3,485,398
3,694,820
//   Chicago        3,620,962  3,550,904  3,366,957  3,005,072  2,783,726
2,896,016
```

Remarks

You can dynamically determine the type of the Item7 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item7 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7> object, and retrieving the seventh element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7> object is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example defines an array of sextuples that contain population data for Los Angeles and New York from 1950 to 2000. The first component of each septuple identifies the city. The first, third, and fourth septuples contain data for New York. The first septuple is a duplicate of the fourth septuple. The third septuple identifies the city as "New York City" instead of "New York". As the example shows, only the fourth septuple is equal to the first septuple.

C#

```
using System;
```

```
public class Example
{
   public static void Main()
   {
      // Get population data for New York City and Los Angeles, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] urbanPopulations =
           { Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
7322564, 8008278),
             Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("New York City", 7891957, 7781984, 7894862,
7071639, 7322564, 8008278),
             Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
7322564, 8008278) };
      // Compare each tuple with every other tuple for equality.
      for (int ctr = 0; ctr <= urbanPopulations.Length - 2; ctr++)
      {
         var urbanPopulation = urbanPopulations[ctr];
         Console.WriteLine(urbanPopulation.ToString() + " = ");
         for (int innerCtr = ctr +1; innerCtr <= urbanPopulations.Length -
1; innerCtr++)
            Console.WriteLine("   {0}: {1}", urbanPopulations[innerCtr],

urbanPopulation.Equals(urbanPopulations[innerCtr]));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278) =
//       (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398,
3694820): False
//       (New York City, 7891957, 7781984, 7894862, 7071639, 7322564,
8008278): False
//       (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278):
True
//
//    (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398, 3694820) =
//       (New York City, 7891957, 7781984, 7894862, 7071639, 7322564,
8008278): False
//       (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278):
False
//
//    (New York City, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
=
//       (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278):
False
```

Remarks

The `obj` parameter is considered to be equal to the current instance under the following conditions:

- It is a Tuple<T1,T2,T3,T4,T5,T6,T7> object.
- Its seven components are of the same types as the current instance.
- Its seven components are equal to those of the current instance. Equality is determined by the default object equality comparer for each component.

Tuple<T1,T2,T3,T4,T5,T6,T7>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions

Tuple<T1,T2,T3,T4,T5,T6,T7>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5,T6,T7> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2,T3,T4,T5,T6,T7> object.

Examples

The following example defines a Tuple<T1,T2,T3,T4,T5,T6,T7> object that contains population data for New York City for each census from 1950 through 2000. The components of the sextuple are then displayed by a call to the ToString method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Get population data for New York City, 1960-2000.
      var population = Tuple.Create("New York", 7891957, 7781984,
                                    7894862, 7071639, 7322564, 8008278);
      Console.WriteLine(population.ToString());
   }
}
```

```
// The example displays the following output:
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, `Item5, Item6, Item7`), where *Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, and *Item7* represent the values of the Item1, Item2, Item3, Item4, Item5, Item6, and Item7 properties, respectively. If any of the property values is `null`, it is represented as String.Empty.

Tuple<T1,T2,T3,T4,T5,T6,T7>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7> object to a specified object by using a specified comparer, and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

An object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2,T3,T4,T5,T6,T7> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects that contains population data for three U.S. cities from 1950 to 2000. The septuple's first component is the city name. The remaining five components represent the population at 10-year intervals from 1950 to 2000.

The `PopulationComparer` class provides an IComparer implementation that allows the array of septuples to be sorted by any one of its components. Two values are provided to the `PopulationComparer` class in its constructor: The position of the component that defines the sort order, and a Boolean value that indicates whether the tuple objects should be sorted in ascending or descending order.

The example then displays the elements in the array in unsorted order, sorts them by the third component (the population in 1960) and displays them, and then sorts them by the sixth component (the population in 1990) and displays them.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class PopulationComparer<T1, T2, T3, T4, T5, T6, T7> : IComparer
{
   private int itemPosition;
   private int multiplier = -1;

   public PopulationComparer(int component) : this(component, true)
   { }

   public PopulationComparer(int component, bool descending)
```

```
   {
      if (! descending) multiplier = 1;

      if (component <= 0 || component > 7)
         throw new ArgumentException("The component argument is out of
range.");

      itemPosition = component;
   }

   public int Compare(object x, object y)
   {
      Tuple<T1, T2, T3, T4, T5, T6, T7> tX = x as Tuple<T1, T2, T3, T4, T5,
T6, T7>;
      if (tX == null)
      {
         return 0;
      }
      else
      {
         Tuple<T1, T2, T3, T4, T5, T6, T7> tY = y as Tuple<T1, T2, T3, T4,
T5, T6, T7>;
         switch (itemPosition)
         {
            case 1:
               return Comparer<T1>.Default.Compare(tX.Item1, tY.Item1) *
multiplier;
            case 2:
               return Comparer<T2>.Default.Compare(tX.Item2, tY.Item2) *
multiplier;
            case 3:
               return Comparer<T3>.Default.Compare(tX.Item3, tY.Item3) *
multiplier;
            case 4:
               return Comparer<T4>.Default.Compare(tX.Item4, tY.Item4) *
multiplier;
            case 5:
               return Comparer<T5>.Default.Compare(tX.Item5, tY.Item5) *
multiplier;
            case 6:
               return Comparer<T6>.Default.Compare(tX.Item6, tY.Item6) *
multiplier;
            case 7:
               return Comparer<T7>.Default.Compare(tX.Item7, tY.Item7) *
multiplier;
            default:
               return Comparer<T1>.Default.Compare(tX.Item1, tY.Item1) *
multiplier;
         }
      }
   }
}

public class Example
{
```

```
   public static void Main()
   {
      // Create array of sextuple with population data for three U.S.
      // cities, 1960-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
           { Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
             Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
7322564, 8008278),
             Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display array in unsorted order.
      Console.WriteLine("In unsorted order:");
      foreach (var city in cities)
         Console.WriteLine(city.ToString());
      Console.WriteLine();

      Array.Sort(cities, new PopulationComparer<string, int, int, int, int,
int, int>(3));

      // Display array in sorted order.
      Console.WriteLine("Sorted by population in 1960:");
      foreach (var city in cities)
         Console.WriteLine(city.ToString());
      Console.WriteLine();

      Array.Sort(cities, new PopulationComparer<string, int, int, int, int,
int, int>(6));

      // Display array in sorted order.
      Console.WriteLine("Sorted by population in 1990:");
      foreach (var city in cities)
         Console.WriteLine(city.ToString());
   }
}
// The example displays the following output:
//    In unsorted order:
//    (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Chicago, 3620962, 3550904, 3366957, 3005072, 2783726, 2896016)
//
//    Sorted by population in 1960:
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Chicago, 3620962, 3550904, 3366957, 3005072, 2783726, 2896016)
//    (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398, 3694820)
//
//    Sorted by population in 1990:
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (Chicago, 3620962, 3550904, 3366957, 3005072, 2783726, 2896016)
```

Remarks

This member is an explicit interface implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7> instance is cast to an IStructuralComparable interface.

This method lets you define customized comparisons of Tuple<T1,T2,T3,T4,T5,T6,T7> objects. For example, you can use this method to order Tuple<T1,T2,T3,T4,T5,T6,T7> objects based on the value of a specific component.

Although this method can be called directly, it is most commonly called by collection-sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals** method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Examples

The following example defines a `RateComparer` class that performs a custom test for equality. If the values that are passed to its IStructuralEquatable.Equals method are of

type Single or Double, the method tests for equality by using only up to three fractional digits. Otherwise, it simply calls the `x` parameter's `Equals` method. The example uses this IEqualityComparer implementation to determine whether four Tuple<T1,T2,T3,T4,T5,T6,T7> objects that contain data on the rate of population change between 1950 and 2000 are equal.

C#

```
using System;
using System.Collections;

public class RateComparer<T1, T2, T3, T4, T5, T6, T7> : IEqualityComparer
{
   private int argument = 0;

   public new bool Equals(object x, object y)
   {
      argument++;
      if (argument == 1) return true;

      double fx, fy;
      if (x is Double || x is Single)
      {
            fx = (double) x;
            fy = (double) y;
            return Math.Round(fx * 1000).Equals(Math.Round(fy * 1000));
      }
      else
      {
         return x.Equals(y);
      }
   }

   public int GetHashCode(object obj)
   {
      if (obj is Single || obj is Double)
         return Math.Round(((double) obj) * 1000).GetHashCode();
      else
         return obj.GetHashCode();
   }
}

public class Example
{
   public static void Main()
   {
      var rate1 = Tuple.Create("New York", -.013934, .014505,
                               -.1042733, .0354833, .093644, .0290792);
      var rate2 = Tuple.Create("Unknown City", -.013934, .014505,
                               -.1042733, .0354833, .093644, .0290792);
      var rate3 = Tuple.Create("Unknown City", -.013934, .014505,
                               -.1042733, .0354833, .093644, .029079);
```

```
        var rate4 = Tuple.Create("San Francisco", -.0451934, -.0332858,
                                 -.0512803, .0662544, .0728964, .0491912);
        IStructuralEquatable eq = rate1;
        // Compare first tuple with remaining two tuples.
        Console.WriteLine("{0} = ", rate1.ToString());
        Console.WriteLine("   {0} : {1}", rate2,
                          eq.Equals(rate2, new RateComparer<string, double,
double, double, double, double, double>()));
        Console.WriteLine("   {0} : {1}", rate3,
                          eq.Equals(rate3, new RateComparer<string, double,
double, double, double, double, double>()));
        Console.WriteLine("   {0} : {1}", rate4,
                          eq.Equals(rate4, new RateComparer<string, double,
double,double,  double, double, double>()));
    }
}
// The example displays the following output:
//    (New York, -0.013934, 0.014505, -0.1042733, 0.0354833, 0.093644,
0.0290792) =
//       (Unknown City, -0.013934, 0.014505, -0.1042733, 0.0354833,
0.093644, 0.0290792) : True
//       (Unknown City, -0.013934, 0.014505, -0.1042733, 0.0354833,
0.093644, 0.029079) : True
//       (San Francisco, -0.0451934, -0.0332858, -0.0512803, 0.0662544,
0.0728964, 0.0491912) : False
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if other is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2,T3,T4,T5,T6,T7> object whose components are of the same types as the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the Tuple<T1,T2,T3,T4,T5,T6,T7> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two Tuple<T1,T2,T3,T4,T5,T6,T7> objects. This continues until the method call returns `false` when it compares a specific pair of `Item` values, or the two Item7 values are passed to the method.

Tuple<T1,T2,T3,T4,T5,T6,T7>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2,T3,T4,T5,T6,T7> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7> instance is cast to an IStructuralEquatable interface.

the method simply wraps a call to the comparer object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2,T3,T4,T5,T6,T7> objects that are considered to be equal.

Tuple<T1,T2,T3,T4,T5,T6,T7>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

```
C#

int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2,T3,T4,T5,T6,T7> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5,T6,T7> objects that contain population data for three cities in the United States from 1950 to 2000. The seven components consist of the city name followed by the city's population at 10-year intervals from 1950 to 2000. The example displays the components of each tuple in the array in unsorted order, sorts the array, and then calls the ToString method to display each tuple in sorted order. The output shows that the array has been sorted by name, which is the first component. Note that the example does not directly call the IComparable.CompareTo(Object) method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Create array of sextuple with population data for three U.S.
      // cities, 1950-2000.
      Tuple<string, int, int, int, int, int, int>[] cities =
          { Tuple.Create("Los Angeles", 1970358, 2479015, 2816061, 2966850,
3485398, 3694820),
            Tuple.Create("New York", 7891957, 7781984, 7894862, 7071639,
7322564, 8008278),
            Tuple.Create("Chicago", 3620962, 3550904, 3366957, 3005072,
2783726, 2896016) };

      // Display array in unsorted order.
      Console.WriteLine("In unsorted order:");
      foreach (var city in cities)
         Console.WriteLine(city.ToString());

      Console.WriteLine();

      Array.Sort(cities);

      // Display array in sorted order.
```

```
        Console.WriteLine("In sorted order:");
        foreach (var city in cities)
           Console.WriteLine(city.ToString());
    }
}
// The example displays the following output:
//    In unsorted order:
//    (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
//    (Chicago, 3620962, 3550904, 3366957, 3005072, 2783726, 2896016)
//
//    In sorted order:
//    (Chicago, 3620962, 3550904, 3366957, 3005072, 2783726, 2896016)
//    (Los Angeles, 1970358, 2479015, 2816061, 2966850, 3485398, 3694820)
//    (New York, 7891957, 7781984, 7894862, 7071639, 7322564, 8008278)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2,T3,T4,T5,T6,T7> class. Although the method can be called directly, it is most commonly called by the default overloads of collection-sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Tuple<T1,T2,T3,T4,T5,T6,T7>.Equals(Object)** method.

This method uses the default object comparer to compare each component.

Tuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 to 6.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 6.

Remarks

The Tuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5,T6,T7>

object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Tuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

7, the number of elements in a Tuple<T1,T2,T3,T4,T5,T6,T7> object.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5,T6,T7> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an *n*-tuple, where *n* is 8 or greater.

C#

```
public class Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> : IComparable,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the tuple's first component.

T2

The type of the tuple's second component.

T3

The type of the tuple's third component.

T4

The type of the tuple's fourth component.

T5

The type of the tuple's fifth component.

T6

The type of the tuple's sixth component.

T7

The type of the tuple's seventh component.

`TRest`

Any generic `Tuple` object that defines the types of the tuple's remaining components.

Inheritance Object → Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>

Implements IStructuralComparable , IStructuralEquatable , IComparable , ITuple

Remarks

A tuple is a data structure that has a specific number and sequence of values. The Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> class represents an *n*-tuple that has eight or more components.

You can instantiate a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object with exactly eight components by calling the static Tuple.Create method. The following example creates an 8-tuple (octuple) that contains prime numbers that are less than 20. Note that it uses type inference to determine the type of each component.

C#

```
var primes = Tuple.Create(2, 3, 5, 7, 11, 13, 17, 19);
Console.WriteLine("Prime numbers less than 20: " +
                  "{0}, {1}, {2}, {3}, {4}, {5}, {6}, and {7}",
                  primes.Item1, primes.Item2, primes.Item3,
                  primes.Item4, primes.Item5, primes.Item6,
                  primes.Item7, primes.Rest.Item1);
// The example displays the following output:
//    Prime numbers less than 20: 2, 3, 5, 7, 11, 13, 17, and 19
```

You can also instantiate an n-tuple object with eight or more components by calling the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> constructor. The following example uses the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> constructor to create an 8-tuple that is equivalent to the tuple created in the previous example.

C#

```
var primes = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32, Int32,
             Tuple<Int32>> (2, 3, 5, 7, 11, 13, 17, new Tuple<Int32>(19));
```

> **Note**
>
> To create an n-tuple with nine or more components, you must call the **Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>** constructor. The static factory methods of the

Tuple class do not support the creation of `Tuple` objects with more than eight components.

To instantiate an n-tuple that has eight or more components with the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> constructor, you supply a generic `Tuple` object as the `rest` parameter to define the eighth through *n*th components of the tuple. By nesting generic `Tuple` objects in this way, you can create a tuple that has no practical limitation on the number of its components.

The following example creates a 17-tuple that contains population data for the city of Detroit, Michigan, for each national census from 1860 to 2000. The first component of the tuple is the city name. The second component is the start date of the data series, and the third component is the population at the start date. Each subsequent component provides the population at decade intervals. The 17-tuple is created by nesting a Tuple<T1,T2,T3> object inside a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object. (That is, the Tuple<T1,T2,T3> object is supplied as the value of the `rest` parameter in the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> class constructor.) This Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object is, in turn, nested in an outer Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object. (That is, the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object is supplied as the value of the `rest` parameter in the outer Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's class constructor.)

C#

```
var from1980 = Tuple.Create(1203339, 1027974, 951270);
var from1910 = new Tuple<int, int, int, int, int, int, int, Tuple<int, int,
int>>
    (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462, from1980);
var population = new Tuple<string, int, int, int, int, int, int,
    Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
    ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704, from1910);
```

You can retrieve the value of the tuple's first seven components by using the read-only Item1, Item2, Item3, Item4, Item5, Item6, and Item7 instance properties. Any additional components are nested and can be retrieved from the Rest property. In the previous example, the Item1 through Item7 properties retrieve the first through seventh components of the tuple. The eighth through fourteenth components are contained in the tuple that is nested at the second level, and are represented by the `Rest.Item1` through `Rest.Item7` properties. The fifteenth through seventeenth components are contained in the tuple that is nested at the third level, and are represented by the `Rest.Rest.Item1` though `Rest.Rest.Item3` properties.

Tuples are commonly used in four different ways:

- To represent a single set of data. For example, a tuple can represent a database record, and its components can represent individual fields of the record.
- To provide easy access to, and manipulation of, a data set.
- To return multiple values from a method without the use of `out` parameters (in C#) or `ByRef` parameters (in Visual Basic). For example, the previous example returns its computed statistics, along with the city name, in a Tuple<T1,T2,T3,T4,T5,T6,T7> object.
- To pass multiple values to a method through a single parameter. For example, the Thread.Start(Object) method has a single parameter that lets you supply one value to the method that the thread executes at startup. If you supply a Tuple<T1,T2,T3,T4,T5,T6,T7> object as the method argument, you can supply the thread's startup routine with seven items of data.

Constructors

Expand table

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>(T1, T2, T3, T4, T5, T6, T7, TRest)	Initializes a new instance of the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> class.

Properties

Expand table

Item1	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's first component.
Item2	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's second component.
Item3	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's third component.
Item4	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's fourth component.
Item5	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's fifth component.
Item6	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's sixth component.
Item7	Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's seventh

	component.
Rest	Gets the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's remaining components.

Methods

Expand table

Equals(Object)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object is equal to a specified object.
GetHashCode()	Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise Clone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Explicit Interface Implementations

Expand table

IComparable.Compare To(Object)	Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable. CompareTo(Object, IComparer)	Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable. Equals(Object, IEquality Comparer)	Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object is equal to a specified object based on a specified comparison method.
IStructuralEquatable.Get HashCode(IEquality Comparer)	Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `Tuple` element.

ITuple.Length	Gets the number of elements in the `Tuple`.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> class.

C#

```
public Tuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6, T7
item7, TRest rest);
```

Parameters

item1 T1

The value of the tuple's first component.

item2 T2

The value of the tuple's second component.

item3 T3

The value of the tuple's third component.

item4 T4

The value of the tuple's fourth component.

item5 T5

The value of the tuple's fifth component.

item6 T6

The value of the tuple's sixth component.

item7 T7

The value of the tuple's seventh component.

`rest` TRest

Any generic `Tuple` object that contains the values of the tuple's remaining components.

Exceptions

ArgumentException

`rest` is not a generic `Tuple` object.

Examples

The following example creates a 17-tuple that contains population data for the city of Detroit, Michigan, for each census from 1860 to 2000. The first component of the tuple is the city name. The second component is the start date of the series of data, and the third component is the population at the start date. Each subsequent component provides the population at decade intervals. The example uses two layers of nesting to create the 17-tuple: It defines a 7-tuple whose third through seventh components contain population data for 1860 through 1900, a nested 7-tuple that contains population data for 1910 through 1970, and an inner nested 3-tuple that contains population data for 1980 through 2000.

C#

```
var from1980 = Tuple.Create(1203339, 1027974, 951270);
var from1910 = new Tuple<int, int, int, int, int, int, int, Tuple<int, int,
int>>
    (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462, from1980);
var population = new Tuple<string, int, int, int, int, int, int,
    Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
    ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704, from1910);
```

Remarks

You can also use the static Tuple.Create method to instantiate an 8-tuple (octuple) object without having to explicitly specify the types of its components. The following example uses the Tuple.Create method to instantiate an 8-tuple object that contains prime numbers that are less than 20.

C#

```
var primes = Tuple.Create(2, 3, 5, 7, 11, 13, 17, 19);
Console.WriteLine("Prime numbers less than 20: " +
                  "{0}, {1}, {2}, {3}, {4}, {5}, {6}, and {7}",
                  primes.Item1, primes.Item2, primes.Item3,
```

```
                    primes.Item4, primes.Item5, primes.Item6,
                    primes.Item7, primes.Rest.Item1);
// The example displays the following output:
//    Prime numbers less than 20: 2, 3, 5, 7, 11, 13, 17, and 19
```

This is equivalent to the following call to the Tuple<T1,T2,T3,T4,T5,T6,T7> class constructor.

```
C#

var primes = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32, Int32,
             Tuple<Int32>> (2, 3, 5, 7, 11, 13, 17, new Tuple<Int32>(19));
```

However, the static Tuple.Create method cannot be used to create a tuple object with more than eight components.

When using the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> constructor to create an n-tuple with eight or more components, you use the `rest` parameter to create a nested n-tuple that has from one to seven components. By using successive levels of nesting, you can create an n-tuple that has a virtually unlimited number of components. For example, to create a 25-tuple, you instantiate a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object with three levels of nesting, as follows:

- The outermost Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object contains the first through seventh components. Its Rest property provides access to an Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object at the first level of nesting.
- The outermost nested Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object contains the eighth through fourteenth components, and its Rest property provides access to an Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object at the second level of nesting.
- The Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object at the second level of nesting contains the fifteenth through twenty-first components, and its Rest property provides access to an Tuple<T1,T2,T3,T4> object at the third level of nesting.
- The innermost tuple is a Tuple<T1,T2,T3,T4> object that contains the twenty-second through twenty-fifth components.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item1 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's first component.

C#

```
public T1 Item1 { get; }
```

Property Value

T1

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's first component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The first component of the 17-tuple is the city name. The example uses the Item1 property to display the city name in the table header before displaying the population data.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
```

```
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item1, population.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item2,
population.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item3,
population.Rest.Item2);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item4,
population.Rest.Item3);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item5,
population.Rest.Item4);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item6,
population.Rest.Item5);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item7,
population.Rest.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item1,
population.Rest.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item2,
population.Rest.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item3,
population.Rest.Rest.Item2);
    }

    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
```

```
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//
//    Population of Detroit
//    Year      Population      Change
//    1860          45,619         n/a
//    1870          79,577      7.44 %
//    1880         116,340      4.62 %
//    1890         205,876      7.70 %
//    1900         285,704      3.88 %
//    1910         465,766      6.30 %
//    1920         993,078     11.32 %
//    1930       1,568,622      5.80 %
//    1940       1,623,452      0.35 %
//    1950       1,849,568      1.39 %
//    1960       1,670,144     -0.97 %
//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

You can dynamically determine the type of the Item1 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item1 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object, and retrieving the first element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item2 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's second component.

C#

```
public T2 Item2 { get; }
```

Property Value

T2

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's second component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The second component of the 17-tuple is the first year of the data series. The example assigns the value of the Item2 property to a variable, and then uses that variable to represent the year whose data is displayed.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
```

```
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item1, population.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item2,
population.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item3,
population.Rest.Item2);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item4,
population.Rest.Item3);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item5,
population.Rest.Item4);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item6,
population.Rest.Item5);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item7,
population.Rest.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item1,
population.Rest.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item2,
population.Rest.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item3,
population.Rest.Rest.Item2);
    }

    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
```

```
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//
//    Population of Detroit
//    Year      Population      Change
//    1860          45,619         n/a
//    1870          79,577      7.44 %
//    1880         116,340      4.62 %
//    1890         205,876      7.70 %
//    1900         285,704      3.88 %
//    1910         465,766      6.30 %
//    1920         993,078     11.32 %
//    1930       1,568,622      5.80 %
//    1940       1,623,452      0.35 %
//    1950       1,849,568      1.39 %
//    1960       1,670,144     -0.97 %
//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

You can dynamically determine the type of the Item2 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item2 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object, and retrieving the second element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item3 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's third component.

C#

```
public T3 Item3 { get; }
```

Property Value

T3

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's third component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The third component of the 17-tuple is the population in 1860. The example uses the Item3 property to display the population value and to calculate the annual rate of population change between 1860 and 1870.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);

//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

You can dynamically determine the type of the Item3 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item3 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object, and retrieving the third element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item4 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's fourth component.

C#

```
public T4 Item4 { get; }
```

Property Value

T4

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's fourth component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The fourth component of the 17-tuple is the population in 1870. The example uses the Item4 property to display the population value and to calculate the annual rate of population change between 1870 and 1880.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
```

```
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item1, population.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item2,
population.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item3,
population.Rest.Item2);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item4,
population.Rest.Item3);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item5,
population.Rest.Item4);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item6,
population.Rest.Item5);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item7,
population.Rest.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item1,
population.Rest.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item2,
population.Rest.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item3,
population.Rest.Rest.Item2);
    }

    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
```

```
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//
//    Population of Detroit
//    Year      Population      Change
//    1860          45,619         n/a
//    1870          79,577      7.44 %
//    1880         116,340      4.62 %
//    1890         205,876      7.70 %
//    1900         285,704      3.88 %
//    1910         465,766      6.30 %
//    1920         993,078     11.32 %
//    1930       1,568,622      5.80 %
//    1940       1,623,452      0.35 %
//    1950       1,849,568      1.39 %
//    1960       1,670,144     -0.97 %
//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item5 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's fifth component.

C#

```
public T5 Item5 { get; }
```

Property Value

T5

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's fifth component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The fifth component of the 17-tuple is the population in 1880. The example uses the Item5 property to display the population value and to calculate the annual rate of population change between 1880 and 1890.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
```

```
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item6 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's sixth component.

C#

```
public T6 Item6 { get; }
```

Property Value

T6

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's sixth component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The sixth component of the 17-tuple is the population in 1890. The example uses the Item6 property to display the population value and to calculate the annual rate of population change between 1890 and 1900.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
```

```
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item1, population.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item2,
population.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item3,
population.Rest.Item2);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item4,
population.Rest.Item3);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item5,
population.Rest.Item4);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item6,
population.Rest.Item5);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item7,
population.Rest.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item1,
population.Rest.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item2,
population.Rest.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item3,
population.Rest.Rest.Item2);
    }

    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
```

```
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//
//    Population of Detroit
//    Year      Population      Change
//    1860          45,619         n/a
//    1870          79,577      7.44 %
//    1880         116,340      4.62 %
//    1890         205,876      7.70 %
//    1900         285,704      3.88 %
//    1910         465,766      6.30 %
//    1920         993,078     11.32 %
//    1930       1,568,622      5.80 %
//    1940       1,623,452      0.35 %
//    1950       1,849,568      1.39 %
//    1960       1,670,144     -0.97 %
//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

You can dynamically determine the type of the Item6 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item6 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object, and retrieving the sixth element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Item7 Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's seventh component.

C#

```
public T7 Item7 { get; }
```

Property Value

T7

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's seventh component.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The seventh component of the 17-tuple is the population in 1900. The example uses the Item7 property to display the population value and to calculate the annual rate of population change between 1900 and 1910.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
```

```
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item1, population.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item2,
population.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item3,
population.Rest.Item2);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item4,
population.Rest.Item3);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item5,
population.Rest.Item4);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item6,
population.Rest.Item5);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item7,
population.Rest.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item1,
population.Rest.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item2,
population.Rest.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item3,
population.Rest.Rest.Item2);
    }

    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
```

```
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//
//    Population of Detroit
//    Year      Population      Change
//    1860          45,619         n/a
//    1870          79,577      7.44 %
//    1880         116,340      4.62 %
//    1890         205,876      7.70 %
//    1900         285,704      3.88 %
//    1910         465,766      6.30 %
//    1920         993,078     11.32 %
//    1930       1,568,622      5.80 %
//    1940       1,623,452      0.35 %
//    1950       1,849,568      1.39 %
//    1960       1,670,144     -0.97 %
//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

You can dynamically determine the type of the Item7 component in one of two ways:

- By calling the `GetType` method on the value that is returned by the Item7 property.
- By retrieving the Type object that represents the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object, and retrieving the seventh element from the array that is returned by its Type.GetGenericArguments method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's remaining components.

C#

```
public TRest Rest { get; }
```

Property Value

TRest

The value of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's remaining components.

Examples

The following example creates a 17-tuple object that contains population data for the city of Detroit, Michigan, from 1860 to 2000. The seventh component of the 17-tuple is the population in 1900. The example uses the Rest property to retrieve the values of the eighth through fourteenth components, and it uses the Rest property of the nested Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to retrieve the values of the remaining components.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
```

```
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
from1980);
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine("Population of {0}", population.Item1);
        Console.WriteLine();
        Console.WriteLine("{0,5}  {1,14}  {2,10}", "Year", "Population",
"Change");

        int year = population.Item2;
        ShowPopulation(year, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item4, population.Item3);
        year += 10;
        ShowPopulationChange(year, population.Item5, population.Item4);
        year += 10;
        ShowPopulationChange(year, population.Item6, population.Item5);
        year += 10;
        ShowPopulationChange(year, population.Item7, population.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item1, population.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item2,
population.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item3,
population.Rest.Item2);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item4,
population.Rest.Item3);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item5,
population.Rest.Item4);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item6,
population.Rest.Item5);
        year += 10;
        ShowPopulationChange(year, population.Rest.Item7,
population.Rest.Item6);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item1,
population.Rest.Item7);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item2,
population.Rest.Rest.Item1);
        year += 10;
        ShowPopulationChange(year, population.Rest.Rest.Item3,
population.Rest.Rest.Item2);
    }
```

```
    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//
//    Population of Detroit
//    Year      Population      Change
//    1860          45,619         n/a
//    1870          79,577      7.44 %
//    1880         116,340      4.62 %
//    1890         205,876      7.70 %
//    1900         285,704      3.88 %
//    1910         465,766      6.30 %
//    1920         993,078     11.32 %
//    1930       1,568,622      5.80 %
//    1940       1,623,452      0.35 %
//    1950       1,849,568      1.39 %
//    1960       1,670,144     -0.97 %
//    1970       1,511,462     -0.95 %
//    1980       1,203,339     -2.04 %
//    1990       1,027,974     -1.46 %
//    2000         951,270     -0.75 %
```

Remarks

The Rest property returns a nested `Tuple` object that allows access to the eighth though *n*th components of the tuple. Depending on the total number of components in the tuple, the values of the eighth through fourteenth components can be retrieved from the nested `Tuple` object's Item1 through Item7 properties. You can then use the Rest property of a nested Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to retrieve the `Tuple` object at the next level of nesting.

You can dynamically determine the number of components in a nested `Tuple` object that is returned by the Rest property by extracting the digit from its type name. The following example provides an illustration.

```
VB
```

```
Imports System.Reflection

Module Example
    Sub Main()
        Dim from1980 As Tuple(Of Integer, Integer, Integer) =
            Tuple.Create(1203339, 1027974, 951270)
        Dim from1910 As New Tuple(Of Integer, Integer, Integer, Integer,
Integer, Integer, Integer, _
            Tuple(Of Integer, Integer, Integer)) _
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
from1980)
        Dim population As New Tuple(Of String, Integer, Integer, Integer,
Integer, Integer, Integer, _
            Tuple(Of Integer, Integer, Integer, Integer, Integer, Integer,
Integer, Tuple(Of Integer, Integer, Integer))) _
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910)

        ShowComponentCount(population)
   End Sub

   Private Sub ShowComponentCount(tuple As Object)
      Static ctr As Integer = 0
      Static totalComponents As Integer = 0
      Dim components As Integer = 0

      ctr += 1
      Dim name As String = tuple.GetType().Name
      components += Int32.Parse(name.Substring(name.IndexOf("`") + 1))
      If components = 8 Then
         totalComponents += 7
         Console.WriteLine("The tuple at level {0} has 7 components.", ctr)
         ShowComponentCount(tuple.Rest)
      Else
         totalComponents += components
         Console.WriteLine("The tuple at level {0} has {1} components.",
                           ctr, components)
         Console.WriteLine("Total components in tuple: {0}",
totalComponents)
      End If
   End Sub
End Module
' The example displays the following output:
'       The tuple at level 1 has 7 components.
'       The tuple at level 2 has 7 components.
'       The tuple at level 3 has 3 components.
'       Total components in tuple: 17
```

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Examples

The following example defines five Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects that contain prime numbers. It then compares the first object with each of the remaining objects. As the output shows, only the first and the last Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects are equal, because they have an identical number of components with identical values.

C#

```
using System;

public class Class1
```

```
{
   public static void Main()
   {
      // Create five 8-tuple objects containing prime numbers.
      var prime1 = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                           Tuple<Int32>> (2, 3, 5, 7, 11, 13, 17,
                           new Tuple<Int32>(19));
      var prime2 = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                           Tuple<Int32>> (23, 29, 31, 37, 41, 43, 47,
                           new Tuple<Int32>(55));
      var prime3 = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                           Tuple<Int32>> (3, 2, 5, 7, 11, 13, 17,
                           new Tuple<Int32>(19));
      var prime4 = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                           Tuple<Int32, Int32>> (2, 3, 5, 7, 11, 13, 17,
                           new Tuple<Int32, Int32>(19, 23));
      var prime5 = new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                           Tuple<Int32>> (2, 3, 5, 7, 11, 13, 17,
                           new Tuple<Int32>(19));
      Console.WriteLine("{0} = {1} : {2}", prime1, prime2,
prime1.Equals(prime2));
      Console.WriteLine("{0} = {1} : {2}", prime1, prime3,
prime1.Equals(prime3));
      Console.WriteLine("{0} = {1} : {2}", prime1, prime4,
prime1.Equals(prime4));
      Console.WriteLine("{0} = {1} : {2}", prime1, prime5,
prime1.Equals(prime5));
   }
}
// The example displays the following output:
//    (2, 3, 5, 7, 11, 13, 17, 19) = (23, 29, 31, 37, 41, 43, 47, 55) :
False
//    (2, 3, 5, 7, 11, 13, 17, 19) = (3, 2, 5, 7, 11, 13, 17, 19) : False
//    (2, 3, 5, 7, 11, 13, 17, 19) = (2, 3, 5, 7, 11, 13, 17, 19, 23) :
False
//    (2, 3, 5, 7, 11, 13, 17, 19) = (2, 3, 5, 7, 11, 13, 17, 19) : True
```

Remarks

The `obj` parameter is considered to be equal to the current instance if it meets all the following conditions:

- It is a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.
- It has the same total number of components that are of the same types as the current instance.

- Its components (including its nested components) are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Examples

The following example creates a 17-tuple that contains population data for the city of Detroit, Michigan, from 1860 to 1900. It then uses the ToString method to display the tuple's data.

C#

```
using System;

class Example
{
    static void Main(string[] args)
    {
        Tuple<int, int, int> from1980 = Tuple.Create(1203339, 1027974,
951270);
        var from1910 = new Tuple<int, int, int, int, int, int, int,
Tuple<int, int, int>>
            (465766, 993078, 1568622, 1623452, 1849568, 1670144, 1511462,
from1980);
```

```
        var population = new Tuple<string, int, int, int, int, int, int,
            Tuple<int, int, int, int, int, int, int, Tuple<int, int, int>>>
            ("Detroit", 1860, 45619, 79577, 116340, 205876, 285704,
from1910);

        Console.WriteLine(population.ToString());
    }

    private static void ShowPopulationChange(int year, int newPopulation,
int oldPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation,
                          ((double)(newPopulation - oldPopulation) /
oldPopulation) / 10);
    }

    private static void ShowPopulation(int year, int newPopulation)
    {
        Console.WriteLine("{0,5}  {1,14:N0}  {2,10:P2}", year,
newPopulation, "n/a");
    }
}
// The example displays the following output:
//   (Detroit, 1860, 45619, 79577, 116340, 205876, 285704, 465766, 993078,
//    1568622, 1623452, 1849568, 1670144, 1511462, 1203339, 1027974, 951270)
```

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, `Item5, Item6, Item7`, *Item8*...), where *Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, and *Item7* represent the values of the Item1, Item2, Item3, Item4, Item5, Item6, and Item7 properties. *Item8* represents the value of the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object's `Next.Item1` property. The value of any additional nested components follow *Item8*. If any of the property values is `null`, it is represented as String.Empty.

Applies to

Product	Versions

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

An object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Examples

The following example creates an array of Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects that contains population data for four U.S. cities from 1940 to 2000. The octuple's first component is the city name. The remaining six components represent the population at 10-year intervals from 1940 to 2000.

The `PopulationComparer` class provides an IComparer implementation that allows the array of octuples to be sorted by any one of its components. Two values are provided to the `PopulationComparer` class in its constructor: The position of the component that defines the sort order, and a Boolean value that indicates whether the tuple objects should be sorted in ascending or descending order.

The example then displays the elements in the array in unsorted order, sorts them by the third component (the population in 1950) and displays them, and then sorts them by the eighth component (the population in 2000) and displays them.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class PopulationComparer<T1, T2, T3, T4, T5, T6, T7, T8> : IComparer
{
   private int itemPosition;
   private int multiplier = -1;

   public PopulationComparer(int component) : this(component, true)
   { }

   public PopulationComparer(int component, bool descending)
```

```
   {
      if (! descending) multiplier = 1;

      if (component <= 0 || component > 8)
         throw new ArgumentException("The component argument is out of
range.");

      itemPosition = component;
   }

   public int Compare(object x, object y)
   {
      Tuple<T1, T2, T3, T4, T5, T6, T7, Tuple<T8>> tX = x as Tuple<T1, T2,
T3, T4, T5, T6, T7, Tuple<T8>>;
      if (tX == null)
         return 0;

      Tuple<T1, T2, T3, T4, T5, T6, T7, Tuple<T8>> tY = y as Tuple<T1, T2,
T3, T4, T5, T6, T7, Tuple<T8>>;
      switch (itemPosition)
      {
         case 1:
            return Comparer<T1>.Default.Compare(tX.Item1, tY.Item1) *
multiplier;
         case 2:
            return Comparer<T2>.Default.Compare(tX.Item2, tY.Item2) *
multiplier;
         case 3:
            return Comparer<T3>.Default.Compare(tX.Item3, tY.Item3) *
multiplier;
         case 4:
            return Comparer<T4>.Default.Compare(tX.Item4, tY.Item4) *
multiplier;
         case 5:
            return Comparer<T5>.Default.Compare(tX.Item5, tY.Item5) *
multiplier;
         case 6:
            return Comparer<T6>.Default.Compare(tX.Item6, tY.Item6) *
multiplier;
         case 7:
            return Comparer<T7>.Default.Compare(tX.Item7, tY.Item7) *
multiplier;
         case 8:
            return Comparer<T8>.Default.Compare(tX.Rest.Item1,
tY.Rest.Item1) * multiplier;
         default:
            return Comparer<T1>.Default.Compare(tX.Item1, tY.Item1) *
multiplier;
      }
   }
}

public class Example
{
   public static void Main()
```

```
   {
      // Create array of octuples with population data for three U.S.
      // cities, 1940-2000.
      Tuple<string, int, int, int, int, int, int, Tuple<int>>[] cities  =
          { Tuple.Create("Los Angeles", 1504277, 1970358, 2479015, 2816061,
2966850, 3485398, 3694820),
            Tuple.Create("New York", 7454995, 7891957, 7781984, 7894862,

951270)
//
//    Sorted by population in 1950:
//    (New York, 7454995, 7891957, 7781984, 7894862, 7071639, 7322564,
8008278)
//    (Chicago, 3396808, 3620962, 3550904, 3366957, 3005072, 2783726,
2896016)
//    (Detroit, 1623452, 1849568, 1670144, 1511462, 1203339, 1027974,
951270)
//    (Los Angeles, 1504277, 1970358, 2479015, 2816061, 2966850, 3485398,
```

```
3694820)
//
//    Sorted by population in 2000:
//    (New York, 7454995, 7891957, 7781984, 7894862, 7071639, 7322564,
8008278)
//    (Los Angeles, 1504277, 1970358, 2479015, 2816061, 2966850, 3485398,
3694820)
//    (Chicago, 3396808, 3620962, 3550904, 3366957, 3005072, 2783726,
2896016)
//    (Detroit, 1623452, 1849568, 1670144, 1511462, 1203339, 1027974,
951270)
```

Remarks

This member is an explicit interface implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IStructuralComparable interface.

This method lets you define customized comparisons of Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects. For example, you can use this method to order Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects based on the value of a specific component.

Although this method can be called directly, it is most commonly called by collection-sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals** method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IStructuralEquatable

interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast (in C#) or converted (in Visual Basic) to a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object that has the same total number of components (including those in nested `Tuple` objects) of the same types as the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects. This continues until the method call returns `false` when it compares a specific pair of values, or the two Rest values are passed to the method.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IStructuralEquatable interface.

The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects that are considered to be equal.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object obj);
```

Parameters

obj Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `obj`.
Zero	This instance and `obj` have the same position in the sort order.
A positive integer	This instance follows `obj`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`obj` is not a Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Examples

The following example creates an array of octuples whose components are integers that contain a range of prime numbers. The example displays the elements of the array in unsorted order, sorts the array, and then displays the array in sorted order. The output shows that the array has been sorted by Item1, or the tuple's first component. Note that the example does not directly call the IComparable.CompareTo(Object) method. This method is called implicitly by the Sort(Array) method for each element in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      // Create array of 8-tuple objects containing prime numbers.
      Tuple<Int32, Int32, Int32, Int32, Int32, Int32, Int32, Tuple<Int32>>[]
primes =
                     { new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                         Tuple<Int32>>(2, 3, 5, 7, 11, 13, 17, new
Tuple<Int32>(19)),
                       new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                         Tuple<Int32>>(23, 29, 31, 37, 41, 43, 47, new
Tuple<Int32>(55)),
                       new Tuple<Int32, Int32, Int32, Int32, Int32, Int32,
Int32,
                         Tuple<Int32>>(3, 2, 5, 7, 11, 13, 17, new
Tuple<Int32>(19)) };
      // Display 8-tuples in unsorted order.
      foreach (var prime in primes)
         Console.WriteLine(prime.ToString());
      Console.WriteLine();

      // Sort the array and display its 8-tuples.
      Array.Sort(primes);
      foreach (var prime in primes)
         Console.WriteLine(prime.ToString());
   }
```

```
}
// The example displays the following output:
//       (2, 3, 5, 7, 11, 13, 17, 19)
//       (23, 29, 31, 37, 41, 43, 47, 55)
//       (3, 2, 5, 7, 11, 13, 17, 19)
//
//       (2, 3, 5, 7, 11, 13, 17, 19)
//       (3, 2, 5, 7, 11, 13, 17, 19)
//       (23, 29, 31, 37, 41, 43, 47, 55)
```

Remarks

This member is an explicit interface member implementation. It can be used only when the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> class. Although the method can be called directly, it is most commonly called by the default overloads of collection-sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> ⊗ **Caution**
>
> The **IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Equals(Object)** method.

This method uses the default object comparer to compare each component.

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `Tuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `Tuple` element. `index` can range from 0 for `Item1` to one less than the number of elements in the `Tuple`.

Property Value

Object

The value of the `Tuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0.

-or-

`index` is greater than or equal to ITuple.Length.

Remarks

The Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `Tuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

The number of elements in the `Tuple`.

Implements

Length

Remarks

The ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the Tuple<T1,T2,T3,T4,T5,T6,T7,TRest> type to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

TupleExtensions Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides extension methods for tuples to interoperate with language support for tuples in C#.

C#

```
public static class TupleExtensions
```

Inheritance Object → TupleExtensions

Remarks

Although these methods can be called directly, they are primarily intended for use by the C# compiler in creating and deconstructing tuples.

Methods

Expand table

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19,T20,T21>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19, T20, T21)	Deconstructs a tuple with 21 elements into separate variables.

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10, T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19, T20)	Deconstructs a tuple with 20 elements into separate variables.

	of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11, T12,T13,T14,ValueTuple<T15,T16,T17>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>(ValueTuple<T1, T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15, T16>>>)	Converts an instance of the `ValueTuple` structure

	to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tupl`

	`e` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11>>)	Converts an instance

	of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9>>)	Converts an instance of the `ValueTuple` structure

	to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7>(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tupl`

	`e` class.
ToTuple<T1,T2,T3,T4,T5,T6>(ValueTuple<T1,T2,T3,T4,T5,T6>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5>(ValueTuple<T1,T2,T3,T4,T5>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4>(ValueTuple<T1,T2,T3,T4>)	Converts an instance

	of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3>(ValueTuple<T1,T2,T3>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2>(ValueTuple<T1,T2>)	Converts an instance of the `ValueTuple` structure

	to an instance of the `Tuple` class.
ToTuple<T1>(ValueTuple<T1>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19,T20,T21>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple`

	structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10, T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11, T12,T13,T14,Tuple<T15,T16,T17,T18,T19>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12, T13,T14,Tuple<T15,T16,T17,T18>>>)	Converts an instance

	of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13, T14,Tuple<T15,T16,T17>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>>)	Converts an instance of the `Tuple` class to an insta

	nce of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple`

	structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>)	Converts an instance

	of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>)	Converts an instance of the `Tuple` class to an insta

	nce of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple`

	structure.
ToValueTuple<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5>(Tuple<T1,T2,T3,T4,T5>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>)	Converts an instance

	of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3>(Tuple<T1,T2,T3>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2>(Tuple<T1,T2>)	Converts an instance of the `Tuple` class to an insta

	nce of the `ValueTuple` structure.
ToValueTuple<T1>(Tuple<T1>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

TupleExtensions.Deconstruct Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Deconstructs the components of a tuple into separate variables.

Overloads

Expand table

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20,T21>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8, T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19, T20, T21)	Deconstructs a tuple with 21 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10, T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19, T20)	Deconstructs a tuple with 20 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11, T12,T13,T14,Tuple<T15,T16,T17,T18,T19>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19)	Deconstructs a tuple with 19 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12, T13,T14,Tuple<T15,T16,T17,T18>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18)	Deconstructs a tuple with 18 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13, T14,Tuple<T15,T16,T17>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17)	Deconstructs a tuple with 17 elements into separate variables.

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14, Tuple<T15,T16>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16)	Deconstructs a tuple with 16 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>(Tuple<T1, T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15)	Deconstructs a tuple with 15 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14>(Tuple<T1, T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14)	Deconstructs a tuple with 14 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>(Tuple<T1, T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13)	Deconstructs a tuple with 13 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>(Tuple<T1, T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12)	Deconstructs a tuple with 12 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11)	Deconstructs a tuple with 11 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10)	Deconstructs a tuple with 10 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>, T1, T2, T3, T4, T5, T6, T7, T8, T9)	Deconstructs a tuple with 9 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>, T1, T2, T3, T4, T5, T6, T7, T8)	Deconstructs a tuple with 8 elements into

	separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>, T1, T2, T3, T4, T5, T6, T7)	Deconstructs a tuple with 7 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>, T1, T2, T3, T4, T5, T6)	Deconstructs a tuple with 6 elements into separate variables.
Deconstruct<T1,T2,T3,T4,T5>(Tuple<T1,T2,T3,T4,T5>, T1, T2, T3, T4, T5)	Deconstructs a tuple with 5 elements into separate variables.
Deconstruct<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>, T1, T2, T3, T4)	Deconstructs a tuple with 4 elements into separate variables.
Deconstruct<T1,T2,T3>(Tuple<T1,T2,T3>, T1, T2, T3)	Deconstructs a tuple with 3 elements into separate variables.
Deconstruct<T1,T2>(Tuple<T1,T2>, T1, T2)	Deconstructs a tuple with 2 elements into separate variables.
Deconstruct<T1>(Tuple<T1>, T1)	Deconstructs a tuple with 1 element into a separate variable.

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11, T12,T13,T14,T15, T16,T17,T18,T19,T20,T21>

(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16, T17, T18, T19, T20, T21)

Deconstructs a tuple with 21 elements into separate variables.

C#

```
public static void
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19,T20,T21> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>> value, out T1 item1, out T2 item2, out T3 item3, out T4 item4, out T5 item5, out T6 item6, out T7 item7, out T8 item8, out T9 item9, out T10 item10, out T11 item11, out T12 item12, out T13 item13, out T14 item14, out T15 item15, out T16 item16, out T17 item17, out T18 item18, out T19 item19, out T20 item20, out T21 item21);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element.

`T9`

The type of the ninth element.

`T10`

The type of the tenth element.

`T11`

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

`T15`

The type of the fifteenth element.

`T16`

The type of the sixteenth element.

`T17`

The type of the seventeenth element.

`T18`

The type of the eighteenth element.

`T19`

The type of the nineteenth element.

`T20`

The type of the twentieth element.

`T21`

The type of the twenty-first element.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>

The 21-element tuple to deconstruct into 21 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

`item15` T15

When this method returns, contains the value of the fifteenth element, or `value.Rest.Rest.Item1`.

`item16` T16

When this method returns, contains the value of the sixteenth element, or `value.Rest.Rest.Item2`.

`item17` T17

When this method returns, contains the value of the seventeenth element, or `value.Rest.Rest.Item3`.

`item18` T18

When this method returns, contains the value of the eighteenth element, or `value.Rest.Rest.Item4`.

`item19` T19

When this method returns, contains the value of the nineteenth element, or `value.Rest.Rest.Item5`.

`item20` T20

When this method returns, contains the value of the twentieth element, or `value.Rest.Rest.Item6`.

`item21` T21

When this method returns, contains the value of the twenty-first element, or `value.Rest.Rest.Item7`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item21` are elements of nested tuples.

Deconstructs a tuple with 20 elements into separate variables.

C#

```
public static void
Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19,T20> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>> value, out T1 item1, out T2 item2, out T3 item3, out T4 item4, out T5 item5, out T6 item6, out T7 item7, out T8 item8, out T9 item9, out T10 item10, out T11 item11, out T12 item12, out T13 item13, out T14 item14, out T15 item15, out T16 item16, out T17 item17, out T18 item18, out T19 item19, out T20 item20);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element.

`T9`

The type of the ninth element.

`T10`

The type of the tenth element.

`T11`

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

`T15`

The type of the fifteenth element.

`T16`

The type of the sixteenth element.

`T17`

The type of the seventeenth element.

`T18`

The type of the eighteenth element.

`T19`

The type of the nineteenth element.

`T20`

The type of the twentieth element.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>>

The 20-element tuple to deconstruct into 20 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

`item15` T15

When this method returns, contains the value of the fifteenth element, or `value.Rest.Rest.Item1`.

`item16` T16

When this method returns, contains the value of the sixteenth element, or `value.Rest.Rest.Item2`.

`item17` T17

When this method returns, contains the value of the seventeenth element, or `value.Rest.Rest.Item3`.

`item18` T18

When this method returns, contains the value of the eighteenth element, or `value.Rest.Rest.Item4`.

`item19` T19

When this method returns, contains the value of the nineteenth element, or `value.Rest.Rest.Item5`.

`item20` T20

When this method returns, contains the value of the twentieth element, or `value.Rest.Rest.Item6`.

out T14 item14, out T15 item15, out T16 item16, out T17 item17, out T18
item18, out T19 item19);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element.

T9

The type of the ninth element.

T10

The type of the tenth element.

T11

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

`T15`

The type of the fifteenth element.

`T16`

The type of the sixteenth element.

`T17`

The type of the seventeenth element.

`T18`

The type of the eighteenth element.

`T19`

The type of the nineteenth element.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19>>>

The 19-element tuple to deconstruct into 19 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

`item15` T15

When this method returns, contains the value of the fifteenth element, or `value.Rest.Rest.Item1`.

`item16` T16

When this method returns, contains the value of the sixteenth element, or `value.Rest.Rest.Item2`.

`item17` T17

When this method returns, contains the value of the seventeenth element, or `value.Rest.Rest.Item3`.

`item18` T18

When this method returns, contains the value of the eighteenth element, or `value.Rest.Rest.Item4`.

`item19` T19

When this method returns, contains the value of the nineteenth element, or `value.Rest.Rest.Item5`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item19` are elements of nested tuples.

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element.

T9

The type of the ninth element.

T10

The type of the tenth element.

T11

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

`T15`

The type of the fifteenth element.

`T16`

The type of the sixteenth element.

`T17`

The type of the seventeenth element.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17>>>

The 17-element tuple to deconstruct into 17 separate variables.

`item1`	T1

When this method returns, contains the value of the first element.

`item2`	T2

When this method returns, contains the value of the second element.

`item3`	T3

When this method returns, contains the value of the third element.

`item4`	T4

When this method returns, contains the value of the fourth element.

`item5`	T5

When this method returns, contains the value of the fifth element.

`item6`	T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

`item15` T15

When this method returns, contains the value of the fifteenth element, or `value.Rest.Rest.Item1`.

`item16` T16

When this method returns, contains the value of the sixteenth element, or `value.Rest.Rest.Item2`.

`item17` T17

When this method returns, contains the value of the seventeenth element, or `value.Rest.Rest.Item3`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item17` are elements of nested tuples.

item10, out T11 item11, out T12 item12, out T13 item13, out T14 item14,
out T15 item15, out T16 item16);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element.

`T9`

The type of the ninth element.

`T10`

The type of the tenth element.

`T11`

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

`T15`

The type of the fifteenth element.

`T16`

The type of the sixteenth element.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>>

The 16-element tuple to deconstruct into 16 separate variables.

`item1`	T1

When this method returns, contains the value of the first element.

`item2`	T2

When this method returns, contains the value of the second element.

`item3`	T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

`item15` T15

When this method returns, contains the value of the fifteenth element, or `value.Rest.Rest.Item1`.

`item16` T16

When this method returns, contains the value of the sixteenth element, or `value.Rest.Rest.Item2`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item16` are elements of nested tuples.

out T15 item15);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element.

`T9`

The type of the ninth element.

`T10`

The type of the tenth element.

`T11`

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

`T15`

The type of the fifteenth element.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>

The 15-element tuple to deconstruct into 15 separate variables.

`item1`	T1

When this method returns, contains the value of the first element.

`item2`	T2

When this method returns, contains the value of the second element.

`item3`	T3

When this method returns, contains the value of the third element.

`item4`	T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

`item15` T15

When this method returns, contains the value of the fifteenth element, or `value.Rest.Rest.Item1`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item15` are elements of nested tuples.

item11, out T12 item12, out T13 item13, out T14 item14);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element.

T9

The type of the ninth element.

T10

The type of the tenth element.

T11

The type of the eleventh element.

`T12`

The type of the twelfth element.

`T13`

The type of the thirteenth element.

`T14`

The type of the fourteenth element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>

The 14-element tuple to deconstruct into 14 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

`item12` T12

When this method returns, contains the value of the twelfth element, or `value.Rest.Item5`.

`item13` T13

When this method returns, contains the value of the thirteenth element, or `value.Rest.Item6`.

`item14` T14

When this method returns, contains the value of the fourteenth element, or `value.Rest.Item7`.

item7, out T8 item8, out T9 item9, out T10 item10, out T11 item11);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element.

`T9`

The type of the ninth element.

`T10`

The type of the tenth element.

`T11`

The type of the eleventh element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>

The 11-element tuple to deconstruct into 11 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

`item11` T11

When this method returns, contains the value of the eleventh element, or `value.Rest.Item4`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item11` are elements of nested tuples.

- ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>, T1, T2, T3, T4, T5, T6, T7, T8, T9, T10)

Deconstructs a tuple with 10 elements into separate variables.

C#

```
public static void Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>> value, out T1 item1, out T2
item2, out T3 item3, out T4 item4, out T5 item5, out T6 item6, out T7
item7, out T8 item8, out T9 item9, out T10 item10);
```

Type Parameters

T1

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element.

`T9`

The type of the ninth element.

`T10`

The type of the tenth element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>

The 10-element tuple to deconstruct into 10 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

`item10` T10

When this method returns, contains the value of the tenth element, or `value.Rest.Item3`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` through `item10` are elements of nested tuples.

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>, T1, T2, T3, T4, T5, T6, T7, T8, T9)

Deconstructs a tuple with 9 elements into separate variables.

C#

```
public static void Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8,T9> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>> value, out T1 item1, out T2
item2, out T3 item3, out T4 item4, out T5 item5, out T6 item6, out T7
item7, out T8 item8, out T9 item9);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element.

`T9`

The type of the ninth element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>

The 9-element tuple to deconstruct into 9 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

`item9` T9

When this method returns, contains the value of the ninth element, or `value.Rest.Item2`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` and `item9` are elements of nested tuples.

Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>, T1, T2, T3, T4, T5, T6, T7, T8)

Deconstructs a tuple with 8 elements into separate variables.

```
C#

public static void Deconstruct<T1,T2,T3,T4,T5,T6,T7,T8> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>> value, out T1 item1, out T2 item2,
out T3 item3, out T4 item4, out T5 item5, out T6 item6, out T7 item7, out
T8 item8);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element.

Parameters

value Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>

The 8-element tuple to deconstruct into 8 separate variables.

item1 T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

`item6` T6

When this method returns, contains the value of the sixth element.

`item7` T7

When this method returns, contains the value of the seventh element.

`item8` T8

When this method returns, contains the value of the eighth element, or `value.Rest.Item1`.

Remarks

This method is implemented primarily to support the tuple language features in C#.

Because the .NET Framework tuple types implement tuples with more than 7 elements by nesting a tuple in Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest, `item8` is an element in a nested tuple.

Deconstruct<T1,T2,T3,T4,T5> (Tuple<T1,T2,T3,T4,T5>, T1, T2, T3, T4, T5)

Deconstructs a tuple with 5 elements into separate variables.

C#

```
public static void Deconstruct<T1,T2,T3,T4,T5> (this
Tuple<T1,T2,T3,T4,T5> value, out T1 item1, out T2 item2, out T3 item3,
out T4 item4, out T5 item5);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

Parameters

value Tuple<T1,T2,T3,T4,T5>

The 5-element tuple to deconstruct into 5 separate variables.

item1 T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

`item5` T5

When this method returns, contains the value of the fifth element.

Deconstruct<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>, T1, T2, T3, T4)

Deconstructs a tuple with 4 elements into separate variables.

```
C#
```

```
public static void Deconstruct<T1,T2,T3,T4> (this Tuple<T1,T2,T3,T4>
value, out T1 item1, out T2 item2, out T3 item3, out T4 item4);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

Parameters

`value` Tuple<T1,T2,T3,T4>

The 4-element tuple to deconstruct into 4 separate variables.

`item1` T1

When this method returns, contains the value of the first element.

`item2` T2

When this method returns, contains the value of the second element.

`item3` T3

When this method returns, contains the value of the third element.

`item4` T4

When this method returns, contains the value of the fourth element.

Deconstruct<T1>(Tuple<T1>, T1)

Deconstructs a tuple with 1 element into a separate variable.

```
C#
public static void Deconstruct<T1> (this Tuple<T1> value, out T1 item1);
```

Type Parameters

`T1`

The type of the single element.

Parameters

`value` Tuple<T1>

The 1-element tuple to deconstruct into a separate variable.

`item1` T1

When this method returns, contains the value of the single element.

Remarks

This method is implemented primarily to support the tuple language features in C#.

TupleExtensions.ToTuple Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a value tuple to a tuple.

Overloads

Expand table

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17,T18,T19,T20,T21>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20,T21>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17,T18,T19,T20>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17,T18,T19>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17,T18> (ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10, T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17> (ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11, T12,T13,T14,ValueTuple<T15,T16,T17>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>(ValueTuple<T1, T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15, T16>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15> (ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15>>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> (ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8>>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6,T7>(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5,T6>(ValueTuple<T1,T2,T3,T4,T5,T6>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4,T5>(ValueTuple<T1,T2,T3,T4,T5>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2,T3,T4>(ValueTuple<T1,T2,T3,T4>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

ToTuple<T1,T2,T3>(ValueTuple<T1,T2,T3>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1,T2>(ValueTuple<T1,T2>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.
ToTuple<T1>(ValueTuple<T1>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17,T18,T19,T20,T21>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20,T21>>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>
```

```
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19
,T20,T21> (this (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14, (T15, T16, T17, T18, T19, T20, T21))) value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

`T17`

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

`T18`

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

`T19`

The type of the nineteenth element, or `value.Rest.Rest.Item5`.

`T20`

The type of the twentieth element, or `value.Rest.Rest.Item6`.

`T21`

The type of the twenty-first element, or `value.Rest.Rest.Item7`.

Parameters

`value`	ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20,T21>>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>

The converted tuple.

```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

`T17`

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

`T18`

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

`T19`

The type of the nineteenth element, or `value.Rest.Rest.Item5`.

Parameters

value	ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19>>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19>>>

The converted tuple.

```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

`T17`

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

`T18`

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

Parameters

`value`	ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18>>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18>>>

The converted tuple.

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17>>> ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17>(this (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13, T14, (T15, T16, T17))) value);
```

Type Parameters

T1

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

T15

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

T16

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

T17

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

Parameters

value	ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17>>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17>>>

The converted tuple.

.NET Standard	2.0, 2.1

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>(ValueTuple<T1,

T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15, T16>>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>
> ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16> (this
(T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13, T14, (T15,
T16))) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

T10

The type of the tenth element, or `value.Rest.Item3`.

T11

The type of the eleventh element, or `value.Rest.Item4`.

T12

The type of the twelfth element, or `value.Rest.Item5`.

T13

The type of the thirteenth element, or `value.Rest.Item6`.

T14

The type of the fourteenth element, or `value.Rest.Item7`.

T15

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

T16

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

Parameters

value	ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16>>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>>

The converted tuple.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15>>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15> (this (T1, T2,
T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13, T14, (T15))) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

T10

The type of the tenth element, or `value.Rest.Item3`.

T11

The type of the eleventh element, or `value.Rest.Item4`.

T12

The type of the twelfth element, or `value.Rest.Item5`.

T13

The type of the thirteenth element, or `value.Rest.Item6`.

T14

The type of the fourteenth element, or `value.Rest.Item7`.

T15

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

Parameters

value	ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15>>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>

The converted tuple.

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> (this (T1, T2, T3,
T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13, T14)) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>

The converted tuple.

See also

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>>
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13> (this (T1, T2, T3, T4,
T5, T6, T7, (T8, T9, T10, T11, T12, T13)) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>>

The converted tuple.

T6, T7, (T8, T9, T10, T11, T12)) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12>>

The converted tuple.

```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>

The converted tuple.

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10> (this (T1, T2, T3, T4, T5, T6, T7,
(T8, T9, T10)) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>

The converted tuple.

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9> (this (T1, T2, T3, T4, T5, T6, T7,
(T8, T9)) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>)

ToTuple<T1,T2,T3,T4,T5,T6,T7,T8>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8>>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>
ToTuple<T1,T2,T3,T4,T5,T6,T7,T8> (this (T1, T2, T3, T4, T5, T6, T7, (T8))
value);
```

Type Parameters

`T1`

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

Parameters

value ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8>>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToTuple<T1,T2,T3,T4,T5,T6,T7> (ValueTuple<T1,T2,T3,T4,T5,T6,T7>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2,T3,T4,T5,T6,T7> ToTuple<T1,T2,T3,T4,T5,T6,T7>
(this (T1, T2, T3, T4, T5, T6, T7) value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6,T7>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6,T7>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ToTuple<T1,T2,T3,T4,T5,T6>(ValueTuple<T1,T2,T3,T4,T5,T6>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

C#

```
public static Tuple<T1,T2,T3,T4,T5,T6> ToTuple<T1,T2,T3,T4,T5,T6> (this
(T1, T2, T3, T4, T5, T6) value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5,T6>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5,T6>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToTuple<T1,T2,T3,T4,T5> (ValueTuple<T1,T2,T3,T4,T5>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2,T3,T4,T5> ToTuple<T1,T2,T3,T4,T5> (this (T1, T2,
T3, T4, T5) value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

Parameters

`value` ValueTuple<T1,T2,T3,T4,T5>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4,T5>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3,T4,T5>(Tuple<T1,T2,T3,T4,T5>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToTuple<T1,T2,T3,T4>(ValueTuple<T1,T2,T3,T4>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2,T3,T4> ToTuple<T1,T2,T3,T4> (this (T1, T2, T3,
T4) value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

Parameters

`value` ValueTuple<T1,T2,T3,T4>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3,T4>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToTuple<T1,T2,T3>(ValueTuple<T1,T2,T3>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2,T3> ToTuple<T1,T2,T3> (this (T1, T2, T3) value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

Parameters

`value` ValueTuple<T1,T2,T3>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2,T3>

The converted tuple.

See also

- ToValueTuple<T1,T2,T3>(Tuple<T1,T2,T3>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToTuple<T1,T2>(ValueTuple<T1,T2>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1,T2> ToTuple<T1,T2> (this (T1, T2) value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

Parameters

`value` ValueTuple<T1,T2>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1,T2>

The converted tuple.

.NET Standard	2.0, 2.1

ToTuple<T1>(ValueTuple<T1>)

Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

```
C#

public static Tuple<T1> ToTuple<T1> (this (T1) value);
```

Type Parameters

`T1`

The type of the first element.

Parameters

`value` ValueTuple<T1>

The value tuple instance to convert to a tuple.

Returns

Tuple<T1>

The converted tuple.

TupleExtensions.ToValueTuple Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a tuple to a value tuple.

Overloads

Expand table

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20,T21>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8, T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10, T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11, T12,T13,T14,Tuple<T15,T16,T17,T18,T19>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12, T13,T14,Tuple<T15,T16,T17,T18>>>)	Converts an instance of the `Tuple`

	class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13, T14,Tuple<T15,T16,T17>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>)	Converts an instance of the `Tuple` class to an instance of

	the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4,T5>(Tuple<T1,T2,T3,T4,T5>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2,T3>(Tuple<T1,T2,T3>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.
ToValueTuple<T1,T2>(Tuple<T1,T2>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

ToValueTuple<T1>(Tuple<T1>)	Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18,T19,T20,T21>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14, (T15, T16, T17, T18, T19, T20, T21)))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T
18,T19,T20,T21> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,
T17,T18,T19,T20,T21>>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

`T17`

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

`T18`

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

`T19`

The type of the nineteenth element, or `value.Rest.Rest.Item5`.

`T20`

The type of the twentieth element, or `value.Rest.Rest.Item6`.

`T21`

The type of the twenty-first element, or `value.Rest.Rest.Item7`.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20,T21>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20,T21>>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19,T20,T21>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20,T21>>>)

Applies to

```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

`T17`

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

`T18`

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

`T19`

The type of the nineteenth element, or `value.Rest.Rest.Item5`.

`T20`

The type of the twentieth element, or `value.Rest.Rest.Item6`.

Parameters

value	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19,T20>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20>>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T18,T19,T20>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19,T20>>>)

Applies to

▼ .NET 9 and other versions

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

```
C#

public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14, (T15, T16, T17, T18, T19)))
```

```
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T
18,T19> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,
T17,T18,T19>>> value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

T12

The type of the twelfth element, or `value.Rest.Item5`.

T13

The type of the thirteenth element, or `value.Rest.Item6`.

T14

The type of the fourteenth element, or `value.Rest.Item7`.

T15

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

T16

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

T17

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

T18

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

T19

The type of the nineteenth element, or `value.Rest.Rest.Item5`.

Parameters

value	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18,T19>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18,T19>>>

The converted value tuple instance.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17,T18>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12, T13,T14,Tuple<T15,T16,T17,T18>>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14, (T15, T16, T17, T18)))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17,T
18> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,
T17,T18>>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

`T17`

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

`T18`

The type of the eighteenth element, or `value.Rest.Rest.Item4`.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17,T18>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18>>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17,T18>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17,T18>>>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15, T16,T17>

(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13, T14,Tuple<T15,T16,T17>>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

```
C#

public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14, (T15, T16, T17)))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16,T17>
(this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,
T17>>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

T10

The type of the tenth element, or `value.Rest.Item3`.

T11

The type of the eleventh element, or `value.Rest.Item4`.

T12

The type of the twelfth element, or `value.Rest.Item5`.

T13

The type of the thirteenth element, or `value.Rest.Item6`.

T14

The type of the fourteenth element, or `value.Rest.Item7`.

T15

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

T16

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

T17

The type of the seventeenth element, or `value.Rest.Rest.Item3`.

Parameters

value	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16,T17>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17>>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16, T17>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16,T17>>>)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14, (T15, T16)))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15,T16>
(this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>
>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

`T14`

The type of the fourteenth element, or `value.Rest.Item7`.

`T15`

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

`T16`

The type of the sixteenth element, or `value.Rest.Rest.Item2`.

Parameters

`value`	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15,T16>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15,T16>>>

The converted value tuple instance.

See also

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>
value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

T11

The type of the eleventh element, or `value.Rest.Item4`.

T12

The type of the twelfth element, or `value.Rest.Item5`.

T13

The type of the thirteenth element, or `value.Rest.Item6`.

T14

The type of the fourteenth element, or `value.Rest.Item7`.

T15

The type of the fifteenth element, or `value.Rest.Rest.Item1`.

Parameters

value	Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14,Tuple<T15>>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15>>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14,T15>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14,ValueTuple<T15>>>)

Applies to

▼ .NET 9 and other versions

Product	Versions

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> (Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

```
C#

public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12, T13,
T14)) ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13,T14> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

T10

The type of the tenth element, or `value.Rest.Item3`.

T11

The type of the eleventh element, or `value.Rest.Item4`.

T12

The type of the twelfth element, or `value.Rest.Item5`.

T13

The type of the thirteenth element, or `value.Rest.Item6`.

T14

The type of the fourteenth element, or `value.Rest.Item7`.

Parameters

value Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13,T14>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13,T14>>

The converted value tuple instance.

Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

`T13`

The type of the thirteenth element, or `value.Rest.Item6`.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12,T13>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12,T13>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12,T13>>)

Applies to

▼ .NET 9 and other versions

Product	Versions

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

```
C#

public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11, T12))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11,T12> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

`T12`

The type of the twelfth element, or `value.Rest.Item5`.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11,T12>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11,T12>>

The converted value tuple instance.

See also

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10, T11))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10,T11> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

`T11`

The type of the eleventh element, or `value.Rest.Item4`.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10,T11>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10,T11>>

The converted value tuple instance.

.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9, T10))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9,T10> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

`T7`

The type of the seventh element.

`T8`

The type of the eighth element, or `value.Rest.Item1`.

`T9`

The type of the ninth element, or `value.Rest.Item2`.

`T10`

The type of the tenth element, or `value.Rest.Item3`.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9,T10>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9,T10>>

The converted value tuple instance.

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

```
C#

public static (T1, T2, T3, T4, T5, T6, T7, (T8, T9))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

T9

The type of the ninth element, or `value.Rest.Item2`.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8,T9>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9>>

The converted value tuple instance.

See also

- ToTuple<T1,T2,T3,T4,T5,T6,T7,T8,T9>(ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8,T9>>)

Applies to

ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8>(Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7, (T8))
ToValueTuple<T1,T2,T3,T4,T5,T6,T7,T8> (this
Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>> value);
```

Type Parameters

`T1`

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

T7

The type of the seventh element.

T8

The type of the eighth element, or `value.Rest.Item1`.

Parameters

value Tuple<T1,T2,T3,T4,T5,T6,T7,Tuple<T8>>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8>>

The converted value tuple instance.

ToValueTuple<T1,T2,T3,T4,T5,T6,T7>(Tuple<T1,T2,T3,T4,T5,T6,T7>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6, T7)
ToValueTuple<T1,T2,T3,T4,T5,T6,T7> (this Tuple<T1,T2,T3,T4,T5,T6,T7>
value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

T4

The type of the fourth element.

T5

The type of the fifth element.

T6

The type of the sixth element.

`T7`

The type of the seventh element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6,T7>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7>

The converted value tuple instance.

.NET Standard	2.0, 2.1

ToValueTuple<T1,T2,T3,T4,T5,T6>(Tuple<T1,T2,T3,T4,T5,T6>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5, T6) ToValueTuple<T1,T2,T3,T4,T5,T6>
(this Tuple<T1,T2,T3,T4,T5,T6> value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

`T6`

The type of the sixth element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5,T6>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6>

The converted value tuple instance.

ToValueTuple<T1,T2,T3,T4,T5> (Tuple<T1,T2,T3,T4,T5>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4, T5) ToValueTuple<T1,T2,T3,T4,T5> (this
Tuple<T1,T2,T3,T4,T5> value);
```

Type Parameters

`T1`

The type of the first element.

`T2`

The type of the second element.

`T3`

The type of the third element.

`T4`

The type of the fourth element.

`T5`

The type of the fifth element.

Parameters

`value` Tuple<T1,T2,T3,T4,T5>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4,T5>

The converted value tuple instance.

ToValueTuple<T1,T2,T3,T4>(Tuple<T1,T2,T3,T4>)

Converts an instance of the `Tuple` class to an instance of the `ValueTuple` structure.

C#

```
public static (T1, T2, T3, T4) ToValueTuple<T1,T2,T3,T4> (this
Tuple<T1,T2,T3,T4> value);
```

Type Parameters

T1

The type of the first element.

T2

The type of the second element.

T3

The type of the third element.

`T4`

The type of the fourth element.

Parameters

`value` Tuple<T1,T2,T3,T4>

The tuple object to convert to a value tuple.

Returns

ValueTuple<T1,T2,T3,T4>

The converted value tuple instance.

Type Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents type declarations: class types, interface types, array types, value types, enumeration types, type parameters, generic type definitions, and open or closed constructed generic types.

C#

```
public abstract class Type : System.Reflection.MemberInfo,
System.Reflection.IReflect
```

Inheritance Object → MemberInfo → Type

Derived System.Reflection.TypeInfo

Implements IReflect

Examples

The following example shows a few representative features of Type. The C# `typeof` operator (`GetType` operator in Visual Basic) is used to get a Type object representing String. From this Type object, the GetMethod method is used to get a MethodInfo representing the String.Substring overload that takes a starting location and a length.

To identify the overload signature, the code example creates a temporary array containing two Type objects representing `int` (`Integer` in Visual Basic).

The code example uses the MethodInfo to invoke the Substring method on the string "Hello, World!", and displays the result.

C#

```
using System;
using System.Reflection;
```

```
class Example
{
    static void Main()
    {
        Type t = typeof(String);

        MethodInfo substr = t.GetMethod("Substring",
            new Type[] { typeof(int), typeof(int) });

        Object result =
            substr.Invoke("Hello, World!", new Object[] { 7, 5 });
        Console.WriteLine("{0} returned \"{1}\".", substr, result);
    }
}

/* This code example produces the following output:

System.String Substring(Int32, Int32) returned "World".
 */
```

Remarks

For more information about this API, see Supplemental API remarks for Type.

Notes to Implementers

When you inherit from `Type`, you must override the following members:

- Assembly
- AssemblyQualifiedName
- BaseType
- FullName
- GetAttributeFlagsImpl()
- GetConstructorImpl(BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])
- GetConstructors(BindingFlags)
- GetElementType()
- GetEvent(String, BindingFlags)
- GetEvents(BindingFlags)
- GetField(String, BindingFlags)
- GetFields(BindingFlags)
- GetInterface(String, Boolean)
- GetInterfaces()

- GetMethodImpl(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])
- GetMethods(BindingFlags)
- GetNestedType(String, BindingFlags)
- GetNestedTypes(BindingFlags)
- GetProperties(BindingFlags)
- GetPropertyImpl(String, BindingFlags, Binder, Type, Type[], ParameterModifier[])
- GUID
- HasElementTypeImpl()
- InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[], CultureInfo, String[])
- IsArrayImpl()
- IsByRefImpl()
- IsCOMObjectImpl()
- IsPointerImpl()
- IsPrimitiveImpl()
- Module
- Namespace
- TypeHandle
- UnderlyingSystemType
- GetCustomAttributes(Boolean)
- GetCustomAttributes(Type, Boolean)
- IsDefined(Type, Boolean)
- Name

Constructors

Expand table

Type()	Initializes a new instance of the Type class.

Fields

Expand table

Delimiter	Separates names in the namespace of the Type. This field is read-only.
EmptyTypes	Represents an empty array of type Type. This field is read-only.
FilterAttribute	Represents the member filter used on attributes. This field is read-only.

FilterName	Represents the case-sensitive member filter used on names. This field is read-only.
FilterNameIgnoreCase	Represents the case-insensitive member filter used on names. This field is read-only.
Missing	Represents a missing value in the Type information. This field is read-only.

Properties

Expand table

Assembly	Gets the Assembly in which the type is declared. For generic types, gets the Assembly in which the generic type is defined.
AssemblyQualifiedName	Gets the assembly-qualified name of the type, which includes the name of the assembly from which this Type object was loaded.
Attributes	Gets the attributes associated with the Type.
BaseType	Gets the type from which the current Type directly inherits.
ContainsGenericParameters	Gets a value indicating whether the current Type object has type parameters that have not been replaced by specific types.
CustomAttributes	Gets a collection that contains this member's custom attributes. (Inherited from MemberInfo)
DeclaringMethod	Gets a MethodBase that represents the declaring method, if the current Type represents a type parameter of a generic method.
DeclaringType	Gets the type that declares the current nested type or generic type parameter.
DefaultBinder	Gets a reference to the default binder, which implements internal rules for selecting the appropriate members to be called by InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[], CultureInfo, String[]).
FullName	Gets the fully qualified name of the type, including its namespace but not its assembly.
GenericParameterAttributes	Gets a combination of GenericParameterAttributes flags that describe the covariance and special constraints of the current generic type parameter.
GenericParameterPosition	Gets the position of the type parameter in the type parameter list of the generic type or method that declared the parameter, when the Type object represents a type parameter of a generic type or a generic method.

GenericType Arguments	Gets an array of the generic type arguments for this type.
GUID	Gets the GUID associated with the Type.
HasElementType	Gets a value indicating whether the current Type encompasses or refers to another type; that is, whether the current Type is an array, a pointer, or is passed by reference.
IsAbstract	Gets a value indicating whether the Type is abstract and must be overridden.
IsAnsiClass	Gets a value indicating whether the string format attribute `AnsiClass` is selected for the Type.
IsArray	Gets a value that indicates whether the type is an array.
IsAutoClass	Gets a value indicating whether the string format attribute `AutoClass` is selected for the Type.
IsAutoLayout	Gets a value indicating whether the fields of the current type are laid out automatically by the common language runtime.
IsByRef	Gets a value indicating whether the Type is passed by reference.
IsByRefLike	Gets a value that indicates whether the type is a byref-like structure.
IsClass	Gets a value indicating whether the Type is a class or a delegate; that is, not a value type or interface.
IsCollectible	Gets a value that indicates whether this MemberInfo object is part of an assembly held in a collectible AssemblyLoadContext. (Inherited from MemberInfo)
IsCOMObject	Gets a value indicating whether the Type is a COM object.
IsConstructed GenericType	Gets a value that indicates whether this object represents a constructed generic type. You can create instances of a constructed generic type.
IsContextful	Gets a value indicating whether the Type can be hosted in a context.
IsEnum	Gets a value indicating whether the current Type represents an enumeration.
IsExplicitLayout	Gets a value indicating whether the fields of the current type are laid out at explicitly specified offsets.
IsFunctionPointer	Gets a value that indicates whether the current Type is a function pointer.
IsGenericMethod Parameter	Gets a value that indicates whether the current Type represents a type parameter in the definition of a generic method.
IsGeneric Parameter	Gets a value indicating whether the current Type represents a type parameter in the definition of a generic type or method.

IsGenericType	Gets a value indicating whether the current type is a generic type.
IsGenericType Definition	Gets a value indicating whether the current Type represents a generic type definition, from which other generic types can be constructed.
IsGenericType Parameter	Gets a value that indicates whether the current Type represents a type parameter in the definition of a generic type.
IsImport	Gets a value indicating whether the Type has a ComImportAttribute attribute applied, indicating that it was imported from a COM type library.
IsInterface	Gets a value indicating whether the Type is an interface; that is, not a class or a value type.
IsLayout Sequential	Gets a value indicating whether the fields of the current type are laid out sequentially, in the order that they were defined or emitted to the metadata.
IsMarshalByRef	Gets a value indicating whether the Type is marshaled by reference.
IsNested	Gets a value indicating whether the current Type object represents a type whose definition is nested inside the definition of another type.
IsNested Assembly	Gets a value indicating whether the Type is nested and visible only within its own assembly.
IsNestedFam ANDAssem	Gets a value indicating whether the Type is nested and visible only to classes that belong to both its own family and its own assembly.
IsNestedFamily	Gets a value indicating whether the Type is nested and visible only within its own family.
IsNestedFam ORAssem	Gets a value indicating whether the Type is nested and visible only to classes that belong to either its own family or to its own assembly.
IsNestedPrivate	Gets a value indicating whether the Type is nested and declared private.
IsNestedPublic	Gets a value indicating whether a class is nested and declared public.
IsNotPublic	Gets a value indicating whether the Type is not declared public.
IsPointer	Gets a value indicating whether the Type is a pointer.
IsPrimitive	Gets a value indicating whether the Type is one of the primitive types.
IsPublic	Gets a value indicating whether the Type is declared public.
IsSealed	Gets a value indicating whether the Type is declared sealed.
IsSecurityCritical	Gets a value that indicates whether the current type is security-critical or security-safe-critical at the current trust level, and therefore can perform critical operations.

IsSecuritySafe Critical	Gets a value that indicates whether the current type is security-safe-critical at the current trust level; that is, whether it can perform critical operations and can be accessed by transparent code.
IsSecurity Transparent	Gets a value that indicates whether the current type is transparent at the current trust level, and therefore cannot perform critical operations.
IsSerializable	**Obsolete.** Gets a value indicating whether the Type is binary serializable.
IsSignatureType	Gets a value that indicates whether the type is a signature type.
IsSpecialName	Gets a value indicating whether the type has a name that requires special handling.
IsSZArray	Gets a value that indicates whether the type is an array type that can represent only a single-dimensional array with a zero lower bound.
IsTypeDefinition	Gets a value that indicates whether the type is a type definition.
IsUnicodeClass	Gets a value indicating whether the string format attribute `UnicodeClass` is selected for the Type.
IsUnmanaged FunctionPointer	Gets a value that indicates whether the current Type is an unmanaged function pointer.
IsValueType	Gets a value indicating whether the Type is a value type.
IsVariableBound Array	Gets a value that indicates whether the type is an array type that can represent a multi-dimensional array or an array with an arbitrary lower bound.
IsVisible	Gets a value indicating whether the Type can be accessed by code outside the assembly.
MemberType	Gets a MemberTypes value indicating that this member is a type or a nested type.
MetadataToken	Gets a value that identifies a metadata element. (Inherited from MemberInfo)
Module	Gets the module (the DLL) in which the current Type is defined.
Name	Gets the name of the current member. (Inherited from MemberInfo)
Namespace	Gets the namespace of the Type.
ReflectedType	Gets the class object that was used to obtain this member.
StructLayout	Gets a StructLayoutAttribute that describes the layout of the current type.

Attribute	
TypeHandle	Gets the handle for the current Type.
TypeInitializer	Gets the initializer for the type.
Underlying SystemType	Indicates the type provided by the common language runtime that represents this type.

Methods

Expand table

Equals(Object)	Determines if the underlying system type of the current Type object is the same as the underlying system type of the specified Object.
Equals(Type)	Determines if the underlying system type of the current Type is the same as the underlying system type of the specified Type.
FindInterfaces(TypeFilter, Object)	Returns an array of Type objects representing a filtered list of interfaces implemented or inherited by the current Type.
FindMembers(MemberTypes, BindingFlags, MemberFilter, Object)	Returns a filtered array of MemberInfo objects of the specified member type.
GetArrayRank()	Gets the number of dimensions in an array.
GetAttributeFlagsImpl()	When overridden in a derived class, implements the Attributes property and gets a bitwise combination of enumeration values that indicate the attributes associated with the Type.
GetConstructor(BindingFlags, Binder, Calling Conventions, Type[], ParameterModifier[])	Searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetConstructor(BindingFlags, Binder, Type[], ParameterModifier[])	Searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints.

GetConstructor(BindingFlags, Type[])	Searches for a constructor whose parameters match the specified argument types, using the specified binding constraints.
GetConstructor(Type[])	Searches for a public instance constructor whose parameters match the types in the specified array.
GetConstructorImpl(BindingFlags, Binder, Calling Conventions, Type[], ParameterModifier[])	When overridden in a derived class, searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetConstructors()	Returns all the public constructors defined for the current Type.
GetConstructors(BindingFlags)	When overridden in a derived class, searches for the constructors defined for the current Type, using the specified `BindingFlags`.
GetCustomAttributes(Boolean)	When overridden in a derived class, returns an array of all custom attributes applied to this member. (Inherited from MemberInfo)
GetCustomAttributes(Type, Boolean)	When overridden in a derived class, returns an array of custom attributes applied to this member and identified by Type. (Inherited from MemberInfo)
GetCustomAttributesData()	Returns a list of CustomAttributeData objects representing data about the attributes that have been applied to the target member. (Inherited from MemberInfo)
GetDefaultMembers()	Searches for the members defined for the current Type whose DefaultMemberAttribute is set.
GetElementType()	When overridden in a derived class, returns the Type of the object encompassed or referred to by the current array, pointer or reference type.
GetEnumName(Object)	Returns the name of the constant that has the specified value, for the current enumeration type.

GetEnumNames()	Returns the names of the members of the current enumeration type.
GetEnumUnderlyingType()	Returns the underlying type of the current enumeration type.
GetEnumValues()	Returns an array of the values of the constants in the current enumeration type.
GetEnumValuesAsUnderlyingType()	Retrieves an array of the values of the underlying type constants of this enumeration type.
GetEvent(String)	Returns the EventInfo object representing the specified public event.
GetEvent(String, BindingFlags)	When overridden in a derived class, returns the EventInfo object representing the specified event, using the specified binding constraints.
GetEvents()	Returns all the public events that are declared or inherited by the current Type.
GetEvents(BindingFlags)	When overridden in a derived class, searches for events that are declared or inherited by the current Type, using the specified binding constraints.
GetField(String)	Searches for the public field with the specified name.
GetField(String, BindingFlags)	Searches for the specified field, using the specified binding constraints.
GetFields()	Returns all the public fields of the current Type.
GetFields(BindingFlags)	When overridden in a derived class, searches for the fields defined for the current Type, using the specified binding constraints.
GetFunctionPointerCallingConventions()	When overridden in a derived class, returns the calling conventions of the current function pointer Type.
GetFunctionPointerParameterTypes()	When overridden in a derived class, returns the parameter types of the current function pointer Type.
GetFunctionPointerReturnType()	When overridden in a derived class, returns the return type of the current function

	pointer Type.
GetGenericArguments()	Returns an array of Type objects that represent the type arguments of a closed generic type or the type parameters of a generic type definition.
GetGenericParameterConstraints()	Returns an array of Type objects that represent the constraints on the current generic type parameter.
GetGenericTypeDefinition()	Returns a Type object that represents a generic type definition from which the current generic type can be constructed.
GetHashCode()	Returns the hash code for this instance.
GetInterface(String)	Searches for the interface with the specified name.
GetInterface(String, Boolean)	When overridden in a derived class, searches for the specified interface, specifying whether to do a case-insensitive search for the interface name.
GetInterfaceMap(Type)	Returns an interface mapping for the specified interface type.
GetInterfaces()	When overridden in a derived class, gets all the interfaces implemented or inherited by the current Type.
GetMember(String)	Searches for the public members with the specified name.
GetMember(String, BindingFlags)	Searches for the specified members, using the specified binding constraints.
GetMember(String, MemberTypes, BindingFlags)	Searches for the specified members of the specified member type, using the specified binding constraints.
GetMembers()	Returns all the public members of the current Type.
GetMembers(BindingFlags)	When overridden in a derived class, searches for the members defined for the current Type, using the specified binding constraints.
GetMemberWithSameMetadataDefinition As(MemberInfo)	Searches for the MemberInfo on the current Type that matches the specified MemberInfo.

GetMethod(String)	Searches for the public method with the specified name.
GetMethod(String, BindingFlags)	Searches for the specified method, using the specified binding constraints.
GetMethod(String, BindingFlags, Binder, Calling Conventions, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethod(String, BindingFlags, Binder, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints.
GetMethod(String, BindingFlags, Type[])	Searches for the specified method whose parameters match the specified argument types, using the specified binding constraints.
GetMethod(String, Int32, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethod(String, Int32, BindingFlags, Binder, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints.
GetMethod(String, Int32, Type[])	Searches for the specified public method whose parameters match the specified generic parameter count and argument types.
GetMethod(String, Int32, Type[], Parameter Modifier[])	Searches for the specified public method whose parameters match the specified generic parameter count, argument types and modifiers.
GetMethod(String, Type[])	Searches for the specified public method whose parameters match the specified argument types.
GetMethod(String, Type[], ParameterModifier[])	Searches for the specified public method whose parameters match the specified

	argument types and modifiers.
GetMethodImpl(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	When overridden in a derived class, searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethodImpl(String, Int32, BindingFlags, Binder, CallingConventions, Type[], Parameter Modifier[])	When overridden in a derived class, searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethods()	Returns all the public methods of the current Type.
GetMethods(BindingFlags)	When overridden in a derived class, searches for the methods defined for the current Type, using the specified binding constraints.
GetNestedType(String)	Searches for the public nested type with the specified name.
GetNestedType(String, BindingFlags)	When overridden in a derived class, searches for the specified nested type, using the specified binding constraints.
GetNestedTypes()	Returns the public types nested in the current Type.
GetNestedTypes(BindingFlags)	When overridden in a derived class, searches for the types nested in the current Type, using the specified binding constraints.
GetOptionalCustomModifiers()	When overridden in a derived class, returns the optional custom modifiers of the current Type.
GetProperties()	Returns all the public properties of the current Type.
GetProperties(BindingFlags)	When overridden in a derived class, searches for the properties of the current Type, using the specified binding constraints.
GetProperty(String)	Searches for the public property with the specified name.

GetProperty(String, BindingFlags)	Searches for the specified property, using the specified binding constraints.
GetProperty(String, BindingFlags, Binder, Type, Type[], ParameterModifier[])	Searches for the specified property whose parameters match the specified argument types and modifiers, using the specified binding constraints.
GetProperty(String, Type)	Searches for the public property with the specified name and return type.
GetProperty(String, Type, Type[])	Searches for the specified public property whose parameters match the specified argument types.
GetProperty(String, Type, Type[], Parameter Modifier[])	Searches for the specified public property whose parameters match the specified argument types and modifiers.
GetProperty(String, Type[])	Searches for the specified public property whose parameters match the specified argument types.
GetPropertyImpl(String, BindingFlags, Binder, Type, Type[], ParameterModifier[])	When overridden in a derived class, searches for the specified property whose parameters match the specified argument types and modifiers, using the specified binding constraints.
GetRequiredCustomModifiers()	When overridden in a derived class, returns the required custom modifiers of the current Type.
GetType()	Gets the current Type.
GetType(String)	Gets the Type with the specified name, performing a case-sensitive search.
GetType(String, Boolean)	Gets the Type with the specified name, performing a case-sensitive search and specifying whether to throw an exception if the type is not found.
GetType(String, Boolean, Boolean)	Gets the Type with the specified name, specifying whether to throw an exception if the type is not found and whether to perform a case-sensitive search.
GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>)	Gets the type with the specified name, optionally providing custom methods to resolve the assembly and the type.

GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean)	Gets the type with the specified name, specifying whether to throw an exception if the type is not found, and optionally providing custom methods to resolve the assembly and the type.
GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean)	Gets the type with the specified name, specifying whether to perform a case-sensitive search and whether to throw an exception if the type is not found, and optionally providing custom methods to resolve the assembly and the type.
GetTypeArray(Object[])	Gets the types of the objects in the specified array.
GetTypeCode(Type)	Gets the underlying type code of the specified Type.
GetTypeCodeImpl()	Returns the underlying type code of this Type instance.
GetTypeFromCLSID(Guid)	Gets the type associated with the specified class identifier (CLSID).
GetTypeFromCLSID(Guid, Boolean)	Gets the type associated with the specified class identifier (CLSID), specifying whether to throw an exception if an error occurs while loading the type.
GetTypeFromCLSID(Guid, String)	Gets the type associated with the specified class identifier (CLSID) from the specified server.
GetTypeFromCLSID(Guid, String, Boolean)	Gets the type associated with the specified class identifier (CLSID) from the specified server, specifying whether to throw an exception if an error occurs while loading the type.
GetTypeFromHandle(RuntimeTypeHandle)	Gets the type referenced by the specified type handle.
GetTypeFromProgID(String)	Gets the type associated with the specified program identifier (ProgID), returning null if an error is encountered while loading the Type.
GetTypeFromProgID(String, Boolean)	Gets the type associated with the specified program identifier (ProgID), specifying

	whether to throw an exception if an error occurs while loading the type.
GetTypeFromProgID(String, String)	Gets the type associated with the specified program identifier (progID) from the specified server, returning null if an error is encountered while loading the type.
GetTypeFromProgID(String, String, Boolean)	Gets the type associated with the specified program identifier (progID) from the specified server, specifying whether to throw an exception if an error occurs while loading the type.
GetTypeHandle(Object)	Gets the handle for the Type of a specified object.
HasElementTypeImpl()	When overridden in a derived class, implements the HasElementType property and determines whether the current Type encompasses or refers to another type; that is, whether the current Type is an array, a pointer, or is passed by reference.
HasSameMetadataDefinitionAs(MemberInfo)	(Inherited from MemberInfo)
InvokeMember(String, BindingFlags, Binder, Object, Object[])	Invokes the specified member, using the specified binding constraints and matching the specified argument list.
InvokeMember(String, BindingFlags, Binder, Object, Object[], CultureInfo)	Invokes the specified member, using the specified binding constraints and matching the specified argument list and culture.
InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[], CultureInfo, String[])	When overridden in a derived class, invokes the specified member, using the specified binding constraints and matching the specified argument list, modifiers and culture.
IsArrayImpl()	When overridden in a derived class, implements the IsArray property and determines whether the Type is an array.
IsAssignableFrom(Type)	Determines whether an instance of a specified type `c` can be assigned to a variable of the current type.
IsAssignableTo(Type)	Determines whether the current type can be assigned to a variable of the specified `targetType`.

IsByRefImpl()	When overridden in a derived class, implements the IsByRef property and determines whether the Type is passed by reference.
IsCOMObjectImpl()	When overridden in a derived class, implements the IsCOMObject property and determines whether the Type is a COM object.
IsContextfulImpl()	Implements the IsContextful property and determines whether the Type can be hosted in a context.
IsDefined(Type, Boolean)	When overridden in a derived class, indicates whether one or more attributes of the specified type or of its derived types is applied to this member. (Inherited from MemberInfo)
IsEnumDefined(Object)	Returns a value that indicates whether the specified value exists in the current enumeration type.
IsEquivalentTo(Type)	Determines whether two COM types have the same identity and are eligible for type equivalence.
IsInstanceOfType(Object)	Determines whether the specified object is an instance of the current Type.
IsMarshalByRefImpl()	Implements the IsMarshalByRef property and determines whether the Type is marshaled by reference.
IsPointerImpl()	When overridden in a derived class, implements the IsPointer property and determines whether the Type is a pointer.
IsPrimitiveImpl()	When overridden in a derived class, implements the IsPrimitive property and determines whether the Type is one of the primitive types.
IsSubclassOf(Type)	Determines whether the current Type derives from the specified Type.
IsValueTypeImpl()	Implements the IsValueType property and determines whether the Type is a value type; that is, not a class or an interface.

MakeArrayType()	Returns a Type object representing a one-dimensional array of the current type, with a lower bound of zero.
MakeArrayType(Int32)	Returns a Type object representing an array of the current type, with the specified number of dimensions.
MakeByRefType()	Returns a Type object that represents the current type when passed as a `ref` parameter (`ByRef` parameter in Visual Basic).
MakeGenericMethodParameter(Int32)	Returns a signature type object that can be passed into the `Type[]` array parameter of a GetMethod method to represent a generic parameter reference.
MakeGenericSignatureType(Type, Type[])	Creates a generic signature type, which allows third party reimplementations of Reflection to fully support the use of signature types in querying type members.
MakeGenericType(Type[])	Substitutes the elements of an array of types for the type parameters of the current generic type definition and returns a Type object representing the resulting constructed type.
MakePointerType()	Returns a Type object that represents a pointer to the current type.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ReflectionOnlyGetType(String, Boolean, Boolean)	**Obsolete.** Gets the Type with the specified name, specifying whether to perform a case-sensitive search and whether to throw an exception if the type is not found. The type is loaded for reflection only, not for execution.
ToString()	Returns a `String` representing the name of the current `Type`.

Operators

Expand table

Equality(Type, Type)	Indicates whether two Type objects are equal.
Inequality(Type, Type)	Indicates whether two Type objects are not equal.

Extension Methods

Expand table

GetCustomAttribute(MemberInfo, Type)	Retrieves a custom attribute of a specified type that is applied to a specified member.
GetCustomAttribute(MemberInfo, Type, Boolean)	Retrieves a custom attribute of a specified type that is applied to a specified member, and optionally inspects the ancestors of that member.
GetCustomAttribute<T>(MemberInfo)	Retrieves a custom attribute of a specified type that is applied to a specified member.
GetCustomAttribute<T>(MemberInfo, Boolean)	Retrieves a custom attribute of a specified type that is applied to a specified member, and optionally inspects the ancestors of that member.
GetCustomAttributes(MemberInfo)	Retrieves a collection of custom attributes that are applied to a specified member.
GetCustomAttributes(MemberInfo, Boolean)	Retrieves a collection of custom attributes that are applied to a specified member, and optionally inspects the ancestors of that member.
GetCustomAttributes(MemberInfo, Type)	Retrieves a collection of custom attributes of a specified type that are applied to a specified member.
GetCustomAttributes(MemberInfo, Type, Boolean)	Retrieves a collection of custom attributes of a specified type that are applied to a specified member, and optionally inspects the ancestors of that member.
GetCustomAttributes<T>(MemberInfo)	Retrieves a collection of custom attributes of a specified type that are applied to a specified member.
GetCustomAttributes<T>(MemberInfo, Boolean)	Retrieves a collection of custom attributes of a specified type that are applied to a specified member, and optionally inspects the ancestors of that member.
IsDefined(MemberInfo, Type)	Indicates whether custom attributes of a specified type are applied to a specified member.
IsDefined(MemberInfo, Type, Boolean)	Indicates whether custom attributes of a specified type are applied to a specified member, and, optionally, applied to its ancestors.

GetTypeInfo(Type)	Returns the TypeInfo representation of the specified type.
GetMetadataToken(MemberInfo)	Gets a metadata token for the given member, if available.
HasMetadataToken(MemberInfo)	Returns a value that indicates whether a metadata token is available for the specified member.
GetRuntimeEvent(Type, String)	Retrieves an object that represents the specified event.
GetRuntimeEvents(Type)	Retrieves a collection that represents all the events defined on a specified type.
GetRuntimeField(Type, String)	Retrieves an object that represents a specified field.
GetRuntimeFields(Type)	Retrieves a collection that represents all the fields defined on a specified type.
GetRuntimeMethod(Type, String, Type[])	Retrieves an object that represents a specified method.
GetRuntimeMethods(Type)	Retrieves a collection that represents all methods defined on a specified type.
GetRuntimeProperties(Type)	Retrieves a collection that represents all the properties defined on a specified type.
GetRuntimeProperty(Type, String)	Retrieves an object that represents a specified property.
GetConstructor(Type, Type[])	
GetConstructors(Type)

Type Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Type class.

C#

```
protected Type ();
```

Remarks

This constructor is invoked by derived classes during the construction of type objects.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.Delimiter Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Separates names in the namespace of the Type. This field is read-only.

C#

```
public static readonly char Delimiter;
```

Field Value

Char

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.EmptyTypes Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an empty array of type Type. This field is read-only.

C#

```
public static readonly Type[] EmptyTypes;
```

Field Value

Type[]

Examples

The following code example shows the `EmptyTypes` field used in one of the `GetConstructor` methods to get a constructor that takes no parameters.

C#

```
cInfo = type.GetConstructor (BindingFlags.ExactBinding, null,
         Type.EmptyTypes, null);
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Type.FilterAttribute Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the member filter used on attributes. This field is read-only.

C#

```
public static readonly System.Reflection.MemberFilter FilterAttribute;
```

Field Value

MemberFilter

Examples

The following example gets the `FilterAttribute` delegate, passes it as a parameter to the FindMembers method, and displays the specified members and their attributes.

C#

```
using System;
using System.Reflection;
using System.Security;

public class MyFilterAttributeSample
{
    public static void Main()
    {
        try
        {
            MemberFilter myFilter = Type.FilterAttribute;
            Type myType = typeof(System.String);
            MemberInfo[] myMemberInfoArray =
myType.FindMembers(MemberTypes.Constructor
                |MemberTypes.Method, BindingFlags.Public |
BindingFlags.Static |
                BindingFlags.Instance, myFilter,
MethodAttributes.SpecialName);
            foreach (MemberInfo myMemberinfo in myMemberInfoArray)
            {
```

```
                Console.Write ("\n" + myMemberinfo.Name);
                Console.Write (" is a " +
myMemberinfo.MemberType.ToString());
            }
        }
        catch(ArgumentNullException e)
        {
            Console.Write("ArgumentNullException : " + e.Message);
        }
        catch(SecurityException e)
        {
            Console.Write("SecurityException : " + e.Message);
        }
        catch(Exception e)
        {
            Console.Write("Exception :" + e.Message);
        }
    }
}
```

Remarks

This field holds a reference to the delegate used by the FindMembers method. The method encapsulated by this delegate takes two parameters: the first is a MemberInfo object and the second is an `Object`. The method determines whether the `MemberInfo` object matches the criteria specified by the `Object`. The `Object` may be assigned the value of any one of the fields on the classes FieldAttributes, MethodAttributes, or MethodImplAttributes.

For example, the `Object` can be assigned the value of a field from `FieldAttributes` such as Public. In that case, when the `FilterAttribute` delegate is invoked, it will return `true` only if the method represented by the `MemberInfo` object is decorated with the public field attribute in metadata.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.FilterName Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the case-sensitive member filter used on names. This field is read-only.

C#

```
public static readonly System.Reflection.MemberFilter FilterName;
```

Field Value

MemberFilter

Examples

The following code example gets the methods associated with the user-defined `Application` type.

C#

```
// Get the set of methods associated with the type
MemberInfo[] mi = typeof(Application).FindMembers(MemberTypes.Constructor |
    MemberTypes.Method,
    BindingFlags.Public | BindingFlags.Static | BindingFlags.NonPublic |
    BindingFlags.Instance | BindingFlags.DeclaredOnly,
    Type.FilterName, "*");
  Console.WriteLine("Number of methods (includes constructors): " +
mi.Length);
```

Remarks

This field holds a reference to the delegate used by the FindMembers method. The method encapsulated by this delegate takes two parameters: the first is a MemberInfo object and the second is an `Object`. The method determines whether the `MemberInfo` object matches the criteria specified by the `Object`. The `Object` is assigned a string

value, which may include a trailing "*" wildcard character. Only wildcard end string matching is supported.

For example, the `Object` may be assigned the value "Byte*". In that case, when the `FilterName` delegate is invoked, it will return `true` only if the method represented by the `MemberInfo` object has a name that begins with "Byte".

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.FilterNameIgnoreCase Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the case-insensitive member filter used on names. This field is read-only.

C#

```
public static readonly System.Reflection.MemberFilter FilterNameIgnoreCase;
```

Field Value

MemberFilter

Examples

The following example gets the `MemberFilter` delegate, passes it as a parameter to the FindMembers method, and displays the methods and their attributes of the `String` class that begin with the letter "c", disregarding the case.

C#

```
using System;
using System.Reflection;
using System.Security;
public class MyFilterNameIgnoreCaseSample
{
    public static void Main()
    {
        try
        {
            MemberFilter myFilter = Type.FilterNameIgnoreCase;
            Type myType = typeof(System.String);
            MemberInfo[] myMemberinfo1 =
myType.FindMembers(MemberTypes.Constructor
                |MemberTypes.Method, BindingFlags.Public |
BindingFlags.Static |
                BindingFlags.Instance, myFilter, "C*");
            foreach (MemberInfo myMemberinfo2 in myMemberinfo1)
            {
```

```
                Console.Write("\n" + myMemberinfo2.Name);
                MemberTypes Mymembertypes = myMemberinfo2.MemberType;
                Console.WriteLine(" is a " + Mymembertypes.ToString());
            }
        }
        catch(ArgumentNullException e)
        {
            Console.Write("ArgumentNullException : " + e.Message);
        }
        catch(SecurityException e)
        {
            Console.Write("SecurityException : " + e.Message);
        }
        catch(Exception e)
        {
            Console.Write("Exception : " + e.Message);
        }
    }
}
```

Remarks

This field holds a reference to the delegate used by the FindMembers method. The method encapsulated by this delegate takes two parameters: the first is a MemberInfo object and the second is an `Object`. The method determines whether the `MemberInfo` object matches the criteria specified by the `Object`. The `Object` is assigned a string value, which may include a trailing "*" wildcard character. Only wildcard end string matching is supported.

For example, the `Object` may be assigned the value "ByTe*". In that case, when the `FilterName` delegate is invoked, it will return true only if the method represented by the `MemberInfo` object has a name that begins with "byte", ignoring case.

Type.Missing Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a missing value in the Type information. This field is read-only.

C#

```
public static readonly object Missing;
```

Field Value

Object

Examples

The following code example shows the use of the `Missing` field to invoke a method with its default arguments.

C#

```
using System;
using System.Reflection;
using System.CodeDom.Compiler;

class Example
{
    public static void Main()
    {
        // VB source for example. Not all versions of CS and CPP compilers
        // support optional arguments.
        string codeLines =
            "Imports System\n\n" +
            "Public Class OptionalArg\n" +
            "  Public Sub MyMethod(ByVal a As Integer, _\n" +
            "    Optional ByVal b As Double = 1.2, _\n" +
            "    Optional ByVal c As Integer = 1)\n\n" +
            "    Console.WriteLine(\"a = \" & a & \" b = \" & b & \" c = \"
& c)\n" +
            "  End Sub\n" +
            "End Class\n";
```

```
        // Generate a OptionalArg instance from the source above.
        object o = GenerateObjectFromSource("OptionalArg", codeLines,
"VisualBasic");
        Type t;

        t = o.GetType();
        BindingFlags bf = BindingFlags.Public | BindingFlags.Instance |
            BindingFlags.InvokeMethod | BindingFlags.OptionalParamBinding;

        t.InvokeMember("MyMethod", bf, null, o, new object[] {10, 55.3,
12});
        t.InvokeMember("MyMethod", bf, null, o, new object[] {10, 1.3,
Type.Missing});
        t.InvokeMember("MyMethod", bf, null, o, new object[] {10,
Type.Missing, Type.Missing});
    }

    private static object GenerateObjectFromSource(string objectName,
        string sourceLines, string providerName)
    {
        object genObject = null;
        CodeDomProvider codeProvider =
CodeDomProvider.CreateProvider(providerName);
        CompilerParameters cp = new CompilerParameters();

        cp.GenerateExecutable = false;
        cp.GenerateInMemory = true;

        CompilerResults results =
            codeProvider.CompileAssemblyFromSource(cp, sourceLines);
        if (results.Errors.Count == 0)
        {
            genObject = results.CompiledAssembly.CreateInstance(objectName);
        }

        return genObject;
    }
}
```

This code produces the following output:

a = 10 b = 55.3 c = 12

a = 10 b = 1.3 c = 1

a = 10 b = 1.2 c = 1

Remarks

Use the `Missing` field for invocation through reflection to obtain the default value of a parameter. If the `Missing` field is passed in for a parameter value and there is no default value for that parameter, an ArgumentException is thrown.

Type.Assembly Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the Assembly in which the type is declared. For generic types, gets the Assembly in which the generic type is defined.

C#

```
public abstract System.Reflection.Assembly Assembly { get; }
```

Property Value

Assembly

An Assembly instance that describes the assembly containing the current type. For generic types, the instance describes the assembly that contains the generic type definition, not the assembly that creates and uses a particular constructed type.

Examples

The following example displays the assembly name associated with the class and the fully qualified name of the type.

C#

```
using System;

class MyAssemblyClass
{
    public static void Main()
    {
        Type objType = typeof(Array);

        // Print the assembly full name.
        Console.WriteLine($"Assembly full name:\n
{objType.Assembly.FullName}.");

        // Print the assembly qualified name.
```

```
        Console.WriteLine($"Assembly qualified name:\n
{objType.AssemblyQualifiedName}.");
    }
}
// The example displays the following output if run under the .NET Framework
4.5:
//    Assembly full name:
//       mscorlib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089.
//    Assembly qualified name:
//       System.Array, mscorlib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089.
```

Remarks

If the current Type object represents a constructed generic type, this property returns the assembly that contains the generic type definition. For example, suppose you create an assembly named MyGenerics.dll that contains the generic type definition `MyGenericStack<T>` (`MyGenericStack(Of T)` in Visual Basic, `generic<T> ref class MyGenericStack` in C++). If you create an instance of `MyGenericStack<int>` (`MyGenericStack(Of Integer)` in Visual Basic) in another assembly, the Assembly property for the constructed type returns an Assembly object that represents MyGenerics.dll.

Similarly, if the current Type object represents an unassigned generic parameter `T`, this property returns the assembly that contains the generic type that defines `T`.

If the Type.Assembly property is not available on a particular .NET implementation, such as .NET Core or the Universal Windows Platform, use the TypeInfo.Assembly property instead.

This property is read-only.

Type.AssemblyQualifiedName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the assembly-qualified name of the type, which includes the name of the assembly from which this Type object was loaded.

C#

```
public abstract string? AssemblyQualifiedName { get; }
```

Property Value

String

The assembly-qualified name of the Type, which includes the name of the assembly from which the Type was loaded, or `null` if the current instance represents a generic type parameter.

Examples

The following example displays the assembly name associated with the class and the fully qualified name of the type.

C#

```
using System;

class MyAssemblyClass
{
    public static void Main()
    {
        Type objType = typeof(Array);

        // Print the assembly full name.
        Console.WriteLine($"Assembly full name:\n
{objType.Assembly.FullName}.");

        // Print the assembly qualified name.
```

```
        Console.WriteLine($"Assembly qualified name:\n
{objType.AssemblyQualifiedName}.");
    }
}
// The example displays the following output if run under the .NET Framework
4.5:
//    Assembly full name:
//       mscorlib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089.
//    Assembly qualified name:
//       System.Array, mscorlib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089.
```

The following example compares the strings returned by the ToString method and the Name, FullName, and `AssemblyQualifiedName` properties.

C#

```
using System;
using System.Collections.Generic;
using System.Globalization;

public class Example
{
    public static void Main()
    {
        Type t = typeof(String);
        ShowTypeInfo(t);

        t = typeof(List<>);
        ShowTypeInfo(t);

        var list = new List<String>();
        t = list.GetType();
        ShowTypeInfo(t);

        Object v = 12;
        t = v.GetType();
        ShowTypeInfo(t);

        t = typeof(IFormatProvider);
        ShowTypeInfo(t);

        IFormatProvider ifmt = NumberFormatInfo.CurrentInfo;
        t = ifmt.GetType();
        ShowTypeInfo(t);
    }

    private static void ShowTypeInfo(Type t)
    {
        Console.WriteLine($"Name: {t.Name}");
        Console.WriteLine($"Full Name: {t.FullName}");
        Console.WriteLine($"ToString:  {t}");
```

```
        Console.WriteLine($"Assembly Qualified Name:
{t.AssemblyQualifiedName}");
        Console.WriteLine();
    }
}
// The example displays output like the following:
//    Name: String
//    Full Name: System.String
//    ToString:  System.String
//    Assembly Qualified Name: System.String, mscorlib, Version=4.0.0.0,
Culture=neutr
//    al, PublicKeyToken=b77a5c561934e089
//
//    Name: List`1
//    Full Name: System.Collections.Generic.List`1
//    ToString:  System.Collections.Generic.List`1[T]
//    Assembly Qualified Name: System.Collections.Generic.List`1, mscorlib,
Version=4.
//    0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: List`1
//    Full Name: System.Collections.Generic.List`1[[System.String, mscorlib,
Version=4
//    .0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089]]
//    ToString:  System.Collections.Generic.List`1[System.String]
//    Assembly Qualified Name:
System.Collections.Generic.List`1[[System.String, mscor
//    lib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089]], mscorl
//    ib, Version=4.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: Int32
//    Full Name: System.Int32
//    ToString:  System.Int32
//    Assembly Qualified Name: System.Int32, mscorlib, Version=4.0.0.0,
Culture=neutra
//    l, PublicKeyToken=b77a5c561934e089
//
//    Name: IFormatProvider
//    Full Name: System.IFormatProvider
//    ToString:  System.IFormatProvider
//    Assembly Qualified Name: System.IFormatProvider, mscorlib,
Version=4.0.0.0, Cult
//    ure=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: NumberFormatInfo
//    Full Name: System.Globalization.NumberFormatInfo
//    ToString:  System.Globalization.NumberFormatInfo
//    Assembly Qualified Name: System.Globalization.NumberFormatInfo,
mscorlib, Versio
//    n=4.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
```

Remarks

The assembly-qualified name of a type consists of the type name, including its namespace, followed by a comma, followed by the display name of the assembly. The display name of an assembly is obtained using the Assembly.FullName property.

> **Note**
>
> In the .NET Framework version 2.0, processor architecture is added to assembly identity, and can be specified as part of assembly name strings. For example, "ProcessorArchitecture=msil". However, it is not included in the string returned by the **AssemblyQualifiedName** property, for compatibility reasons. See **AssemblyName.ProcessorArchitecture**.

All compilers that support the common language runtime emit the simple name of a nested class, and reflection constructs a mangled name when queried, in accordance with the following conventions.

Expand table

Delimiter	Meaning
Backslash (\)	Escape character.
Comma (,)	Precedes the Assembly name.
Plus sign (+)	Precedes a nested class.
Period (.)	Denotes namespace identifiers.
Brackets ([])	After a type name, denotes an array of that type. -or- For a generic type, encloses the generic type argument list. -or- Within a type argument list, encloses an assembly-qualified type.

For example, the assembly-qualified name for a class might look like this:

```
TopNamespace.SubNameSpace.ContainingClass+NestedClass, MyAssembly,
```

```
Version=1.3.0.0, Culture=neutral, PublicKeyToken=b17a5c561934e089
```

If the namespace contained a plus sign, for example TopNamespace.Sub+Namespace, then the plus sign (+) would be preceded by an escape character (\) to prevent it from being interpreted as a nesting separator. Reflection would emit this string as follows:

```

TopNamespace.Sub\+Namespace.ContainingClass+NestedClass, MyAssembly,
Version=1.3.0.0, Culture=neutral, PublicKeyToken=b17a5c561934e089
```

A "++" becomes "\+\+", and a "\" becomes "\\".

This qualified name can be persisted and later used to load the Type. To search for and load a Type, use GetType either with the type name only or with the assembly qualified type name. GetType with the type name only will look for the Type in the caller's assembly and then in the System assembly. GetType with the assembly qualified type name will look for the Type in any assembly.

Type names may include trailing characters that denote additional information about the type, such as whether the type is a reference type, a pointer type or an array type. To retrieve the type name without these trailing characters, use `t.GetElementType().ToString()`, where `t` is the type.

Spaces are relevant in all type name components except the assembly name. In the assembly name, spaces before the ',' separator are relevant, but spaces after the ',' separator are ignored.

Generic arguments of generic types are themselves qualified by assembly name. For example, in the assembly-qualified type name for `MyGenericClass<int>` (`MyGenericClass(Of Integer)` in Visual Basic), `int` is expanded to the assembly-qualified type name for Int32.

If the current Type object represents a generic parameter, this property returns `null`.

Type.Attributes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the attributes associated with the Type.

C#

```
public System.Reflection.TypeAttributes Attributes { get; }
```

Property Value

TypeAttributes

A TypeAttributes object representing the attribute set of the Type, unless the Type represents a generic type parameter, in which case the value is unspecified.

Examples

The following example uses the Attributes property.

C#

```
using System;
using System.Reflection;

internal struct S
{
    public int X;
}

public abstract class Example
{
    protected sealed class NestedClass {}

    public interface INested {}

    public static void Main()
    {
        // Create an array of types.
```

```
        Type[] types = { typeof(Example), typeof(NestedClass),
                         typeof(INested), typeof(S) };

        foreach (var t in types)
        {
           Console.WriteLine("Attributes for type {0}:", t.Name);

           TypeAttributes attr = t.Attributes;

           // To test for visibility attributes, you must use the visibility
mask.
           TypeAttributes visibility = attr & TypeAttributes.VisibilityMask;
           switch (visibility)
           {
               case TypeAttributes.NotPublic:
                   Console.WriteLine("   ...is not public");
                   break;
               case TypeAttributes.Public:
                   Console.WriteLine("   ...is public");
                   break;
               case TypeAttributes.NestedPublic:
                   Console.WriteLine("   ...is nested and public");
                   break;
               case TypeAttributes.NestedPrivate:
                   Console.WriteLine("   ...is nested and private");
                   break;
               case TypeAttributes.NestedFamANDAssem:
                   Console.WriteLine("   ...is nested, and inheritable only
within the assembly" +
                       "\n         (cannot be declared in C#)");
                   break;
               case TypeAttributes.NestedAssembly:
                   Console.WriteLine("   ...is nested and internal");
                   break;
               case TypeAttributes.NestedFamily:
                   Console.WriteLine("   ...is nested and protected");
                   break;
               case TypeAttributes.NestedFamORAssem:
                   Console.WriteLine("   ...is nested and protected
internal");
                   break;
           }

           // Use the layout mask to test for layout attributes.
           TypeAttributes layout = attr & TypeAttributes.LayoutMask;
           switch (layout)
           {
               case TypeAttributes.AutoLayout:
                   Console.WriteLine("   ...is AutoLayout");
                   break;
               case TypeAttributes.SequentialLayout:
                   Console.WriteLine("   ...is SequentialLayout");
                   break;
               case TypeAttributes.ExplicitLayout:
                   Console.WriteLine("   ...is ExplicitLayout");
```

```
                    break;
            }

            // Use the class semantics mask to test for class semantics
attributes.
            TypeAttributes classSemantics = attr &
TypeAttributes.ClassSemanticsMask;
            switch (classSemantics)
            {
                case TypeAttributes.Class:
                    if (t.IsValueType)
                    {
                        Console.WriteLine("   ...is a value type");
                    }
                    else
                    {
                        Console.WriteLine("   ...is a class");
                    }
                    break;
                case TypeAttributes.Interface:
                    Console.WriteLine("   ...is an interface");
                    break;
            }

            if ((attr & TypeAttributes.Abstract) != 0)
            {
                Console.WriteLine("   ...is abstract");
            }

            if ((attr & TypeAttributes.Sealed) != 0)
            {
                Console.WriteLine("   ...is sealed");
            }

            Console.WriteLine();
        }
    }
}
// The example displays the following output:
// Attributes for type Example:
//    ...is public
//    ...is AutoLayout
//    ...is a class
//    ...is abstract

// Attributes for type NestedClass:
//    ...is nested and protected
//    ...is AutoLayout
//    ...is a class
//    ...is sealed

// Attributes for type INested:
//    ...is nested and public
//    ...is AutoLayout
//    ...is an interface
```

```
//    ...is abstract

// Attributes for type S:
//    ...is not public
//    ...is SequentialLayout
//    ...is a value type
//    ...is sealed
```

Remarks

Some members of the TypeAttributes enumeration are masks that represent a group of values. Each group includes one member whose underlying value is zero. For example, the underlying value of the TypeAttributes.NotPublic member in the TypeAttributes.VisibilityMask group is zero, as is the TypeAttributes.AutoLayout member in the TypeAttributes.SequentialLayout group. Because of this, you must use the mask before testing for those values. The example provides an illustration.

> **Tip**
>
> For most purposes, properties like **IsClass**,**IsAutoLayout**, and **IsSpecialName** are easier to use than type attributes.

If the current Type represents a constructed generic type, this property returns the attributes of the generic type definition. For example, the attributes returned for `MyGenericClass<int>` (`MyGenericClass(Of Integer)` in Visual Basic) are the attributes of `MyGenericClass<T>` (`MyGenericClass(Of T)` in Visual Basic).

If the current Type represents a generic type parameter - that is, if the IsGenericParameter property returns `true` - the TypeAttributes value returned by this property is unspecified.

Applies to

Product	Versions

Type.BaseType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the type from which the current Type directly inherits.

C#

```
public abstract Type? BaseType { get; }
```

Property Value

Type

The Type from which the current Type directly inherits, or `null` if the current `Type` represents the Object class or an interface.

Examples

The following example demonstrates using the BaseType property.

C#

```
using System;
class TestType
{
    public static void Main()
    {
        Type t = typeof(int);
        Console.WriteLine("{0} inherits from {1}.", t,t.BaseType);
    }
}
```

The following example uses recursion to list the complete inheritance hierarchy of each class found in an assembly. The example defines a class named `C` that derives from a class named `B`, which, in turn, derives from a class named `A`.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      foreach (var t in typeof(Example).Assembly.GetTypes()) {
         Console.WriteLine("{0} derived from: ", t.FullName);
         var derived = t;
         do {
            derived = derived.BaseType;
            if (derived != null)
               Console.WriteLine("   {0}", derived.FullName);
         } while (derived != null);
         Console.WriteLine();
      }
   }
}

public class A {}

public class B : A
{}

public class C : B
{}
// The example displays the following output:
//       Example derived from:
//          System.Object
//
//       A derived from:
//          System.Object
//
//       B derived from:
//          A
//          System.Object
//
//       C derived from:
//          B
//          A
//          System.Object
```

Remarks

The base type is the type from which the current type directly inherits. Object is the only type that does not have a base type, therefore `null` is returned as the base type of Object.

Interfaces inherit from zero or more base interfaces; therefore, this property returns `null` if the `Type` object represents an interface. The base interfaces can be determined

with GetInterfaces or FindInterfaces.

If the current Type represents a constructed generic type, the base type reflects the generic arguments. For example, consider the following declarations:

```
C#

class B<U> { }
class C<T> : B<T> { }
```

For the constructed type `C<int>` (`C(Of Integer)` in Visual Basic), the BaseType property returns `B<int>`.

If the current Type represents a type parameter of a generic type definition, BaseType returns the class constraint, that is, the class the type parameter must inherit. If there is no class constraint, BaseType returns System.Object.

This property is read-only.

Type.ContainsGenericParameters Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Type object has type parameters that have not been replaced by specific types.

C#

```
public virtual bool ContainsGenericParameters { get; }
```

Property Value

Boolean

`true` if the Type object is itself a generic type parameter or has type parameters for which specific types have not been supplied; otherwise, `false`.

Examples

The following example defines a generic class with two type parameters and then defines a second generic class that derives from the first class. The derived class's base class has two type arguments: the first is Int32 and the second is a type parameter of the derived type. The example displays information about these generic classes, including the positions reported by the GenericParameterPosition property.

C#

```
using System;
using System.Reflection;
using System.Collections.Generic;

// Define a base class with two type parameters.
public class Base<T, U> { }

// Define a derived class. The derived class inherits from a constructed
```

```
// class that meets the following criteria:
//   (1) Its generic type definition is Base<T, U>.
//   (2) It specifies int for the first type parameter.
//   (3) For the second type parameter, it uses the same type that is used
//       for the type parameter of the derived class.
// Thus, the derived class is a generic type with one type parameter, but
// its base class is an open constructed type with one type argument and
// one type parameter.
public class Derived<V> : Base<int, V> { }

public class Test
{
    public static void Main()
    {
        Console.WriteLine(
            "\r\n--- Display a generic type and the open constructed");
        Console.WriteLine("    type from which it is derived.");

        // Create a Type object representing the generic type definition
        // for the Derived type, by omitting the type argument. (For
        // types with multiple type parameters, supply the commas but
        // omit the type arguments.)
        //
        Type derivedType = typeof(Derived<>);
        DisplayGenericTypeInfo(derivedType);

        // Display its open constructed base type.
        DisplayGenericTypeInfo(derivedType.BaseType);
    }

    private static void DisplayGenericTypeInfo(Type t)
    {
        Console.WriteLine("\r\n{0}", t);

        Console.WriteLine("\tIs this a generic type definition? {0}",
            t.IsGenericTypeDefinition);

        Console.WriteLine("\tIs it a generic type? {0}",
            t.IsGenericType);

        Console.WriteLine("\tDoes it have unassigned generic parameters?
{0}",
            t.ContainsGenericParameters);

        if (t.IsGenericType)
        {
            // If this is a generic type, display the type arguments.
            //
            Type[] typeArguments = t.GetGenericArguments();

            Console.WriteLine("\tList type arguments ({0}):",
                typeArguments.Length);

            foreach (Type tParam in typeArguments)
            {
```

```
                // IsGenericParameter is true only for generic type
                // parameters.
                //
                if (tParam.IsGenericParameter)
                {
                    Console.WriteLine(
                        "\t\t{0}  (unassigned - parameter position {1})",
                        tParam,
                        tParam.GenericParameterPosition);
                }
                else
                {
                    Console.WriteLine("\t\t{0}", tParam);
                }
            }
        }
    }
}

/* This example produces the following output:

--- Display a generic type and the open constructed
    type from which it is derived.

Derived`1[V]
        Is this a generic type definition? True
        Is it a generic type? True
        Does it have unassigned generic parameters? True
        List type arguments (1):
                V  (unassigned - parameter position 0)

Base`2[System.Int32,V]
        Is this a generic type definition? False
        Is it a generic type? True
        Does it have unassigned generic parameters? True
        List type arguments (2):
                System.Int32
                V  (unassigned - parameter position 0)
 */
```

Remarks

In order to create an instance of a type, there must be no generic type definitions or open constructed types in the type arguments of the type itself, in any enclosing generic types, or in any elements of the type. Another way of saying this is that when examined recursively, the type must contain no generic type parameters.

Since types can be arbitrarily complex, making this determination is difficult. For convenience and to reduce the chance of error, the ContainsGenericParameters property provides a standard way to distinguish between closed constructed types, which can be

instantiated, and open constructed types, which cannot. If the ContainsGenericParameters property returns `true`, the type cannot be instantiated.

The ContainsGenericParameters property searches recursively for type parameters. For example, it returns `true` for an array whose elements are type `A<T>` (`A(Of T)` in Visual Basic), even though the array is not itself generic. Contrast this with the behavior of the IsGenericType property, which returns `false` for arrays.

For a set of example classes and a table showing the values of the ContainsGenericParameters property, see IsGenericType.

Type.DeclaringMethod Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a MethodBase that represents the declaring method, if the current Type represents a type parameter of a generic method.

C#

```
public virtual System.Reflection.MethodBase? DeclaringMethod { get; }
```

Property Value

MethodBase

If the current Type represents a type parameter of a generic method, a MethodBase that represents declaring method; otherwise, `null`.

Examples

The following code example defines a class that has a generic method, assigns a type argument to the method, and invokes the resulting constructed generic method. It also displays information about the generic method definition and the constructed method. When displaying information about the type parameters of the generic method definition, in the `DisplayGenericMethodInfo` method, the example code shows the value of the DeclaringMethod property for the method's generic type parameter.

C#

```
using System;
using System.Reflection;

// Define a class with a generic method.
public class Example
{
    public static void Generic<T>(T toDisplay)
    {
        Console.WriteLine("\r\nHere it is: {0}", toDisplay);
```

```
    }
}

public class Test
{
    public static void Main()
    {
        Console.WriteLine("\r\n--- Examine a generic method.");

        // Create a Type object representing class Example, and
        // get a MethodInfo representing the generic method.
        //
        Type ex = typeof(Example);
        MethodInfo mi = ex.GetMethod("Generic");

        DisplayGenericMethodInfo(mi);

        // Assign the int type to the type parameter of the Example
        // method.
        //
        MethodInfo miConstructed = mi.MakeGenericMethod(typeof(int));

        DisplayGenericMethodInfo(miConstructed);

        // Invoke the method.
        object[] args = {42};
        miConstructed.Invoke(null, args);

        // Invoke the method normally.
        Example.Generic<int>(42);

        // Get the generic type definition from the closed method,
        // and show it's the same as the original definition.
        //
        MethodInfo miDef = miConstructed.GetGenericMethodDefinition();
        Console.WriteLine("\r\nThe definition is the same: {0}",
            miDef == mi);
    }

    private static void DisplayGenericMethodInfo(MethodInfo mi)
    {
        Console.WriteLine("\r\n{0}", mi);

        Console.WriteLine("\tIs this a generic method definition? {0}",
            mi.IsGenericMethodDefinition);

        Console.WriteLine("\tIs it a generic method? {0}",
            mi.IsGenericMethod);

        Console.WriteLine("\tDoes it have unassigned generic parameters?
{0}",
            mi.ContainsGenericParameters);

        // If this is a generic method, display its type arguments.
        //
```

```
        if (mi.IsGenericMethod)
        {
            Type[] typeArguments = mi.GetGenericArguments();

            Console.WriteLine("\tList type arguments ({0}):",
                typeArguments.Length);

            foreach (Type tParam in typeArguments)
            {
                // IsGenericParameter is true only for generic type
                // parameters.
                //
                if (tParam.IsGenericParameter)
                {
                    Console.WriteLine("\t\t{0}  parameter position {1}" +
                        "\n\t\t   declaring method: {2}",
                        tParam,
                        tParam.GenericParameterPosition,
                        tParam.DeclaringMethod);
                }
                else
                {
                    Console.WriteLine("\t\t{0}", tParam);
                }
            }
        }
    }
}

/* This example produces the following output:

--- Examine a generic method.

Void Generic[T](T)
        Is this a generic method definition? True
        Is it a generic method? True
        Does it have unassigned generic parameters? True
        List type arguments (1):
                T  parameter position 0
                   declaring method: Void Generic[T](T)

Void Generic[Int32](Int32)
        Is this a generic method definition? False
        Is it a generic method? True
        Does it have unassigned generic parameters? False
        List type arguments (1):
                System.Int32

Here it is: 42

Here it is: 42

The definition is the same: True

 */
```

Remarks

The declaring method is a generic method definition. That is, if DeclaringMethod does not return `null`, then `DeclaringMethod.IsGenericMethodDefinition` returns `true`.

The DeclaringType and DeclaringMethod properties identify the generic type definition or generic method definition in which the generic type parameter was originally defined:

- If the DeclaringMethod property returns a MethodInfo, that MethodInfo represents a generic method definition, and the current Type object represents a type parameter of that generic method definition.
- If the DeclaringMethod property returns `null`, then the DeclaringType property always returns a Type object representing a generic type definition, and the current Type object represents a type parameter of that generic type definition.
- Getting the DeclaringMethod property on a type whose IsGenericParameter property is `false` throws an InvalidOperationException.

The MethodBase that is returned by the DeclaringMethod property is either a MethodInfo in the case of a generic method, or a ConstructorInfo in the case of a generic constructor.

> **Note**
>
> In the .NET Framework version 2.0, generic constructors are not supported.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.

Type.DeclaringType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the type that declares the current nested type or generic type parameter.

C#

```
public override Type? DeclaringType { get; }
```

Property Value

Type

A Type object representing the enclosing type, if the current type is a nested type; or the generic type definition, if the current type is a type parameter of a generic type; or the type that declares the generic method, if the current type is a type parameter of a generic method; otherwise, `null`.

Examples

This example displays the declaring type of a method in a derived class.

C#

```
using System;
using System.Reflection;

public abstract class dtype
{

    public abstract class MyClassA
    {
        public abstract int m();
    }

    public abstract class MyClassB : MyClassA
    {
    }
```

```
    public static void Main(string[] args)
    {
        Console.WriteLine("The declaring type of m is {0}.",
            typeof(MyClassB).GetMethod("m").DeclaringType);
    }
}
/* The example produces the following output:

The declaring type of m is dtype+MyClassA.
*/
```

Remarks

If the current Type object represents a type parameter of a generic type, this property returns the generic type definition.

If the current Type object represents a type parameter of a generic method, this property returns the type that contains the generic method definition. If the type is generic, the generic type definition is returned. That is, the following code returns the generic type definition of the List<T> generic class, which contains the ConvertAll generic method:

```
C#

Type t = typeof(List<string>).GetMethod("ConvertAll").GetGenericArguments()
[0].DeclaringType;
```

If the current Type represents a type parameter in the definition of a generic type or generic method, the DeclaringType and DeclaringMethod properties identify the generic type definition or generic method definition where the generic type parameter was originally defined:

- If the DeclaringMethod property returns a MethodInfo, that MethodInfo represents a generic method definition, and the current Type object represents a type parameter of that generic method definition.
- If the DeclaringMethod property returns `null`, then the DeclaringType property always returns a Type object representing a generic type definition, and the current Type object represents a type parameter of that generic type definition.
- Getting the DeclaringType property on a type whose IsGenericParameter property is `false` throws an InvalidOperationException.

Type.DefaultBinder Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a reference to the default binder, which implements internal rules for selecting the appropriate members to be called by InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[], CultureInfo, String[]).

C#

```
public static System.Reflection.Binder DefaultBinder { get; }
```

Property Value

Binder

A reference to the default binder used by the system.

Examples

The following example gets the default binder from the `DefaultBinder` property, and invokes a member of MyClass by passing the `DefaultBinder` value as a parameter to InvokeMember.

C#

```
using System;
using System.Reflection;

public class MyDefaultBinderSample
{
    public static void Main()
    {
        try
        {
            Binder defaultBinder = Type.DefaultBinder;
            MyClass myClass = new MyClass();
            // Invoke the HelloWorld method of MyClass.
            myClass.GetType().InvokeMember("HelloWorld",
```

```
BindingFlags.InvokeMethod,
                defaultBinder, myClass, new object [] {});
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception :" + e.Message);
        }
    }

    class MyClass
    {
        public void HelloWorld()
        {
            Console.WriteLine("Hello World");
        }
    }
}
```

Remarks

The default binder provided with the common language runtime is applicable in all but the most specialized circumstances. If you need a binder that follows rules that differ from those of the supplied default binder, define a type derived from the Binder class and pass an instance of that type using the `binder` parameter of one of the InvokeMember overloads.

Reflection models the accessibility rules of the common type system. For example, if the caller is in the same assembly, the caller does not need special permissions for internal members. Otherwise, the caller needs ReflectionPermission. This is consistent with lookup of members that are protected, private, and so on.

The general principle is that ChangeType should perform only widening conversions, which never lose data. An example of a widening conversion is converting a value that is a 32-bit signed integer to a value that is a 64-bit signed integer. This is distinguished from a narrowing conversion, which may lose data. An example of a narrowing conversion is converting a 64-bit signed integer to a 32-bit signed integer.

The following table lists the conversions supported by the default binder.

Expand table

Source Type	Target Type
Any type	Its base type.
Any type	The interface it implements.

Source Type	Target Type
Char	Unt16, UInt32, Int32, UInt64, Int64, Single, Double
Byte	Char, Unt16, Int16, UInt32, Int32, UInt64, Int64, Single, Double
SByte	Int16, Int32, Int64, Single, Double
UInt16	UInt32, Int32, UInt64, Int64, Single, Double
Int16	Int32, Int64, Single, Double
UInt32	UInt64, Int64, Single, Double
Int32	Int64, Single, Double
UInt64	Single, Double
Int64	Single, Double
Single	Double
Non-reference	By-reference.

Type.FullName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the fully qualified name of the type, including its namespace but not its assembly.

C#

```
public abstract string? FullName { get; }
```

Property Value

String

The fully qualified name of the type, including its namespace but not its assembly; or `null` if the current instance represents a generic type parameter, an array type, pointer type, or `byref` type based on a type parameter, or a generic type that is not a generic type definition but contains unresolved type parameters.

Examples

The following example displays the full name of the specified type.

C#

```
using System;
class TestFullName
{
public static void Main()
    {
    Type t = typeof(Array);
    Console.WriteLine("The full name of the Array type is {0}.",
t.FullName);
    }
}

/* This example produces the following output:
```

```
The full name of the Array type is System.Array.
 */
```

The following example compares the strings returned by the ToString method and the Name, `FullName`, and AssemblyQualifiedName properties.

C#

```
using System;
using System.Collections.Generic;
using System.Globalization;

public class Example
{
    public static void Main()
    {
        Type t = typeof(String);
        ShowTypeInfo(t);

        t = typeof(List<>);
        ShowTypeInfo(t);

        var list = new List<String>();
        t = list.GetType();
        ShowTypeInfo(t);

        Object v = 12;
        t = v.GetType();
        ShowTypeInfo(t);

        t = typeof(IFormatProvider);
        ShowTypeInfo(t);

        IFormatProvider ifmt = NumberFormatInfo.CurrentInfo;
        t = ifmt.GetType();
        ShowTypeInfo(t);
    }

    private static void ShowTypeInfo(Type t)
    {
        Console.WriteLine($"Name: {t.Name}");
        Console.WriteLine($"Full Name: {t.FullName}");
        Console.WriteLine($"ToString:  {t}");
        Console.WriteLine($"Assembly Qualified Name:
{t.AssemblyQualifiedName}");
        Console.WriteLine();
    }
}
// The example displays output like the following:
//    Name: String
//    Full Name: System.String
//    ToString:  System.String
//    Assembly Qualified Name: System.String, mscorlib, Version=4.0.0.0,
```

```
Culture=neutr
//    al, PublicKeyToken=b77a5c561934e089
//
//    Name: List`1
//    Full Name: System.Collections.Generic.List`1
//    ToString:  System.Collections.Generic.List`1[T]
//    Assembly Qualified Name: System.Collections.Generic.List`1, mscorlib,
Version=4.
//    0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: List`1
//    Full Name: System.Collections.Generic.List`1[[System.String, mscorlib,
Version=4
//    .0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089]]
//    ToString:  System.Collections.Generic.List`1[System.String]
//    Assembly Qualified Name:
System.Collections.Generic.List`1[[System.String, mscor
//    lib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089]], mscorl
//    ib, Version=4.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: Int32
//    Full Name: System.Int32
//    ToString:  System.Int32
//    Assembly Qualified Name: System.Int32, mscorlib, Version=4.0.0.0,
Culture=neutra
//    l, PublicKeyToken=b77a5c561934e089
//
//    Name: IFormatProvider
//    Full Name: System.IFormatProvider
//    ToString:  System.IFormatProvider
//    Assembly Qualified Name: System.IFormatProvider, mscorlib,
Version=4.0.0.0, Cult
//    ure=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: NumberFormatInfo
//    Full Name: System.Globalization.NumberFormatInfo
//    ToString:  System.Globalization.NumberFormatInfo
//    Assembly Qualified Name: System.Globalization.NumberFormatInfo,
mscorlib, Versio
//    n=4.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
```

Remarks

For example, the fully qualified name of the String type is `System.String`. Contrast this with the assembly-qualified name returned by the AssemblyQualifiedName property, which consists of the full name plus the full assembly name.

If the current type represents a closed generic type, the type arguments in the string returned by the FullName property are qualified by their full assembly name, even

though the string representation of the generic type itself is not qualified by its full assembly name. The following example illustrates the difference in the FullName property for a type that represents generic type definition and one that represents a closed generic type.

C#

```
using System;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Type t = typeof(List<>);
      Console.WriteLine(t.FullName);
      Console.WriteLine();

      List<String> list = new List<String>();
      t = list.GetType();
      Console.WriteLine(t.FullName);
   }
}
// The example displays the following output:
// System.Collections.Generic.List`1
//
// System.Collections.Generic.List`1[[System.String, mscorlib,
//        Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089]]
```

This property returns `null` if:

- The current Type object represents a type parameter of a generic type.

  The following example retrieves the type parameter of the Nullable<T> type and attempts to display its FullName property.

  C#

  ```
  using System;
  using System.Reflection;

  public class Example
  {
     public static void Main()
     {
        Type t = typeof(Nullable<>);
        Console.WriteLine(t.FullName);
        if (t.IsGenericType) {
           Console.Write("   Generic Type Parameters: ");
           Type[] gtArgs = t.GetGenericArguments();
  ```

```
            for (int ctr = 0; ctr < gtArgs.Length; ctr++) {
               Console.WriteLine(gtArgs[ctr].FullName ??
                                 "(unassigned) " +
gtArgs[ctr].ToString());
             }
            Console.WriteLine();
         }
      }
}
// The example displays the following output:
//       System.Nullable`1
//          Generic Type Parameters: (unassigned) T
```

- The current Type object represents an array type, a pointer type, or a `byref` type that is based on a generic type parameter.

  The following example defines a generic type, `Genericype1<T>`, with three methods: `Display(T[])`, which is passed an array of type T; `HandleT(T)`, which is passed a T object; and `ChangeValue(ref T)`, which is passed a T object by reference. Because C# and Visual Basic do not allow us to define T as a pointer in the `HandleT` method, we have to call the MakePointerType method on the Type object that represents the method's parameter type to create a pointer to a generic type. The output from the example shows that in all three cases, the FullName property is `null`.

C#

```
using System;
using System.Reflection;

public class GenericType1<T>
{
   public void Display(T[] elements)
   {}

   public void HandleT(T obj)
   {}

   public bool ChangeValue(ref T arg)
   {
      return true;
   }
}

public class Example
{
   public static void Main()
   {
      Type t = typeof(GenericType1<>);
      Console.WriteLine("Type Name: {0}", t.FullName);
```

```
      MethodInfo[] methods = t.GetMethods(BindingFlags.Instance |
                                          BindingFlags.DeclaredOnly |
                                          BindingFlags.Public);
      foreach (var method in methods) {
         Console.WriteLine("   Method: {0}", method.Name);
         // Get method parameters.
         ParameterInfo param = method.GetParameters()[0];
         Type paramType = param.ParameterType;
         if (method.Name == "HandleT")
            paramType = paramType.MakePointerType();
         Console.WriteLine("      Parameter: {0}",
                           paramType.FullName ??
                           paramType.ToString() + " (unassigned)");
      }
   }
}
// The example displays the following output:
//       Type Name: GenericType1`1
//          Method: Display
//             Parameter: T[] (unassigned))
//          Method: HandleT
//             Parameter: T* (unassigned)
//          Method: ChangeValue
//             Parameter: T& (unassigned)
```

- The current type contains generic type parameters that have not been replaced by specific types (that is, the ContainsGenericParameters property returns `true`), but the type is not a generic type definition (that is, the IsGenericTypeDefinition property returns `false`

  In the following example, `Derived<T>` inherits from `Base<T>`. The BaseType property obtains the Type object that represents the base type of `Derived<T>`, and its FullName property returns `null`.

C#

```
using System;
using System.Reflection;

public class Base<T> { }

public class Derived<T> : Base<T> { }

public class Example
{
   public static void Main()
   {
      Type t = typeof(Derived<>);
      Console.WriteLine("Generic Class: {0}", t.FullName);
      Console.WriteLine("   Contains Generic Paramters: {0}",
                        t.ContainsGenericParameters);
```

```
        Console.WriteLine("   Generic Type Definition: {0}\n",
                          t.IsGenericTypeDefinition);

        Type baseType = t.BaseType;
        Console.WriteLine("Its Base Class: {0}",
                          baseType.FullName ??
                          "(unassigned) " + baseType.ToString());
        Console.WriteLine("   Contains Generic Paramters: {0}",
                          baseType.ContainsGenericParameters);
        Console.WriteLine("   Generic Type Definition: {0}",
                          baseType.IsGenericTypeDefinition);
        Console.WriteLine("   Full Name: {0}\n",
                          baseType.GetGenericTypeDefinition().FullName);

        t = typeof(Base<>);
        Console.WriteLine("Generic Class: {0}", t.FullName);
        Console.WriteLine("   Contains Generic Paramters: {0}",
                          t.ContainsGenericParameters);
        Console.WriteLine("   Generic Type Definition: {0}\n",
                          t.IsGenericTypeDefinition);
    }
}
// The example displays the following output:
//       Generic Class: Derived`1
//          Contains Generic Paramters: True
//          Generic Type Definition: True
//
//       Its Base Class: (unassigned) Base`1[T]
//          Contains Generic Paramters: True
//          Generic Type Definition: False
//          Full Name: Base`1
//
//       Generic Class: Base`1
//          Contains Generic Paramters: True
//          Generic Type Definition: True
```

To get a FullName that is not `null`, you can use the GetGenericTypeDefinition method to get the generic type definition, as the example illustrates.

This property is read-only.

Type.GenericParameterAttributes Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a combination of GenericParameterAttributes flags that describe the covariance and special constraints of the current generic type parameter.

C#

```
public virtual System.Reflection.GenericParameterAttributes
GenericParameterAttributes { get; }
```

Property Value

GenericParameterAttributes

A bitwise combination of GenericParameterAttributes values that describes the covariance and special constraints of the current generic type parameter.

Exceptions

InvalidOperationException

The current Type object is not a generic type parameter. That is, the IsGenericParameter property returns `false`.

NotSupportedException

The invoked method is not supported in the base class.

Examples

The following code example defines a generic type `Test` with two type parameters that have different constraints. When the program executes, the constraints are examined using the GenericParameterAttributes property and the GetGenericParameterConstraints method.

C#

```
using System;
using System.Reflection;

// Define a sample interface to use as an interface constraint.
public interface ITest {}

// Define a base type to use as a base class constraint.
public class Base {}

// Define the generic type to examine. The first generic type parameter,
// T, derives from the class Base and implements ITest. This demonstrates
// a base class constraint and an interface constraint. The second generic
// type parameter, U, must be a reference type (class) and must have a
// default constructor (new()). This demonstrates special constraints.
//
public class Test<T,U>
    where T : Base, ITest
    where U : class, new() {}

// Define a type that derives from Base and implements ITest. This type
// satisfies the constraints on T in class Test.
public class Derived : Base, ITest {}

public class Example
{
    public static void Main()
    {
        // To get the generic type definition, omit the type
        // arguments but retain the comma to indicate the number
        // of type arguments.
        //
        Type def = typeof(Test<,>);
        Console.WriteLine("\r\nExamining generic type {0}", def);

        // Get the type parameters of the generic type definition,
        // and display them.
        //
        Type[] defparams = def.GetGenericArguments();
        foreach (Type tp in defparams)
        {
            Console.WriteLine("\r\nType parameter: {0}", tp.Name);
            Console.WriteLine("\t{0}",
                ListGenericParameterAttributes(tp));

            // List the base class and interface constraints. The
            // constraints are returned in no particular order. If
            // there are no class or interface constraints, an empty
            // array is returned.
            //
            Type[] tpConstraints = tp.GetGenericParameterConstraints();
            foreach (Type tpc in tpConstraints)
            {
```

```
                Console.WriteLine("\t{0}", tpc);
            }
        }
    }

    // List the variance and special constraint flags.
    //
    private static string ListGenericParameterAttributes(Type t)
    {
        string retval;
        GenericParameterAttributes gpa = t.GenericParameterAttributes;
        GenericParameterAttributes variance = gpa &
            GenericParameterAttributes.VarianceMask;

        // Select the variance flags.
        if (variance == GenericParameterAttributes.None)
        {
            retval = "No variance flag;";
        }
        else
        {
            if ((variance & GenericParameterAttributes.Covariant) != 0)
                retval = "Covariant;";
            else
                retval = "Contravariant;";
        }

        // Select
        GenericParameterAttributes constraints = gpa &
            GenericParameterAttributes.SpecialConstraintMask;

        if (constraints == GenericParameterAttributes.None)
        {
            retval += " No special constraints";
        }
        else
        {
            if ((constraints &
GenericParameterAttributes.ReferenceTypeConstraint) != 0)
                retval += " ReferenceTypeConstraint";
            if ((constraints &
GenericParameterAttributes.NotNullableValueTypeConstraint) != 0)
                retval += " NotNullableValueTypeConstraint";
            if ((constraints &
GenericParameterAttributes.DefaultConstructorConstraint) != 0)
                retval += " DefaultConstructorConstraint";
        }

        return retval;
    }
}
/* This example produces the following output:

Examining generic type Test`2[T,U]
```

```
Type parameter: T
        No variance flag; no special constraints.
        Base
        ITest

Type parameter: U
        No variance flag; ReferenceTypeConstraint
DefaultConstructorConstraint
 */
```

Remarks

The value of this property contains flags that describe whether the current generic type parameter is covariant, and flags that describe any special constraints. Use the GenericParameterAttributes.VarianceMask value to select the covariance flags, and use the GenericParameterAttributes.SpecialConstraintMask value to select the constraint flags.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.

Type.GenericParameterPosition Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the position of the type parameter in the type parameter list of the generic type or method that declared the parameter, when the Type object represents a type parameter of a generic type or a generic method.

```
C#

public virtual int GenericParameterPosition { get; }
```

Property Value

Int32

The position of a type parameter in the type parameter list of the generic type or method that defines the parameter. Position numbers begin at 0.

Exceptions

InvalidOperationException

The current type does not represent a type parameter. That is, IsGenericParameter returns `false`.

Examples

The following example defines a generic class with two type parameters and defines a second generic class that derives from the first class. The derived class's base class has two type arguments: the first is Int32, and the second is a type parameter of the derived type. The example displays information about these generic classes, including the positions reported by the GenericParameterPosition property.

```
C#

using System;
using System.Reflection;
```

```
using System.Collections.Generic;

// Define a base class with two type parameters.
public class Base<T, U> { }

// Define a derived class. The derived class inherits from a constructed
// class that meets the following criteria:
//   (1) Its generic type definition is Base<T, U>.
//   (2) It specifies int for the first type parameter.
//   (3) For the second type parameter, it uses the same type that is used
//       for the type parameter of the derived class.
// Thus, the derived class is a generic type with one type parameter, but
// its base class is an open constructed type with one type argument and
// one type parameter.
public class Derived<V> : Base<int, V> { }

public class Test
{
    public static void Main()
    {
        Console.WriteLine(
            "\r\n--- Display a generic type and the open constructed");
        Console.WriteLine("    type from which it is derived.");

        // Create a Type object representing the generic type definition
        // for the Derived type, by omitting the type argument. (For
        // types with multiple type parameters, supply the commas but
        // omit the type arguments.)
        //
        Type derivedType = typeof(Derived<>);
        DisplayGenericTypeInfo(derivedType);

        // Display its open constructed base type.
        DisplayGenericTypeInfo(derivedType.BaseType);
    }

    private static void DisplayGenericTypeInfo(Type t)
    {
        Console.WriteLine("\r\n{0}", t);

        Console.WriteLine("\tIs this a generic type definition? {0}",
            t.IsGenericTypeDefinition);

        Console.WriteLine("\tIs it a generic type? {0}",
            t.IsGenericType);

        Console.WriteLine("\tDoes it have unassigned generic parameters?
{0}",
            t.ContainsGenericParameters);

        if (t.IsGenericType)
        {
            // If this is a generic type, display the type arguments.
            //
            Type[] typeArguments = t.GetGenericArguments();
```

```
            Console.WriteLine("\tList type arguments ({0}):",
                typeArguments.Length);

            foreach (Type tParam in typeArguments)
            {
                // IsGenericParameter is true only for generic type
                // parameters.
                //
                if (tParam.IsGenericParameter)
                {
                    Console.WriteLine(
                        "\t\t{0}  (unassigned - parameter position {1})",
                        tParam,
                        tParam.GenericParameterPosition);
                }
                else
                {
                    Console.WriteLine("\t\t{0}", tParam);
                }
            }
        }
    }
}

/* This example produces the following output:

--- Display a generic type and the open constructed
    type from which it is derived.

Derived`1[V]
        Is this a generic type definition? True
        Is it a generic type? True
        Does it have unassigned generic parameters? True
        List type arguments (1):
                V  (unassigned - parameter position 0)

Base`2[System.Int32,V]
        Is this a generic type definition? False
        Is it a generic type? True
        Does it have unassigned generic parameters? True
        List type arguments (2):
                System.Int32
                V  (unassigned - parameter position 0)
 */
```

Remarks

The GenericParameterPosition property returns the position of a type parameter in the parameter list of the generic type definition or generic method definition where the type

parameter was originally defined. The DeclaringType and DeclaringMethod properties identify the generic type or method definition:

- If the DeclaringMethod property returns a MethodInfo, that MethodInfo represents a generic method definition, and the current Type object represents a type parameter of that generic method definition.
- If the DeclaringMethod property returns `null`, then the DeclaringType property always returns a Type object representing a generic type definition, and the current Type object represents a type parameter of that generic type definition.

To provide the correct context for the value of the GenericParameterPosition property, it is necessary to identify the generic type or method a type parameter belongs to. For example, consider the return value of the generic method `GetSomething` in the following code:

C#

```
public class B<T, U> { }
public class A<V>
{
    public B<V, X> GetSomething<X>()
    {
        return new B<V, X>();
    }
}
```

The type returned by `GetSomething` depends on the type arguments supplied to class `A` and to `GetSomething` itself. You can obtain a MethodInfo for `GetSomething`, and from that you can obtain the return type. When you examine the type parameters of the return type, GenericParameterPosition returns 0 for both. The position of `V` is 0 because `V` is the first type parameter in the type parameter list for class `A`. The position of `X` is 0 because `X` is the first type parameter in the type parameter list for `GetSomething`.

> **Note**
>
> Calling the **GenericParameterPosition** property causes an exception if the current **Type** does not represent a type parameter. When you examine the type arguments of an open constructed type, use the **IsGenericParameter** property to tell which are type parameters and which are types. The **IsGenericParameter** property returns `true` for a type parameter; you can then use the **GenericParameterPosition** method to obtain its position and use the **DeclaringMethod** and **DeclaringType** properties to determine the generic method or type definition that defines it.

Type.GenericTypeArguments Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an array of the generic type arguments for this type.

C#

```
public virtual Type[] GenericTypeArguments { get; }
```

Property Value

Type[]

An array of the generic type arguments for this type.

Remarks

This property gets only the generic type arguments; that is, the types that have been specified for the generic type parameters of the current type. If the current type is a generic type definition, this property returns an empty array.

> **Note**
>
> If a generic type is used in a generic method or in another generic type, some of its generic type arguments might be generic type parameters of the enclosing method or type.

To get the generic type parameters of a type that represents a generic type definition, use the TypeInfo.GenericTypeParameters property. To get a TypeInfo object for the current Type object, use the IntrospectionExtensions.GetTypeInfo extension method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.GUID Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the GUID associated with the Type.

C#

```
public abstract Guid GUID { get; }
```

Property Value

Guid

The GUID associated with the Type.

Examples

The following example creates the class `MyClass1` with a public method, creates a `Type` object corresponding to `MyClass1`, and gets the Guid structure using the `GUID` property of the `Type` class.

C#

```
using System;

class MyGetTypeFromCLSID
{
    public class MyClass1
    {
        public void MyMethod1()
        {
        }
    }
    public static void Main()
    {
        // Get the type corresponding to the class MyClass.
        Type myType = typeof(MyClass1);
        // Get the object of the Guid.
        Guid myGuid =(Guid) myType.GUID;
```

```
        Console.WriteLine("The name of the class is "+myType.ToString());
        Console.WriteLine("The ClassId of MyClass is "+myType.GUID);
    }
}
```

Remarks

A GUID is associated with a type using the GuidAttribute attribute.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.HasElementType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Type encompasses or refers to another type; that is, whether the current Type is an array, a pointer, or is passed by reference.

C#

```
public bool HasElementType { get; }
```

Property Value

Boolean

`true` if the Type is an array, a pointer, or is passed by reference; otherwise, `false`.

Examples

The following example returns `true` or `false` depending on whether or not the object is an array, a reference type, or a pointer.

C#

```
// This code must be compiled with the /unsafe switch:
//   csc /unsafe source.cs
using System;
using System.Reflection;

public class Example
{
    // This method is for demonstration purposes.
    unsafe public void Test(ref int x, out int y, int* z)
    {
        *z = x = y = 0;
    }

    public static void Main()
    {
        // All of the following display 'True'.
```

```
        // Define an array, get its type, and display HasElementType.
        int[] nums = {1, 1, 2, 3, 5, 8, 13};
        Type t = nums.GetType();
        Console.WriteLine("HasElementType is '{0}' for array types.",
t.HasElementType);

        // Test an array type without defining an array.
        t = typeof(Example[]);
        Console.WriteLine("HasElementType is '{0}' for array types.",
t.HasElementType);

        // When you use Reflection Emit to emit dynamic methods and
        // assemblies, you can create array types using MakeArrayType.
        // The following creates the type 'array of Example'.
        t = typeof(Example).MakeArrayType();
        Console.WriteLine("HasElementType is '{0}' for array types.",
t.HasElementType);

        // When you reflect over methods, HasElementType is true for
        // ref, out, and pointer parameter types. The following
        // gets the Test method, defined above, and examines its
        // parameters.
        MethodInfo mi = typeof(Example).GetMethod("Test");
        ParameterInfo[] parms = mi.GetParameters();
        t = parms[0].ParameterType;
        Console.WriteLine("HasElementType is '{0}' for ref parameter
types.", t.HasElementType);
        t = parms[1].ParameterType;
        Console.WriteLine("HasElementType is '{0}' for out parameter
types.", t.HasElementType);
        t = parms[2].ParameterType;
        Console.WriteLine("HasElementType is '{0}' for pointer parameter
types.", t.HasElementType);

        // When you use Reflection Emit to emit dynamic methods and
        // assemblies, you can create pointer and ByRef types to use
        // when you define method parameters.
        t = typeof(Example).MakePointerType();
        Console.WriteLine("HasElementType is '{0}' for pointer types.",
t.HasElementType);
        t = typeof(Example).MakeByRefType();
        Console.WriteLine("HasElementType is '{0}' for ByRef types.",
t.HasElementType);
    }
}
```

Remarks

For example, Type.GetType("Int32[]").HasElementType returns `true`, but Type.GetType("Int32").HasElementType returns `false`. HasElementType also returns

`true` for "Int32*" and "Int32&".

If the current Type represents a generic type, or a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.IsAbstract Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is abstract and must be overridden.

```
C#
public bool IsAbstract { get; }
```

Property Value

Boolean

`true` if the Type is abstract; otherwise, `false`.

Examples

The following example creates an array of Type objects that represent the following types:contains type returns `true` if the specified object is `abstract`; otherwise, it returns `false`.

- `AbstractClass`, an abstract class (a class marked as `abstract` in C# and `MustInherit` in Visual Basic).
- `DerivedClass`, a class that inherits from `AbstractClass`.
- `SingleClass`, a non-inheritable class. It is defined as `sealed` in C# and `NotInheritable` in Visual Basic.
- `ITypeInfo`, an interface.
- `ImplementingClass`, a class that implements the `ITypeInfo` interface.

The method returns `true` only for `AbstractClass`, the abstract class, and `ITypeInfo`, the interface.

C#

```
using System;

public abstract class AbstractClass
{}

public class DerivedClass : AbstractClass
{}

public sealed class SingleClass
{}

public interface ITypeInfo
{
   string GetName();
}

public class ImplementingClass : ITypeInfo
{
   public string GetName()
   {
      return this.GetType().FullName;
   }
}

delegate string InputOutput(string inp);

public class Example
{
   public static void Main()
   {
      Type[] types= { typeof(AbstractClass),
                      typeof(DerivedClass),
                      typeof(ITypeInfo),
                      typeof(SingleClass),
                      typeof(ImplementingClass),
                      typeof(InputOutput) };
      foreach (var type in types)
         Console.WriteLine("{0} is abstract: {1}",
                           type.Name, type.IsAbstract);
   }
}
// The example displays the following output:
//       AbstractClass is abstract: True
//       DerivedClass is abstract: False
//       ITypeInfo is abstract: True
//       SingleClass is abstract: False
//       ImplementingClass is abstract: False
//       InputOutput is abstract: False
```

Remarks

The IsAbstract property returns `true` in the following cases:

- The current type is abstract; that is, it cannot be instantiated, but can only serve as the base class for derived classes. In C#, abstract classes are marked with the abstract keyword; in F#, they are marked with the AbstractClass attribute; in Visual Basic, they are marked with the MustInherit keyword.
- The current type is an interface.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsAnsiClass Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the string format attribute `AnsiClass` is selected for the Type.

C#

```
public bool IsAnsiClass { get; }
```

Property Value

Boolean

`true` if the string format attribute `AnsiClass` is selected for the Type; otherwise, `false`.

Examples

The following example gets the field information and checks for the `AnsiClass` attribute.

C#

```
using System;
using System.Reflection;
public class MyClass
{
    protected string myField = "A sample protected field." ;
}
public class MyType_IsAnsiClass
{
    public static void Main()
    {
        try
        {
            MyClass myObject = new MyClass();
            // Get the type of the 'MyClass'.
            Type myType = typeof(MyClass);
            // Get the field information and the attributes associated with
MyClass.
```

```
            FieldInfo myFieldInfo = myType.GetField("myField",
BindingFlags.NonPublic|BindingFlags.Instance);
            Console.WriteLine( "\nChecking for the AnsiClass attribute for a
field.\n");
            // Get and display the name, field, and the AnsiClass attribute.
            Console.WriteLine("Name of Class: {0} \nValue of Field: {1}
\nIsAnsiClass = {2}", myType.FullName, myFieldInfo.GetValue(myObject),
myType.IsAnsiClass);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: {0}",e.Message);
        }
    }
}
```

Remarks

The StringFormatMask selects the string format attributes. The string format attributes enhance interoperability by defining how strings should be interpreted.

If the current Type represents a generic type, this property pertains to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter of a generic type, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsArray Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the type is an array.

C#

```
public bool IsArray { get; }
```

Property Value

Boolean

`true` if the current type is an array; otherwise, `false`.

Examples

The following example demonstrates using the IsArray property.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;

public class Example
{
   public static void Main()
   {
      Type[] types = { typeof(String), typeof(int[]),
                       typeof(ArrayList), typeof(Array),
                       typeof(List<String>),
                       typeof(IEnumerable<Char>) };
      foreach (var t in types)
         Console.WriteLine("{0,-15} IsArray = {1}", t.Name + ":",
                           t.IsArray);
   }
}
// The example displays the following output:
//       String:         IsArray = False
```

```
//       Int32[]:        IsArray = True
//       ArrayList:      IsArray = False
//       Array:          IsArray = False
//       List`1:         IsArray = False
//       IEnumerable`1:  IsArray = False
```

Remarks

The IsArray property returns `false` for the Array class. It also returns `false` if the current instance is a Type object that represents a collection type or an interface designed to work with collections, such as IEnumerable or IEnumerable<T>.

To check for an array, use code such as:

C#

```
typeof(Array).IsAssignableFrom(type)
```

If the current type represents a generic type, or a type parameter in the definition of a generic type or generic method, this property always returns `false`.

This property is read-only.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.IsAutoClass Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the string format attribute `AutoClass` is selected for the Type.

```
C#
public bool IsAutoClass { get; }
```

Property Value

Boolean

`true` if the string format attribute `AutoClass` is selected for the Type; otherwise, `false`.

Remarks

The StringFormatMask selects the string format attributes. The string format attributes enhance interoperability by defining how strings should be interpreted.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter of a generic type, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsAutoLayout Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the fields of the current type are laid out automatically by the common language runtime.

C#

```
public bool IsAutoLayout { get; }
```

Property Value

Boolean

`true` if the Attributes property of the current type includes AutoLayout; otherwise, `false`.

Examples

The following example creates an instance of the type and displays the IsAutoLayout property.

C#

```
using System;
using System.Runtime.InteropServices;

// The Demo class is attributed as AutoLayout.
[StructLayoutAttribute(LayoutKind.Auto)]
public class Demo
{
}

public class Example
{
    public static void Main()
    {
        // Create an instance of the Type class using the GetType method.
        Type  myType=typeof(Demo);
```

```
        // Get and display the IsAutoLayout property of the
        // Demoinstance.
        Console.WriteLine("\nThe AutoLayout property for the Demo class is
{0}.",
            myType.IsAutoLayout);
    }
}
```

Remarks

This property is provided as a convenience. Alternatively, you can use the TypeAttributes.LayoutMask enumeration value to select the type layout attributes, and then test whether TypeAttributes.AutoLayout is set. The TypeAttributes.AutoLayout,TypeAttributes.ExplicitLayout, and TypeAttributes.SequentialLayout enumeration values indicate the way the fields of the type are laid out in memory.

For dynamic types, you can specify TypeAttributes.AutoLayout when you create the type. In code, apply the StructLayoutAttribute attribute with the LayoutKind.Auto enumeration value to the type, to let the runtime determine the appropriate way to lay out the class.

> ⓘ **Note**
>
> You cannot use the **GetCustomAttributes** method to determine whether the **StructLayoutAttribute** has been applied to a type.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>.`

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Type.IsByRef Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is passed by reference.

C#

```
public bool IsByRef { get; }
```

Property Value

Boolean

`true` if the Type is passed by reference; otherwise, `false`.

Examples

The following example demonstrates a use of the `IsByRef` property to check whether a specified type is passed by reference. The example defines the class `MyTypeDelegator`, which overrides the `HasElementTypeImpl` method. The main class checks for the `HasElementType` property and displays the element type.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegator : TypeDelegator
{
    public string myElementType = null;
    private Type myType = null ;
    public MyTypeDelegator(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override Type.HasElementTypeImpl().
    protected override bool HasElementTypeImpl()
    {
        // Determine whether the type is an array.
```

```
        if(myType.IsArray)
        {
            myElementType = "array";
            return true;
        }
        // Determine whether the type is a reference.
        if(myType.IsByRef)
        {
            myElementType = "reference";
            return true;
        }
        // Determine whether the type is a pointer.
        if(myType.IsPointer)
        {
            myElementType = "pointer";
            return true;
        }
        // Return false if the type is not a reference, array, or pointer
type.
        return false;
    }
}
public class Type_HasElementTypeImpl
{
    public static void Main()
    {
        try
        {
            int myInt = 0 ;
            int[] myArray = new int[5];
            MyTypeDelegator myType = new MyTypeDelegator(myArray.GetType());
            // Determine whether myType is an array, pointer, reference
type.
            Console.WriteLine("\nDetermine whether a variable is an array,
pointer, or reference type.\n");
            if( myType.HasElementType)
                Console.WriteLine("The type of myArray is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myArray is not an array, pointer, or
reference type.");
            myType = new MyTypeDelegator(myInt.GetType());
            // Determine whether myType is an array, pointer, reference
type.
            if( myType.HasElementType)
                Console.WriteLine("The type of myInt is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myInt is not an array, pointer, or
reference type.");
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message);
        }
```

```
    }
}
```

Remarks

To get to the actual type, dereference the type that was passed by reference, and then call GetElementType on that type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Type.IsByRefLike Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the type is a byref-like structure.

C#

```
public virtual bool IsByRefLike { get; }
```

Property Value

Boolean

`true` if the Type is a byref-like structure; otherwise, `false`.

Remarks

Byref-like structures are declared using `ref struct` keyword in C#. An instance of the byref-like structure can't be placed on the managed heap. For more information, see Ref struct.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Type.IsClass Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is a class or a delegate; that is, not a value type or interface.

C#

```
public bool IsClass { get; }
```

Property Value

Boolean

`true` if the Type is a class; otherwise, `false`.

Examples

The following example creates an instance of a type and indicates whether the type is a class.

C#

```
using System;
using System.Reflection;

public  class MyDemoClass
{
}

public class MyTypeClass
{
    public static void Main(string[] args)
    {
        try
        {
            Type  myType = typeof(MyDemoClass);
            // Get and display the 'IsClass' property of the 'MyDemoClass'
instance.
```

```
            Console.WriteLine("\nIs the specified type a class? {0}.",
myType.IsClass);
        }
        catch(Exception e)
        {
            Console.WriteLine("\nAn exception occurred: {0}." ,e.Message);
        }
    }
}
```

Remarks

This property returns `true` for classes as well as delegates. It returns `false` for value types (for structures and enumerations) even if they are boxed.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `true`. If the current Type represents a constructed generic type, this property returns `true` if the generic type definition is a class definition; that is, it does not define an interface or a value type.

> **Note**
>
> This property returns `true` for `Type` instances that represent the **Enum** and **ValueType** classes. These two classes are the base types for enumerations and value types, respectively, but they are not enumerations or value types themselves. For more information, see the **IsValueType** and **IsEnum** properties.

The TypeAttributes.ClassSemanticsMask enumeration value distinguishes a type declaration as class or interface. However, both classes and value types are marked with the TypeAttributes.Class attribute. If you retrieve the value of a type's Attributes property and use the TypeAttributes.ClassSemanticsMask value to determine whether a type is a class instead of a value type, you must also call the IsValueType property. The example for the TypeAttributes enumeration contains additional information as well as anexample.

This property is read-only.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsCOMObject Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is a COM object.

C#

```
public bool IsCOMObject { get; }
```

Property Value

Boolean

`true` if the Type is a COM object; otherwise, `false`.

Remarks

This method returns `false` for COM interfaces because they are not objects. COM interfaces can be implemented by Microsoft .NET Framework objects.

You can also load a COM class and get a `Type` object for that COM class by using the Tlbimp.exe (Type Library Importer) tool.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsConstructedGenericType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether this object represents a constructed generic type. You can create instances of a constructed generic type.

```
C#
public virtual bool IsConstructedGenericType { get; }
```

Property Value

Boolean

`true` if this object represents a constructed generic type; otherwise, `false`.

Remarks

A constructed generic type has had explicit types supplied for all of its generic type parameters. It is also referred to as a closed generic type.

When this property is `true`, you can create instances of the current type; when it is `false`, you can't.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Type.IsContextful Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type can be hosted in a context.

C#

```
public bool IsContextful { get; }
```

Property Value

Boolean

`true` if the Type can be hosted in a context; otherwise, `false`.

Examples

The following example demonstrates the `IsContextful`, IsMarshalByRef, and IsPrimitive properties of the Type class. It checks whether the given type can be hosted in the context, whether it can be marshaled by reference, and whether the type is a primitive data type.

C#

```
using System;
using System.Runtime.Remoting.Contexts;

public class ContextBoundClass: ContextBoundObject
{
    public string Value = "The Value property.";
}

public class Example
{
    public static void Main()
    {
         // Determine whether the types can be hosted in a Context.
         Console.WriteLine("The IsContextful property for the {0} type is
{1}.",
```

```
                            typeof(Example).Name,
typeof(Example).IsContextful);
         Console.WriteLine("The IsContextful property for the {0} type is
{1}.",
                            typeof(ContextBoundClass).Name,
typeof(ContextBoundClass).IsContextful);

         // Determine whether the types are marshalled by reference.
         Console.WriteLine("The IsMarshalByRef property of {0} is {1}.",
                            typeof(Example).Name,
typeof(Example).IsMarshalByRef);
         Console.WriteLine("The IsMarshalByRef property of {0} is {1}.",
                            typeof(ContextBoundClass).Name,
typeof(ContextBoundClass).IsMarshalByRef);

         // Determine whether the types are primitive datatypes.
         Console.WriteLine("{0} is a primitive data type: {1}.",
                            typeof(int).Name, typeof(int).IsPrimitive);
         Console.WriteLine("{0} is a primitive data type: {1}.",
                            typeof(string).Name, typeof(string).IsPrimitive);
    }
}
// The example displays the following output:
//    The IsContextful property for the Example type is False.
//    The IsContextful property for the ContextBoundClass type is True.
//    The IsMarshalByRef property of Example is False.
//    The IsMarshalByRef property of ContextBoundClass is True.
//    Int32 is a primitive data type: True.
//    String is a primitive data type: False.
```

Remarks

A context intercepts calls to the class members and enforces policies that are applied to the class, such as synchronization. For more detailed information on remoting contexts, see Context.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsEnum Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Type represents an enumeration.

C#

```
public virtual bool IsEnum { get; }
```

Property Value

Boolean

`true` if the current Type represents an enumeration; otherwise, `false`.

Examples

The following example demonstrates how to use the `IsEnum` property.

C#

```
using System;
public enum Color
{ Red, Blue, Green }

class TestIsEnum
{
    public static void Main()
    {
       Type colorType = typeof(Color);
       Type enumType = typeof(Enum);
       Console.WriteLine("Is Color an enum? {0}.", colorType.IsEnum);
       Console.WriteLine("Is Color a value type? {0}.",
colorType.IsValueType);
       Console.WriteLine("Is Enum an enum Type? {0}.", enumType.IsEnum);
       Console.WriteLine("Is Enum a value type? {0}.",
enumType.IsValueType);
   }
}
// The example displays the following output:
```

```
//     Is Color an enum? True.
//     Is Color a value type? True.
//     Is Enum an enum type? False.
//     Is Enum a value type? False.
```

Remarks

This property returns `true` for an enumeration, but not for the Enum type itself.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

This property is read-only.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsExplicitLayout Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the fields of the current type are laid out at explicitly specified offsets.

C#

```
public bool IsExplicitLayout { get; }
```

Property Value

Boolean

`true` if the Attributes property of the current type includes ExplicitLayout; otherwise, `false`.

Examples

The following example creates an instance of a type and displays the value of its IsExplicitLayout property. It uses the `MySystemTime` class, which is also in the code example for StructLayoutAttribute.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;
using System.Runtime.InteropServices;

// Class to test for the ExplicitLayout property.
[StructLayout(LayoutKind.Explicit, Size=16, CharSet=CharSet.Ansi)]
public class MySystemTime
{
   [FieldOffset(0)]public ushort wYear;
   [FieldOffset(2)]public ushort wMonth;
   [FieldOffset(4)]public ushort wDayOfWeek;
   [FieldOffset(6)]public ushort wDay;
```

```
    [FieldOffset(8)]public ushort wHour;
    [FieldOffset(10)]public ushort wMinute;
    [FieldOffset(12)]public ushort wSecond;
    [FieldOffset(14)]public ushort wMilliseconds;
}

public class Program
{
    public static void Main(string[] args)
    {
        // Create an instance of the type using the GetType method.
        Type  t = typeof(MySystemTime);
        // Get and display the IsExplicitLayout property.
        Console.WriteLine("\nIsExplicitLayout for MySystemTime is {0}.",
            t.IsExplicitLayout);
    }
}
```

Remarks

This property is provided as a convenience. Alternatively, you can use the TypeAttributes.LayoutMask enumeration value to select the type layout attributes, and then test whether TypeAttributes.ExplicitLayout is set. The TypeAttributes.AutoLayout, TypeAttributes.ExplicitLayout, and TypeAttributes.SequentialLayout enumeration values indicate the way the fields of the type are laid out in memory.

For dynamic types, you can specify TypeAttributes.ExplicitLayout when you create the type. In code, apply the StructLayoutAttribute attribute with the LayoutKind.Explicit enumeration value to the type, to specify that the offsets at which the fields start are specified explicitly.

> ⓘ **Note**
>
> You cannot use the **GetCustomAttributes** method to determine whether the **StructLayoutAttribute** has been applied to a type.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsGenericParameter Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Type represents a type parameter in the definition of a generic type or method.

C#

```
public virtual bool IsGenericParameter { get; }
```

Property Value

Boolean

`true` if the Type object represents a type parameter of a generic type definition or generic method definition; otherwise, `false`.

Examples

The following example uses the IsGenericParameter property to test for generic type parameters in a generic type.

C#

```
if (t.IsGenericType)
{
    // If this is a generic type, display the type arguments.
    //
    Type[] typeArguments = t.GetGenericArguments();

    Console.WriteLine("\tList type arguments ({0}):",
        typeArguments.Length);

    foreach (Type tParam in typeArguments)
    {
        // If this is a type parameter, display its
        // position.
        //
        if (tParam.IsGenericParameter)
```

```
        {
            Console.WriteLine("\t\t{0}\t(unassigned - parameter position
{1})",
                tParam,
                tParam.GenericParameterPosition);
        }
        else
        {
            Console.WriteLine("\t\t{0}", tParam);
        }
    }
}
```

Remarks

Type objects that represent generic type parameters can be obtained by calling the GetGenericArguments method of a Type object that represents a generic type definition, or the GetGenericArguments method of a MethodInfo object that represents a generic method definition.

- For a generic type or method definition, the IsGenericParameter property returns `true` for every element of the resulting array.
- For a closed constructed type or method, the IsGenericParameter property returns `false` for every element of the array returned by the GetGenericArguments method.
- For an open constructed type or method, some elements of the array might be specific types and others might be type parameters. IsGenericParameter returns `false` for the types and `true` for the type parameters. The code example for the ContainsGenericParameters property demonstrates a generic class with a mixture of types and type parameters.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.

Type.IsGenericType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current type is a generic type.

C#

```
public virtual bool IsGenericType { get; }
```

Property Value

Boolean

`true` if the current type is a generic type; otherwise, `false`.

Examples

The following code example displays the value of the IsGenericType, IsGenericTypeDefinition, IsGenericParameter, and ContainsGenericParameters properties for the types described in the Remarks section. For explanations of the property values, see the accompanying table in Remarks.

C#

```
using System;
using System.Reflection;

public class Base<T, U> {}

public class Derived<V> : Base<string, V>
{
    public G<Derived <V>> F;

    public class Nested {}
}

public class G<T> {}

class Example
```

```
{
    public static void Main()
    {
        // Get the generic type definition for Derived, and the base
        // type for Derived.
        //
        Type tDerived = typeof(Derived<>);
        Type tDerivedBase = tDerived.BaseType;

        // Declare an array of Derived<int>, and get its type.
        //
        Derived<int>[] d = new Derived<int>[0];
        Type tDerivedArray = d.GetType();

        // Get a generic type parameter, the type of a field, and a
        // type that is nested in Derived. Notice that in order to
        // get the nested type it is necessary to either (1) specify
        // the generic type definition Derived<>, as shown here,
        // or (2) specify a type parameter for Derived.
        //
        Type tT = typeof(Base<,>).GetGenericArguments()[0];
        Type tF = tDerived.GetField("F").FieldType;
        Type tNested = typeof(Derived<>.Nested);

        DisplayGenericType(tDerived, "Derived<V>");
        DisplayGenericType(tDerivedBase, "Base type of Derived<V>");
        DisplayGenericType(tDerivedArray, "Array of Derived<int>");
        DisplayGenericType(tT, "Type parameter T from Base<T>");
        DisplayGenericType(tF, "Field type, G<Derived<V>>");
        DisplayGenericType(tNested, "Nested type in Derived<V>");
    }

    public static void DisplayGenericType(Type t, string caption)
    {
        Console.WriteLine("\n{0}", caption);
        Console.WriteLine("    Type: {0}", t);

        Console.WriteLine("\t            IsGenericType: {0}",
            t.IsGenericType);
        Console.WriteLine("\t  IsGenericTypeDefinition: {0}",
            t.IsGenericTypeDefinition);
        Console.WriteLine("\tContainsGenericParameters: {0}",
            t.ContainsGenericParameters);
        Console.WriteLine("\t       IsGenericParameter: {0}",
            t.IsGenericParameter);
    }
}

/* This code example produces the following output:

Derived<V>
    Type: Derived`1[V]
                    IsGenericType: True
          IsGenericTypeDefinition: True
        ContainsGenericParameters: True
```

```
                IsGenericParameter: False

Base type of Derived<V>
    Type: Base`2[System.String,V]
                    IsGenericType: True
          IsGenericTypeDefinition: False
        ContainsGenericParameters: True
                IsGenericParameter: False

Array of Derived<int>
    Type: Derived`1[System.Int32][]
                    IsGenericType: False
          IsGenericTypeDefinition: False
        ContainsGenericParameters: False
                IsGenericParameter: False

Type parameter T from Base<T>
    Type: T
                    IsGenericType: False
          IsGenericTypeDefinition: False
        ContainsGenericParameters: True
                IsGenericParameter: True

Field type, G<Derived<V>>
    Type: G`1[Derived`1[V]]
                    IsGenericType: True
          IsGenericTypeDefinition: False
        ContainsGenericParameters: True
                IsGenericParameter: False

Nested type in Derived<V>
    Type: Derived`1+Nested[V]
                    IsGenericType: True
          IsGenericTypeDefinition: True
        ContainsGenericParameters: True
                IsGenericParameter: False
 */
```

Remarks

Use the IsGenericType property to determine whether a Type object represents a generic type. Use the ContainsGenericParameters property to determine whether a Type object represents an open constructed type or a closed constructed type.

> ⓘ **Note**

The **IsGenericType** property returns `false` if the immediate type is not generic. For example, an array whose elements are of type `A<int>` (`A(Of Integer)` in Visual Basic) is not itself a generic type.

The following table summarizes the invariant conditions for common terms used in generic reflection.

Expand table

Term	Invariant
generic type definition	The IsGenericTypeDefinition property is `true`. Defines a generic type. A constructed type is created by calling the MakeGenericType method on a Type object that represents a generic type definition and specifying an array of type arguments. MakeGenericType can be called only on generic type definitions. Any generic type definition is a generic type (the IsGenericType property is `true`), but the converse is not true.
generic type	The IsGenericType property is `true`. Can be a generic type definition, an open constructed type, or a closed constructed type. Note that an array type whose element type is generic is not itself a generic type. The same is true of a Type object representing a pointer to a generic type.
open constructed type	The ContainsGenericParameters property is `true`. Examples are a generic type that has unassigned type parameters, a type that is nested in a generic type definition or in an open constructed type, or a generic type that has a type argument for which the ContainsGenericParameters property is `true`. It is not possible to create an instance of an open constructed type. Note that not all open constructed types are generic. For example, an array whose element type is a generic type definition is not generic, and a pointer to an open constructed type is not generic.
closed constructed type	The ContainsGenericParameters property is `false`. When examined recursively, the type has no unassigned generic parameters.

Term	Invariant
generic type parameter	The IsGenericParameter property is `true`. The ContainsGenericParameters property is `true`. In a generic type definition, a placeholder for a type that will be assigned later.
generic type argument	Can be any type, including a generic type parameter. Type arguments are specified as an array of Type objects passed to the MakeGenericType method when creating a constructed generic type. If instances of the resulting type are to be created, the ContainsGenericParameters property must be `false` for all the type arguments.

The following code example and table illustrate some of these terms and invariants. The `Derived` class is of particular interest because its base type is a constructed type that has a mixture of types and type parameters in its type argument list.

C#

```
public class Base<T, U> {}

public class Derived<V> : Base<string, V>
{
    public G<Derived <V>> F;

    public class Nested {}
}

public class G<T> {}
```

The following table shows examples that use and build on the classes `Base`, `Derived`, and `G`. When the C++ and C# code is the same, only one entry is shown.

Expand table

Example	Invariants

`Derived(Of V)`
 	
`Derived<V>`
	For this type:
	
	IsGenericType is `true`.
	
	IsGenericTypeDefinition is `true`.
	
	ContainsGenericParameters is `true`.

Example	Invariants

`Base(Of String, V)`
 	
`Base<String,V>`
 	
`Base<String^,V>`
	For this type:
	
	IsGenericType is `true`.
	
	IsGenericTypeDefinition is `false`.
	
	ContainsGenericParameters is `true`.

`Dim d() As Derived(Of Integer)`
 	
`Derived<int>[] d;`
 	
`array<Derived<int>^>^ d;`
	For the type of variable `d`:
	
	IsGenericType is `false` because `d` is an array.
	
	IsGenericTypeDefinition is `false`.
	
	ContainsGenericParameters is `false`.

`T`, `U`, and `V` (everywhere they appear)	IsGenericParameter is `true`. IsGenericType is `false` because there is no way to constrain a type parameter to generic types. IsGenericTypeDefinition is `false`. ContainsGenericParameters is `true` because `T`, `U`, and `V` are themselves generic type parameters. This does not imply anything about type arguments that are assigned to them later.
The type of field `F`	IsGenericType is `true`. IsGenericTypeDefinition is `false` because a type has been assigned to the type parameter of `G`. Note that this is equivalent to having called the MakeGenericType method. ContainsGenericParameters is `true` because the type of field `F` has a type argument that is an open constructed type. The constructed type is open because its type argument (that is, `Base`) is a generic type definition. This illustrates the recursive nature of the IsGenericType property.
The nested class `Nested`	IsGenericType is `true`, even though the `Nested` class has no generic type parameters of its own, because it is nested in a generic type. IsGenericTypeDefinition is `true`. That is, you can call the MakeGenericType method and supply the type parameter of the enclosing type, `Derived`. ContainsGenericParameters is `true` because the enclosing type,

Example	Invariants
	`Derived`, has generic type parameters. This illustrates the recursive nature of the ContainsGenericParameters property.

Type.IsGenericTypeDefinition Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Type represents a generic type definition, from which other generic types can be constructed.

C#

```
public virtual bool IsGenericTypeDefinition { get; }
```

Property Value

Boolean

`true` if the Type object represents a generic type definition; otherwise, `false`.

Examples

The following example displays information about a type, including whether or not it is a generic type definition. Information is displayed for a constructed type, for its generic type definition, and for an ordinary type.

C#

```
using System;
using System.Reflection;
using System.Collections.Generic;

public class Test
{
    private static void DisplayGenericTypeInfo(Type t)
    {
        Console.WriteLine("\r\n{0}", t);

        Console.WriteLine("\tIs this a generic type definition? {0}",
            t.IsGenericTypeDefinition);

        Console.WriteLine("\tIs it a generic type? {0}",
            t.IsGenericType);
```

```
        if (t.IsGenericType)
        {
            // If this is a generic type, display the type arguments.
            //
            Type[] typeArguments = t.GetGenericArguments();

            Console.WriteLine("\tList type arguments ({0}):",
                typeArguments.Length);

            foreach (Type tParam in typeArguments)
            {
                // If this is a type parameter, display its
                // position.
                //
                if (tParam.IsGenericParameter)
                {
                    Console.WriteLine("\t\t{0}\t(unassigned - parameter
position {1})",
                        tParam,
                        tParam.GenericParameterPosition);
                }
                else
                {
                    Console.WriteLine("\t\t{0}", tParam);
                }
            }
        }
    }

    public static void Main()
    {
        Console.WriteLine("\r\n--- Display information about a constructed
type, its");
        Console.WriteLine("    generic type definition, and an ordinary
type.");

        // Create a Dictionary of Test objects, using strings for the
        // keys.
        Dictionary<string, Test> d = new Dictionary<string, Test>();

        // Display information for the constructed type and its generic
        // type definition.
        DisplayGenericTypeInfo(d.GetType());
        DisplayGenericTypeInfo(d.GetType().GetGenericTypeDefinition());

        // Display information for an ordinary type.
        DisplayGenericTypeInfo(typeof(string));
    }
}

/* This example produces the following output:

--- Display information about a constructed type, its
    generic type definition, and an ordinary type.
```

```
System.Collections.Generic.Dictionary[System.String,Test]
        Is this a generic type definition? False
        Is it a generic type? True
        List type arguments (2):
                System.String
                Test

System.Collections.Generic.Dictionary[TKey,TValue]
        Is this a generic type definition? True
        Is it a generic type? True
        List type arguments (2):
                TKey    (unassigned - parameter position 0)
                TValue  (unassigned - parameter position 1)

System.String
        Is this a generic type definition? False
        Is it a generic type? False
 */
```

Remarks

A generic type definition is a template from which other types can be constructed. For example, from the generic type definition `G<T>` (expressed in C# syntax; `G(Of T)` in Visual Basic or `generic <typename T> ref class G` in C++) you can construct and instantiate the type `G<int>` (`G(Of Integer)` in Visual Basic), by calling the MakeGenericType method with a generic argument list containing the Int32 type. Given a Type object representing this constructed type, the GetGenericTypeDefinition method gets the generic type definition back again.

Use the IsGenericTypeDefinition property to determine whether you can create new types from the current type. If the IsGenericTypeDefinition property returns `true`, you can call the MakeGenericType method to create new generic types.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.
